## Overview

JSON (JavaScript Object Notation) is a lightweight data-interchange format widely used on the Internet. Many applications, generally written in JavaScript or PHP use and produce JSON data, which are exchanged as files of different physical formats. JSON data is often returned from REST queries.

It is also possible to query, create or update such information in a database-like manner. MongoDB does it using a JavaScript-like language. PostgreSQL includes these facilities by using a specific data type and related functions like dynamic columns.

The CONNECT engine adds this facility to MariaDB by supporting tables based on JSON data files. This is done like for XML tables by creating tables describing what should be retrieved from the file and how it should be processed.

Starting with 1.07.0002, the internal way JSON was parsed and handled was changed. The main advantage of the new way is to reduce the memory required to parse JSON. It was from 6 to 10 times the size of the JSON source and is now only 2 to 4 times. However, this is in Beta mode and JSON

tables are still handled using the old mode. To use the new mode, tables should be created with TABLE\_TYPE=BSON. Another way is to set the `connect_force_bson` session variable to 1 or ON. Then all JSON tables will be handled as BSON. Of course, this is temporary and when successfully tested, the new way will replace the old way and all tables be created as JSON.

Let us start from the file "biblio3.json" that is the JSON equivalent of the XML Xsample file described in the XML table chapter:

```
[  
  {  
    "ISBN": "9782212090819",  
    "LANG": "fr",  
    "SUBJECT": "applications",  
    "AUTHOR": [  
      {  
        "FIRSTNAME": "Jean-Christophe",  
        "LASTNAME": "Bernadac"  
      },  
      {  
        "FIRSTNAME": "François",  
        "LASTNAME": "Knab"  
      }  
    ],  
    "TITLE": "Construire une application XML",  
    "PUBLISHER": {  
      "NAME": "Eyrolles",  
      "PLACE": "Paris"  
    },  
    "DATEPUB": 1999  
  },  
  {  
    "ISBN": "9782840825685",  
    "LANG": "fr",  
    "SUBJECT": "applications",  
    "AUTHOR": [  
      {  
        "FIRSTNAME": "William J.",  
        "LASTNAME": "Pardi"  
      }  
    ],  
    "TITLE": "XML en Action",  
    "TRANSLATED": {  
      "PREFIX": "adapté de l'anglais par",  
      "TRANSLATOR": {  
        "FIRSTNAME": "James",  
        "LASTNAME": "Guerin"  
      }  
    },  
    "PUBLISHER": {  
      "NAME": "Microsoft Press",  
      "PLACE": "Paris"  
    },  
    "DATEPUB": 1999  
  }]  
]
```

This file contains the different items existing in JSON.

- **Arrays**  
: They are enclosed in square brackets and contain a list of comma separated values.
- **Objects**  
: They are enclosed in curly brackets. They contain a comma separated list of pairs, each pair composed of a key name between double quotes, followed by a ":" character and followed by a value.
- **Values**  
: Values can be an array or an object. They also can be a string between double quotes, an integer or float number, a Boolean value or a null value. The simplest way for CONNECT to locate a table in such a file is by an array containing a list of objects (this is what MongoDB calls a collection of documents). Each array value will be a table row and each pair of the row objects will represent a column, the key being the column name and the value the column value.

A first try to create a table on this file will be to take the outer array as the table:

```

create table jsample (
ISBN char(15),
LANG char(2),
SUBJECT char(32),
AUTHOR char(128),
TITLE char(32),
TRANSLATED char(80),
PUBLISHER char(20),
DATEPUB int(4))
engine=CONNECT table_type=JSON
File_name='biblio3.json';

```

If we execute the query:

```
select isbn, author, title, publisher from jsample;
```

We get the result:

| isbn          | author                   | title                          | publisher            |
|---------------|--------------------------|--------------------------------|----------------------|
| 9782212090819 | Jean-Christophe Bernadac | Construire une application XML | Eyrolles Paris       |
| 9782840825685 | William J. Pardi         | XML en Action                  | Microsoft Press Pari |

Note that by default, column values that are objects have been set to the concatenation of all the string values of the object separated by a blank. When a column value is an array, only the first item of the array is retrieved (This will change in later versions of Connect).

However, things are generally more complicated. If JSON files do not contain attributes (although object pairs are similar to attributes) they contain a new item, arrays. We have seen that they can be used like XML multiple nodes, here to specify several authors, but they are more general because they can contain objects of different types, even it may not be advisable to do so.

This is why CONNECT enables the specification of a column field\_format option "JPATH" (FIELD\_FORMAT until Connect 1.6) that is used to describe exactly where the items to display are and how to handle arrays.

Here is an example of a new table that can be created on the same file, allowing choosing the column names, to get some sub-objects and to specify how to handle the author array.

Until Connect 1.5:

```

create table jsampall (
ISBN char(15),
Language char(2) field_format='LANG',
Subject char(32) field_format='SUBJECT',
Author char(128) field_format='AUTHOR:[ " and "]',
Title char(32) field_format='TITLE',
Translation char(32) field_format='TRANSLATOR:PREFIX',
Translator char(80) field_format='TRANSLATOR',
Publisher char(20) field_format='PUBLISHER:NAME',
Location char(16) field_format='PUBLISHER:PLACE',
Year int(4) field_format='DATEPUB')
engine=CONNECT table_type=JSON File_name='biblio3.json';

```

From Connect 1.6:

```

create table jsampall (
ISBN char(15),
Language char(2) field_format='LANG',
Subject char(32) field_format='SUBJECT',
Author char(128) field_format='AUTHOR.[ " and "]',
Title char(32) field_format='TITLE',
Translation char(32) field_format='TRANSLATOR.PREFIX',
Translator char(80) field_format='TRANSLATOR',
Publisher char(20) field_format='PUBLISHER.NAME',
Location char(16) field_format='PUBLISHER.PLACE',
Year int(4) field_format='DATEPUB')
engine=CONNECT table_type=JSON File_name='biblio3.json';

```

From Connect 1.07.0002

```

create table jsampall (
ISBN char(15),
Language char(2) jpath='$.LANG',
Subject char(32) jpath='$.SUBJECT',
Author char(128) jpath='$.AUTHOR[" and "]',
Title char(32) jpath='$.TITLE',
Translation char(32) jpath='$.TRANSLATOR.PREFIX',
Translator char(80) jpath='$.TRANSLATOR',
Publisher char(20) jpath='$.PUBLISHER.NAME',
Location char(16) jpath='$.PUBLISHER.PLACE',
Year int(4) jpath='$.DATEPUB'
engine=CONNECT table_type=JSON File_name='biblio3.json';

```

Given the query:

```
select title, author, publisher, location from jsampall;
```

The result is:

| title                          | author                                     | publisher       | location |
|--------------------------------|--------------------------------------------|-----------------|----------|
| Construire une application XML | Jean-Christophe Bernadac and François Knab | Eyrolles        | Paris    |
| XML en Action                  | William J. Pardi                           | Microsoft Press | Paris    |

Note: The JPATH was not specified for column ISBN because it defaults to the column name.

Here is another example showing that one can choose what to extract from the file and how to “expand” an array, meaning to generate one row for each array value:

Until Connect 1.5:

```

create table jsampex (
ISBN char(15),
Title char(32) field_format='TITLE',
AuthorFN char(128) field_format='AUTHOR:[X]:FIRSTNAME',
AuthorLN char(128) field_format='AUTHOR:[X]:LASTNAME',
Year int(4) field_format='DATEPUB'
engine=CONNECT table_type=JSON File_name='biblio3.json';

```

From Connect 1.6:

```

create table jsampex (
ISBN char(15),
Title char(32) field_format='TITLE',
AuthorFN char(128) field_format='AUTHOR.[X].FIRSTNAME',
AuthorLN char(128) field_format='AUTHOR.[X].LASTNAME',
Year int(4) field_format='DATEPUB'
engine=CONNECT table_type=JSON File_name='biblio3.json';

```

From Connect 1.06.006:

```

create table jsampex (
ISBN char(15),
Title char(32) field_format='TITLE',
AuthorFN char(128) field_format='AUTHOR[*].FIRSTNAME',
AuthorLN char(128) field_format='AUTHOR[*].LASTNAME',
Year int(4) field_format='DATEPUB'
engine=CONNECT table_type=JSON File_name='biblio3.json';

```

From Connect 1.07.0002

```

create table jsampex (
ISBN char(15),
Title char(32) jpath='TITLE',
AuthorFN char(128) jpath='AUTHOR[*].FIRSTNAME',
AuthorLN char(128) jpath='AUTHOR[*].LASTNAME',
Year int(4) jpath='DATEPUB'
engine=CONNECT table_type=JSON File_name='biblio3.json';

```

It is displayed as:

| ISBN | Title | AuthorFN | AuthorLN | Year |
|------|-------|----------|----------|------|
|------|-------|----------|----------|------|

|               |                                |                 |          |      |
|---------------|--------------------------------|-----------------|----------|------|
| 9782212090819 | Construire une application XML | Jean-Christophe | Bernadac | 1999 |
| 9782212090819 | Construire une application XML | François        | Knab     | 1999 |
| 9782840825685 | XML en Action                  | William J.      | Pardi    | 1999 |

Note: The example above shows that the '\$.', that means the beginning of the path, can be omitted.

## The Jpath Specification

From Connect 1.6, the Jpath specification has changed to be the one of the native JSON functions and more compatible with what is generally used. It is close to the standard definition and compatible to what MongoDB and other products do. The ':' separator is replaced by '.'. Position in array is accepted MongoDB style with no square brackets. Array specification specific to CONNECT are still accepted but [\*] is used for expanding and [x] for multiply. However, tables created with the previous syntax can still be used by adding SEP\_CHAR=':' (can be done with alter table). Also, it can be now specified as JPATH (was FIELD\_FORMAT) but FIELD\_FORMAT is still accepted.

Until Connect 1.5, it is the description of the path to follow to reach the required item. Each step is the key name (case sensitive) of the pair when crossing an object, and the number of the value between square brackets when crossing an array. Each specification is separated by a ':' character.

From Connect 1.6, It is the description of the path to follow to reach the required item. Each step is the key name (case sensitive) of the pair when crossing an object, and the position number of the value when crossing an array. Key specifications are separated by a '.' character.

For instance, in the above file, the last name of the second author of a book is reached by:

`$AUTHOR[1].LASTNAME` standard style `$AUTHOR.1.LASTNAME` MongoDB style `AUTHOR:[1]:LASTNAME` old style when `SEP_CHAR=':'` or until Connect 1.5

The '\$' or "\$." prefix specifies the root of the path and can be omitted with CONNECT.

The array specification can also indicate how it must be processed:

For instance, in the above file, the last name of the second author of a book is reached by:

`AUTHOR:[1]:LASTNAME`

The array specification can also indicate how it must be processed:

| Specification                                     | Array Type | Limit | Description                                                                                               |
|---------------------------------------------------|------------|-------|-----------------------------------------------------------------------------------------------------------|
| n (Connect >= 1.6) or [n]                         | All        | N.A   | Take the nth value of the array.                                                                          |
| [*] (Connect >= 1.6), [X] or [x] (Connect <= 1.5) | All        |       | Expand. Generate one row for each array value.                                                            |
| ["string"]                                        | String     |       | Concatenate all values separated by the specified string.                                                 |
| [+]                                               | Numeric    |       | Make the sum of all the non-null array values.                                                            |
| [x] (Connect >= 1.6), [*] (Connect <= 1.5)        | Numeric    |       | Make the product of all non-null array values.                                                            |
| [!]                                               | Numeric    |       | Make the average of all the non-null array values.                                                        |
| [>] or [<]                                        | All        |       | Return the greatest or least non-null value of the array.                                                 |
| [#]                                               | All        | N.A   | Return the number of values in the array.                                                                 |
| []                                                | All        |       | Expand if under an expanded object. Otherwise sum if numeric, else concatenation separated by ", ".       |
|                                                   | All        |       | Between two separators, if an array, expand it if under an expanded object or take the first value of it. |

Note 1: When the LIMIT restriction is applicable, only the first *m* array items are used, *m* being the value of the LIMIT option (to be specified in option\_list). The LIMIT default value is 10.

Note 2: An alternative way to indicate what is to be expanded is to use the expand option in the option list, for instance:

`OPTION_LIST='Expand=AUTHOR'`

`AUTHOR`

is here the key of the pair that has the array as a value (case sensitive). Expand is limited to only one branch (expanded arrays must be under the same object).

Let us take as an example the file

`expense.json`

([found here](#)). The table jexpall expands all under and including the week array:

From Connect 1.07.0002

```
create table jexpall (
WHO char(12),
WEEK int(2) jpath='$.WEEK[*].NUMBER',
WHAT char(32) jpath='$.WEEK[*].EXPENSE[*].WHAT',
AMOUNT double(8,2) jpath='$.WEEK[*].EXPENSE[*].AMOUNT')
engine=CONNECT table_type=JSON File_name='expense.json';
```

From Connect.1.6

```
create table jexpall (
WHO char(12),
WEEK int(2) field_format='$.WEEK[*].NUMBER',
WHAT char(32) field_format='$.WEEK[*].EXPENSE[*].WHAT',
AMOUNT double(8,2) field_format='$.WEEK[*].EXPENSE[*].AMOUNT')
engine=CONNECT table_type=JSON File_name='expense.json';
```

Until Connect 1.5:

```
create table jexpall (
WHO char(12),
WEEK int(2) field_format='WEEK:[x]:NUMBER',
WHAT char(32) field_format='WEEK:[x]:EXPENSE:[x]:WHAT',
AMOUNT double(8,2) field_format='WEEK:[x]:EXPENSE:[x]:AMOUNT'
engine=CONNECT table_type=JSON File_name='expense.json';
```

| WHO   | WEEK | WHAT | AMOUNT |
|-------|------|------|--------|
| Joe   | 3    | Beer | 18.00  |
| Joe   | 3    | Food | 12.00  |
| Joe   | 3    | Food | 19.00  |
| Joe   | 3    | Car  | 20.00  |
| Joe   | 4    | Beer | 19.00  |
| Joe   | 4    | Beer | 16.00  |
| Joe   | 4    | Food | 17.00  |
| Joe   | 4    | Food | 17.00  |
| Joe   | 4    | Beer | 14.00  |
| Joe   | 5    | Beer | 14.00  |
| Joe   | 5    | Food | 12.00  |
| Beth  | 3    | Beer | 16.00  |
| Beth  | 4    | Food | 17.00  |
| Beth  | 4    | Beer | 15.00  |
| Beth  | 5    | Food | 12.00  |
| Beth  | 5    | Beer | 20.00  |
| Janet | 3    | Car  | 19.00  |
| Janet | 3    | Food | 18.00  |
| Janet | 3    | Beer | 18.00  |
| Janet | 4    | Car  | 17.00  |
| Janet | 5    | Beer | 14.00  |
| Janet | 5    | Car  | 12.00  |
| Janet | 5    | Beer | 19.00  |
| Janet | 5    | Food | 12.00  |

The table

jexpw

shows what was bought and the sum and average of amounts for each person and week:

From Connect 1.07.0002

```

create table jexpw (
WHO char(12) not null,
WEEK int(2) not null jpath='$.WEEK[*].NUMBER',
WHAT char(32) not null jpath='$.WEEK[].EXPENSE[", "] .WHAT',
SUM double(8,2) not null jpath='$.WEEK[].EXPENSE[+].AMOUNT',
AVERAGE double(8,2) not null jpath='$.WEEK[].EXPENSE[!].AMOUNT')
engine=CONNECT table_type=JSON File_name='expense.json';

```

From Connect 1.6:

```

create table jexpw (
WHO char(12) not null,
WEEK int(2) not null field_format='$.WEEK[*].NUMBER',
WHAT char(32) not null field_format='$.WEEK[].EXPENSE[", "] .WHAT',
SUM double(8,2) not null field_format='$.WEEK[].EXPENSE[+].AMOUNT',
AVERAGE double(8,2) not null field_format='$.WEEK[].EXPENSE[!].AMOUNT')
engine=CONNECT table_type=JSON File_name='expense.json';

```

Until Connect 1.5:

```

create table jexpw (
WHO char(12) not null,
WEEK int(2) not null field_format='WEEK:[x]:NUMBER',
WHAT char(32) not null field_format='WEEK::EXPENSE[", "] :WHAT',
SUM double(8,2) not null field_format='WEEK::EXPENSE[+]:AMOUNT',
AVERAGE double(8,2) not null field_format='WEEK::EXPENSE[!]:AMOUNT')
engine=CONNECT table_type=JSON File_name='expense.json';

```

| WHO   | WEEK | WHAT                         | SUM   | AVERAGE |
|-------|------|------------------------------|-------|---------|
| Joe   | 3    | Beer, Food, Food, Car        | 69.00 | 17.25   |
| Joe   | 4    | Beer, Beer, Food, Food, Beer | 83.00 | 16.60   |
| Joe   | 5    | Beer, Food                   | 26.00 | 13.00   |
| Beth  | 3    | Beer                         | 16.00 | 16.00   |
| Beth  | 4    | Food, Beer                   | 32.00 | 16.00   |
| Beth  | 5    | Food, Beer                   | 32.00 | 16.00   |
| Janet | 3    | Car, Food, Beer              | 55.00 | 18.33   |
| Janet | 4    | Car                          | 17.00 | 17.00   |
| Janet | 5    | Beer, Car, Beer, Food        | 57.00 | 14.25   |

Let us see what the table

```

jexpz
does:

```

From Connect 1.6:

```

create table jexpz (
WHO char(12) not null,
WEEKS char(12) not null field_format='WEEK[", "] .NUMBER',
SUMS char(64) not null field_format='WEEK["+"].EXPENSE[+].AMOUNT',
SUM double(8,2) not null field_format='WEEK[+].EXPENSE[+].AMOUNT',
AVGS char(64) not null field_format='WEEK["+"].EXPENSE[!].AMOUNT',
SUMAVG double(8,2) not null field_format='WEEK[+].EXPENSE[!].AMOUNT',
AVGSUM double(8,2) not null field_format='WEEK[!].EXPENSE[+].AMOUNT',
AVERAGE double(8,2) not null field_format='WEEK[!].EXPENSE[*].AMOUNT')
engine=CONNECT table_type=JSON File_name='expense.json';

```

From Connect 1.07.0002

```

create table jexpz (
WHO char(12) not null,
WEEKS char(12) not null jpath='WEEK[", "].NUMBER',
SUMS char(64) not null jpath='WEEK["+"].EXPENSE[+].AMOUNT',
SUM double(8,2) not null jpath='WEEK[+].EXPENSE[+].AMOUNT',
AVGS char(64) not null jpath='WEEK["+"].EXPENSE[!].AMOUNT',
SUMAVG double(8,2) not null jpath='WEEK[+].EXPENSE[!].AMOUNT',
AVGSUM double(8,2) not null jpath='WEEK[!].EXPENSE[+].AMOUNT',
AVERAGE double(8,2) not null jpath='WEEK[!].EXPENSE[*].AMOUNT')
engine=CONNECT table_type=JSON File_name='expense.json';

```

Until Connect 1.5:

```

create table jexpz (
WHO char(12) not null,
WEEKS char(12) not null field_format='WEEK:[", "]:NUMBER',
SUMS char(64) not null field_format='WEEK:[+]::EXPENSE:[+]:AMOUNT',
SUM double(8,2) not null field_format='WEEK:[+]:EXPENSE:[+]:AMOUNT',
AVGS char(64) not null field_format='WEEK:[+]::EXPENSE:[!]:AMOUNT',
SUMAVG double(8,2) not null field_format='WEEK:[+]:EXPENSE:[!]:AMOUNT',
AVGSUM double(8,2) not null field_format='WEEK:[!]:EXPENSE:[+]:AMOUNT',
AVERAGE double(8,2) not null field_format='WEEK:[!]:EXPENSE:[x]:AMOUNT'
engine=CONNECT table_type=JSON
File_name='E:/Data/Json/expense2.json';

```

| WHO   | WEEKS   | SUMS              | SUM    | AVGS              | SUMAVG | AVGSUM | AVERAGE |
|-------|---------|-------------------|--------|-------------------|--------|--------|---------|
| Joe   | 3, 4, 5 | 69.00+83.00+26.00 | 178.00 | 17.25+16.60+13.00 | 46.85  | 59.33  | 16.18   |
| Beth  | 3, 4, 5 | 16.00+32.00+32.00 | 80.00  | 16.00+16.00+16.00 | 48.00  | 26.67  | 16.00   |
| Janet | 3, 4, 5 | 55.00+17.00+57.00 | 129.00 | 18.33+17.00+14.25 | 49.58  | 43.00  | 16.12   |

For all persons:

- Column 1 show the person name.
- Column 2 shows the weeks for which values are calculated.
- Column 3 lists the sums of expenses for each week.
- Column 4 calculates the sum of all expenses by person.
- Column 5 shows the week's expense averages.
- Column 6 calculates the sum of these averages.
- Column 7 calculates the average of the week's sum of expenses.
- Column 8 calculates the average expense by person.

It would be very difficult, if even possible, to obtain this result from table

```

jexpall
using an SQL query.

```

## Handling of NULL Values

Json has a null explicit value that can be met in arrays or object key values. When regarding json as a relational table, a column value can be null because the corresponding json item is explicitly null, or implicitly because the corresponding item is missing in an array or object. CONNECT does not make any distinction between explicit and implicit nulls.

However, it is possible to specify how nulls are handled and represented. This is done by setting the string session variable `connect_json_null`. The default value of `connect_json_null` is "`<null>`"; it can be changed, for instance, by:

```
SET connect_json_null='NULL';
```

This changes its representation when a column displays the text of an object or the concatenation of the values of an array.

It is also possible to tell CONNECT to ignore nulls by:

```
SET connect_json_null=NULL;
```

When doing so, nulls do not appear in object text or array lists. However, this does not change the behavior of array calculation nor the result of array count.

## Having Columns defined by Discovery

It is possible to let the MariaDB discovery process do the job of column specification. When columns are not defined in the create table statement, CONNECT endeavors to analyze the JSON file and to provide the column specifications. This is possible only for tables represented by an array of objects because CONNECT retrieves the column names from the object pair keys and their definition from the object pair values. For instance, the

jsample table could be created saying:

```
create table jsample engine=connect table_type=JSON file_name='biblio3.json';
```

Let's check how it was actually specified using the show create table statement:

```
CREATE TABLE `jsample` (
  `ISBN` char(13) NOT NULL,
  `LANG` char(2) NOT NULL,
  `SUBJECT` char(12) NOT NULL,
  `AUTHOR` varchar(256) DEFAULT NULL,
  `TITLE` char(30) NOT NULL,
  `TRANSLATED` varchar(256) DEFAULT NULL,
  `PUBLISHER` varchar(256) DEFAULT NULL,
  `DATEPUB` int(4) NOT NULL
) ENGINE=CONNECT DEFAULT CHARSET=latin1 `TABLE_TYPE`='JSON' `FILE_NAME`='biblio3.json';
```

It is equivalent except for the column sizes that have been calculated from the file as the maximum length of the corresponding column when it was a normal value. For columns that are json arrays or objects, the column is specified as a varchar string of length 256, supposedly big enough to contain the sub-object's concatenated values. Nullable is set to true if the column is null or missing in some rows or if its JPATH contains arrays.

If a more complex definition is desired, you can ask CONNECT to analyse the JPATH up to a given depth using the DEPTH or LEVEL option in the option list. Its default value is 0 but can be changed setting the [connect\\_default\\_depth](#) session variable (in future versions the default will be 5). The depth value is the number of sub-objects that are taken in the JPATH2 (this is different from what is defined and returned by the native [Json\\_Depth](#) function).

For instance:

```
create table jsampall2 engine=connect table_type=JSON
file_name='biblio3.json' option_list='level=1';
```

This will define the table as:

From Connect 1.07.0002

```
CREATE TABLE `jsampall2` (
  `ISBN` char(13) NOT NULL,
  `LANG` char(2) NOT NULL,
  `SUBJECT` char(12) NOT NULL,
  `AUTHOR_FIRSTNAME` char(15) NOT NULL `JPATH`='$.AUTHOR.[0].FIRSTNAME',
  `AUTHOR_LASTNAME` char(8) NOT NULL `JPATH`='$.AUTHOR.[0].LASTNAME',
  `TITLE` char(30) NOT NULL,
  `TRANSLATED_PREFIX` char(23) DEFAULT NULL `JPATH`='$.TRANSLATED.PREFIX',
  `TRANSLATED_TRANSLATOR` varchar(256) DEFAULT NULL `JPATH`='$.TRANSLATED.TRANSLATOR',
  `PUBLISHER_NAME` char(15) NOT NULL `JPATH`='$.PUBLISHER.NAME',
  `PUBLISHER_PLACE` char(5) NOT NULL `JPATH`='$.PUBLISHER.PLACE',
  `DATEPUB` int(4) NOT NULL
) ENGINE=CONNECT DEFAULT CHARSET=latin1 `TABLE_TYPE`='JSON'
`FILE_NAME`='biblio3.json' `OPTION_LIST`='depth=1';
```

From Connect 1.6:

```
CREATE TABLE `jsampall2` (
  `ISBN` char(13) NOT NULL,
  `LANG` char(2) NOT NULL,
  `SUBJECT` char(12) NOT NULL,
  `AUTHOR_FIRSTNAME` char(15) NOT NULL `FIELD_FORMAT`='AUTHOR..FIRSTNAME',
  `AUTHOR_LASTNAME` char(8) NOT NULL `FIELD_FORMAT`='AUTHOR..LASTNAME',
  `TITLE` char(30) NOT NULL,
  `TRANSLATED_PREFIX` char(23) DEFAULT NULL `FIELD_FORMAT`='TRANSLATED.PREFIX',
  `TRANSLATED_TRANSLATOR` varchar(256) DEFAULT NULL `FIELD_FORMAT`='TRANSLATED.TRANSLATOR',
  `PUBLISHER_NAME` char(15) NOT NULL `FIELD_FORMAT`='PUBLISHER.NAME',
  `PUBLISHER_PLACE` char(5) NOT NULL `FIELD_FORMAT`='PUBLISHER.PLACE',
  `DATEPUB` int(4) NOT NULL
) ENGINE=CONNECT DEFAULT CHARSET=latin1 `TABLE_TYPE`='JSON'
`FILE_NAME`='biblio3.json' `OPTION_LIST`='level=1';
```

Until Connect 1.5:

```

CREATE TABLE `jsampall2` (
  `ISBN` char(13) NOT NULL,
  `LANG` char(2) NOT NULL,
  `SUBJECT` char(12) NOT NULL,
  `AUTHOR_FIRSTNAME` char(15) NOT NULL `FIELD_FORMAT`='AUTHOR::FIRSTNAME',
  `AUTHOR_LASTNAME` char(8) NOT NULL `FIELD_FORMAT`='AUTHOR::LASTNAME',
  `TITLE` char(30) NOT NULL,
  `TRANSLATED_PREFIX` char(23) DEFAULT NULL `FIELD_FORMAT`='TRANSLATED:PREFIX',
  `TRANSLATED_TRANSLATOR` varchar(256) DEFAULT NULL `FIELD_FORMAT`='TRANSLATED:TRANSLATOR',
  `PUBLISHER_NAME` char(15) NOT NULL `FIELD_FORMAT`='PUBLISHER:NAME',
  `PUBLISHER_PLACE` char(5) NOT NULL `FIELD_FORMAT`='PUBLISHER:PLACE',
  `DATEPUB` int(4) NOT NULL
) ENGINE=CONNECT DEFAULT CHARSET=latin1 `TABLE_TYPE`='JSON' `FILE_NAME`='biblio3.json' `OPTION_LIST`='level=1';

```

For columns that are a simple value, the Json path is the column name. This is the default when the Jpath option is not specified, so it was not specified for such columns. However, you can force discovery to specify it by setting the connect\_all\_path variable to 1 or ON. This can be useful if you plan to change the name of such columns and relieves you of manually specifying the path (otherwise it would default to the new name and cause the column to not or wrongly be found).

Another problem is that CONNECT cannot guess what you want to do with arrays. Here the AUTHOR array is set to 0, which means that only its first value will be retrieved unless you also had specified "Expand=AUTHOR" in the option list. But of course, you can replace it with anything else.

This method can be used as a quick way to make a "template" table definition that can later be edited to make the desired definition. In particular, column names are constructed from all the object keys of their path in order to have distinct column names. This can be manually edited to have the desired names, provided their JPATH key names are not modified.

DEPTH can also be given the value -1 to create only columns that are simple values (no array or object). It normally defaults to 0 but this can be modified setting the `connect_default_depth` variable.

Note: Since version 1.6.4, CONNECT eliminates columns that are "void" or whose type cannot be determined. For instance given the file sresto.json:

```
{"_id":1,"name":"Corner Social","cuisine":"American","grades":[{"grade":"A","score":6}]}
{"_id":2,"name":"La Nueva Clasica Antillana","cuisine":"Spanish","grades":[]}
```

Previously, when using discovery, creating the table by:

```
create table sjr0
engine=connect table_type=JSON file_name='sresto.json'
option_list='Pretty=0,Depth=1' lrecl=128;
```

The table was previously created as:

```

CREATE TABLE `sjr0` (
  `_id` bigint(1) NOT NULL,
  `name` char(26) NOT NULL,
  `cuisine` char(8) NOT NULL,
  `grades` char(1) DEFAULT NULL,
  `grades_grade` char(1) DEFAULT NULL `JPATH`='$.grades[0].grade',
  `grades_score` bigint(1) DEFAULT NULL `JPATH`='$.grades[0].score'
) ENGINE=CONNECT DEFAULT CHARSET=latin1 `TABLE_TYPE`='JSON'
`FILE_NAME`='sresto.json'
`OPTION_LIST`='Pretty=0,Depth=1,Accept=1' `LRECL`=128;

```

The column "grades" was added because of the void array in line 2. Now this column is skipped and does not appear anymore (unless the option

```
Accept=1
is added in the option list).
```

## JSON Catalogue Tables

Another way to see JSON table column specifications is to use a catalogue table. For instance:

```
create table bibcol engine=connect table_type=JSON file_name='biblio3.json'
option_list='level=2' catfunc=columns;
select column_name, type_name type, column_size size, jpath from bibcol;
```

which returns:

From Connect 1.07.0002:

| column_name | type | size | jpath   |
|-------------|------|------|---------|
| ISBN        | CHAR | 13   | \$.ISBN |

|                                 |         |    |                                    |
|---------------------------------|---------|----|------------------------------------|
| LANG                            | CHAR    | 2  | \$.LANG                            |
| SUBJECT                         | CHAR    | 12 | \$.SUBJECT                         |
| AUTHOR_FIRSTNAME                | CHAR    | 15 | \$.AUTHOR[0].FIRSTNAME             |
| AUTHOR_LASTNAME                 | CHAR    | 8  | \$.AUTHOR[0].LASTNAME              |
| TITLE                           | CHAR    | 30 | \$.TITLE                           |
| TRANSLATED_PREFIX               | CHAR    | 23 | \$.TRANSLATED.PREFIX               |
| TRANSLATED_TRANSLATOR_FIRSTNAME | CHAR    | 5  | \$.TRANSLATED.TRANSLATOR.FIRSTNAME |
| TRANSLATED_TRANSLATOR_LASTNAME  | CHAR    | 6  | \$.TRANSLATED.TRANSLATOR.LASTNAME  |
| PUBLISHER_NAME                  | CHAR    | 15 | \$.PUBLISHER.NAME                  |
| PUBLISHER_PLACE                 | CHAR    | 5  | \$.PUBLISHER.PLACE                 |
| DATEPUB                         | INTEGER | 4  | \$.DATEPUB                         |

From Connect 1.6:

| column_name                     | type    | size | jpath                           |
|---------------------------------|---------|------|---------------------------------|
| ISBN                            | CHAR    | 13   |                                 |
| LANG                            | CHAR    | 2    |                                 |
| SUBJECT                         | CHAR    | 12   |                                 |
| AUTHOR_FIRSTNAME                | CHAR    | 15   | AUTHOR..FIRSTNAME               |
| AUTHOR_LASTNAME                 | CHAR    | 8    | AUTHOR..LASTNAME                |
| TITLE                           | CHAR    | 30   |                                 |
| TRANSLATED_PREFIX               | CHAR    | 23   | TRANSLATED.PREFIX               |
| TRANSLATED_TRANSLATOR_FIRSTNAME | CHAR    | 5    | TRANSLATED.TRANSLATOR.FIRSTNAME |
| TRANSLATED_TRANSLATOR_LASTNAME  | CHAR    | 6    | TRANSLATED.TRANSLATOR.LASTNAME  |
| PUBLISHER_NAME                  | CHAR    | 15   | PUBLISHER.NAME                  |
| PUBLISHER_PLACE                 | CHAR    | 5    | PUBLISHER.PLACE                 |
| DATEPUB                         | INTEGER | 4    |                                 |

Until Connect 1.5:

| column_name                     | type    | size | jpath                           |
|---------------------------------|---------|------|---------------------------------|
| ISBN                            | CHAR    | 13   |                                 |
| LANG                            | CHAR    | 2    |                                 |
| SUBJECT                         | CHAR    | 12   |                                 |
| AUTHOR_FIRSTNAME                | CHAR    | 15   | AUTHOR::FIRSTNAME               |
| AUTHOR_LASTNAME                 | CHAR    | 8    | AUTHOR::LASTNAME                |
| TITLE                           | CHAR    | 30   |                                 |
| TRANSLATED_PREFIX               | CHAR    | 23   | TRANSLATED:PREFIX               |
| TRANSLATED_TRANSLATOR_FIRSTNAME | CHAR    | 5    | TRANSLATED:TRANSLATOR:FIRSTNAME |
| TRANSLATED_TRANSLATOR_LASTNAME  | CHAR    | 6    | TRANSLATED:TRANSLATOR:LASTNAME  |
| PUBLISHER_NAME                  | CHAR    | 15   | PUBLISHER:NAME                  |
| PUBLISHER_PLACE                 | CHAR    | 5    | PUBLISHER:PLACE                 |
| DATEPUB                         | INTEGER | 4    |                                 |

All this is mostly useful when creating a table on a remote file that you cannot easily see.

## Finding the table within a JSON file

Given the file "facebook.json":

```
{
  "data": [
    {
      "id": "X999_Y999",
      "from": {
        "name": "Tom Brady", "id": "X12"
      },
      "message": "Looking forward to 2010!",
      "actions": [
        {
          "name": "Comment",
          "link": "http://www.facebook.com/X999/posts/Y999"
        },
        {
          "name": "Like",
          "link": "http://www.facebook.com/X999/posts/Y999"
        }
      ],
      "type": "status",
      "created_time": "2010-08-02T21:27:44+0000",
      "updated_time": "2010-08-02T21:27:44+0000"
    },
    {
      "id": "X998_Y998",
      "from": {
        "name": "Peyton Manning", "id": "X18"
      },
      "message": "Where's my contract?",
      "actions": [
        {
          "name": "Comment",
          "link": "http://www.facebook.com/X998/posts/Y998"
        },
        {
          "name": "Like",
          "link": "http://www.facebook.com/X998/posts/Y998"
        }
      ],
      "type": "status",
      "created_time": "2010-08-02T21:27:44+0000",
      "updated_time": "2010-08-02T21:27:44+0000"
    }
  ]
}
```

The table we want to analyze is represented by the array value of the “data” object. Here is how this is specified in the create table statement:

From Connect 1.07.0002:

```
create table jfacebook (
`ID` char(10) jpath='id',
`Name` char(32) jpath='from.name',
`MyID` char(16) jpath='from.id',
`Message` varchar(256) jpath='message',
`Action` char(16) jpath='actions..name',
`Link` varchar(256) jpath='actions..link',
`Type` char(16) jpath='type',
`Created` datetime date_format='YYYY-MM-DD\T\hh:mm:ss' jpath='created_time',
`Updated` datetime date_format='YYYY-MM-DD\T\hh:mm:ss' jpath='updated_time')
engine=connect table_type=JSON file_name='facebook.json' option_list='Object=data,Expand=actions';
```

From Connect 1.6:

```
create table jfacebook (
`ID` char(10) field_format='id',
`Name` char(32) field_format='from.name',
`MyID` char(16) field_format='from.id',
`Message` varchar(256) field_format='message',
`Action` char(16) field_format='actions..name',
`Link` varchar(256) field_format='actions..link',
`Type` char(16) field_format='type',
`Created` datetime date_format='YYYY-MM-DD\T\hh:mm:ss' field_format='created_time',
`Updated` datetime date_format='YYYY-MM-DD\T\hh:mm:ss' field_format='updated_time')
engine=connect table_type=JSON file_name='facebook.json' option_list='Object=data,Expand=actions';
```

Until Connect 1.5:

```
create table jfacebook (
`ID` char(10) field_format='id',
`Name` char(32) field_format='from:name',
`MyID` char(16) field_format='from:id',
`Message` varchar(256) field_format='message',
`Action` char(16) field_format='actions::name',
`Link` varchar(256) field_format='actions::link',
`Type` char(16) field_format='type',
`Created` datetime date_format='YYYY-MM-DD\T\hh:mm:ss' field_format='created_time',
`Updated` datetime date_format='YYYY-MM-DD\T\hh:mm:ss' field_format='updated_time')
engine=connect table_type=JSON file_name='facebook.json' option_list='Object=data,Expand=actions';
```

This is the object option that gives the Jpath of the table. Note also an alternate way to declare the array to be expanded by the expand option of the option\_list.

Because some string values contain a date representation, the corresponding columns are declared as datetime and the date format is specified for them.

The Jpath of the object option has the same syntax as the column Jpath but of course all array steps must be specified using the [n] (until Connect 1.5) or n (from Connect 1.6) format.

Note: This applies to the whole document for tables having

PRETTY = 2

(see below). Otherwise, it applies to the document objects of each file records.

## JSON File Formats

The examples we have seen so far are files that, even they can be formatted in different ways (blanks, tabs, carriage return and line feed are ignored when parsing them), respect the JSON syntax and are made of only one item (Object or Array). Like for XML files, they are entirely parsed and a memory representation is made used to process them. This implies that they are of reasonable size to avoid an out of memory condition. Tables based on such files are recognized by the option Pretty=2 that we did not specify above because this is the default.

An alternate format, which is the format of exported MongoDB files, is a file where each row is physically stored in one file record. For instance:

```
{ "_id" : "01001", "city" : "AGAWAM", "loc" : [ -72.622739, 42.070206 ], "pop" : 15338, "state" : "MA" }
{ "_id" : "01002", "city" : "CUSHMAN", "loc" : [ -72.51564999999999, 42.377017 ], "pop" : 36963, "state" : "MA" }
{ "_id" : "01005", "city" : "BARRE", "loc" : [ -72.1083540000001, 42.409698 ], "pop" : 4546, "state" : "MA" }
{ "_id" : "01007", "city" : "BELCHERTOWN", "loc" : [ -72.4109530000001, 42.275103 ], "pop" : 10579, "state" : "MA" }
...
{ "_id" : "99929", "city" : "WRANGELL", "loc" : [ -132.352918, 56.433524 ], "pop" : 2573, "state" : "AK" }
{ "_id" : "99950", "city" : "KETCHIKAN", "loc" : [ -133.18479, 55.942471 ], "pop" : 422, "state" : "AK" }
```

The original file, "cities.json", has 29352 records. To base a table on this file we must specify the option Pretty=0 in the option list. For instance:

From Connect 1.07.0002:

```
create table cities (
`_id` char(5) key,
`city` char(32),
`lat` double(12,6) jpath='loc.0',
`long` double(12,6) jpath='loc.1',
`pop` int(8),
`state` char(2) distrib='clustered')
engine=CONNECT table_type=JSON file_name='cities.json' lrec=128 option_list='pretty=0';
```

From Connect 1.6:

```
create table cities (
`_id` char(5) key,
`city` char(32),
`lat` double(12,6) field_format='loc.0',
`long` double(12,6) field_format='loc.1',
`pop` int(8),
`state` char(2) distrib='clustered')
engine=CONNECT table_type=JSON file_name='cities.json' lrec=128 option_list='pretty=0';
```

Until Connect 1.5:

```

create table cities (
`_id` char(5) key,
`city` char(32),
`long` double(12,6) field_format='loc:[0]',
`lat` double(12,6) field_format='loc:[1]',
`pop` int(8),
`state` char(2) distrib='clustered')
engine=CONNECT table_type=JSON file_name='cities.json' lrecl=128 option_list='pretty=0';

```

Note the use of [n] (until Connect 1.5) or n (from Connect 1.6) array specifications for the longitude and latitude columns.

When using this format, the table is processed by CONNECT like a DOS, CSV or FMT table. Rows are retrieved and parsed by records and the table can be very large. Another advantage is that such a table can be indexed, which can be of great value for very large tables. The “distrib” option of the “state” column tells CONNECT to use block indexing when possible.

For such tables – as well as for pretty=1 ones – the record size must be specified using the LRECL option. Be sure you don’t specify it too small as it is used to allocate the read/write buffers and the memory used for parsing the rows. If in doubt, be generous as it does not cost much in memory allocation.

Another format exists, noted by Pretty=1, which is similar to this one but has some additions to represent a JSON array. A header and a trailer records are added containing the opening and closing square bracket, and all records but the last are followed by a comma. It has the same advantages for reading and updating, but inserting and deleting are executed in the pretty=2 way.

## Alternate Table Arrangement

We have seen that the most natural way to represent a table in a JSON file is to make it on an array of objects. However, other possibilities exist. A table can be an array of arrays, a one column table can be an array of values, or a one row table can be just one object or one value. Single row tables are internally handled by adding a one value array around them.

Let us see how to handle, for instance, a table that is an array of arrays. The file:

```

[
  [56, "Coucou", 500.00],
  [[2,0,1,4], "Hello World", 2.0316],
  ["1784", "John Doo", 32.4500],
  [1914, ["Nabucho","donosor"], 5.12],
  [7, "sept", [0.77,1.22,2.01]],
  [8, "huit", 13.0]
]
```

A table can be created on this file as:

From Connect 1.07.0002:

```

create table xjson (
`a` int(6) jpath='1',
`b` char(32) jpath='2',
`c` double(10,4) jpath='3')
engine=connect table_type=JSON file_name='test.json' option_list='Pretty=1,Jmode=1,Base=1' lrecl=128;

```

From Connect 1.6:

```

create table xjson (
`a` int(6) field_format='1',
`b` char(32) field_format='2',
`c` double(10,4) field_format='3')
engine=connect table_type=JSON file_name='test.json' option_list='Pretty=1,Jmode=1,Base=1' lrecl=128;

```

Until Connect 1.5:

```

create table xjson (
`a` int(6) field_format='[1]',
`b` char(32) field_format='[2]',
`c` double(10,4) field_format='[3]')
engine=connect table_type=JSON file_name='test.json'
option_list='Pretty=1,Jmode=1,Base=1' lrecl=128;

```

Columns are specified by their position in the row arrays. By default, this is zero-based but for this table the base was set to 1 by the Base option of the option list. Another new option in the option list is Jmode=1. It indicates what type of table this is. The Jmode values are:

1. An array of objects. This is the default.
2. An array of Array. Like this one.
3. An array of values.

When reading, this is not required as the type of the array items is specified for the columns; however, it is required when inserting new rows so

CONNECT knows what to insert. For instance:

```
insert into xjson values(25, 'Breakfast', 1.414);
```

After this, it is displayed as:

| a    | b           | c        |
|------|-------------|----------|
| 56   | Coucou      | 500.0000 |
| 2    | Hello World | 2.0316   |
| 1784 | John Doo    | 32.4500  |
| 1914 | Nabucho     | 5.1200   |
| 7    | sept        | 0.7700   |
| 8    | huit        | 13.0000  |
| 25   | Breakfast   | 1.4140   |

Unspecified array values are represented by their first element.

## Getting and Setting JSON Representation of a Column

We have seen that columns corresponding to a Json object or array are retrieved by default as the concatenation of all its values separated by a blank. It is also possible to retrieve and display such column contains as the full JSON string corresponding to it in the JSON file. This is specified in the JPATH by a "\*" where the object or array would be specified.

Note: When having columns generated by discovery, this can be specified by adding the STRINGIFY option to ON or 1 in the option list.

For instance:

From Connect 1.07.0002:

```
create table jsample2 (
ISBN char(15),
Lng char(2) jpath='LANG',
json_Author char(255) jpath='AUTHOR.*',
Title char(32) jpath='TITLE',
Year int(4) jpath='DATEPUB')
engine=CONNECT table_type=JSON file_name='biblio3.json';
```

From Connect 1.6:

```
create table jsample2 (
ISBN char(15),
Lng char(2) field_format='LANG',
json_Author char(255) field_format='AUTHOR.*',
Title char(32) field_format='TITLE',
Year int(4) field_format='DATEPUB')
engine=CONNECT table_type=JSON file_name='biblio3.json';
```

Until Connect 1.5:

```
create table jsample2 (
ISBN char(15),
Lng char(2) field_format='LANG',
json_Author char(255) field_format='AUTHOR:*',
Title char(32) field_format='TITLE',
Year int(4) field_format='DATEPUB')
engine=CONNECT table_type=JSON file_name='biblio3.json';
```

Now the query:

```
select json_Author from jsample2;
```

will return and display :

| json_Author                                                                                         |
|-----------------------------------------------------------------------------------------------------|
| [{"FIRSTNAME":"Jean-Christophe","LASTNAME":"Bernadac"}, {"FIRSTNAME":"François","LASTNAME":"Knab"}] |
| [{"FIRSTNAME":"William J.","LASTNAME":"Pardi"}]                                                     |

Note: Prefixing the column name by `json_` is optional but is useful when using the column as argument to Connect UDF functions, making it to be surely recognized as valid Json without aliasing.

This also works on input, a column specified so that it can be directly set to a valid JSON string.

This feature is of great value as we will see below.

## Create, Read, Update and Delete Operations on JSON Tables

The SQL commands INSERT, UPDATE and DELETE are fully supported for JSON tables except those returned by REST queries. For INSERT and UPDATE, if the target values are simple values, there are no problems.

However, there are some issues when the added or modified values are objects or arrays.

Concerning objects, the same problems exist that we have already seen with the XML type. The added or modified object will have the format described in the table definition, which can be different from the one of the JSON file. Modifications should be done using a file specifying the full path of modified objects.

New problems are raised when trying to modify the values of an array. Only updates can be done on the original table. First of all, for the values of the array to be distinct values, all update operations concerning array values must be done using a table expanding this array.

For instance, to modify the authors of the

```
biblio.json  
based table, the  
jsampex
```

table must be used. Doing so, updating and deleting authors is possible using standard SQL commands. For example, to change the first name of Knab from François to John:

```
update jsampex set authorfn = 'John' where authorln = 'Knab';
```

However It would be wrong to do:

```
update jsampex set authorfn = 'John' where isbn = '9782212090819';
```

Because this would change the first name of both authors as they share the same ISBN.

Where things become more difficult is when trying to delete or insert an author of a book. Indeed, a delete command will delete the whole book and an insert command will add a new complete row instead of adding a new author in the same array. Here we are penalized by the SQL language that cannot give us a way to specify this. Something like:

```
update jsampex add authorfn = 'Charles', authorln = 'Dickens'  
where title = 'XML en Action';
```

However this does not exist in SQL. Does this mean that it is impossible to do it? No, but it requires us to use a table specified on the same file but adapted to this task. One way to do it is to specify a table for which the authors are no more an expanded array. Supposing we want to add an author to the "XML en Action" book. We will do it on a table containing just the author(s) of that book, which is the second book of the table.

From Connect 1.6:

```
create table jaauthor (  
FIRSTNAME char(64),  
LASTNAME char(64))  
engine=CONNECT table_type=JSON File_name='biblio3.json' option_list='Object=1.AUTHOR';
```

Until Connect 1.5

```
create table jaauthor (  
FIRSTNAME char(64),  
LASTNAME char(64))  
engine=CONNECT table_type=JSON File_name='biblio3.json' option_list='Object=[1]:AUTHOR';
```

The command:

```
select * from jaauthor;
```

replies:

| FIRSTNAME  | LASTNAME |
|------------|----------|
| William J. | Pardi    |

It is a standard JSON table that is an array of objects in which we can freely insert or delete rows.

```
insert into jauthor values('Charles','Dickens');
```

We can check that this was done correctly by:

```
select * from jsampex;
```

This will display:

| ISBN          | Title                          | AuthorFN        | AuthorLN | Year |
|---------------|--------------------------------|-----------------|----------|------|
| 9782212090819 | Construire une application XML | Jean-Christophe | Bernadac | 1999 |
| 9782212090819 | Construire une application XML | John            | Knab     | 1999 |
| 9782840825685 | XML en Action                  | William J.      | Pardi    | 1999 |
| 9782840825685 | XML en Action                  | Charles         | Dickens  | 1999 |

Note: If this table were a big table with many books, it would be difficult to know what the order of a specific book is in the table. This can be found by adding a special ROWID column in the table.

However, an alternate way to do it is by using direct JSON column representation as in the JSAMPLE2 table. This can be done by:

```
update jsample2 set json_Author =
'[{"FIRSTNAME":"William J.","LASTNAME":"Pardi"}, {"FIRSTNAME":"Charles","LASTNAME":"Dickens"}]'
where isbn = '9782840825685';
```

Here, we didn't have to find the index of the sub array to modify. However, this is not quite satisfying because we had to manually write the whole JSON value to set to the json\_Author column.

Therefore we need specific functions to do so. They are introduced now.

## JSON User Defined Functions

Although such functions written by other parties do exist, [2] CONNECT provides its own UDFs that are specifically adapted to the JSON table type and easily available because, being inside the CONNECT library or DLL, they require no additional module to be loaded (see [CONNECT - Compiling JSON UDFs in a Separate Library](#) to make these functions in a separate library module).

In particular, [MariaDB 10.2](#) and 10.3 feature native JSON functions. In some cases, it is possible that these native functions can be used. However, mixing native and UDF JSON functions in the same query often does not work because the way they recognize their arguments is different and might even cause a server crash.

Here is the list of the CONNECT functions; more can be added if required.

| Name                  | Type     | Return  | Description                                               | Added                          |
|-----------------------|----------|---------|-----------------------------------------------------------|--------------------------------|
| jbin_array            | Function | STRING* | Make a JSON array containing its arguments.               | <a href="#">MariaDB 10.1.9</a> |
| jbin_array_add        | Function | STRING* | Adds to its first array argument its second arguments.    | <a href="#">MariaDB 10.1.9</a> |
| jbin_array_add_values | Function | STRING* | Adds to its first array argument all following arguments. |                                |
| jbin_array_delete     | Function | STRING* | Deletes the nth element of its first array argument.      | <a href="#">MariaDB 10.1.9</a> |
| jbin_file             | Function | STRING* | Returns of a (json) file contain.                         | <a href="#">MariaDB 10.1.9</a> |
| jbin_get_item         | Function | STRING* | Access and returns a json item by a JPATH key.            | <a href="#">MariaDB 10.1.9</a> |
| jbin_insert_item      | Function | STRING  | Insert item values located to paths.                      |                                |
| jbin_item_merge       | Function | STRING* | Merges two arrays or two objects.                         | <a href="#">MariaDB 10.1.9</a> |
| jbin_object           | Function | STRING* | Make a JSON object containing its arguments.              | <a href="#">MariaDB 10.1.9</a> |
| jbin_object_nonull    | Function | STRING* | Make a JSON object containing its not null arguments.     | <a href="#">MariaDB 10.1.9</a> |
| jbin_object_add       | Function | STRING* | Adds to its first object argument its second argument.    | <a href="#">MariaDB 10.1.9</a> |
| jbin_object_delete    | Function | STRING* | Deletes the nth element of its first object argument.     | <a href="#">MariaDB 10.1.9</a> |
| jbin_object_key       | Function | STRING* | Make a JSON object for key/value pairs.                   |                                |
| jbin_object_list      | Function | STRING* | Returns the list of object keys as an array.              | <a href="#">MariaDB 10.1.9</a> |
| jbin_set_item         | Function | STRING  | Set item values located to paths.                         |                                |

|                       |           |         |                                                                                                          |                                                                      |
|-----------------------|-----------|---------|----------------------------------------------------------------------------------------------------------|----------------------------------------------------------------------|
| jbin_update_item      | Function  | STRING  | Update item values located to paths.                                                                     |                                                                      |
| jfile_json            | Function  | STRING  | Convert a pretty=0 file to another BJson file.                                                           | MariaDB 10.5.9 , MariaDB 10.4.18 , MariaDB 10.3.28 , MariaDB 10.2.36 |
| jfile_convert         | Function  | STRING  | Convert a Json file to another pretty=0 file.                                                            | MariaDB 10.5.9 , MariaDB 10.4.18 , MariaDB 10.3.28 , MariaDB 10.2.36 |
| jfile_make            | Function  | STRING  | Make a json file from its json item first argument.                                                      | MariaDB 10.1.9                                                       |
| json_array            | Function  | STRING  | Make a JSON array containing its arguments.                                                              | MariaDB 10.0.17 until Connect 1.5                                    |
| json_array_add        | Function  | STRING  | Adds to its first array argument its second arguments (before MariaDB 10.1.9 , all following arguments). |                                                                      |
| json_array_add_values | Function  | STRING  | Adds to its first array argument all following arguments.                                                | MariaDB 10.1.9                                                       |
| json_array_delete     | Function  | STRING  | Deletes the nth element of its first array argument.                                                     |                                                                      |
| json_array_grp        | Aggregate | STRING  | Makes JSON arrays from coming argument.                                                                  |                                                                      |
| json_file             | Function  | STRING  | Returns the contains of (json) file.                                                                     | MariaDB 10.1.9                                                       |
| json_get_item         | Function  | STRING  | Access and returns a json item by a JPATH key.                                                           | MariaDB 10.1.9                                                       |
| json_insert_item      | Function  | STRING  | Insert item values located to paths.                                                                     |                                                                      |
| json_item_merge       | Function  | STRING  | Merges two arrays or two objects.                                                                        | MariaDB 10.1.9                                                       |
| json_locate_all       | Function  | STRING  | Returns the JPATH's of all occurrences of an element.                                                    | MariaDB 10.1.9                                                       |
| json_make_array       | Function  | STRING  | Make a JSON array containing its arguments.                                                              | From Connect 1.6                                                     |
| json_make_object      | Function  | STRING  | Make a JSON object containing its arguments.                                                             | From Connect 1.6                                                     |
| json_object           | Function  | STRING  | Make a JSON object containing its arguments.                                                             | MariaDB 10.0.17 until Connect 1.5                                    |
| json_object_delete    | Function  | STRING  | Deletes the nth element of its first object argument.                                                    | MariaDB 10.1.9                                                       |
| json_object_grp       | Aggregate | STRING  | Makes JSON objects from coming arguments.                                                                |                                                                      |
| json_object_list      | Function  | STRING  | Returns the list of object keys as an array.                                                             | MariaDB 10.1.9                                                       |
| json_object_nonull    | Function  | STRING  | Make a JSON object containing its not null arguments.                                                    |                                                                      |
| json_serialize        | Function  | STRING  | Serializes the return of a "Jbin" function.                                                              | MariaDB 10.1.9                                                       |
| json_set_item         | Function  | STRING  | Set item values located to paths.                                                                        |                                                                      |
| json_update_item      | Function  | STRING  | Update item values located to paths.                                                                     |                                                                      |
| jsonvalue             | Function  | STRING  | Make a JSON value from its unique argument. Called json_value until MariaDB 10.0.22 and MariaDB 10.1.8 . | MariaDB 10.0.17                                                      |
| jsoncontains          | Function  | INTEGER | Returns 0 or 1 if an element is contained in the document.                                               |                                                                      |
| jsoncontains_path     | Function  | INTEGER | Returns 0 or 1 if a JPATH is contained in the document.                                                  |                                                                      |
| jsonget_string        | Function  | STRING  | Access and returns a string element by a JPATH key.                                                      | MariaDB 10.1.9                                                       |
| jsonget_int           | Function  | INTEGER | Access and returns an integer element by a JPATH key.                                                    | MariaDB 10.1.9                                                       |
| jsonget_real          | Function  | REAL    | Access and returns a real element by a JPATH key.                                                        | MariaDB 10.1.9                                                       |
| jsonlocate            | Function  | STRING  | Returns the JPATH to access one element.                                                                 | MariaDB 10.1.9                                                       |

String values are mapped to JSON strings. These strings are automatically escaped to conform to the JSON syntax. The automatic escaping is bypassed when the value has an alias beginning with 'json\_'. This is automatically the case when a JSON UDF argument is another JSON UDF whose name begins with "json\_" (not case sensitive). This is why all functions that do not return a Json item are not prefixed by "json\_".

Argument string values, for some functions, can alternatively be json file names. When this is ambiguous, alias them as *jfile\_*. Full path should be used because UDF functions has no means to know what the current database is. Apparently, when the file name path is not full, it is based on the MariaDB data directory but I am not sure it is always true.

Numeric values are (big) integers, double floating point values or decimal values. Decimal values are character strings containing a numeric representation and are treated as strings. Floating point values contain a decimal point and/or an exponent. Integers are written without decimal points.

To install these functions execute the following commands : [3]

Note: Json function names are often written on this page with leading upper case letters for clarity. It is possible to do so in SQL queries because function names are case insensitive. However, when creating or dropping them, their names must match the case they are in the library module (lower case from MariaDB 10.1.9 ).

On Unix systems (from Connect 1.7.02):

```
create function jsonvalue returns string soname 'ha_connect.so';
create function json_make_array returns string soname 'ha_connect.so';
create function json_array_add_values returns string soname 'ha_connect.so';
create function json_array_add returns string soname 'ha_connect.so';
create function json_array_delete returns string soname 'ha_connect.so';
create function json_make_object returns string soname 'ha_connect.so';

create function jbin_set_item returns string soname 'ha_connect';
create function jbin_insert_item returns string soname 'ha_connect';
create function jbin_update_item returns string soname 'ha_connect';
create function jbin_file returns string soname 'ha_connect';

```

## Jfile\_Bjson

MariaDB starting with 10.2.36

JFile\_Bjson was introduced in [MariaDB 10.5.9](#) , [MariaDB 10.4.18](#) , [MariaDB 10.3.28](#) and [MariaDB 10.2.36](#) .

```
Jfile_Bjson(in_file_name, out_file_name, lrecl)
```

Converts the first argument pretty=0 json file to Bjson file. B(binary)json is a pre-parsed json format. It is described below in the Performance chapter (available in next Connect versions).

## Jfile\_Convert

MariaDB starting with 10.2.36

JFile\_Convert was introduced in [MariaDB 10.5.9](#) , [MariaDB 10.4.18](#) , [MariaDB 10.3.28](#) and [MariaDB 10.2.36](#) .

```
Jfile_Convert(in_file_name, out_file_name, lrecl)
```

Converts the first argument json file to another *pretty=0* json file. The third integer argument is the record length to use. This is often required to process huge json files that would be very slow if they were in *pretty=2* format.

This is done without completely parsing the file, is very fast and requires no big memory.

## Jfile\_Make

MariaDB starting with [10.1.9](#)

Jfile\_Make was added in CONNECT 1.4 (from [MariaDB 10.1.9](#) ).

```
Jfile_Make(arg1, arg2, [arg3], ...)
```

The first argument must be a json item (if it is just a string, Jfile\_Make will try its best to see if it is a json item or an input file name). The following arguments are a string file name and an integer pretty value (defaulting to 2) in any order. This function creates a json file containing the first argument item.

The returned string value is the created file name. If not specified as an argument, the file name can in some cases be retrieved from the first argument; in such cases the file itself is modified.

This function can be used to create or format a json file. For instance, supposing we want to format the file tb.json, this can be done with the query:

```
select Jfile_Make('tb.json' jfile_, 2);
```

The tb.json file will be changed to:

```
[  
  {  
    "_id": 5,  
    "type": "food",  
    "ratings": [  
      5,  
      8,  
      9  
    ]  
  },  
  {  
    "_id": 6,  
    "type": "car",  
    "ratings": [  
      5,  
      9  
    ]  
  }  
]
```

## Json\_Array\_Add

```
Json_Array_Add(arg1, arg2, [arg3][, arg4][, ...])
```

Note: In CONNECT version 1.3 (before [MariaDB 10.1.9](#) ), this function behaved like the new

`Json_Array_Add_Values`

function. The following describes this function for CONNECT version 1.4 (from [MariaDB 10.1.9](#) ) only. The first argument must be a JSON array. The second argument is added as member of this array. For example:

```
select Json_Array_Add(Json_Array(56,3.1416,'machin',NULL),  
'One more') Array;
```

Array

```
[56,3.141600,"machin",null,"One more"]
```

Note: The first array is not escaped, its (alias) name beginning with 'json\_.'

Now we can see how adding an author to the JSAMPLE2 table can alternatively be done:

```
update jsample2 set  
  json_author = json_array_add(json_author, json_object('Charles' FIRSTNAME, 'Dickens' LASTNAME))  
  where isbn = '9782840825685';
```

Note: Calling a column returning JSON a name prefixed by `json_` (like `json_author` here) is good practice and removes the need to give it an alias to prevent escaping when used as an argument.

Additional arguments: If a third integer argument is given, it specifies the position (zero based) of the added value:

```
select Json_Array_Add('[5,3,8,7,9]' json_, 4, 2) Array;
```

## Array

```
[5,3,4,8,7,9]
```

If a string argument is added, it specifies the Json path to the array to be modified. For instance:

```
select Json_Array_Add('{"a":1,"b":2,"c":[3,4]}' json_, 5, 1, 'c');
```

## Json\_Array\_Add('{"a":1,"b":2,"c":[3,4]}' json\_, 5, 1, 'c')

```
{"a":1,"b":2,"c":[3,5,4]}
```

## Json\_Array\_Add\_Values

Json\_Array\_Add\_Values added in CONNECT 1.4 replaces the function Json\_Array\_Add of CONNECT version 1.3 (before MariaDB 10.1.9 ).

```
Json_Array_Add_Values(arg, arglist)
```

The first argument must be a JSON array string. Then all other arguments are added as members of this array. For example:

```
select Json_Array_Add_Values  
(Json_Array(56, 3.1416, 'machin', NULL), 'One more', 'Two more') Array;
```

## Array

```
[56,3.141600,"machin",null,"One more","Two more"]
```

## Json\_Array\_Delete

```
Json_Array_Delete(arg1, arg2 [,arg3] [...])
```

The first argument should be a JSON array. The second argument is an integer indicating the rank (0 based conforming to general json usage) of the element to delete. For example:

```
select Json_Array_Delete(Json_Array(56,3.1416,'foo',NULL),1) Array;
```

## Array

```
[56,"foo",null]
```

Now we can see how to delete the second author from the JSAMPLE2 table:

```
update jsample2 set json_author = json_array_delete(json_author, 1)  
where isbn = '9782840825685';
```

A Json path can be specified as a third string argument

## Json\_Array\_Grp

```
Json_Array_Grp(arg)
```

This is an aggregate function that makes an array filled from values coming from the rows retrieved by a query. Let us suppose we have the pet table:

| name    | race   | number |
|---------|--------|--------|
| John    | dog    | 2      |
| Bill    | cat    | 1      |
| Mary    | dog    | 1      |
| Mary    | cat    | 1      |
| Lisbeth | rabbit | 2      |
| Kevin   | cat    | 2      |

|        |      |   |
|--------|------|---|
| Kevin  | bird | 6 |
| Donald | dog  | 1 |
| Donald | fish | 3 |

The query:

```
select name, json_array_grp(race) from pet group by name;
```

will return:

| name    | json_array_grp(race) |
|---------|----------------------|
| Bill    | ["cat"]              |
| Donald  | ["dog", "fish"]      |
| John    | ["dog"]              |
| Kevin   | ["cat", "bird"]      |
| Lisbeth | ["rabbit"]           |
| Mary    | ["dog", "cat"]       |

One problem with the JSON aggregate functions is that they construct their result in memory and cannot know the needed amount of storage, not knowing the number of rows of the used table.

Therefore, the number of values for each group is limited. This limit is the value of JsonGrpSize whose default value is 10 but can be set using the JsonSet\_Grp\_Size function. Nevertheless, working on a larger table is possible, but only after setting JsonGrpSize to the ceiling of the number of rows per group for the table. Try not to set it to a very large value to avoid memory exhaustion.

## JsonContains

```
JsonContains(json_doc, item [, int])<
```

This function can be used to check whether an item is contained in a document. Its arguments are the same than the ones of the JsonLocate function; only the return value changes. The integer returned value is 1 if the item is contained in the document or 0 otherwise.

## JsonContains\_Path

```
JsonContains_Path(json_doc, path)
```

This function can be used to check whether a Json path is contained in the document. The integer returned value is 1 if the path is contained in the document or 0 otherwise.

## Json\_File

```
Json_File(arg1, [arg2, [arg3]], ...)
```

The first argument must be a file name. This function returns the text of the file that is supposed to be a json file. If only one argument is specified, the file text is returned without being parsed. Up to two additional arguments can be specified:

A string argument is the path to the sub-item to be returned. An integer argument specifies the pretty format value of the file.

This function is chiefly used to get the json item argument of other json functions from a json file. For instance, supposing the file tb.json is:

```
{ "_id" : 5, "type" : "food", "ratings" : [ 5, 8, 9 ] }
{ "_id" : 6, "type" : "car", "ratings" : [ 5, 9 ] }
```

Extracting a value from it can be done with a query such as:

```
select JsonGet_String(Json_File('tb.json', 0), '[1]:type') "Type";
```

or, from MariaDB 10.2.8 :

```
select JsonGet_String(Json_File('tb.json', 0), '$[1].type') "Type";
```

This query returns:

**Type**

car

However, we'll see that, most of the time, it is better to use Jbin\_File or to directly specify the file name in queries. In particular this function should not be used for queries that must modify the json item because, even if the modified json is returned, the file itself would be unchanged.

## Json\_Get\_Item

MariaDB starting with [10.1.9](#)

Json\_Get\_Item was added in CONNECT 1.4 (from [MariaDB 10.1.9](#) ).

```
Json_Get_Item(arg1, arg2, ...)
```

This function returns a subset of the json document passed as first argument. The second argument is the json path of the item to be returned and should be one returning a json item (terminated by a '\*'). If not, the function will try to make it right but this is not foolproof. For instance:

```
select Json_Get_Item(Json_Object('foo' as "first", Json_Array('a', 33)
                                as "json_second"), 'second') as "item";
```

The correct path should have been 'second:'\* (or from [MariaDB 10.2.8](#) , 'second.\*'), but in this simple case the function was able to make it right. The returned item:

**item**

["a",33]

Note: The array is aliased "json\_second" to indicate it is a json item and avoid escaping it. However, the "json\_" prefix is skipped when making the object and must not be added to the path.

## JsonGet\_Grp\_Size

```
JsonGet_Grp_Size(val)
```

This function returns the JsonGrpSize value.

## JsonGet\_String / JsonGet\_Int / JsonGet\_Real

MariaDB starting with [10.1.9](#)

JsonGet\_String, JsonGet\_Int and JsonGet\_Real were added in CONNECT 1.4 (from [MariaDB 10.1.9](#) ).

```
JsonGet_String(arg1, arg2, [arg3] ...)
JsonGet_Int(arg1, arg2, [arg3] ...)
JsonGet_Real(arg1, arg2, [arg3] ...)
```

The first argument should be a JSON item. If it is a string with no alias, it will be converted as a json item. The second argument is the path of the item to be located in the first argument and returned, eventually converted according to the used function. For example:

```
select
JsonGet_String('{"qty":7,"price":29.50,"garanty":null}', 'price') "String",
JsonGet_Int('{"qty":7,"price":29.50,"garanty":null}', 'price') "Int",
JsonGet_Real('{"qty":7,"price":29.50,"garanty":null}', 'price') "Real";
```

This query returns:

| String | Int | Real               |
|--------|-----|--------------------|
| 29.50  | 29  | 29.500000000000000 |

The function `JsonGet_Real` can be given a third argument to specify the number of decimal digits of the returned value. For instance:

```
select
JsonGet_Real('{"qty":7,"price":29.50,"garanty":null}', 'price', 4) "Real";
```

This query returns:

## String

29.50

The given path can specify all operators for arrays except the "expand" [X] operator (or from [MariaDB 10.2.8](#), the "expand" [\*] operator). For instance:

```
select
JsonGet_Int(Json_Array(45,28,36,45,89), '[4]') "Rank",
JsonGet_Int(Json_Array(45,28,36,45,89), '[#]') "Number",
JsonGet_String(Json_Array(45,28,36,45,89), '[""]') "Concat",
JsonGet_Int(Json_Array(45,28,36,45,89), '[+]') "Sum",
JsonGet_Real(Json_Array(45,28,36,45,89), '[!]', 2) "Avg";
```

The result:

| Rank | Number | Concat         | Sum | Avg   |
|------|--------|----------------|-----|-------|
| 89   | 5      | 45,28,36,45,89 | 243 | 48.60 |

## Json\_Item\_Merge

```
Json_Item_Merge(arg1, arg2, ...)
```

This function merges two arrays or two objects. For arrays, this is done by adding to the first array all the values of the second array. For instance:

```
select Json_Item_Merge(Json_Array('a','b','c'), Json_Array('d','e','f')) as "Result";
```

The function returns:

| Result                    |
|---------------------------|
| ["a","b","c","d","e","f"] |

For objects, the pairs of the second object are added to the first object if the key does not yet exist in it; otherwise the pair of the first object is set with the value of the matching pair of the second object. For instance:

```
select Json_Item_Merge(Json_Object(1 "a", 2 "b", 3 "c"), Json_Object(4 "d",5 "b",6 "f"))
as "Result";
```

The function returns:

| Result                          |
|---------------------------------|
| {"a":1,"b":5,"c":3,"d":4,"f":6} |

## JsonLocate

```
JsonLocate(arg1, arg2, [arg3], ...):
```

The first argument must be a JSON tree. The second argument is the item to be located. The item to be located can be a constant or a json item. Constant values must be equal in type and value to be found. This is "shallow equality" – strings, integers and doubles won't match.

This function returns the json path to the located item or null if it is not found. For example:

```
select JsonLocate('{"AUTHORS":[{"FN":"Jules", "LN":"Verne"}, {"FN":"Jack", "LN":"London"}]}' json_, 'Jack') Path;
```

This query returns:

| Path           |
|----------------|
| AUTHORS:[1]:FN |

or, from [MariaDB 10.2.8](#):

| Path             |
|------------------|
| \$.AUTHORS[1].FN |

The path syntax is the same used in JSON CONNECT tables.

By default, the path of the first occurrence of the item is returned. The third parameter can be used to specify the occurrence whose path is to be returned.

For instance:

```
select
JsonLocate('[[45,28],[36,45],89]',45) first,
JsonLocate('[[45,28],[36,45],89]',45,2) second,
JsonLocate('[[45,28],[36,45],89]',45,0) `wrong type`,
JsonLocate('[[45,28],[36,45],89]','[36,45]' json_) json;
```

| first | second  | wrong type | json |
|-------|---------|------------|------|
| [0]   | [2]:[1] | <null>     | [2]  |

or, from [MariaDB 10.2.8](#):

| first | second   | wrong type | json  |
|-------|----------|------------|-------|
| [\$0] | [\$2][1] | <null>     | [\$2] |

For string items, the comparison is case sensitive by default. However, it is possible to specify a string to be compared case insensitively by giving it an alias beginning by "ci":

```
select JsonLocate('{"AUTHORS":[{"FN":"Jules", "LN":"Verne"}, {"FN":"Jack", "LN":"London"}]}', json_, 'VERNE' ci) Path;
```

| Path           |
|----------------|
| AUTHORS:[0]:LN |

or, from [MariaDB 10.2.8](#):

| Path             |
|------------------|
| \$.AUTHORS[0].LN |

## Json\_Locate\_All

```
Json_Locate_All(arg1, arg2, [arg3], ...):
```

The first argument must be a JSON item. The second argument is the item to be located. This function returns the paths to all locations of the item as an array of strings. For example:

```
select Json_Locate_All('[[45,28],[[36,45],89]]',45);
```

This query returns:

| All paths                |
|--------------------------|
| "[0]:[0]", "[1]:[0]:[1]" |

or, from [MariaDB 10.2.8](#):

| All paths                 |
|---------------------------|
| "\$[0][0]", "\$[1][0][1]" |

The returned array can be applied other functions. For instance, to get the number of occurrences of an item in a json tree, you can do:

```
select JsonGet_Int(Json_Locate_All('[[45,28],[[36,45],89]]',45), '[#]') "Nb of occurs";
```

or, from [MariaDB 10.2.8](#):

```
select JsonGet_Int(Json_Locate_All('[[45,28],[[36,45],89]]',45), '$[#]') "Nb of occurs";
```

The displayed result:

| Nb of occurs |
|--------------|
| 2            |

If specified, the third integer argument set the depth to search in the document. This means the maximum items in the paths (until [MariaDB 10.2.7](#), the number of ':' separator characters in them plus one). This value defaults to 10 but can be increased for complex documents or reduced to set the maximum wanted depth of the returned paths.

## Json\_Make\_Array

```
Json_Make_Array(val1, ..., valn)
```

This function was named “Json\_Array” in previous versions of CONNECT. It was renamed because MariaDB 10.2 features native JSON functions including a [Json\\_Array](#) function. The native function does almost the same as the UDF one, but does not accept CONNECT-specific arguments such as the result from JBIN functions.

Json\_Make\_Array returns a string denoting a JSON array with all its arguments as members. For example:

```
select Json_Make_Array(56, 3.1416, 'My name is "Foo"', NULL);
```

```
Json_Make_Array(56, 3.1416, 'My name is "Foo"', NULL)
```

```
[56,3.141600,"My name is \"Foo\"",null]
```

Note: The argument list can be void. If so, a void array is returned.

This function was named “Json\_Array” in previous versions of CONNECT. It was renamed because MariaDB 10.2 features native JSON functions including a “Json\_Array” function. The native function does almost the same as the UDF one but does not accept CONNECT specific arguments such as the result from JBIN functions.

## Json\_Make\_Object

```
Json_Make_Object(arg1, ..., argn)
```

This function was named “Json\_Object” in previous versions of CONNECT. It was renamed because MariaDB 10.2 features native JSON functions including a [Json\\_Object](#) function. The native function does what the UDF Json\_Object\_Key does.

Json\_Make\_Object returns a string denoting a JSON object. For instance:

```
select Json_Make_Object(56, 3.1416, 'machin', NULL);
```

The object is filled with pairs corresponding to the given arguments. The key of each pair is made from the argument (default or specified) alias.

```
Json_Make_Object(56, 3.1416, 'machin', NULL)
```

```
{"56":56,"3.1416":3.141600,"machin":"machin","NULL":null}
```

When needed, it is possible to specify the keys by giving an alias to the arguments:

```
select Json_Make_Object(56 qty, 3.1416 price, 'machin' truc, NULL garanty);
```

```
Json_Make_Object(56 qty, 3.1416 price, 'machin' truc, NULL garanty)
```

```
{"qty":56,"price":3.141600,"truc":"machin","garanty":null}
```

If the alias is prefixed by ‘json\_’ (to prevent escaping) the key name is stripped from that prefix.

This function is chiefly useful when entering values retrieved from a table, the key being by default the column name:

```
select Json_Make_Object(matricule, nom, titre, salaire) from connect.employe where nom = 'PANTIER';
```

```
Json_Make_Object(matricule, nom, titre, salaire)
```

```
{"matricule":40567,"nom":"PANTIER","titre":"DIRECTEUR","salaire":14000.000000}
```

This function was named “Json\_Object” in previous versions of CONNECT. It was renamed because MariaDB 10.2 features native JSON functions including a “Json\_Object” function. The native function does what the UDF Json\_Object\_Key does.

## Json\_Object\_Add

```
Json_Object_Add(arg1, arg2, [arg3] ...)
```

The first argument must be a JSON object. The second argument is added as a pair to this object. For example:

```
select Json_Object_Add
('{"item":"T-shirt","qty":27,"price":24.99}' json_old,'blue' color) newobj;
```

## newobj

```
{"item":"T-shirt","qty":27,"price":24.990000,"color":"blue"}
```

Note: If the specified key already exists in the object, its value is replaced by the new one.

The third string argument is a Json path to the target object.

## Json\_Object\_Delete

```
Json_Object_Delete(arg1, arg2, [arg3] ...):
```

The first argument must be a JSON object. The second argument is the key of the pair to delete. For example:

```
select Json_Object_Delete('{"item":"T-shirt","qty":27,"price":24.99}' json_old, 'qty') newobj;
```

## newobj

```
{"item":"T-shirt","price":24.99}
```

The third string argument is a Json path to the object to be the target of deletion.

## Json\_Object\_Grp

```
Json_Object_Grp(arg1,arg2)
```

This function works like Json\_Array\_Grp. It makes a JSON object filled with value pairs whose keys are passed from its first argument and values are passed from its second argument.

This can be seen with the query:

```
select name, json_object_grp(number,race) from pet group by name;
```

This query returns:

| name    | json_object_grp(number,race) |
|---------|------------------------------|
| Bill    | {"cat":1}                    |
| Donald  | {"dog":1,"fish":3}           |
| John    | {"dog":2}                    |
| Kevin   | {"cat":2,"bird":6}           |
| Lisbeth | {"rabbit":2}                 |
| Mary    | {"dog":1,"cat":1}            |

## Json\_Object\_Key

```
Json_Object_Key([key1, val1 [, ..., keyn, valn]])
```

Return a string denoting a JSON object. For instance:

```
select Json_Object_Key('qty', 56, 'price', 3.1416, 'truc', 'machin', 'garanty', NULL);
```

The object is filled with pairs made from each key/value arguments.

## Json\_Object\_Key('qty', 56, 'price', 3.1416, 'truc', 'machin', 'garanty', NULL)

```
{"qty":56,"price":3.1416,"truc":"machin","garanty":null}
```

## Json\_Object\_List

```
Json_Object_List(arg1, ...):
```

The first argument must be a JSON object. This function returns an array containing the list of all keys existing in the object. For example:

```
select Json_Object_List(Json_Object(56 qty, 3.1416 price, 'machin' truc, NULL garanty))
"Key List";
```

## Key List

```
["qty","price","truc","garanty"]
```

## Json\_Object\_Nonull

```
Json_Object_Nonull(arg1, ..., argn)
```

This function works like [Json\\_Make\\_Object](#) but “null” arguments are ignored and not inserted in the object. Arguments are regarded as “null” if they are JSON null values, void arrays or objects, or arrays or objects containing only null members.

It is mainly used to avoid constructing useless null items when converting tables (see later).

## Json\_Object\_Values

```
Json_Object_Values(json_object)
```

The first argument must be a JSON object. This function returns an array containing the list of all values existing in the object. For example:

```
select Json_Object_Values('{"One":1,"Two":2,"Three":3}') "Value List";
```

## Value List

```
[1,2,3]
```

## JsonSet\_Grp\_Size

```
JsonSet_Grp_Size(val)
```

This function is used to set the JsonGrpSize value. This value is used by the following aggregate functions as a ceiling value of the number of items in each group. It returns the JsonGrpSize value that can be its default value when passed 0 as argument.

## Json\_Set\_Item / Json\_Insert\_Item / Json\_Update\_Item

```
Json_{Set | Insert | Update}_Item(json_doc, [item, path [, val, path ...]])
```

These functions insert or update data in a JSON document and return the result. The value/path pairs are evaluated left to right. The document produced by evaluating one pair becomes the new value against which the next pair is evaluated.

- `Json_Set_Item` replaces existing values and adds non-existing values.
- `Json_Insert_Item` inserts values without replacing existing values.
- `Json_Update_Item` replaces only existing values.

Example:

```
set @j = Json_Array(1, 2, 3, Json_Object_Key('quatre', 4));
select Json_Set_Item(@j, 'foo', '[1]', 5, '[3]:cinq') as "Set",
Json_Insert_Item(@j, 'foo', '[1]', 5, '[3]:cinq') as "Insert",
Json_Update_Item(@j, 'foo', '[1]', 5, '[3]:cinq') as "Update";
```

or, from [MariaDB 10.2.8](#) :

```
set @j = Json_Array(1, 2, 3, Json_Object_Key('quatre', 4));
select Json_Set_Item(@j, 'foo', '$[1]', 5, '$[3].cinq') as "Set",
Json_Insert_Item(@j, 'foo', '$[1]', 5, '$[3].cinq') as "Insert",
Json_Update_Item(@j, 'foo', '$[1]', 5, '$[3].cinq') as "Update";
```

This query returns:

| Set                               | Insert                        | Update                   |
|-----------------------------------|-------------------------------|--------------------------|
| [1,"foo",3,{"quatre":4,"cinq":5}] | [1,2,3,{"quatre":4,"cinq":5}] | [1,"foo",3,{"quatre":4}] |

## JsonValue

```
JsonValue (val)
```

Returns a JSON value as a string, for instance:

```
select JsonValue(3.1416);
```

**JsonValue(3.1416)**

3.141600

Before MariaDB 10.1.9 , this function was called `Json_Value`, but was renamed to avoid clashing with the `JSON_VALUE` function.

## The “JBIN” return type

Almost all functions returning a json string - whose name begins with `Json_` - have a counterpart with a name beginning with `Jbin_`. This is both for performance (speed and memory) as well as for better control of what the functions should do.

This is due to the way CONNECT UDFs work internally. The `Json` functions, when receiving json strings as parameters, parse them and construct a binary tree in memory. They work on this tree and before returning; serialize this tree to return a new json string.

If the json document is large, this can take up a large amount of time and storage space. It is all right when one simple `json` function is called – it must be done anyway – but is a waste of time and memory when `json` functions are used as parameters to other `json` functions.

To avoid multiple serializing and parsing, the `Jbin` functions should be used as parameters to other functions. Indeed, they do not serialize the memory document tree, but return a structure allowing the receiving function to have direct access to the memory tree. This saves the serialize-parse steps otherwise needed to pass the argument and removes the need to reallocate the memory of the binary tree, which by the way is 6 to 7 times the size of the json string. For instance:

```
select Json_Object(Jbin_Array_Add(Jbin_Array('a','b','c'), 'd') as "Jbin_foo") as "Result";
```

This query returns:

**Result**

{"foo":["a","b","c","d"]}

Here the binary json tree allocated by `Jbin_Array` is completed by `Jbin_Array_Add` and `Json_Object` and serialized only once to make the final result string. It would be serialized and parsed two more times if using “`Json`” functions.

Note that `Jbin` results are recognized as such because they are aliased beginning with “`Jbin_`”. This is why in the `Json_Object` function the alias is specified as “`Jbin_foo`”.

What happens if it is not recognized as such? These functions are declared as returning a string and to take care of this, the returned structure begins with a zero-terminated string. For instance:

```
select Jbin_Array('a','b','c');
```

This query replies:

**Jbin\_Array('a','b','c')**

Binary Json array

Note: When testing, the tree returned by a “`Jbin`” function can be seen using the `Json_Serialize` function whose unique parameter must be a “`Jbin`” result. For instance:

```
select Json_Serialize(Jbin_Array('a','b','c'));
```

This query returns:

**Json\_Serialize(Jbin\_Array('a','b','c'))**

["a","b","c"]

Note: For this simple example, this is equivalent to using the `Json_Array` function.

## Using a file as json UDF first argument

We have seen that many json UDFs can have an additional argument not yet described. This is in the case where the json item argument was referring to a file. Then the additional integer argument is the pretty value of the json file. It matters only when the first argument is just a file name (to make the UDF understand this argument is a file name, it should be aliased with a name beginning with `jfile_`) or if the function modifies the file, in which case it will be

rewritten with this pretty format.

The json item is created by extracting the required part from the file. This can be the whole file but more often only some of it. There are two ways to specify the sub-item of the file to be used:

1. Specifying it in the *Json\_File* or *Jbin\_File* arguments.
2. Specifying it in the receiving function (not possible for all functions).

It doesn't make any difference when the *Jbin\_File* is used but it does with *Json\_File*. For instance:

```
select Jfile_Make('{"a":1, "b":[44, 55]}' json_, 'test.json');
select Json_Array_Add(Json_File('test.json', 'b'), 66);
```

The second query returns:

```
Json_Array_Add(Json_File('test.json', 'b'), 66)
[44,55,66]
```

It just returns the – modified -- subset returned by the *Json\_File* function, while the query:

```
select Json_Array_Add(Json_File('test.json'), 66, 'b');
```

returns what was received from *Json\_File* with the modification made on the subset.

```
Json_Array_Add(Json_File('test.json'), 66, 'b')
>{"a":1,"b":[44,55,66]}
```

Note that in both case the *test.json* file is not modified. This is because the *Json\_File* function returns a string representing all or part of the file text but no information about the file name. This is all right to check what would be the effect of the modification to the file.

However, to have the file modified, use the *Jbin\_File* function or directly give the file name. *Jbin\_File* returns a structure containing the file name, a pointer to the file parsed tree and eventually a pointer to the subset when a path is given as a second argument:

```
select Json_Array_Add(Jbin_File('test.json', 'b'), 66);
```

This query returns:

```
Json_Array_Add(Jbin_File('test.json', 'b'), 66)
test.json
```

This time the file is modified. This can be checked with:

```
select Json_File('test.json', 3);
```

```
Json_File('test.json', 3)
>{"a":1,"b":[44,55,66]}
```

The reason why the first argument is returned by such a query is because of tables such as:

```
create table tb (
n int key,
jfile_cols char(10) not null;
insert into tb values(1,'test.json');
```

In this table, the *jfile\_cols* column just contains a file name. If we update it by:

```
update tb set jfile_cols = select Json_Array_Add(Jbin_File('test.json', 'b'), 66)
where n = 1;
```

This is the *test.json* file that must be modified, not the *jfile\_cols* column. This can be checked by:

```
select JsonGet_String(jfile_cols, '[1]:*') from tb;
```

```
JsonGet_String(jfile_cols, '[1]:*')
>{"a":1,"b":[44,55,66]}
```

Note: It was an important facility to name the second column of the table beginning by “*jfile\_*” so the json functions knew it was a file name without obliging to specify an alias in the queries.

## Using “Jbin” to control what the query execution does

This is applying in particular when acting on json files. We have seen that a file was not modified when using the `Json_File` function as an argument to a modifying function because the modifying function just received a copy of the json file. This is not true when using the `Jbin_File` function that does not serialize the binary document and make it directly accessible. Also, as we have seen earlier, json functions that modify their first file parameter modify the file and return the file name. This is done by directly serializing the internal binary document as a file.

However, the “Jbin” counterpart of these functions does not serialize the binary document and thus does not modify the json file. For example let us compare these two queries:

```
/* First query */
```

```
select Json_Object(Jbin_Object_Add(Jbin_File('bt2.json'), 4 as "d") as "Jbin_bt1")
as "Result";
```

```
/* Second query */
```

```
select Json_Object(Json_Object_Add(Jbin_File('bt2.json'), 4 as "d") as "Jfile_bt1")
as "Result";
```

Both queries return:

| Result                            |
|-----------------------------------|
| {"bt1":{"a":1,"b":2,"c":3,"d":4}} |

In the first query `Jbin_Object_Add` does not serialize the document (no “Jbin” functions do) and `Json_Object` just returns a serialized modified tree. Consequently, the file `bt2.json` is not modified. This query is all right to copy a modified version of the json file without modifying it.

However, in the second query `Json_Object_Add` does modify the json file and returns the file name. The `Json_Object` function receives this file name, reads and parses the file, makes an object from it and returns the serialized result. This modification can be done willingly but can be an unwanted side effect of the query.

Therefore, using “Jbin” argument functions, in addition to being faster and using less memory, are also safer when dealing with json files that should not be modified.

## Using JSON as Dynamic Columns

The JSON nosql language has all the features to be used as an alternative to dynamic columns. For instance, take the following example of dynamic columns:

```
create table assets (
    item_name varchar(32) primary key, /* A common attribute for all items */
    dynamic_cols blob /* Dynamic columns will be stored here */
);

INSERT INTO assets VALUES
('MariaDB T-shirt', COLUMN_CREATE('color', 'blue', 'size', 'XL'));

INSERT INTO assets VALUES
('Thinkpad Laptop', COLUMN_CREATE('color', 'black', 'price', 500));

SELECT item_name, COLUMN_GET(dynamic_cols, 'color' as char) AS color FROM assets;
+-----+-----+
| item_name | color |
+-----+-----+
| MariaDB T-shirt | blue |
| Thinkpad Laptop | black |
+-----+-----+
```

```
/* Remove a column: */
```

```
UPDATE assets SET dynamic_cols=COLUMN_DELETE(dynamic_cols, "price")
WHERE COLUMN_GET(dynamic_cols, 'color' as char)='black';
```

```
/* Add a column: */
```

```
UPDATE assets SET dynamic_cols=COLUMN_ADD(dynamic_cols, 'warranty', '3 years')
WHERE item_name='Thinkpad Laptop';
```

```
/* You can also list all columns, or get them together with their values in JSON format: */
```

```
SELECT item_name, column_list(dynamic_cols) FROM assets;
+-----+-----+
| item_name | column_list(dynamic_cols) |
+-----+-----+
| MariaDB T-shirt | `size`, `color` |
| Thinkpad Laptop | `color`, `warranty` |
+-----+-----+  
  
SELECT item_name, COLUMN_JSON(dynamic_cols) FROM assets;
+-----+-----+
| item_name | COLUMN_JSON(dynamic_cols) |
+-----+-----+
| MariaDB T-shirt | [{"size": "XL", "color": "blue"}] |
| Thinkpad Laptop | [{"color": "black", "warranty": "3 years"}] |
+-----+-----+
```

The same result can be obtained with json columns using the json UDF's:

/\* JSON equivalent \*/

```

create table jassets (
    item_name varchar(32) primary key, /* A common attribute for all items */
    json_cols varchar(512) /* Jason columns will be stored here */
);

INSERT INTO jassets VALUES
    ('MariaDB T-shirt', Json_Object('blue' color, 'XL' size));

INSERT INTO jassets VALUES
    ('Thinkpad Laptop', Json_Object('black' color, 500 price));

SELECT item_name, JsonGet_String(json_cols, 'color') AS color FROM jassets;
+-----+-----+
| item_name | color |
+-----+-----+
| MariaDB T-shirt | blue |
| Thinkpad Laptop | black |
+-----+-----+

```

```
/* Remove a column: */
```

```
UPDATE jassets SET json_cols=Json_Object_Delete(json_cols, 'price')  
WHERE JsonGet String(json_cols, 'color')='black';
```

```
/* Add a column */
```

```
UPDATE jassets SET json_cols=Json_Object_Add(json_cols, '3 years' warranty)
 WHERE item name='Thinkpad Laptop';
```

*/\* You can also list all columns, or get them together with their values in JSON format: \*/*

```
SELECT item_name, Json_Object_List(json_cols) FROM jassets;
+-----+-----+
| item_name | Json_Object_List(json_cols) |
+-----+-----+
| MariaDB T-shirt | [{"color","size"}] |
| Thinkpad Laptop | [{"color","warranty"}] |
+-----+-----+  
  
SELECT item_name, json_cols FROM jassets;
+-----+-----+
| item_name | json_cols |
+-----+-----+
| MariaDB T-shirt | [{"color":"blue","size":"XL"}] |
| Thinkpad Laptop | [{"color":"black","warranty":"3 years"}] |
+-----+-----+
```

However, using JSON brings features not existing in dynamic columns:

- Use of a language used by many implementation and developers.
  - Full support of arrays, currently missing from dynamic columns.
  - Access of subpart of json by JPATH that can include calculations on arrays.
  - Possible references to json files

With more experience, additional UDFs can be easily written to support new needs.

## New Set of BSON Functions

All these functions have been rewritten using the new JSON handling way and are temporarily available changing the J starting name to B. Then Json\_Make\_Array new style is called using Bson\_Make\_Array. Some, such as Bson\_Item\_Delete, are new and some fix bugs found in their Json counterpart.

## Converting Tables to JSON

The JSON UDF's and the direct Jpath "\*" facility are powerful tools to convert table and files to the JSON format. For instance, the file

```
biblio3.json  
we used previously can be obtained by converting the  
xsample.xml file  
. This can be done like this:
```

From Connect 1.07.0002

```
create table xj1 (row varchar(500) jpath='*') engine=connect table_type=JSON file_name='biblio3.json' option_list='jmode=2';
```

Before Connect 1.07.0002

```
create table xj1 (row varchar(500) field_format='*'  
engine=connect table_type=JSON file_name='biblio3.json' option_list='jmode=2';
```

And then :

```
insert into xj1  
select json_object_nonull(ISBN, language LANG, SUBJECT,  
json_array_grp(json_object(authorfn FIRSTNAME, authorln LASTNAME)) json_AUTHOR, TITLE,  
json_object(translated PREFIX, json_object(tranfn FIRSTNAME, tranln LASTNAME) json_TRANSLATOR)  
json_TRANSLATED, json_object(publisher NAME, location PLACE) json_PUBLISHER, date DATEPUB)  
from xsampall2 group by isbn;
```

The xj1 table rows will directly receive the Json object made by the select statement used in the insert statement and the table file will be made as shown (xj1 is pretty=2 by default) Its mode is Jmode=2 because the values inserted are strings even if they denote json objects.

Another way to do this is to create a table describing the file format we want before the

```
biblio3.json  
file existed:
```

From Connect 1.07.0002

```
create table jsampall3 (  
ISBN char(15),  
LANGUAGE char(2) jpath='LANG',  
SUBJECT char(32),  
AUTHORFN char(128) jpath='AUTHOR:[X]:FIRSTNAME',  
AUTHORLN char(128) jpath='AUTHOR:[X]:LASTNAME',  
TITLE char(32),  
TRANSLATED char(32) jpath='TRANSLATOR:PREFIX',  
TRANSLATORFN char(128) jpath='TRANSLATOR:FIRSTNAME',  
TRANSLATORLN char(128) jpath='TRANSLATOR:LASTNAME',  
PUBLISHER char(20) jpath='PUBLISHER:NAME',  
LOCATION char(20) jpath='PUBLISHER:PLACE',  
DATE int(4) jpath='DATEPUB')  
engine=CONNECT table_type=JSON file_name='biblio3.json';
```

Before Connect 1.07.0002

```

create table jsampall3 (
ISBN char(15),
LANGUAGE char(2) field_format='LANG',
SUBJECT char(32),
AUTHORFN char(128) field_format='AUTHOR:[X]:FIRSTNAME',
AUTHORLN char(128) field_format='AUTHOR:[X]:LASTNAME',
TITLE char(32),
TRANSLATED char(32) field_format='TRANSLATOR:PREFIX',
TRANSLATORFN char(128) field_format='TRANSLATOR:FIRSTNAME',
TRANSLATORLN char(128) field_format='TRANSLATOR:LASTNAME',
PUBLISHER char(20) field_format='PUBLISHER:NAME',
LOCATION char(20) field_format='PUBLISHER:PLACE',
DATE int(4) field_format='DATEPUB'
engine=CONNECT table_type=JSON file_name='biblio3.json';

```

and to populate it by:

```
insert into jsampall3 select * from xsampall;
```

This is a simpler method. However, the issue is that this method cannot handle the multiple column values. This is why we inserted from

```

xsampall
not from
xsampall2
```

. How can we add the missing multiple authors in this table? Here again we must create a utility table able to handle JSON strings. From Connect 1.07.0002

```

create table xj2 (ISBN char(15), author varchar(150) jpath='AUTHOR:*') engine=connect table_type=JSON file_name='biblio3.json' o
,
```

Before Connect 1.07.0002

```

create table xj2 (ISBN char(15), author varchar(150) field_format='AUTHOR:*')
engine=connect table_type=JSON file_name='biblio3.json' option_list='jmode=1';
```

```

update xj2 set author =
(select json_array_gra(json_object(authorfn FIRSTNAME, authorln LASTNAME))
 from xsampall2 where isbn = xj2.isbn);
```

Voilà !

## Converting json files

We have seen that json files can be formatted differently depending on the pretty option. In particular, big data files should be formatted with pretty equal to 0 when used by a CONNECT json table. The best and simplest way to convert a file from one format to another is to use the *Jfile\_Make* function. Indeed this function makes a file of specified format using the syntax:

```
Jfile_Make(json_document, [file_name], [pretty]);
```

The file name is optional when the json document comes from a *Jbin\_File* function because the returned structure makes it available. For instance, to convert back the json file tb.json to pretty=0, this can be simply done by:

```
select Jfile_Make(Jbin_File('tb.json'), 0);
```

## Performance Consideration

MySQL and PostgreSQL have a JSON data type that is not just text but an internal encoding of JSON data. This is to save parsing time when executing JSON functions. Of course, the parse must be done anyway when creating the data and serializing must be done to output the result.

CONNECT directly works on character strings impersonating JSON values with the need of parsing them all the time but with the advantage of working easily on external data. Generally, this is not too penalizing because JSON data are often of some or reasonable size. The only case where it can be a serious problem is when working on a big JSON file.

Then, the file should be formatted or converted to *pretty=0*.

From Connect 1.7.002, this easily done using the *Jfile\_Convert* function, for instance:

```
select jfile_convert('bibdoc.json','bibdoc0.json',350);
```

Such a json file should not be used directly by JSON UDFs because they parse the whole file, even when only a subset is used. Instead, it should be used

by a JSON table created on it. Indeed, JSON tables do not parse the whole document but just the item corresponding to the row they are working on. In addition, indexing can be used by the table as explained previously on this page.

Generally speaking, the maximum flexibility offered by CONNECT is by using JSON tables and JSON UDFs together. Some things are better handled by tables, other by UDFs. The tools are there but it is up to you to discover the best way to resolve your problems.

## Bjson files

Starting with Connect 1.7.002, *pretty=0* json files can be converted to a binary format that is a pre-parsed representation of json. This can be done with the Jfile\_Bjson UDF function, for instance:

```
select jfile_bjson('bigfile.json','binfile.json',3500);
```

Here the third argument, the record length, must 6 to 10 times larger than the lrec of the initial json file because the parsed representation is bigger than the original json text representation.

Tables using such Bjson files must specify 'Pretty=-1' in the option list.

It is probably similar to the BSON used by MongoDB and PostgreSQL and permits to process queries up to 10 times faster than working on text json files. Indexing is also available for tables using this format making even more performance improvement. For instance, some queries on a json table of half a million rows, that were previously done in more than 10 seconds, took only 0.1 second when converted and indexed.

Here again, this has been remade to use the new way Json is handled. The files made using the bfile\_bjson function are only from two to four times the size of the source files. This new representation is not compatible with the old one. Therefore, these files must be used with BSON tables only.

## Specifying a JSON table Encoding

An important feature of JSON is that strings should in UNICODE. As a matter of fact, all examples we have found on the Internet seemed to be just ASCII. This is because UNICODE is generally encoded in JSON files using UTF8 or UTF16 or UTF32.

To specify the required encoding, just use the data\_charset CONNECT option or the native DEFAULT CHARSET option.

## Retrieving JSON data from MongoDB

Classified as a NoSQL database program, MongoDB uses JSON-like documents (BSON) grouped in collections. The simplest way, and only method available before Connect 1.6, to access MongoDB data was to export a collection to a JSON file. This produces a file having the pretty=0 format. Viewed as SQL, a collection is a table and documents are table rows.

Since CONNECT version 1.6, it is now possible to directly access MongoDB collections via their MongoDB C Driver. This is the purpose of the MONGO table type described later. However, JSON tables can also do it in a somewhat different way (providing MONGO support is installed as described for MONGO tables).

It is achieved by specifying the MongoDB connection URI while creating the table. For instance:

From Connect 1.7.002

```
create or replace table jinvent (
  _id char(24) not null,
  item char(12) not null,
  instock varchar(300) not null jpath='instock.*')
engine=connect table_type=JSON tablename='inventory' lrec=512
connection='mongodb://localhost:27017';
```

Before Connect 1.7.002

```
create or replace table jinvent (
  _id char(24) not null,
  item char(12) not null,
  instock varchar(300) not null field_format='instock.*')
engine=connect table_type=JSON tablename='inventory' lrec=512
connection='mongodb://localhost:27017';
```

In this statement, the *file\_name* option was replaced by the *connection* option. It is the URI enabling to retrieve data from a local or remote MongoDB server. The *tablename* option is the name of the MongoDB collection that will be used and the *dbname* option could have been used to indicate the database containing the collection (it defaults to the current database).

The way it works is that the documents retrieved from MongoDB are serialized and CONNECT uses them as if they were read from a file. This implies serializing by MongoDB and parsing by CONNECT and is not the best performance wise. CONNECT tries its best to reduce the data transfer when a query contains a reduced column list and/or a where clause. This way makes all the possibilities of the JSON table type available, such as calculated arrays.

However, to work on large JSON collations, using the MONGO table type is generally the normal way.

Note: JSON tables using the MongoDB access accept the specific MONGO options *colist*, *filter* and *pipeline*. They are described in the MONGO table chapter.

# Summary of Options and Variables Used with Json Tables

Options and variables that can be used when creating Json tables are listed here:

| Table Option | Type    | Description                                                                                                                                                                    |
|--------------|---------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| ENGINE       | String  | Must be specified as CONNECT.                                                                                                                                                  |
| TABLE_TYPE   | String  | Must be JSON or BSON.                                                                                                                                                          |
| FILE_NAME    | String  | The optional file (path) name of the Json file. Can be absolute or relative to the current data directory. If not specified, it defaults to the table name and json file type. |
| DATA_CHARSET | String  | Set it to 'utf8' for most Unicode Json documents.                                                                                                                              |
| LRECL        | Number  | The file record size for pretty < 2 json files.                                                                                                                                |
| HTTP         | String  | The HTTP of the server of REST queries.                                                                                                                                        |
| URI          | String  | THE URI of REST queries                                                                                                                                                        |
| CONNECTION*  | String  | Specifies a connection to<br>MONGODB                                                                                                                                           |
| ZIPPED       | Boolean | True if the json file(s) is/are zipped in one or several zip files.                                                                                                            |
| MULTIPLE     | Number  | Used to specify a multiple file table.                                                                                                                                         |
| SEP_CHAR     | String  | Set it to ':' for old tables using the old json path syntax.                                                                                                                   |
| CATFUNC      | String  | The catalog function (column) used when creating a catalog table.                                                                                                              |
| OPTION_LIST  | String  | Used to specify all other options listed below.                                                                                                                                |

(\*) For Json tables connected to MongoDB, Mongo specific options can also be used.

Other options must be specified in the option list:

| Table Option | Type    | Description                                                                                                                                                    |
|--------------|---------|----------------------------------------------------------------------------------------------------------------------------------------------------------------|
| DEPTH_LEVEL  | Number  | Specifies the depth in the document CONNECT looks when defining columns by discovery or in catalog tables                                                      |
| PRETTY       | Number  | Specifies the format of the Json file (-1 for Bjson files)                                                                                                     |
| EXPAND       | String  | The name of the column to expand.                                                                                                                              |
| OBJECT       | String  | The json path of the sub-document used for the table.                                                                                                          |
| BASE         | Number  | The numbering base for arrays: 0 (the default) or 1.                                                                                                           |
| LIMIT        | Number  | The maximum number of array values to use when concatenating, calculating or expanding arrays. Defaults to 50 (>= Connect 1.7.0003), 10 (<= Connect 1.7.0002). |
| FULLARRAY    | Boolean | Used when creating with Discovery. Make a column for each value of arrays (up to LIMIT).                                                                       |
| JMODE        | Number  | The Json mode (array of objects, array of arrays, or array of values) Only used when inserting new rows.                                                       |
| ACCEPT       | Boolean | Keep null columns (for discovery).                                                                                                                             |
| AVGLEN       | Number  | An estimate average length of rows. This is used only when indexing and can be set if indexing fails by miscalculating the table max size.                     |
| STRINGIFY    | String  | Ask discovery to make a column to return the Json representation of this object.                                                                               |

Column options:

| Column Option      | Type   | Description                                                                                 |
|--------------------|--------|---------------------------------------------------------------------------------------------|
| JPATH_FIELD_FORMAT | String | Defaults to the column name.                                                                |
| DATE_FORMAT        | String | Specifies the date format into the Json file when defining a DATE, DATETIME or TIME column. |

Variables used with Json tables are:

- [connect\\_default\\_depth](#)
- [connect\\_json\\_null](#)
- [connect\\_json\\_all\\_path](#)
- [connect\\_force\\_bson](#)

# Notes

1. ↑ The value n can be 0 based or 1 based depending on the base table option. The default is 0 to match what is the current usage in the Json world but it can be set to 1 for tables created in old versions.
2. ↑ See for instance: <https://mariadb.com/kb/en/mariadb/json-functions/> , [https://github.com/mysqludf/lib\\_mysqludf\\_json#readme](https://github.com/mysqludf/lib_mysqludf_json#readme) and [https://blogs.oracle.com/svetasmirnova/entry/json\\_udf\\_functions\\_version\\_04](https://blogs.oracle.com/svetasmirnova/entry/json_udf_functions_version_04)
3. ↑ This will not work when CONNECT is compiled embedded

### Overview

CONNECT supports tables represented by XML files. For these tables, the standard input/output functions of the operating system are not used but the parsing and processing of the file is delegated to a specialized library. Currently two such systems are supported: libxml2, a part of the GNOME framework, but which does not require GNOME and, on Windows, MS-DOM (DOMDOC), the Microsoft standard support of XML documents.

DOMDOC is the default for the Windows version of CONNECT and libxml2 is always used on other systems. On Windows the choice can be specified using the XMLSUP [CREATE TABLE](#) list option, for instance specifying

```
option_list='xmlsup=libxml2'
```

### Creating XML tables

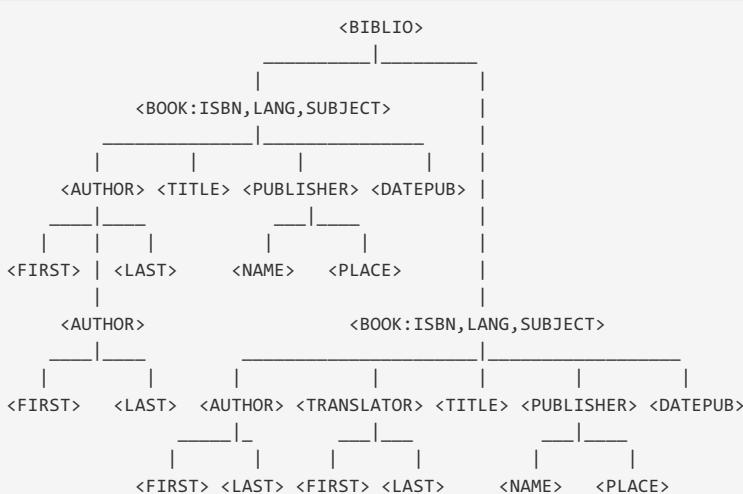

First of all, it must be understood that XML is a very general language used to encode data having any structure. In particular, the tag hierarchy in an XML file describes a tree structure of the data. For instance, consider the file:

```

<?xml version="1.0" encoding="ISO-8859-1"?>
<BIBLIO SUBJECT="XML">
  <BOOK ISBN="9782212090819" LANG="fr" SUBJECT="applications">
    <AUTHOR>
      <FIRSTNAME>Jean-Christophe</FIRSTNAME>
      <LASTNAME>Bernadac</LASTNAME>
    </AUTHOR>
    <AUTHOR>
      <FIRSTNAME>François</FIRSTNAME>
      <LASTNAME>Khab</LASTNAME>
    </AUTHOR>
    <TITLE>Construire une application XML</TITLE>
    <PUBLISHER>
      <NAME>Eyrolles</NAME>
      <PLACE>Paris</PLACE>
    </PUBLISHER>
    <DATEPUB>1999</DATEPUB>
  </BOOK>
  <BOOK ISBN="9782840825685" LANG="fr" SUBJECT="applications">
    <AUTHOR>
      <FIRSTNAME>William J.</FIRSTNAME>
      <LASTNAME>Pardi</LASTNAME>
    </AUTHOR>
    <TRANSLATOR PREFIX="adapté de l'anglais par">
      <FIRSTNAME>James</FIRSTNAME>
      <LASTNAME>Guerin</LASTNAME>
    </TRANSLATOR>
    <TITLE>XML en Action</TITLE>
    <PUBLISHER>
      <NAME>Microsoft Press</NAME>
      <PLACE>Paris</PLACE>
    </PUBLISHER>
    <DATEPUB>1999</DATEPUB>
  </BOOK>
</BIBLIO>

```

It represents data having the structure:

This structure seems at first view far from being tabular. However, modern database management systems, including MariaDB, implement something close to the relational model and work on tables that are structurally not hierarchical but tabular with rows and columns.

Nevertheless, CONNECT can do it. Of course, it cannot guess what you want to extract from the XML structure, but gives you the possibility to specify it when you create the table [1].

Let us take a first example. Suppose you want to make a table from the above document, displaying the node contents.

For this, you can define a table `xsampletag` as:

```

create table xsampletag (
  AUTHOR char(50),
  TITLE char(32),
  TRANSLATOR char(40),
  PUBLISHER char(40),
  DATEPUB int(4))
engine=CONNECT table_type=XML file_name='Xsample.xml';

```

It will be displayed as:

| AUTHOR                   | TITLE                          | TRANSLATOR   | PUBLISHER             | DATEPUB |
|--------------------------|--------------------------------|--------------|-----------------------|---------|
| Jean-Christophe Bernadac | Construire une application XML | <null>       | Eyrolles Paris        | 1999    |
| William J. Pardi         | XML en Action                  | James Guerin | Microsoft Press Paris | 1999    |

Let us try to understand what happened. By default the column names correspond to tag names. Because this file is rather simple, CONNECT was able to default the top tag of the table as the root node

```
<BIBLIO>
of the file, and the row tags as the
<BOOK>
children of the table tag. In a more complex file, this should have been specified, as we will see later. Note that we didn't have to worry about the
sub-tags such as
<FIRSTNAME>
or
<LASTNAME>
because CONNECT automatically retrieves the entire text contained in a tag and its sub-tags [2].
```

Only the first author of the first book appears. This is because only the first occurrence of a column tag has been retrieved so the result has a proper tabular structure. We will see later what we can do about that.

How can we retrieve the values specified by attributes? By using a *Coltype* table option to specify the default column type. The value '@' means that column names match attribute names. Therefore, we can retrieve them by creating a table such as:

```
create table xsampattr (
  ISBN char(15),
  LANG char(2),
  SUBJECT char(32))
engine=CONNECT table_type=XML file_name='Xsample.xml'
option_list='Coltype=@';
```

This table returns the following:

ISBN	LANG	SUBJECT
9782212090819	fr	applications
9782840825685	fr	applications

Now to define a table that will give us all the previous information, we must specify the column type for each column. Because in the next statement the column type defaults to Node, the *field\_format* column parameter was used to indicate which columns are attributes:

From Connect 1.7.0002

```
create table xsamp (
  ISBN char(15) xpath='@',
  LANG char(2) xpath='@',
  SUBJECT char(32) xpath='@',
  AUTHOR char(50),
  TITLE char(32),
  TRANSLATOR char(40),
  PUBLISHER char(40),
  DATEPUB int(4))
engine=CONNECT table_type=XML file_name='Xsample.xml'
tabname='BIBLIO' option_list='rownode=BOOK';
```

Before Connect 1.7.0002

```
create table xsamp (
  ISBN char(15) field_format='@',
  LANG char(2) field_format='@',
  SUBJECT char(32) field_format='@',
  AUTHOR char(50),
  TITLE char(32),
  TRANSLATOR char(40),
  PUBLISHER char(40),
  DATEPUB int(4))
engine=CONNECT table_type=XML file_name='Xsample.xml'
tabname='BIBLIO' option_list='rownode=BOOK';
```

Once done, we can enter the query:

```
select subject, lang, title, author from xsamp;
```

This will return the following result:

SUBJECT	LANG	TITLE	AUTHOR
applications	fr	Construire une application XML	Jean-Christophe Bernadac
applications	fr	XML en Action	William J. Pardi

Note that we have been lucky. Because unlike SQL, XML is case sensitive and the column names have matched the node names only because the column names were given in upper case. Note also that the order of the columns in the table could have been different from the order in which the nodes appear in the XML file.

## Using Xpaths with XML tables

Xpath is used by XML to locate and retrieve nodes. The table's main node Xpath is specified by the

tabname  
option. If just the node name is given, CONNECT constructs an Xpath such as

'

BIBLIO'

in the example above that should retrieve the

BIBLIO  
node wherever it is within the XML file.

The row nodes are by default the children of the table node. However, for instance to eliminate some children nodes that are not real row nodes, the row node name can be specified using the

rownode  
sub-option of the  
option\_list  
option.

The field\_format options we used above can be specified to locate more precisely where and what information to retrieve using an Xpath-like syntax. For instance:

From Connect 1.7.0002

```
create table xsampall (
isbn char(15) xpath='@ISBN',
language char(2) xpath='@LANG',
subject char(32) xpath='@SUBJECT',
authorfn char(20) xpath='AUTHOR/FIRSTNAME',
authorln char(20) xpath='AUTHOR/LASTNAME',
title char(32) xpath='TITLE',
translated char(32) xpath='TRANSLATOR/@PREFIX',
tranfn char(20) xpath='TRANSLATOR/FIRSTNAME',
tranln char(20) xpath='TRANSLATOR/LASTNAME',
publisher char(20) xpath='PUBLISHER/NAME',
location char(20) xpath='PUBLISHER/PLACE',
year int(4) xpath='DATEPUB')
engine=CONNECT table_type=XML file_name='Xsample.xml'
tablename='BIBLIO' option_list='rownode=BOOK';
```

Before Connect 1.7.0002

```
create table xsampall (
isbn char(15) field_format='@ISBN',
language char(2) field_format='@LANG',
subject char(32) field_format='@SUBJECT',
authorfn char(20) field_format='AUTHOR/FIRSTNAME',
authorln char(20) field_format='AUTHOR/LASTNAME',
title char(32) field_format='TITLE',
translated char(32) field_format='TRANSLATOR/@PREFIX',
tranfn char(20) field_format='TRANSLATOR/FIRSTNAME',
tranln char(20) field_format='TRANSLATOR/LASTNAME',
publisher char(20) field_format='PUBLISHER/NAME',
location char(20) field_format='PUBLISHER/PLACE',
year int(4) field_format='DATEPUB')
engine=CONNECT table_type=XML file_name='Xsample.xml'
tablename='BIBLIO' option_list='rownode=BOOK';
```

This very flexible column parameter serves several purposes:

- To specify the tag name, or the attribute name if different from the column name.
- To specify the type (tag or attribute) by a prefix of '@' for attributes.
- To specify the path for sub-tags using the '/' character.

This path is always relative to the current context (the column top node) and cannot be specified as an absolute path from the document root, therefore a leading '/' cannot be used. The path cannot be variable in node names or depth, therefore using '

//  
' is not allowed.

The query:

```
select isbn, title, translated, tranfn, tranln, location from
xsampall where translated is not null;
```

replies:

ISBN	TITLE	TRANSLATED	TRANFN	TRANLN	LOCATION
9782840825685	XML en Action	adapté de l'anglais par	James	Guerin	Paris

## Libxml2 default name space issue

An issue with libxml2 is that some files can declare a default name space in their root node. Because Xpath only searches in that name space, the nodes will not be found if they are not prefixed. If this happens, specify the tablename option as an Xpath ignoring the current name space:

```
TABNAME="//*[local-name()='BIBLIO']"
```

This must also be done for the default of specified Xpath of the not attribute columns. For instance:

```
title char(32) field_format="*[local-name()='TITLE']",
```

Note: This raises an error (and is useless anyway) with DOMDOC.

## Direct access on XML tables

Direct access is available on XML tables. This means that XML tables can be sorted and used in joins, even in the one-side of the join.

However, building a permanent index is not yet implemented. It is unclear whether this can be useful. Indeed, the DOM implementation that is used to access these tables firstly parses the whole file and constructs a node tree in memory. This may often be the longest part of the process, so the use of an index would not be of great value. Note also that this limits the XML files to a reasonable size. Anyway, when speed is important, this table type is not the best to use. Therefore, in these cases, it is probably better to convert the file to another type by inserting the XML table into another table of a more appropriate type for performance.

## Accessing tags with namespaces

With the Windows DOMDOC support, this can be done using the prefix in the tablename column option and/or xpath column option. For instance, given the file gns.xml:

```
<?xml version="1.0" encoding="UTF-8"?>
<gpx xmlns:gns="http:dummy">
<gnss:trkseg>
<trkpt lon="-121.9822235107421875" lat="37.3884925842285156">
<gnss:ele>6.610851287841797</gnss:ele>
<time>2014-04-01T14:54:05.000Z</time>
</trkpt>
<trkpt lon="-121.9821929931640625" lat="37.3885803222656250">
<ele>6.787827968597412</ele>
<time>2014-04-01T14:54:08.000Z</time>
</trkpt>
<trkpt lon="-121.9821624755859375" lat="37.3886299133300781">
<ele>6.771987438201904</ele>
<time>2014-04-01T14:54:10.000Z</time>
</trkpt>
</gnss:trkseg>
</gpx>
```

and the defined CONNECT table:

```

CREATE TABLE xgns (
`lon` double(21,16) NOT NULL `xpath`='@',
`lat` double(20,16) NOT NULL `xpath`='@',
`ele` double(21,16) NOT NULL `xpath`='gns:ele',
`time` datetime date_format="YYYY-MM-DD 'T' hh:mm:ss '.000Z'"
)
ENGINE=CONNECT DEFAULT CHARSET=latin1 `table_type`=XML
`file_name`='gns.xml' tabname='gns:trkseg' option_list='xmlsup=domdoc';

```

```
select * from xgns;
```

Displays:

lon	lat	ele	time
-121,982223510742	37,3884925842285	6,6108512878418	01/04/2014 14:54:05
-121,982192993164	37,3885803222656	0	01/04/2014 14:54:08
-121,982162475586	37,3886299133301	0	01/04/2014 14:54:10

Only the prefixed 'ele' tag is recognized.

However, this does not work with the libxml2 support. The solution is then to use a function ignoring the name space:

```

CREATE TABLE xgns2 (
`lon` double(21,16) NOT NULL `xpath`='@',
`lat` double(20,16) NOT NULL `xpath`='@',
`ele` double(21,16) NOT NULL `xpath`="*[local-name()='ele']",
`time` datetime date_format="YYYY-MM-DD 'T' hh:mm:ss '.000Z'"
)
ENGINE=CONNECT DEFAULT CHARSET=latin1 `table_type`=XML
`file_name`='gns.xml' tabname="*[local-name()='trkseg']" option_list='xmlsup=libxml2';

```

Then :

```
select * from xgns2;
```

Displays:

lon	lat	ele	time
-121,982223510742	37,3884925842285	6,6108512878418	01/04/2014 14:54:05
-121,982192993164	37,3885803222656	6.7878279685974	01/04/2014 14:54:08
-121,982162475586	37,3886299133301	6.7719874382019	01/04/2014 14:54:10

This time, all 'ele' tags are recognized. This solution does not work with DOMDOC.

## Having Columns defined by Discovery

It is possible to let the MariaDB discovery process do the job of column specification. When columns are not defined in the `CREATE TABLE` statement, CONNECT endeavours to analyze the XML file and to provide the column specifications. This is possible only for true XML tables, but not for HTML tables.

For instance, the `xsamp` table could have been created specifying:

```

create table xsamp
engine=CONNECT table_type=XML file_name='Xsample.xml'
tabname='BIBLIO' option_list='rownode=BOOK';

```

Let's check how it was actually specified using the `SHOW CREATE TABLE` statement:

```

CREATE TABLE `xsamp` (
  `ISBN` char(13) NOT NULL `FIELD_FORMAT`='@',
  `LANG` char(2) NOT NULL `FIELD_FORMAT`='@',
  `SUBJECT` char(12) NOT NULL `FIELD_FORMAT`='@',
  `AUTHOR` char(24) NOT NULL,
  `TRANSLATOR` char(12) DEFAULT NULL,
  `TITLE` char(30) NOT NULL,
  `PUBLISHER` char(21) NOT NULL,
  `DATEPUB` char(4) NOT NULL
) ENGINE=CONNECT DEFAULT CHARSET=latin1 `TABLE_TYPE`='XML'
`FILE_NAME`='E:/Data/Xml/Xsample.xml' `TABNAME`='BIBLIO' `OPTION_LIST`='rownode=BOOK';

```

It is equivalent except for the column sizes that have been calculated from the file as the maximum length of the corresponding column when it was a normal value. Also, all columns are specified as type **CHAR** because XML does not provide information about the node content data type. Nullable is set to true if the column is missing in some rows.

If a more complex definition is desired, you can ask CONNECT to analyse the XPATH up to a given level using the level option in the option list. The level value is the number of nodes that are taken in the XPATH. For instance:

```

create table xsampall
engine=CONNECT table_type=XML file_name='Xsample.xml'
tabname='BIBLIO' option_list='rownode=BOOK,Level=1';

```

This will define the table as:

From Connect 1.7.0002

```

CREATE TABLE `xsampall` (
  `ISBN` char(13) NOT NULL `XPATH`='@',
  `LANG` char(2) NOT NULL `XPATH`='@',
  `SUBJECT` char(12) NOT NULL `XPATH`='@',
  `AUTHOR_FIRSTNAME` char(15) NOT NULL `XPATH`='AUTHOR/FIRSTNAME',
  `AUTHOR_LASTNAME` char(8) NOT NULL `XPATH`='AUTHOR/LASTNAME',
  `TRANSLATOR_PREFIX` char(24) DEFAULT NULL `XPATH`='TRANSLATOR/@PREFIX',
  `TRANSLATOR_FIRSTNAME` char(7) DEFAULT NULL `XPATH`='TRANSLATOR/FIRSTNAME',
  `TRANSLATOR_LASTNAME` char(6) DEFAULT NULL `XPATH`='TRANSLATOR/LASTNAME',
  `TITLE` char(30) NOT NULL,
  `PUBLISHER_NAME` char(15) NOT NULL `XPATH`='PUBLISHER/NAME',
  `PUBLISHER_PLACE` char(5) NOT NULL `XPATH`='PUBLISHER/PLACE',
  `DATEPUB` char(4) NOT NULL
) ENGINE=CONNECT DEFAULT CHARSET=latin1 `TABLE_TYPE`='XML' `FILE_NAME`='Xsample.xml' `TABNAME`='BIBLIO' `OPTION_LIST`='rownode=B

```

Before Connect 1.7.0002

```

CREATE TABLE `xsampall` (
  `ISBN` char(13) NOT NULL `FIELD_FORMAT`='@',
  `LANG` char(2) NOT NULL `FIELD_FORMAT`='@',
  `SUBJECT` char(12) NOT NULL `FIELD_FORMAT`='@',
  `AUTHOR_FIRSTNAME` char(15) NOT NULL `FIELD_FORMAT`='AUTHOR/FIRSTNAME',
  `AUTHOR_LASTNAME` char(8) NOT NULL `FIELD_FORMAT`='AUTHOR/LASTNAME',
  `TRANSLATOR_PREFIX` char(24) DEFAULT NULL `FIELD_FORMAT`='TRANSLATOR/@PREFIX',
  `TRANSLATOR_FIRSTNAME` char(7) DEFAULT NULL `FIELD_FORMAT`='TRANSLATOR/FIRSTNAME',
  `TRANSLATOR_LASTNAME` char(6) DEFAULT NULL `FIELD_FORMAT`='TRANSLATOR/LASTNAME',
  `TITLE` char(30) NOT NULL,
  `PUBLISHER_NAME` char(15) NOT NULL `FIELD_FORMAT`='PUBLISHER/NAME',
  `PUBLISHER_PLACE` char(5) NOT NULL `FIELD_FORMAT`='PUBLISHER/PLACE',
  `DATEPUB` char(4) NOT NULL
) ENGINE=CONNECT DEFAULT CHARSET=latin1 `TABLE_TYPE`='XML' `FILE_NAME`='Xsample.xml'
`TABNAME`='BIBLIO' `OPTION_LIST`='rownode=BOOK,Level=1';

```

This method can be used as a quick way to make a “template” table definition that can later be edited to make the desired definition. In particular, column names are constructed from all the nodes of their path in order to have distinct column names. This can be manually edited to have the desired names, provided their XPATH is not modified.

To have a preview of how columns will be defined, you can use a catalog table like this:

```

create table xsacol
engine=CONNECT table_type=XML file_name='Xsample.xml'
tabname='BIBLIO' option_list='rownode=BOOK,Level=1' catfunc=col;

```

And when asking:

```

select column_name Name, type_name Type, column_size Size, nullable, xpath from xsacol;

```

You get the description of what the table columns will be:

Name	Type	Size	nullable	xpath
ISBN	CHAR	13	0	@
LANG	CHAR	2	0	@
SUBJECT	CHAR	12	0	@
AUTHOR_FIRSTNAME	CHAR	15	0	AUTHOR/FIRSTNAME
AUTHOR_LASTNAME	CHAR	8	0	AUTHOR/LASTNAME
TRANSLATOR_PREFIX	CHAR	24	1	TRANSLATOR/@PREFIX
TRANSLATOR_FIRSTNAME	CHAR	7	1	TRANSLATOR/FIRSTNAME
TRANSLATOR_LASTNAME	CHAR	6	1	TRANSLATOR/LASTNAME
TITLE	CHAR	30	0	
PUBLISHER_NAME	CHAR	15	0	PUBLISHER/NAME
PUBLISHER_PLACE	CHAR	5	0	PUBLISHER/PLACE
DATEPUB	CHAR	4	0	

## Write operations on XML tables

You can freely use the Update, Delete and Insert commands with XML tables. However, you must understand that the format of the updated or inserted data follows the specifications of the table you created, not the ones of the original source file. For instance, let us suppose we insert a new book using the `xsamp` table (not the `xsampall` table) with the command:

```
insert into xsamp
(isbn, lang, subject, author, title, publisher,datepub)
values ('9782212090529','fr','général','Alain Michard',
'XML, Langage et Applications','Eyrolles Paris',1998);
```

Then if we ask:

```
select subject, author, title, translator, publisher from xsamp;
```

Everything seems correct when we get the result:

SUBJECT	AUTHOR	TITLE	TRANSLATOR	PUBLISHER
applications	Jean-Christophe Bernadac	Construire une application XML		Eyrolles Paris
applications	William J. Pardi	XML en Action	James Guerin	Microsoft Press Paris
général	Alain Michard	XML, Langage et Applications		Eyrolles Paris

However if we enter the apparently equivalent query on the `xsampall` table, based on the same file:

```
select subject,
concat(authorfn, ' ', authorln) author , title,
concat(tranfn, ' ', tranln) translator,
concat(publisher, ' ', location) publisher from xsampall;
```

this returns an apparently wrong answer:

SUBJECT	AUTHOR	TITLE	TRANSLATOR	PUBLISHER
applications	Jean-Christophe Bernadac	Construire une application XML		Eyrolles Paris
applications	William J. Pardi	XML en Action	James Guerin	Microsoft Press Paris
général		XML, Langage et Applications		

What happened here? Simply, because we used the `xsamp` table to do the Insert, what has been inserted within the XML file had the structure described for `xsamp`:

```

<BOOK ISBN="9782212090529" LANG="fr" SUBJECT="général">
  <AUTHOR>Alain Michard</AUTHOR>
  <TITLE>XML, Langage et Applications</TITLE>
  <TRANSLATOR></TRANSLATOR>
  <PUBLISHER>Eyrolles Paris</PUBLISHER>
  <DATEPUB>1998</DATEPUB>
</BOOK>

```

CONNECT cannot "invent" sub-tags that are not part of the xsamp table. Because these sub-tags do not exist, the xsampall table cannot retrieve the information that should be attached to them. If we want to be able to query the XML file by all the defined tables, the correct way to insert a new book to the file is to use the xsampall table, the only one that addresses all the components of the original document:

```

delete from xsamp where isbn = '9782212090529';

insert into xsampall (isbn, language, subject, authorfn, authorln,
                      title, publisher, location, year)
values('9782212090529', 'fr', 'général', 'Alain', 'Michard',
      'XML, Langage et Applications', 'Eyrolles', 'Paris', 1998);

```

Now the added book, in the XML file, will have the required structure:

```

<BOOK ISBN="9782212090529" LANG="fr" SUBJECT="général">
  <AUTHOR>
    <FIRSTNAME>Alain</FIRSTNAME>
    <LASTNAME>Michard</LASTNAME>
  </AUTHOR>
  <TITLE>XML, Langage et Applications</TITLE>
  <PUBLISHER>
    <NAME>Eyrolles</NAME>
    <PLACE>Paris</PLACE>
  </PUBLISHER>
  <DATEPUB>1998</DATEPUB>
</BOOK>

```

**Note:** We used a column list in the Insert statements when creating the table to avoid generating a <TRANSLATOR> node with sub-nodes, all containing null values (this works on Windows only).

## Multiple nodes in the XML document

Let us come back to the above example XML file. We have seen that the author node can be "multiple" meaning that there can be more than one author of a book. What can we do to get the complete information fitting the relational model? CONNECT provides you with two possibilities, but is restricted to only one such multiple node per table.

The first and most challenging one is to return as many rows than there are authors, the other columns being repeated as if we had make a join between the author column and the rest of the table. To achieve this, simply specify the "multiple" node name and the "expand" option when creating the table. For instance, we can create the xsamp2 table like this:

```

create table xsamp2 (
  ISBN char(15) field_format='@',
  LANG char(2) field_format='@',
  SUBJECT char(32) field_format='@',
  AUTHOR char(40),
  TITLE char(32),
  TRANSLATOR char(32),
  PUBLISHER char(32),
  DATEPUB int(4))
engine=CONNECT table_type=XML file_name='Xsample.xml'
tabname='BIBLIO'
option_list='rownode=BOOK,Expand=1,Mulnode=AUTHOR,Limit=2';

```

In this statement, the Limit option specifies the maximum number of values that will be expanded. If not specified, it defaults to

10

. Any values above the limit will be ignored and a warning message issued [3]. Now you can enter a query such as:

```
select isbn, subject, author, title from xsamp2;
```

This will retrieve and display the following result:

ISBN	SUBJECT	AUTHOR	TITLE
------	---------	--------	-------

9782212090819	applications	Jean-Christophe Bernadac	Construire une application XML
9782212090819	applications	François Knab	Construire une application XML
9782840825685	applications	William J. Pardi	XML en Action
9782212090529	général	Alain Michard	XML, Langage et Applications

In this case, this is as if the table had four rows. However if we enter the query:

```
select isbn, subject, title, publisher from xsamp2;
```

this time the result will be:

ISBN	SUBJECT	TITLE	PUBLISHER
9782212090819	applications	Construire une application XML	Eyrolles Paris
9782840825685	applications	XML en Action	Microsoft Press Paris
9782212090529	général	XML, Langage et Applications	Eyrolles Paris

Because the author column does not appear in the query, the corresponding row was not expanded. This is somewhat strange because this would have been different if we had been working on a table of a different type. However, it is closer to the relational model for which there should not be two identical rows (tuples) in a table. Nevertheless, you should be aware of this somewhat erratic behavior. For instance:

```
select count(*) from xsamp2;          /* Replies 3 */
select count(author) from xsamp2;      /* Replies 4 */
select count(isbn) from xsamp2;        /* Replies 3 */
select isbn, subject, title, publisher from xsamp2 where author <> '';
```

This last query replies:

ISBN	SUBJECT	TITLE	PUBLISHER
9782212090819	applications	Construire une application XML	Eyrolles Paris
9782212090819	applications	Construire une application XML	Eyrolles Paris
9782840825685	applications	XML en Action	Microsoft Press Paris
9782212090529	général	XML, Langage et Applications	Eyrolles Paris

Even though the author column does not appear in the result, the corresponding row was expanded because the multiple column was used in the where clause.

## Intermediate multiple node

The "multiple" node can be an intermediate node. If we want to do the same expanding with the xsampall table, there will be nothing more to do. The xsampall2 table can be created with:

From Connect 1.7.0002

```
create table xsampall2 (
isbn char(15) xpath='@ISBN',
language char(2) xpath='@LANG',
subject char(32) xpath='@SUBJECT',
authorfn char(20) xpath='AUTHOR/FIRSTNAME',
authorln char(20) xpath='AUTHOR/LASTNAME',
title char(32) xpath='TITLE',
translated char(32) xpath='TRANSLATOR/@PREFIX',
tranfn char(20) xpath='TRANSLATOR/FIRSTNAME',
tranln char(20) xpath='TRANSLATOR/LASTNAME',
publisher char(20) xpath='PUBLISHER/NAME',
location char(20) xpath='PUBLISHER/PLACE',
year int(4) xpath='DATEPUB')
engine=CONNECT table_type=XML file_name='Xsample.xml'
tabname='BIBLIO' option_list='rownode=BOOK,Expand=1,Mulnode=AUTHOR,Limit=2';
```

Before Connect 1.7.0002

```

create table xsampall2 (
    isbn char(15) field_format='@ISBN',
    language char(2) field_format='@LANG',
    subject char(32) field_format='@SUBJECT',
    authorfn char(20) field_format='AUTHOR/FIRSTNAME',
    authorln char(20) field_format='AUTHOR/LASTNAME',
    title char(32) field_format='TITLE',
    translated char(32) field_format='TRANSLATOR/@PREFIX',
    tranfn char(20) field_format='TRANSLATOR/FIRSTNAME',
    tranln char(20) field_format='TRANSLATOR/LASTNAME',
    publisher char(20) field_format='PUBLISHER/NAME',
    location char(20) field_format='PUBLISHER/PLACE',
    year int(4) field_format='DATEPUB'
engine=CONNECT table_type=XML file_name='Xsample.xml'
tablename='BIBLIO'
option_list='rownode=BOOK,Expand=1,Mulnode=AUTHOR,Limit=2';

```

The only difference is that the "multiple" node is an intermediate node in the path. The resulting table can be seen with a query such as:

```

select subject, language lang, title, authorfn first, authorln
last, year from xsampall2;

```

This query displays:

SUBJECT	LANG	TITLE	FIRST	LAST	YEAR
applications	fr	Construire une application XML	Jean-Christophe	Bernadac	1999
applications	fr	Construire une application XML	François	Knab	1999
applications	fr	XML en Action	William J.	Pardi	1999
général	fr	XML, Langage et Applications	Alain	Michard	1998

These composite tables, half array half tree, reserve some surprises for us when updating, deleting from or inserting into them. Insert just cannot generate this structure; if two rows are inserted with just a different author, two book nodes will be generated in the XML file. Delete always deletes one book node and all its children nodes even if specified against only one author. Update is more complicated:

```

update xsampall2 set authorfn = 'Simon' where authorln = 'Knab';
update xsampall2 set year = 2002 where authorln = 'Bernadac';
update xsampall2 set authorln = 'Mercier' where year = 2002;

```

After these three updates, the first two responding "Affected rows: 1" and the last one responding "Affected rows: 2", the last query answers:

subject	lang	title	first	last	year
applications	fr	Construire une application XML	Jean-Christophe	Mercier	2002
applications	fr	Construire une application XML	François	Knab	2002
applications	fr	XML en Action	William J.	Pardi	1999
général	fr	XML, Langage et Applications	Alain	Michard	1998

What must be understood here is that the Update modifies node values in the XML file, not cell values in the relational table. The first update worked normally. The second update changed the year value of the book and this shows for the two expanded rows because there is only one DATEPUB node for that book. Because the third update applies to a row having a certain date value, both author names were updated.

## Making a List of Multiple Values

Another way to see multiple values is to ask CONNECT to make a comma separated list of the multiple node values. This time, it can only be done if the "multiple" node is not intermediate. For example, we can modify the xsamp2 table definition by:

```

alter table xsamp2 option_list='rownode=BOOK,Mulnode=AUTHOR,Limit=3';

```

This time 'Expand' is not specified, and Limit gives the maximum number of items in the list. Now if we enter the query:

```

select isbn, subject, author "AUTHOR(S)", title from xsamp2;

```

We will get the following result:

ISBN	SUBJECT	AUTHOR(S)	TITLE
9782212090819	applications	Jean-Christophe Bernadac, François Knab	Construire une application XML

9782840825685	applications	William J. Pardi	XML en Action
9782212090529	général	Alain Michard	XML, Langage et Applications

Note that updating the "multiple" column is not possible because CONNECT does not know which of the nodes to update.

This could not have been done with the xsampall2 table because the author node is intermediate in the path, and making two lists, one of first names and another one of last names would not make sense anyway.

## What if a table contains several multiple nodes

This can be handled by creating several tables on the same file, each containing only one multiple node and constructing the desired result using joins.

## Support of HTML Tables

Most tables included in HTML documents cannot be processed by CONNECT because the HTML language is often not compatible with the syntax of XML. In particular, XML requires all open tags to be matched by a closing tag while it is sometimes optional in HTML. This is often the case concerning column tags.

However, you can meet tables that respect the XML syntax but have some of the features of HTML tables. For instance:

```
<?xml version="1.0"?>
<Beers>
  <table>
    <th><td>Name</td><td>Origin</td><td>Description</td></th>
    <tr>
      <td><brandName>Huntsman</brandName></td>
      <td><origin>Bath, UK</origin></td>
      <td><details>Wonderful hop, light alcohol</details></td>
    </tr>
    <tr>
      <td><brandName>Tuborg</brandName></td>
      <td><origin>Danmark</origin></td>
      <td><details>In small bottles</details></td>
    </tr>
  </table>
</Beers>
```

Here the different column tags are included in

<td></td>

tags as for HTML tables. You cannot just add this tag in the Xpath of the columns, because the search is done on the first occurrence of each tag, and this would cause this search to fail for all columns except the first one. This case is handled by specifying the *Colnode* table option that gives the name of these column tags, for example:

From Connect 1.7.0002

```
create table beers (
`Name` char(16) xpath='brandName',
`Origin` char(16) xpath='origin',
`Description` char(32) xpath='details')
engine=CONNECT table_type=XML file_name='beers.xml'
tabname='table' option_list='rownode=tr,colnode=td';
```

Before Connect 1.7.0002

```
create table beers (
`Name` char(16) field_format='brandName',
`Origin` char(16) field_format='origin',
`Description` char(32) field_format='details')
engine=CONNECT table_type=XML file_name='beers.xml'
tabname='table' option_list='rownode=tr,colnode=td';
```

The table will be displayed as:

Name	Origin	Description
Huntsman	Bath, UK	Wonderful hop, light alcohol
Tuborg	Danmark	In small bottles

However, you can deal with tables even closer to the HTML model. For example the *coffee.htm* file:

```

<TABLE summary="This table charts the number of cups of coffee consumed by each senator, the type of coffee (decaf or regular), and whether taken with sugar.">
  <CAPTION>Cups of coffee consumed by each senator</CAPTION>
  <TR>
    <TH>Name</TH>
    <TH>Cups</TH>
    <TH>Type of Coffee</TH>
    <TH>Sugar?</TH>
  </TR>
  <TR>
    <TD>T. Sexton</TD>
    <TD>10</TD>
    <TD>Espresso</TD>
    <TD>No</TD>
  </TR>
  <TR>
    <TD>J. Dinnen</TD>
    <TD>5</TD>
    <TD>Decaf</TD>
    <TD>Yes</TD>
  </TR>
</TABLE>

```

Here column values are directly represented by the TD tag text. You cannot declare them as tags nor as attributes. In addition, they are not located using their name but by their position within the row. Here is how to declare such a table to CONNECT:

```

create table coffee (
  `Name` char(16),
  `Cups` int(8),
  `Type` char(16),
  `Sugar` char(4))
engine=connect table_type=XML file_name='coffee.htm'
tabname='TABLE' header=1 option_list='Coltype=HTML';

```

You specify the fact that columns are located by position by setting the *Coltype* option to 'HTML'. Each column position (0 based) will be the value of the *flag* column parameter that is set by default in sequence. Now we are able to display the table:

Name	Cups	Type	Sugar
T. Sexton	10	Espresso	No
J. Dinnen	5	Decaf	Yes

**Note 1:** We specified '

```

header=1
' in the create statement to indicate that the first n rows of the table are not data rows and should be skipped.
```

**Note 2:** In this last example, we did not specify the node names using the Rownode and Colnode options because when *Coltype* is set to 'HTML' they default to '

```

Rownode=TR
' and '
Colnode=TD
'.
```

**Note 3:** The *Coltype* option is a word only the first character of which is significant. Recognized values are:

T(ag) or N(ode) Column names match a tag name (the default).

A(tribute) or @ Column names match an attribute name.

H(tml) or C(ol) or P(os) Column are retrieved by their position.

## New file setting

Some create options are used only when creating a table on a new file, i. e. when inserting into a file that does not exist yet. When specified, the 'Header' option will create a header row with the name of the table columns. This is chiefly useful for HTML tables to be displayed on a web browser.

Some new list-options are used in this context:

**Encoding** The encoding of the new document, defaulting to UTF-8.

**Attribute** A list of 'atname=attvalue' separated by ';' to add to the table node.

**HeadAttr** An attribute list to be added to the header row node.

Let us see for instance, the following create statement:

```

create table handlers (
  handler char(64),
  version char(20),
  author char(64),
  description char(255),
  maturity char(12))
engine=CONNECT table_type=XML file_name='handlers.htm'
tabname='TABLE' header=yes
option_list='coltype=HTML,encoding=ISO-8859-1,
attribute=border=1;cellpadding=5,headattr=bgcolor=yellow';

```

Supposing the table file does not exist yet, the first insert into that table, for instance by the following statement:

```

insert into handlers select plugin_name, plugin_version,
  plugin_author, plugin_description, plugin_maturity from
information_schema.plugins where plugin_type = 'DAEMON';

```

will generate the following file:

```

<?xml version="1.0" encoding="ISO-8859-1"?>
<!-- Created by CONNECT Version 3.05.0005 August 17, 2012 -->
<TABLE border="1" cellpadding="5">
  <TR bgcolor="yellow">
    <TH>handler</TH>
    <TH>version</TH>
    <TH>author</TH>
    <TH>description</TH>
    <TH>maturity</TH>
  </TR>
  <TR>
    <TD>Maria</TD>
    <TD>1.5</TD>
    <TD>Monty Program Ab</TD>
    <TD>Compatibility aliases for the Aria engine</TD>
    <TD>Gamma</TD>
  </TR>
</TABLE>

```

This file can be used to display the table on a web browser (encoding should be

```

ISO-8859-x
)
```

handler	version	author	description	maturity
Maria	1.5	Monty Program Ab	Compatibility aliases for the Aria engine	Gamma

**Note:** The XML document encoding is generally specified in the XML header node and can be different from the DATA\_CHARSET, which is always UTF-8 for XML tables. Therefore the table DATA\_CHARSET character set should be unspecified, or specified as UTF8. The Encoding specification is useful only for new XML files and ignored for existing files having their encoding already specified in the header node.

## Notes

- ↑ CONNECT does not claim to be able to deal with any XML document. Besides, those that can usefully be processed for data analysis are likely to have a structure that can easily be transformed into a table.
- ↑ With libxml2, sub tags text can be separated by 0 or several blanks depending on the structure and indentation of the data file.
- ↑ This may cause some rows to be lost because an eventual where clause on the “multiple” column is applied only on the limited number of retrieved rows.

## 4.3.7.6.14 CONNECT INI Table Type

### Contents

1. [Overview](#)
2. [Column layout](#)
3. [Row layout](#)

## Overview

The INI type is one of the configuration or initialization files often found on Windows machines. For instance, let us suppose you have the following contact file *contact.ini*:

```

[BER]
name=Bertrand
forename=Olivier
address=21 rue Ferdinand Buisson
city=Issy-les-Mlx
zipcode=92130
tel=09.54.36.29.60
cell=06.70.06.04.16

[WEL]
name=Schmitt
forename=Bernard
hired=19/02/1985
address=64 tiergarten strasse
city=Berlin
zipcode=95013
tel=03.43.377.360

[UK1]
name=Smith
forename=Henry
hired=08/11/2003
address=143 Blum Rd.
city=London
zipcode=NW1 2BP

```

CONNECT lets you view it as a table in two different ways.

## Column layout

The first way is to regard it as a table having one line per section, the columns being the keys you want to display. In this case, the CREATE statement could be:

```

create table contact (
    contact char(16) flag=1,
    name char(20),
    forename char(32),
    hired date date_format='DD/MM/YYYY',
    address char(64),
    city char(20),
    zipcode char(8),
    tel char(16))
engine=CONNECT table_type=INI file_name='contact.ini';

```

The column that will contain the section name can have any name but must specify

flag=1

. All other columns must have the names of the keys we want to display (case insensitive). The type can be character or numeric depending on the key value type, and the length is the maximum expected length for the key value. Once done, the statement:

```
select contact, name, hired, city, tel from contact;
```

This statement will display the file in tabular format.

contact	name	hired	city	tel
BER	Bertrand	1970-01-01	Issy-les-Mlx	09.54.36.29.60
WEL	Schmitt	1985-02-19	Berlin	03.43.377.360
UK1	Smith	2003-11-08	London	NULL

Only the keys defined in the create statements are visible; keys that do not exist in a section are displayed as null or pseudo null (blank for character, 1/1/70 for dates, and 0 for numeric) for columns declared NOT NULL.

All relational operations can be applied to this table. The table (and the file) can be updated, inserted and conditionally deleted. The only constraint is that when inserting values, the section name must be the first in the list of values.

**Note 1:** When inserting, if a section already exists, no new section will be created but the new values will be added or replace those of the existing section. Thus, the following two commands are equivalent:

```

update contact set forename = 'Harry' where contact = 'UK1';
insert into contact (contact,forename) values('UK1','Harry');

```

**Note 2:** Because sections represent one line, a DELETE statement on a section key will delete the whole section.

## Row layout

To be a good candidate for tabular representation, an INI file should have often the same keys in all sections. In practice, many files commonly found on computers, such as the *win.ini* file of the Windows directory or the *my.ini* file cannot be viewed that way because each section has different keys. In this case, a second way is to regard the file as a table having one row per section key and whose columns can be the section name, the key name, and the key value.

For instance, let us define the table:

```
create table xcont (
  section char(16) flag=1,
  keyname char(16) flag=2,
  value char(32))
engine=CONNECT table_type=INI file_name='contact.ini'
option_list='Layout=Row';
```

In this statement, the "Layout" option sets the display format, Column by default or anything else not beginning by 'C' for row layout display. The names of the three columns can be freely chosen. The Flag option gives the meaning of the column. Specify

flag=1  
for the section name and  
flag=2  
for the key name. Otherwise, the column will contain the key value.

Once done, the command:

```
select * from xcont;
```

Will display the following result:

section	keyname	value
BER	name	Bertrand
BER	forename	Olivier
BER	address	21 rue Ferdinand Buisson
BER	city	Issy-les-Mix
BER	zipcode	92130
BER	tel	09.54.36.29.60
BER	cell	06.70.06.04.16
WEL	name	Schmitt
WEL	forename	Bernard
WEL	hired	19/02/1985
WEL	address	64 tiergarten strasse
WEL	city	Berlin
WEL	zipcode	95013
WEL	tel	03.43.377.360
UK1	name	Smith
UK1	forename	Henry
UK1	hired	08/11/2003
UK1	address	143 Blum Rd.
UK1	city	London
UK1	zipcode	NW1 2BP

**Note:** When processing an INI table, all section names are retrieved in a buffer of 8K bytes (2048 bytes before 10.0.17). For a big file having many sections, this size can be increased using for example:

```
option_list='seclen=16K';
```

## 4.3.7.6.15 CONNECT - External Table Types

Because so many ODBC and JDBC drivers exist and only the main ones have been heavily tested, these table types cannot be ranked as stable. Use

them with care in production applications.

These types can be used to access tables belonging to the current or another database server. Six types are currently provided:

**ODBC** : To be used to access tables from a database management system providing an ODBC connector. ODBC is a standard of Microsoft and is currently available on Windows. On Linux, it can also be used provided a specific application emulating ODBC is installed. Currently only unixODBC is supported.

**JDBC** : To be used to access tables from a database management system providing a JDBC connector. JDBC is an Oracle standard implemented in Java and principally meant to be used by Java applications. Using it directly from C or C++ application seems to be almost impossible due to an Oracle bug still not fixed. However, this can be achieved using a Java wrapper class used as an interface between C++ and JDBC. On another hand, JDBC is available on all platforms and operating systems.

**Mongo** : To access MongoDB collections as tables via their MongoDB C Driver. Because this requires both MongoDB and the C Driver to be installed and operational, this table type is not currently available in binary distributions but only when compiling MariaDB from source.

**MySQL** : This type is the preferred way to access tables belonging to another MySQL or MariaDB server. It uses the MySQL API to access the external table. Even though this can be obtained using the FEDERATED(X) plugin, this specific type is used internally by CONNECT because it also makes it possible to access tables belonging to the current server.

**PROXY** : Internally used by some table types to access other tables from one table.

## External Table Specification

The four main external table types – odbc, jdbc, mongo and mysql – are specified giving the following information:

1. The data source. This is specified in the connection option.
2. The remote table or view to access. This can be specified within the connection string or using specific CONNECT options.
3. The column definitions. This can be also left to CONNECT to find them using the discovery MariaDB feature.
4. The optional Quoted option. Can be set to 1 to quote the identifiers in the query sent to the remote server. This is required if columns or table names can contain blanks.

The way this works is by establishing a connection to the external data source and by sending it an SQL statement (or its equivalent using API functions for MONGO) enabling it to execute the original query. To enhance performance, it is necessary to have the remote data source do the maximum processing. This is needed in particular to reduce the amount of data returned by the data source.

This is why, for SELECT queries, CONNECT uses the `cond_push` MariaDB feature to retrieve the maximum of the where clause of the original query that can be added to the query sent to the data source. This is automatic and does not require anything to be done by the user.

However, more can be done. In addition to accessing a remote table, CONNECT offers the possibility to specify what the remote server must do. This is done by specifying it as a view in the srcdef option. For example:

```
CREATE TABLE custnum ENGINE=CONNECT TABLE_TYPE=XXX
  CONNECTION='connection string'
  SRCDEF='select pays as country, count(*) as customers from custnum group by pays';
```

Doing so, the group by clause will be done by the remote server considerably reducing the amount of data sent back on the connection.

This may even be increased by adding to the srcdef part of the “compatible” part of the query where clauses like this are done for table-based tables. Note that for MariaDB, this table has two columns, country and customers. Supposing the original query is:

```
SELECT * FROM custnum WHERE (country = 'UK' OR country = 'USA') AND customers > 5;
```

How can we make the where clause be added to the sent srcdef? There are many problems:

1. Where to include the additional information.
2. What about the use of alias.
3. How to know what will be a where clause or a having clause.

The first problem is solved by preparing the srcdef view to receive clauses. The above example srcdef becomes:

```
SRCDEF='select pays as country, count(*) as customers from custnum where %s group by pays having %s';
```

The %s in the srcdef are place holders for eventual compatible parts of the original query where clause. If the select query does not specify a where clause, or gives an unacceptable where clause, place holders will be filled by dummy clauses (1=1).

The other problems must be solved by adding to the create table a list of columns that must be translated because they are aliases or/and aliases on aggregate functions that must become a having clause. For example, in this case:

```
CREATE TABLE custnum ENGINE=CONNECT TABLE_TYPE=XXX
  CONNECTION='connection string'
  SRCDEF='select pays as country, count(*) as customers from custnum where %s group by pays having %s'
  OPTION_LIST='Alias=customers=*count(*);country=pays';
```

This is specified by the alias option, to be used in the option list. It is made of a semi-colon separated list of items containing:

1. The local column name (alias in the remote server)
2. An equal sign.

3. An eventual '\*' indicating this is column correspond to an aggregate function.
4. The remote column name.

With this information, CONNECT will be able to make the query sent to the remote data source:

```
select pays as country, count(*) as customers from custnum where (pays = 'UK' OR pays = 'USA') group by country having count(*)
```

Note: Some data sources, including MySQL and MariaDB, accept aliases in the having clause. In that case, the alias option could have been specified as:

```
OPTION_LIST='Alias=customers=*;country=pays';
```

Another option exists, phpos, enabling to specify what place holders are present and in what order. To be specified as "W", "WH", "H", or "HW". It is rarely used because by default CONNECT can set it from the srcdef content. The only cases it is needed is when the srcdef contains only a having place holder or when the having place holder occurs before the where place holder, which can occur on queries containing joins. CONNECT cannot handle more than one place holder of each type.

SRCDEF is not available for MONGO tables, but other ways of achieving this exist and are described in the MONGO table type chapter.

  1. [Using systemd](#)
  2. [Using Windows](#)

ODBC (Open Database Connectivity) is a standard API for accessing database management systems (DBMS). CONNECT uses this API to access data contained in other DBMS without having to implement a specific application for each one. An exception is the access to MySQL that should be done using the [MYSQL table type](#).

**Note:** On Linux, unixODBC must be installed.

These tables are given the type ODBC. For example, if a "Customers" table is contained in an Access ™ database you can define it with a command such as:

```

create table Customer (
    CustomerID varchar(5),
    CompanyName varchar(40),
    ContactName varchar(30),
    ContactTitle varchar(30),
    Address varchar(60),
    City varchar(15),
    Region varchar(15),
    PostalCode varchar(10),
    Country varchar(15),
    Phone varchar(24),
    Fax varchar(24))
engine=connect table_type=ODBC block_size=10
tabname='Customers'
Connection='DSN=MS Access Database;DBQ=C:/Program
Files/Microsoft Office/Office/1033/FPNWIND.MDB';

```

Tabname option defaults to the table name. It is required if the source table name is different from the name of the CONNECT table. Note also that for some data sources this name is case sensitive.

Often, because CONNECT can retrieve the table description using ODBC catalog functions, the column definitions can be unspecified. For instance this table can be simply created as:

```

create table Customer engine=connect table_type=ODBC
block_size=10 tabname='Customers'
Connection='DSN=MS Access Database;DBQ=C:/Program Files/Microsoft Office/Office/1033/FPNWIND.MDB';

```

The

BLOCK\_SIZE

specification will be used later to set the RowsetSize when retrieving rows from the ODBC table. A reasonably large RowsetSize can greatly accelerate the fetching process.

If you specify the column description, the column names of your table must exist in the data source table. However, you are not obliged to define all the data source columns and you can change the order of the columns. Some type conversion can also be done if appropriate. For instance, to access the FireBird sample table EMPLOYEE, you could define your table as:

```

create table empodbc (
    EMP_NO smallint(5) not null,
    FULL_NAME varchar(37) not null,
    PHONE_EXT varchar(4) not null,
    HIRE_DATE date,
    DEPT_NO smallint(3) not null,
    JOB_COUNTRY varchar(15),
    SALARY double(12,2) not null)
engine=CONNECT table_type=ODBC tabname='EMPLOYEE'
connection='DSN=firebird';

```

This definition ignores the FIRST\_NAME, LAST\_NAME, JOB\_CODE, and JOB\_GRADE columns. It places the FULL\_NAME last column of the original table in second position. The type of the HIRE\_DATE column was changed from *timestamp* to *date* and the type of the DEPT\_NO column was changed from *char* to *integer*.

Currently, some restrictions apply to ODBC tables:

1. Cursor type is forward only (sequential reading).
2. No indexing of ODBC tables (do not specify any columns as key). However, because CONNECT can often add a where clause to the query sent to the data source, indexing will be used by the data source if it supports it. (Remote indexing is available with version 1.04, released with [MariaDB 10.1.6](#) )
3. CONNECT ODBC supports [SELECT](#) and [INSERT](#) . [UPDATE](#) and [DELETE](#) are also supported in a somewhat restricted way (see below). For other operations, use an ODBC table with the EXECSRC option (see below) to directly send proper commands to the data source.

## Random Access of ODBC Tables

In CONNECT version 1.03 (until [MariaDB 10.1.5](#) ) ODBC tables are not indexable. Version 1.04 (from [MariaDB 10.1.6](#) ) adds remote indexing facility to the ODBC table type.

However, some queries require random access to an ODBC table; for instance when it is joined to another table or used in an order by queries applied to a long column or large tables.

There are several ways to enable random (position) access to a CONNECT ODBC table. They are dependant on the following table options:

Option	Type	Used For
Block_Size	Integer	Specifying the rowset size.
Memory*	Integer	Storing the result set in memory.

Scorable*	Boolean	Using a scrollable cursor.
-----------	---------	----------------------------

\*

- To be specified in the option\_list.

When dealing with small tables, the simpler way to enable random access is to specify a rowset size equal or larger than the table size (or the result set size if a push down where clause is used). This means that the whole result is in memory on the first fetch and CONNECT will use it for further positional accesses.

Another way to have the result set in memory is to use the memory option. This option can be set to the following values:

0. No memory used (the default). Best when the table is read sequentially as in SELECT statements with only eventual WHERE clauses.
1. Memory size required is calculated during the first sequential table read. The allocated memory is filled during the second sequential read. Then the table rows are retrieved from the memory. This should be used when the table will be accessed several times randomly, such as in sub-selects or being the target table of a join.
2. A first query is executed to get the result set size and the needed memory is allocated. It is filled on the first sequential reading. Then random access of the table is possible. This can be used in the case of ORDER BY clauses, when MariaDB uses position reading.

Note that the best way to handle ORDER BY is to set the max\_length\_for\_sort\_data variable to a larger value (its default value is 1024 that is pretty small). Indeed, it requires less memory to be used, particularly when a WHERE clause limits the retrieved data set. This is because in the case of an order by query, MariaDB firstly retrieves the sequentially the result set and the position of each records. Often the sort can be done from the result set if it is not too big. But if too big, or if it implies some "long" columns, only the positions are sorted and MariaDB retrieves the final result from the table read in random order. If setting the max\_length\_for\_sort\_data variable is not feasible or does not work, to be able to retrieve table data from memory after the first sequential read, the memory option must be set to 2.

For tables too large to be stored in memory another possibility is to make your table to use a scrollable cursor. In this case each randomly accessed row can be retrieved from the data source specifying its cursor position, which is reasonably fast. However, scrollable cursors are not supported by all data sources.

With CONNECT version 1.04 (from [MariaDB 10.1.6](#) ), another way to provide random access is to specify some columns to be indexed. This should be done only when the corresponding column of the source table is also indexed. This should be used for tables too large to be stored in memory and is similar to the remote indexing used by the [MYSQL table type](#) and by the [FEDERATED engine](#) .

There remains the possibility to extract data from the external table and to construct another table of any file format from the data source. For instance to construct a fixed formatted DOS table containing the CUSTOMER table data, create the table as

```
create table Custfix engine=connect File_name='customer.txt'
table_type=fix block_size=20 as select * from customer;
```

Now you can use *custfix* for fast database operations on the copied *customer* table data.

## Retrieving data from a spreadsheet

ODBC can also be used to create tables based on tabular data belonging to an Excel spreadsheet:

```
create table XLCNT
engine=CONNECT table_type=ODBC tablename='CONTACT'
Connection='DSN=Excel Files;DBQ=D:/Ber/Doc/Contact_BP.xls';
```

This supposes that a tabular zone of the sheet including column headers is defined as a table named CONTACT or using a "named reference". Refer to the Excel documentation for how to specify tables inside sheets. Once done, you can ask:

```
select * from xlcont;
```

This will extract the data from Excel and display:

Nom	Fonction	Societe
Boisseau Frederic		9 Telecom
Martelliere Nicolas		Vidal SA (Groupe UBM)
Remy Agathe		Price Minister
Du Halgouet Tanguy		Danone
Vandamme Anna		GDF
Thomas Willy		Europ Assistance France
Thomas Dominique		Acoss (DG des URSSAF)
Thomas Berengere	Responsable SI Decisionnel	DEXIA Credit Local
Husy Frederic	Responsable Decisionnel	Neuf Cegetel

Lemonnier Nathalie	Directeur Marketing Client	Louis Vuitton
Louis Loic	Reporting International Decisionnel	Accor
Menseau Eric		Orange France

Here again, the columns description was left to CONNECT when creating the table.

## Multiple ODBC tables

The concept of multiple tables can be extended to ODBC tables when they are physically represented by files, for instance to Excel or Access tables. The condition is that the connect string for the table must contain a field DBQ= *filename* , in which wildcard characters can be included as for multiple=1 tables in their filename. For instance, a table contained in several Excel files CA200401.xls, CA200402.xls, ...CA200412.xls can be created by a command such as:

```
create table ca04mul (Date char(19), Operation varchar(64),
  Debit double(15,2), Credit double(15,2)
engine=CONNECT table_type=ODBC multiple=1
qchar= '"' tabname='bank account'
connection='DSN=Excel Files;DBQ=D:/Ber/CA/CA2004*.xls';'
```

Providing that in each file the applying information is internally set for Excel as a table named "bank account". This extension to ODBC does not support *multiple* =2. The *qchar* option was specified to make the identifiers quoted in the select statement sent to ODBC, in particular the when the table or column names contain blanks, to avoid SQL syntax errors.

**Caution:** Avoid accessing tables belonging to the currently running MariaDB server via the MySQL ODBC connector. This may not work and may cause the server to be restarted.

## Performance consideration

To avoid extracting entire tables from an ODBC source, which can be a lengthy process, CONNECT extracts the "compatible" part of query WHERE clauses and adds it to the ODBC query. Compatible means that it must be understood by the data source. In particular, clauses involving scalar functions are not kept because the data source may have different functions than MariaDB or use a different syntax. Of course, clauses involving sub-select are also skipped. This will transfer eventual indexing to the data source.

Take care with clauses involving string items because you may not know whether they are treated by the data source as case sensitive or case insensitive. If in doubt, make your queries as if the data source was processing strings as case sensitive to avoid incomplete results.

## Using ODBC Tables inside correlated sub-queries

Unlike not correlated subqueries that are executed only once, correlated subqueries are executed many times. It is what ODBC calls a "requery". Several methods can be used by CONNECT to deal with this depending on the setting of the MEMORY or SCROLLABLE Boolean options:

Option	Description
Default	Implementing "requery" by discarding the current result set and re submitting the query (as MFC does)
Memory=1 or 2	Storing the result set in memory as MYSQL tables do.
Scrollable=Yes	Using a scrollable cursor.

Note: the MEMORY and SCROLLABLE options must be specified in the OPTION \_ LIST.

Because the table is accessed several times, this can make queries last very long except for small tables and is almost unacceptable for big tables. However, if it cannot be avoided, using the memory method is the best choice and can be more than four times faster than the default method. If it is supported by the driver, using a scrollable cursor is slightly slower than using memory but can be an alternative to avoid memory problems when the sub-query returns a huge result set.

If the result set is of reasonable size, it is also possible to specify the block\_size option equal or slightly larger than the result set. The whole result set being read on the first fetch, can be accessed many times without having to do anything else.

Another good workaround is to replace within the correlated sub-query the ODBC table by a local copy of it because MariaDB is often able to optimize the query and to provide a very fast execution.

## Accessing specified views

Instead of specifying a source table name via the TABNAME option, it is possible to retrieve data from a "view" whose definition is given in a new option SRCDEF. For instance:

```

CREATE TABLE custnum (
    country varchar(15) NOT NULL,
    customers int(6) NOT NULL
)
ENGINE=CONNECT TABLE_TYPE=ODBC BLOCK_SIZE=10
CONNECTION='DSN=MS Access Database;DBQ=C:/Program Files/Microsoft Office/Office/1033/FPNWIND.MDB;'
SRCDEF='select country, count(*) as customers from customers group by country';

```

Or simply, because CONNECT can retrieve the returned column definition:

```

CREATE TABLE custnum ENGINE=CONNECT TABLE_TYPE=ODBC BLOCK_SIZE=10
CONNECTION='DSN=MS Access Database;DBQ=C:/Program Files/Microsoft Office/Office/1033/FPNWIND.MDB;'
SRCDEF='select country, count(*) as customers from customers group by country';

```

Then, when executing for instance:

```
select * from custnum where customers > 3;
```

The processing of the group by is done by the data source, which returns only the generated result set on which only the where clause is performed locally. The result:

country	customers
Brazil	9
France	11
Germany	11
Mexico	5
Spain	5
UK	7
USA	13
Venezuela	4

This makes possible to let the data source do complicated operations, such as joining several tables or executing procedures returning a result set. This minimizes the data transfer through ODBC.

## Data Modifying Operations

The only data modifying operations are the [INSERT](#), [UPDATE](#) and [DELETE](#) commands. They can be executed successfully only if the data source database or tables are not read-only.

### INSERT Command

When inserting values to an ODBC table, local values are used and sent to the ODBC table. This does not make any difference when the values are constant but in a query such as:

```
insert into t1 select * from t2;
```

Where t1 is an ODBC table, t2 is a locally defined table that must exist on the local server. Besides, it is a good way to create a distant ODBC table from local data.

CONNECT does not directly support INSERT commands such as:

```
insert into t1 values(2,'Deux') on duplicate key update msg = 'Two';
```

Sure enough, the "on duplicate key update" part of it is ignored, and will result in error if the key value is duplicated.

### UPDATE and DELETE Commands

Unlike the [INSERT](#) command, [UPDATE](#) and [DELETE](#) are supported in a simplified way. Only simple table commands are supported; CONNECT does not support multi-table commands, commands sent from a procedure, or issued via a trigger. These commands are just rephrased to correspond to the data source syntax and sent to the data source for execution. Let us suppose we created the table:

```

create table tolite (
    id int(9) not null,
    nom varchar(12) not null,
    nais date default null,
    rem varchar(32) default null)
ENGINE=CONNECT TABLE_TYPE=ODBC tablename='lite'
CONNECTION='DSN=SQLite3 Datasource;Database=test.sqlite3'
CHARSET=utf8 DATA_CHARSET=utf8;

```

We can populate it by:

```

insert into tolite values(1,'Toto',now(),'First'),
(2,'Foo','2012-07-14','Second'),(4,'Machin','1968-05-30','Third');

```

The function

```
now()
```

will be executed by MariaDB and it returned value sent to the ODBC table.

Let us see what happens when updating the table. If we use the query:

```
update tolite set nom = 'Gillespie' where id = 10;
```

CONNECT will rephrase the command as:

```
update lite set nom = 'Gillespie' where id = 10;
```

What it did is just to replace the local table name with the remote table name and change all the back ticks to blanks or to the data source identifier quoting characters if QUOTED is specified. Then this command will be sent to the data source to be executed by it.

This is simpler and can be faster than doing a positional update using a cursor and commands such as “select ... for update of ...” that are not supported by all data sources. However, there are some restrictions that must be understood due to the way it is handled by MariaDB.

1. MariaDB does not know about all the above. The command will be parsed as if it were to be executed locally. Therefore, it must respect the MariaDB syntax.
2. Being executed by the data source, the (rephrased) command must also respect the data source syntax.
3. All data referenced in the SET and WHERE clause belongs to the data source.

This is possible because both MariaDB and the data source are using the SQL language. But you must use only the basic features that are part of the core SQL language. For instance, keywords like IGNORE or LOW\_PRIORITY will cause syntax error with many data source.

Scalar function names also can be different, which severely restrict the use of them. For instance:

```
update tolite set nais = now() where id = 2;
```

This will not work with SQLite3, the data source returning an “unknown scalar function” error message. Note that in this particular case, you can rephrase it to:

```
update tolite set nais = date('now') where id = 2;
```

This understood by both parsers, and even if this function would return NULL executed by MariaDB, it does return the current date when executed by SQLite3. But this begins to become too trickery so to overcome all these restrictions, and permit to have all types of commands executed by the data source, CONNECT provides a specific ODBC table subtype described now.

## Sending commands to a Data Source

This can be done using a special subtype of ODBC table. Let us see this in an example:

```

create table crlrite (
    command varchar(128) not null,
    number int(5) not null flag=1,
    message varchar(255) flag=2)
engine=connect table_type=odbc
connection='Driver=SQLite3 ODBC Driver;Database=test.sqlite3;NoWCHAR=yes'
option_list='Execsrc=1';

```

The key points in this create statement are the EXECSRC option and the column definition.

The EXECSRC option tells that this table will be used to send a command to the data source. Most of the sent commands do not return result set. Therefore, the table columns are used to specify the command to be executed and to get the result of the execution. The name of these columns can be chosen arbitrarily, their function coming from the FLAG value:

Flag=0: The command to execute.

Flag=1: The affected rows, or -1 in case of error, or the result number of column if the command returns a result set.

Flag=2: The returned (eventually error) message.

How to use this table and specify the command to send? By executing a command such as:

```
select * from crlite where command = 'a command';
```

This will send the command specified in the WHERE clause to the data source and return the result of its execution. The syntax of the WHERE clause must be exactly as shown above. For instance:

```
select * from crlite where command =
'CREATE TABLE lite (
ID integer primary key autoincrement,
name char(12) not null,
birth date,
rem varchar(32))';
```

This command returns:

command	number	message
CREATE TABLE lite (ID integer primary key autoincrement, name... 0	0	Affected rows

Now we can create a standard ODBC table on the newly created table:

```
CREATE TABLE tlite
ENGINE=CONNECT TABLE_TYPE=ODBC tablename='lite'
CONNECTION='Driver=SQLite3 ODBC Driver;Database=test.sqlite3;NoWCHAR=yes'
CHARSET=utf8 DATA_CHARSET=utf8;
```

We can populate it directly using the supported [INSERT](#) statement:

```
insert into tlite(name,birth) values('Toto','2005-06-12');
insert into tlite(name,birth,rem) values('Foo',NULL,'No ID');
insert into tlite(name,birth) values('Truc','1998-10-27');
insert into tlite(name,birth,rem) values('John','1968-05-30','Last');
```

And see the result:

```
select * from tlite;
```

ID	name	birth	rem
1	Toto	2005-06-12	NULL
2	Foo	NULL	No ID
3	Truc	1998-10-27	NULL
4	John	1968-05-30	Last

Any command, for instance [UPDATE](#), can be executed from the *crlite* table:

```
select * from crlite where command =
'update lite set birth = ''2012-07-14'' where ID = 2';
```

This command returns:

command	number	message
update lite set birth = '2012-07-15' where ID = 2	1	Affected rows

Let us verify it:

```
select * from tlite where ID = 2;
```

ID	name	birth	rem
2		2012-07-15	

2	Foo	2012-07-15	No ID
---	-----	------------	-------

The syntax to send a command is rather strange and may seem unnatural. It is possible to use an easier syntax by defining a stored procedure such as:

```
create procedure send_cmd(cmd varchar(255))
MODIFIES SQL DATA
select * from crlite where command = cmd;
```

Now you can send commands like this:

```
call send_cmd('drop tlite');
```

This is possible only when sending one single command.

## Sending several commands together

Grouping commands uses an easier syntax and is faster because only one connection is made for all of them. To send several commands in one call, use the following syntax:

```
select * from crlite where command in (
  'update lite set birth = ''2012-07-14'' where ID = 2',
  'update lite set birth = ''2009-08-10'' where ID = 3');
```

When several commands are sent, the execution stops at the end of them or after a command that is in error. To continue after *n* errors, set the option maxerr= *n* (0 by default) in the option list.

**Note 1:** It is possible to specify the SRCDEF option when creating an EXECSRC table. It will be the command sent by default when a WHERE clause is not specified.

**Note 2:** Most data sources do not allow sending several commands separated by semi-colons.

**Note 3:** Quotes inside commands must be escaped. This can be avoided by using a different quoting character than the one used in the command

**Note 4:** The sent command must obey the data source syntax.

**Note 5:** Sent commands apply in the specified database. However, they can address any table within this database, or belonging to another database using the name syntax *schema.tablename*.

## Connecting to a Data Source

There are two ways to establish a connection to a data source:

1. Using SQLDriverConnect and a Connection String
2. Using SQLConnect and a Data Source Name (DSN)

The first way uses a Connection String whose components describe what is needed to establish the connection. It is the most complete way to do it and by default CONNECT uses it.

The second way is a simplified way in which ODBC is just given the name of a DSN that must have been defined to ODBC or UnixOdbc and that contains the necessary information to establish the connection. Only the user name and password can be specified out of the DSN specification.

## Defining the Connection String

Using the first way, the connection string must be specified. This is sometimes the most difficult task when creating ODBC tables because, depending on the operating system and the data source, this string can widely differ.

The format of the ODBC Connection String is:

```
connection-string ::= empty-string[] | attribute[] | attribute; connection-string
empty-string ::=
attribute ::= attribute-keyword=attribute-value | DRIVER=[{}attribute-value[]]
attribute-keyword ::= DSN | UID | PWD | driver-defined-attribute-keyword
attribute-value ::= character-string
driver-defined-attribute-keyword = identifier
```

Where character-string has zero or more characters; identifier has one or more characters; attribute-keyword is not case-sensitive; attribute-value may be case-sensitive; and the value of the DSN keyword does not consist solely of blanks. Due to the connection string grammar, keywords and attribute values that contain the characters

[{}();,;?\*=!@]

should be avoided. The value of the DSN keyword cannot consist only of blanks, and should not contain leading blanks. Because of the grammar of the system information, keywords and data source names cannot contain the backslash (\) character. Applications do not have to add braces around the attribute value after the DRIVER keyword unless the attribute contains a semicolon (;), in which case the braces are required. If the attribute value that the driver receives includes the braces, the driver should not remove them, but they should be part of the returned connection string.

## ODBC Defined Connection Attributes

The ODBC defined attributes are:

- DSN - the name of the data source to connect to. You must create this before attempting to refer to it. You create new DSNs through the ODBC Administrator (Windows), ODBCAdmin (unixODBC's GUI manager) or in the odbc.ini file.
- DRIVER - the name of the driver to connect to. You can use this in DSN-less connections.
- FILEDSN - the name of a file containing the connection attributes.
- UID/PWD - any username and password the database requires for authentication.
- SAVEFILE - request the DSN attributes are saved in this file.

Other attributes are DSN dependent attributes. The connection string can give the name of the driver in the DRIVER field or the data source in the DSN field (attention! meet the spelling and case) and has other fields that depend on the data source. When specifying a file, the DBQ field must give the full path and name of the file containing the table. Refer to the specific ODBC connector documentation for the exact syntax of the connection string.

## Using a Predefined DSN

This is done by specifying in the option list the Boolean option "UseDSN" as yes or 1. In addition, string options "user" and "password" can be optionally specified in the option list.

When doing so, the connection string just contains the name of the predefined Data Source. For instance:

```
CREATE TABLE tlite ENGINE=CONNECT TABLE_TYPE=ODBC tablename='lite'  
CONNECTION='SQLite3 Datasource'  
OPTION_LIST='UseDSN=Yes,User=me,Password=mypass';
```

Note: the connection data source name (limited to 32 characters) should not be preceded by "DSN=".

## ODBC Tables on Linux/Unix

In order to use ODBC tables, you will need to have unixODBC installed. Additionally, you will need the ODBC driver for your foreign server's protocol. For example, for MS SQL Server or Sybase, you will need to have FreeTDS installed.

Make sure the user running mysqld (usually the mysql user) has permission to the ODBC data source configuration and the ODBC drivers. If you get an error on Linux/Unix when using TABLE\_TYPE=ODBC:

```
Error Code: 1105 [unixODBC][Driver Manager]Can't open lib  
'/usr/cachesys/bin/libcacheodbc.so' : file not found
```

You must make sure that the user running mysqld (usually "mysql") has enough permission to load the ODBC driver library. It can happen that the driver file does not have enough read privileges (use chmod to fix this), or loading is prevented by SELinux configuration (see below).

Try this command in a shell to check if the driver had enough permission:

```
sudo -u mysql ldd /usr/cachesys/bin/libcacheodbc.so
```

### SELinux

SELinux can cause various problems. If you think SELinux is causing problems, check the system log (e.g. /var/log/messages) or the audit log (e.g. /var/log/audit/audit.log).

**mysqld can't load some executable code, so it can't use the ODBC driver.**

Example error:

```
Error Code: 1105 [unixODBC][Driver Manager]Can't open lib  
'/usr/cachesys/bin/libcacheodbc.so' : file not found
```

Audit log:

```
type=AVC msg=audit(1384890085.406:76): avc: denied { execute }  
for pid=1433 comm="mysqld"  
path="/usr/cachesys/bin/libcacheodbc.so" dev=dm-0 ino=3279212  
scontext=unconfined_u:system_r:mysqld_t:s0  
tcontext=unconfined_u:object_r:usr_t:s0 tclass=file
```

**mysqld can't open TCP sockets on some ports, so it can't connect to the foreign server.**

Example error:

```
ERROR 1296 (HY000): Got error 174 '[unixODBC][FreeTDS][SQL Server]Unable to connect to data source' from CONNECT
```

Audit log:

```
type=AVC msg=audit(1423094175.109:433): avc: denied { name_connect } for pid=3193 comm="mysqld" dest=1433 scontext=system_u:object_r:mysqld_db_t:s0 tcontext=unconfined_u:object_r:mysqld_db_t:s0
```

## ODBC Catalog Information

Depending on the version of the used ODBC driver, some additional information on the tables are existing, such as table QUALIFIER or OWNER for old versions, now named CATALOG or SCHEMA since version 3.

CATALOG is apparently rarely used by most data sources, but SCHEMA (formerly OWNER) is and corresponds to the DATABASE information of MySQL.

The issue is that if no schema name is specified, some data sources return information for all schemas while some others only return the information of the "default" schema. In addition, the used "schema" or "database" is sometimes implied by the connection string and sometimes is not. Sometimes, it also can be included in a data source definition.

CONNECT offers two ways to specify this information:

1. When specified, the DBNAME create table option is regarded by ODBC tables as the SCHEMA name.
2. Table names can be specified as "*cat.sch.tab*" allowing to set the catalog and schema info.

When both are used, the qualified table name has precedence over DBNAME . For instance:

Tabname	DBname	Description
test.t1		The t1 table of the test schema.
test.t1	mydb	The t1 table of the test schema (test has precedence)
t1	mydb	The t1 table of the mydb schema
%.%.%		All tables in all catalogs and all schemas
t1		The t1 table in the default or all schema depending on the DSN
%.t1		The t1 table in all schemas for all DSN
test.%		All tables in the test schema

When creating a standard ODBC table, you should make sure only one source table is specified. Specifying more than one source table must be done only for CONNECT catalog tables (with CATFUNC=tables or columns).

In particular, when column definition is left to the Discovery feature, if tables with the same name are present in several schemas and the schema name is not specified, several columns with the same name will be generated. This will make the creation fail with a not very explicit error message.

Note: With some ODBC drivers, the DBNAME option or qualified table name is useless because the schema implied by the connection string or the definition of the data source has priority over the specified DBNAME .

## Table name case

Another issue when dealing with ODBC tables is the way table and column names are handled regarding of the case.

For instance, Oracle follows to the SQL standard here. It converts non-quoted identifiers to upper case. This is correct and expected. PostgreSQL is not standard. It converts identifiers to lower case. MySQL/MariaDB is not standard. They preserve identifiers on Linux, and convert to lower case on Windows.

Think about that if you fail to see a table or a column on an ODBC data source.

## Non-ASCII Character Sets with Oracle

When connecting through ODBC, the MariaDB Server operates as a client to the foreign database management system. As such, it requires that you configure MariaDB as you would configure native clients for the given database server.

In the case of connecting to Oracle, when using non-ASCII character sets, you need to properly set the NLS\_LANG environment variable before starting the MariaDB Server.

For instance, to test this on Oracle, create a table that contains a series of special characters:

```

CREATE TABLE t1 (letter VARCHAR(4000));

INSERT INTO t1 VALUES
(UTL_RAW.CAST_TO_VARCHAR2(HEXTORAW('C4'))),
(UTL_RAW.CAST_TO_VARCHAR2(HEXTORAW('C5'))),
(UTL_RAW.CAST_TO_VARCHAR2(HEXTORAW('C6')));

SELECT letter, RAWTOHEX(letter) FROM t1;

letter | RAWTOHEX(letter)
-----+-----
A      | C4
A      | C5
A      | C6

```

Then create a connecting table on MariaDB and attempt the same query:

```

CREATE TABLE t1 (
    letter VARCHAR(4000)
ENGINE=CONNECT
DEFAULT CHARSET=utf8mb4
CONNECTION='DSN=YOUR_DSN'
TABLE_TYPE = 'ODBC'
DATA_CHARSET = latin1
TABNAME = 'YOUR_SCHEMA.T1';

SELECT letter, HEX(letter) FROM t1;

+-----+-----+
| letter | HEX(letter) |
+-----+-----+
| A      |      41 |
| ?      |      3F |
| ?      |      3F |
+-----+-----+

```

While the character set is defined in a way that satisfies MariaDB, it has not been defined for Oracle, (that is, setting the NLS\_LANG environment variable). As a result, Oracle is not providing the characters you want to MariaDB and Connect. The specific method of setting the NLS\_LANG variable can vary depending on your operating system or distribution. If you're experiencing this issue, check your OS documentation for more details on how to properly set environment variables.

## Using systemd

With Linux distributions that use `systemd`, you need to set the environment variable in the service file, (systemd doesn't read from the `/etc/environment` file).

This is done by setting the Environment variable in the [Service] unit. For instance,

```
# vi /usr/lib/systemd/system/mariadb.service

[Service]
...
Environment=NLS_LANG=GERMAN_GERMANY.WE8ISO8859P1
```

Once this is done, reload the systemd units:

```
# systemctl daemon-reload
```

Then restart MariaDB,

```
# systemctl restart mariadb.service
```

You can now retrieve the appropriate characters from Oracle tables:

```
SELECT letter, HEX(letter) FROM t1;
```

letter	HEX(letter)
À	C384
Á	C385
È	C386

## Using Windows

Microsoft Windows doesn't ignore environment variables the way systemd does on Linux, but it does require that you set the NLS\_LANG environment variable on your system. In order to do so, you need to open an elevated command-prompt, (that is, Cmd.exe with administrative privileges).

From here, you can use the Setx command to set the variable. For instance,

```
Setx NLS_LANG GERMAN_GERMANY.WE8ISO8859P1 /m
```

Note: For more detail about this, see [MDEV-17501](#).

## 4.3.7.6.17 CONNECT JDBC Table Type: Accessing Tables from Another DBMS

### Contents

- 10. [Fixing Problem With mysqldump](#)

The JDBC table type should be distributed with all recent versions of MariaDB. However, if the automatic compilation of it is possible after the java JDK was installed, the complete distribution of it is not fully implemented in older versions. The distributed JdbcInterface.jar file contains the JdbcInterface wrapper only. New versions distribute a JavaWrappers.jar that contains all currently existing wrappers.

This will require that:

1. The Java SDK is installed on your system.
2. The java wrapper class files are available on your system.
3. And of course, some JDBC drivers exist to be used with the matching DBMS.

Point 2 was made automatic in the newest versions of MariaDB.

## Compiling From Source Distribution

Even when the Java JDK has been installed, CMake sometimes cannot find the location where it stands. For instance on Linux the Oracle Java JDK package might be installed in a path not known by the CMake lookup functions causing error message such as:

```
CMake Error at /usr/share/cmake/Modules/FindPackageHandleStandardArgs.cmake:148 (message):  
Could NOT find Java (missing: Java_JAR_EXECUTABLE Java_JAVAC_EXECUTABLE  
Java_JAVAH_EXECUTABLE Java_JAVADOC_EXECUTABLE)
```

When this happen, provide a Java prefix as a hint on where the package was loaded. For instance on Ubuntu I was obliged to enter:

```
export JAVA_HOME=/usr/lib/jvm/java-8-oracle
```

After that, the compilation of the CONNECT JDBC type was completed successfully.

## Compiling the Java source files

They are the source of the java wrapper classes used to access JDBC drivers. In the source distribution, they are located in the CONNECT source directory.

The default wrapper, JdbcInterface, is the only one distributed with binary distribution. It uses the standard way to get a connection to the drivers via the DriverManager.getConnection method. Other wrappers, only available with source distribution, enable connection to a Data Source, eventually implementing pooling. However, they must be compiled and installed manually.

The available wrappers are:

Wrapper	Description
JdbcInterface	Used to make the connection with available drivers the standard way.
ApacheInterface	Based on the Apache common-dbcp2 package this interface enables making connections to DBCP data sources with any JDBC drivers.
MariadbInterface	Makes connection to a MariaDB data source.
MysqlInterface	Makes connection to a Mysql data source. Must be used with a MySQL driver that implements data sources.
OracleInterface	Makes connection to an Oracle data source.
PostgresqlInterface	Makes connection to a Postgresql data source.

The wrapper used by default is specified by the `connect_java_wrapper` session variable and is initially set to

`wrappers/JdbcInterface`

. The wrapper to use for a table can also be specified in the option list as a wrapper option of the "create table" statements.

Note: Conforming java naming usage, class names are preceded by the java package name with a slash separator. However, this is not mandatory for CONNECT which adds the package name if it is missing.

The JdbcInterface wrapper is always usable when Java is present on your machine. Binary distributions have this wrapper already compiled as a JdbcInterface.jar file installed in the plugin directory whose path is automatically included in the class path of the JVM. Recent versions also add a JavaWrappers.jar that contains all these wrappers. Therefore there is no need to worry about its path.

Compiling the ApacheInterface wrapper requires that the Apache common-DBCP2 package be installed. Other wrappers are to be used only with the matching JDBC drivers that must be available when compiling them.

Installing the jar file in the plugin directory is the best place because it is part of the class path. Depending on what is installed on your system, the source files can be reduced accordingly. To compile only the JdbcInterface.java file the CMAKE\_JAVA\_INCLUDE\_PATH is not required. Here the paths are the ones existing on my Windows 7 machine and should be localized.

## Setting the Required Information

Before any operation with a JDBC driver can be made, CONNECT must initialize the environment that will make working with Java possible. This will consist of:

1. Loading dynamically the JVM library module.
2. Creating the Java Virtual Machine.
3. Establishing contact with the java wrapper class.
4. Connecting to the used JDBC driver.

Indeed, the JVM library module is not statically linked to the CONNECT plugin. This is to make it possible to use a CONNECT plugin that has been compiled with the JDBC table type on a machine where the Java SDK is not installed. Otherwise, users not interested in the JDBC table type would be obliged to install the Java SDK on their machine to be able to load the CONNECT storage engine.

## JVM Library Location

If the JVM library (jvm.dll on Windows, libjvm.so on Linux) was not placed in the standard library load path, CONNECT cannot find it and must be told where to search for it. This happens in particular on Linux when the Oracle Javapackage was installed in a private location.

If the JAVA\_HOME variable was exported as explained above, CONNECT can sometimes find it using this information. Otherwise, its search path can be added to the LD\_LIBRARY\_PATH environment variable. But all this is complicated because making environment variables permanent on Linux is painful (many different methods must be used depending on the Linux version and the used shell).

This is why CONNECT introduced a new global variable `connect_jvm_path` to store this information. It can be set when starting the server as a command line option or even afterwards before the first use of the JDBC table type. For example:

```
set global connect_jvm_path="/usr/lib/jvm/java-8-oracle/jre/lib/i386/client"
```

or

```
set global connect_jvm_path="/usr/lib/jvm/java-8-oracle/jre/lib/i386/server"
```

The client library is smaller and faster for connection. The server library is more optimized and can be used in case of heavy load usage.

Note that this may not be required on Windows because the path to the JVM library can sometimes be found in the registry.

Once this library is loaded, CONNECT can create the required Java Virtual Machine.

## Java Class Path

This is the list of paths Java searches when loading classes. With CONNECT, the classes to load will be the java wrapper classes used to communicate with the drivers , and the used JDBC driver classes that are grouped inside jar files. If the ApacheInterface wrapper must be used, the class path must also include all three jars used by the Apache package.

**Caution:** This class path is passed as a parameter to the Java Virtual Machine (JVM) when creating it and cannot be modified as it is a read only property. In addition, because MariaDB is a multi-threading application, this JVM cannot be destroyed and will be used throughout the entire life of the MariaDB server. Therefore, be sure it is correctly set before you use the JDBC table type for the first time. Otherwise, there will be practically no alternative than to shut down the server and restart it.

The path to the wrapper classes must point to the directory containing the wrappers sub-directory. If a JdbcInterface.jar file was made, its path is the directory where it is located followed by the jar file name. It is unclear where because this will depend on the installation process. If you start from a source distribution, it can be in the storage/connect directory where the CONNECT source files are or where you moved them or compiled the JdbcInterface.jar file.

For binary distributions, there is nothing to do because the jar file has been installed in the mysql share directory whose path is always automatically included in the class path available to the JVM.

Remaining are the paths of all the installed JDBC drivers that you intend to use. Remember that their path must include the jar file itself. Some applications use an environment variable CLASSPATH to contain them. Paths are separated by ':' on Linux and by ';' on Windows.

If the CLASSPATH variable actually exists and if it is available inside MariaDB, so far so good. You can check this using an UDF function provided by CONNECT that returns environment variable values:

```
create function envar returns string soname 'ha_connect.so';
select envar('CLASSPATH');
```

Most of the time, this will return null or some required files are missing. This is why CONNECT introduced a global variable to store this information. The paths specified in this variable will be added and have precedence to the ones, if any, of the CLASSPATH environment variable. As for the jvm path, this variable connect\_class\_path should be specified when starting the server but can also be set before using the JDBC table type for the first time.

The current directory (sql/data) is also placed by CONNECT at the beginning of the class path.

As an example, here is how I start MariaDB when doing tests on Linux:

```
olivier@olivier-Aspire-8920:~$ sudo /usr/local/mysql/bin/mysqld -u root --console --default-storage-engine=myisam --skip-innodb
```

## CONNECT JDBC Tables

These tables are given the type JDBC. For instance, supposing you want to access the boys table located on an external local or remote database management system providing a JDBC connector:

```
create table boys (
  name char(12),
  city char(12),
  birth date,
  hired date);
```

To access this table via JDBC you can create a table such as:

```
create table jboys engine=connect table_type=JDBC tablename=boys
connection='jdbc:mysql://localhost/dbname?user=root';
```

The CONNECTION option is the URL used to establish the connection with the remote server. Its syntax depends on the external DBMS and in this example is the one used to connect as root to a MySQL or MariaDB local database using the MySQL JDBC connector.

As for ODBC, the columns definition can be omitted and will be retrieved by the discovery process. The restrictions concerning column definitions are the same as for ODBC.

Note: The dbname indicated in the URL corresponds for many DBMS to the catalog information. For MySQL and MariaDB it is the schema (often called database) of the connection.

## Using a Federated Server

Alternatively, a JDBC table can specify its connection options via a Federated server. For instance, supposing you have a table accessing an external Postgresql table defined as:

```
create table juuid engine=connect table_type=JDBC tablename=testuuid
connection='jdbc:postgresql:test?user=postgres&password=pwd';
```

You can create a Federated server:

```
create server 'post1' foreign data wrapper 'postgresql' options (
HOST 'localhost',
DATABASE 'test',
USER 'postgres',
PASSWORD 'pwd',
PORT 0,
SOCKET '',
OWNER 'postgres');
```

Now the JDBC table can be created by:

```
create table juuid engine=connect table_type=JDBC connection='post1' tablename=testuuid;
```

or by:

```
create table juuid engine=connect table_type=JDBC connection='post1/testuuid';
```

In any case, the location of the remote table can be changed in the Federated server without having to alter all the tables using this server.

JDBC needs a URL to establish a connection. CONNECT was able to construct that URL from the information contained in such Federated server definition when the URL syntax is similar to the one of MySQL, MariaDB or Postgresql. However, other DBMSs such as Oracle use a different URL syntax. In this case, simply replace the HOST information by the required URL in the Federated server definition. For instance:

```
create server 'oracle' foreign data wrapper 'oracle' options (
HOST 'jdbc:oracle:thin:@localhost:1521:xe',
DATABASE 'SYSTEM',
USER 'system',
PASSWORD 'manager',
PORT 0,
SOCKET '',
OWNER 'SYSTEM');
```

Now you can create an Oracle table with something like this:

```
create table empor engine=connect table_type=JDBC connection='oracle/HR.EMPLOYEES';
```

Note: Oracle, as Postgresql, does not seem to understand the DATABASE setting as the table schema that must be specified in the Create Table statement.

## Connecting to a JDBC driver

When the connection to the driver is established by the JdbcInterface wrapper class, it uses the options that are provided when creating the CONNECT JDBC tables. Inside the default Java wrapper, the driver's main class is loaded by the DriverManager.getConnection function that takes three arguments:

<b>URL</b>	That is the URL that you specified in the CONNECTION option.
<b>User</b>	As specified in the OPTION_LIST or NULL if not specified.
<b>Password</b>	As specified in the OPTION_LIST or NULL if not specified.

The URL varies depending on the connected DBMS. Refer to the documentation of the specific JDBC driver for a description of the syntax to use. User and password can also be specified in the option list.

Beware that the database name in the URL can be interpreted differently depending on the DBMS. For MySQL this is the schema in which the tables are found. However, for Postgresql, this is the catalog and the schema must be specified using the CONNECT dbname option.

For instance a table accessing a Postgresql table via JDBC can be created with a create statement such as:

```
create table jt1 engine=connect table_type=JDBC
connection='jdbc:postgresql://localhost/mtr' dbname=public tablename=t1
option_list='User=mtr,Password=mtr';
```

Note: In previous versions of JDBC, to obtain a connection, java first had to initialize the JDBC driver by calling the method Class.forName. In this case, see the documentation of your DBMS driver to obtain the name of the class that implements the interface java.sql.Driver. This name can be specified as an option DRIVER to be put in the option list. However, most modern JDBC drivers since version 4 are self-loading and do not require this option to be specified.

The wrapper class also creates some required items and, in particular, a statement class. Some characteristics of this statement will depend on the options specified when creating the table:

<b>Scrollable</b>	To be specified in the option list. Determines the cursor type: no= forward_only or yes=scroll_insensitive.
<b>Block_size</b>	Will be used to set the statement fetch size.

## Fetch Size

The fetch size determines the number of rows that are internally retrieved by the driver on each interaction with the DBMS. Its default value depends on the JDBC driver. It is equal to 10 for some drivers but not for the MySQL or MariaDB connectors.

The MySQL/MariaDB connectors retrieve all the rows returned by one query and keep them in a memory cache. This is generally fine in most cases, but not when retrieving a large result set that can make the query fail with a memory exhausted exception.

To avoid this, when accessing a big table and expecting large result sets, you should specify the BLOCK\_SIZE option to 1 (the only acceptable value). However a problem remains:

Suppose you execute a query such as:

```
select id, name, phone from jbig limit 10;
```

Not knowing the limit clause, CONNECT sends to the remote DBMS the query:

```
SELECT id, name, phone FROM big;
```

In this query big can be a huge table having million rows. Having correctly specified the block size as 1 when creating the table, the wrapper just reads the 10 first rows and stops. However, when closing the statement, these MySQL/MariaDB drivers must still retrieve all the rows returned by the query. This is why, the wrapper class when closing the statement also cancels the query to stop that extra reading.

The bad news is that if it works all right for some previous versions of the MySQL driver, it does not work for new versions as well as for the MariaDB driver that apparently ignores the cancel command. The good news is that you can use an old MySQL driver to access MariaDB databases. It is also possible that this bug will be fixed in future versions of the drivers.

## Connection to a Data Source

This is the java preferred way to establish a connection because a data source can keep a pool of connections that can be re-used when necessary. This makes establishing connections much faster once it was done for the first time.

CONNECT provide additional wrappers whose files are located in the CONNECT source directory. The wrapper to use can be specified in the global variable connect\_java\_wrapper, which defaults to "JdbcInterface".

It can also be specified for a table in the option list by setting the option wrapper to its name. For instance:

```
create table jboys
engine=CONNECT table_type=JDBC tablename='boys'
connection='jdbc:mariadb://localhost/connect?user=root&useSSL=false'
option_list='Wrapper=MariadbInterface,Scrollable=1';
```

They can be used instead of the standard JdbcInterface and are using created data sources.

The Apache one uses data sources implemented by the Apache-commons-dbc package and can be used with all drivers including those not implementing data sources. However, the Apache package must be installed and its three required jar files accessible via the class path.

1. commons-dbc-2.1.1.jar
2. commons-pool2-2.4.2.jar
3. commons-logging-1.2.jar

Note: the versions numbers can be different on your installation.

The other ones use data sources provided by the matching JDBC driver. There are currently four wrappers to be used with mysql-6.0.2, mariadb, oracle and postgresql.

Unlike the class path, the used wrapper can be changed even after the JVM machine was created.

## Random Access to JDBC Tables

The same methods described for ODBC tables can be used with JDBC tables.

Note that in the case of the MySQL or MariaDB connectors, because they internally read the whole result set in memory, using the MEMORY option would be a waste of memory. It is much better to specify the use of a scrollable cursor when needed.

## Other Operations with JDBC Tables

Except for the way the connection string is specified and the table type set to JDBC, all operations with ODBC tables are done for JDBC tables the same

way. Refer to the ODBC chapter to know about:

- Accessing specified views (SRCDEF)
- Data modifying operations.
- Sending commands to a data source.
- JDBC catalog information.

Note: Some JDBC drivers fail when the global time\_zone variable is ambiguous, which sometimes happens when it is set to SYSTEM. If so, reset it to a not ambiguous value, for instance:

```
set global time_zone = '+2:00';
```

## JDBC Specific Restrictions

Connecting via data sources created externally (for instance using Tomcat) is not supported yet.

Other restrictions are the same as for the ODBC table type.

## Handling the UUID Data Type

PostgreSQL has a native UUID data type, internally stored as BIN(16). This is neither an SQL nor a MariaDB data type. The best we can do is to handle it by its character representation.

UUID will be translated to CHAR(36) when column definitions are set using discovery. Locally a PostgreSQL UUID column will be handled like a CHAR or VARCHAR column. Example:

Using the PostgreSQL table testuuid in the text database:

```
Table « public.testuuid »
Column | Type | Default
-----+-----+
id     | uuid | uuid_generate_v4()
msg    | text |
```

Its column definitions can be queried by:

```
create or replace table juuidcol engine=connect table_type=JDBC tablename=testuuid catfunc=columns
connection='jdbc:postgresql:test?user=postgres&password=pwd';
```

```
select table_name "Table", column_name "Column", data_type "Type", type_name "Name", column_size "Size" from juuidcol;
```

This query returns:

Table	Column	Type	Name	Size
testuuid	id	1111	uuid	2147483647
testuuid	msg	12	text	2147483647

Note: PostgreSQL, when a column size is undefined, returns 2147483647, which is not acceptable for MariaDB. CONNECT change it to the value of the connect\_conv\_size session variable. Also, for TEXT columns the data type returned is 12 (SQL\_VARCHAR) instead of -1 the SQL\_TEXT value.

Accessing this table via JDBC by:

```
CREATE TABLE juuid ENGINE=connect TABLE_TYPE=JDBC TABNAME=testuuid
CONNECTION='jdbc:postgresql:test?user=postgres&password=pwd';
```

it will be created by discovery as:

```
CREATE TABLE `juuid` (
  `id` char(36) DEFAULT NULL,
  `msg` varchar(8192) DEFAULT NULL
) ENGINE=CONNECT DEFAULT CHARSET=latin1 CONNECTION='jdbc:postgresql:test?user=postgres&password=pwd' `TABLE_TYPE`='JDBC' `TABNAME`='juuid'
```

Note: 8192 being here the \_connect\_conv\_size\_ value.

Let's populate it:

```
insert into juuid(msg) values('First');
insert into juuid(msg) values('Second');
select * from juuid;
```

Result:

id	msg
4b173ee1-1488-4355-a7ed-62ba59c2b3e7	First
6859f850-94a7-4903-8d3c-fc3c874fc274	Second

Here the id column values come from the DEFAULT of the PostgreSQL column that was specified as `uuid_generate_v4()`.

It can be set from MariaDB. For instance:

```
insert into juuid
  values('2f835fb8-73b0-42f3-a1d3-8a532b38feca','inserted');
insert into juuid values(NULL,'null');
insert into juuid values('','random');
select * from juuid;
```

Result:

id	msg
4b173ee1-1488-4355-a7ed-62ba59c2b3e7	First
6859f850-94a7-4903-8d3c-fc3c874fc274	Second
2f835fb8-73b0-42f3-a1d3-8a532b38feca	inserted
<null>	null
8fc0a30e-dc66-4b95-ba57-497a161f4180	random

The first insert specifies a valid UUID character representation. The second one set it to NULL. The third one (a void string) generates a Java random UUID. UPDATE commands obey the same specification.

These commands both work:

```
select * from juuid where id = '2f835fb8-73b0-42f3-a1d3-8a532b38feca';
delete from juuid where id = '2f835fb8-73b0-42f3-a1d3-8a532b38feca';
```

However, this one fails:

```
select * from juuid where id like '%42f3%';
```

Returning:

1296: Got error 174 'ExecuteQuery: org.postgresql.util.PSQLException: ERROR: operator does not exist: uuid ~ unknown hint: no operator corresponds to the data name and to the argument types.'

because CONNECT cond\_push feature added the WHERE clause to the query sent to PostgreSQL:

```
SELECT id, msg FROM testuuid WHERE id LIKE '%42f3%'
```

and the LIKE operator does not apply to UUID in PostgreSQL.

To handle this, a new session variable was added to CONNECT: connect\_cond\_push. It permits to specify if cond\_push is enabled or not for CONNECT and defaults to 1 (enabled). In this case, you can execute:

```
set connect_cond_push=0;
```

Doing so, the where clause will be executed by MariaDB only and the query will not fail anymore.

## Executing the JDBC tests

Four tests exist but they are disabled because requiring some work to localized them according to the operating system and available java package and JDBC drivers and DBMS.

Two of them, jdbc.test and jdbc\_new.test, are accessing MariaDB via JDBC drivers that are contained in a fat jar file that is part of the test. They should be executable without anything to do on Windows; simply adding the option --enable-disabled when running the tests.

However, on Linux these tests can fail to locate the JVM library. Before executing them, you should export the JAVA\_HOME environment variable set to the prefix of the java installation or export the LD\_LIBRARY\_PATH containing the path to the JVM lib.

## Fixing Problem With mysqldump

In some case or some platform, when CONNECT is set up for use with JDBC table types, this causes `mysqldump` with the option --all-databases to fail.

## 4.3.7.6.18 CONNECT MONGO Table Type: Accessing Collections from MongoDB

### Contents

4. [Create, Read, Update and Delete Operations](#)
5. [Status of MONGO Table Type](#)
6. [Current Restrictions](#)

Classified as a NoSQL database program, MongoDB uses JSON-like documents (BSON) grouped in collections. The MONGO type is used to directly access MongoDB collections as tables.

## Accessing MongoDB from CONNECT

Accessing MongoDB from CONNECT can be done in different ways:

1. As a MONGO table via the MongoDB C Driver.
2. As a MONGO table via the MongoDB Java Driver.
3. As a JDBC table using some commercially available MongoDB JDBC drivers.
4. As a JSON table via the MongoDB C or Java Driver.

### Using the MongoDB C Driver

This is currently not available from binary distributions but only for versions compiled from source. The preferred version of the MongoDB C Driver is 1.7, because they provide package recognition. What must be done is:

1. Install libbson and the MongoDB C Driver 1.7.
2. Configure, compile and install MariaDB.

With earlier versions of the Mongo C Driver, the additional include directories and libraries will have to be specified manually when compiling.

When possible, this is the preferred means of access because it does not require all the Java path settings etc. and is faster than using the Java driver.

### Using the Mongo Java Driver

This is possible with all distributions including JDBC support, or compiling from source. With a binary distribution that does not enable the MONGO table type, it is possible to access MongoDB using an OEM module. See [CONNECT OEM Table Example](#) for details. The only additional things to do are:

1. Install the MongoDB Java Driver by downloading its jar file. Several versions are available. If possible use the latest version 3 one.
2. Add the path to it in the CLASSPATH environment variable or in the connect\_class\_path variable. This is like what is done to declare JDBC drivers.

Connection is established by new Java wrappers Mongo3Interface and Mongo2Interface. They are available in a JDBC distribution in the Mongo2.jar and Mongo3.jar files (previously JavaWrappers.jar). If version 2 of the Java Driver is used, specify "Version=2" in the option list when creating tables.

### Using JDBC

See the documentation of the existing commercial JDBC Mongo drivers.

### Using JSON

See the specific chapter of the JSON Table Type.

The following describes the MONGO table type.

## CONNECT MONGO Tables

Creating and running MONGO tables requires a connection to a running local or remote MongoDB server.

A MONGO table is defined to access a MongoDB collection. The table rows will be the collection documents. For instance, to create a table based on the MongoDB sample collection restaurants, you can do something such as the following:

```
create table resto (
  _id varchar(24) not null,
  name varchar(64) not null,
  cuisine char(200) not null,
  borough char(16) not null,
  restaurant_id varchar(12) not null)
engine=connect table_type=MONGO tablename='restaurants'
data_charset=utf8 connection='mongodb://localhost:27017';
```

Note: The used driver is by default the C driver if only the MongoDB C Driver is installed and the Java driver if only the MongoDB Java Driver is installed. If both are available, it can be specified by the DRIVER option to be specified in the option list and defaults to C.

Here we did not define all the items of the collection documents but only those that are JSON values. The database is test by default. The connection value is the URI used to establish a connection to a local or remote MongoDB server. The value shown in this example corresponds to a local server started with its default port. It is the default connection value for MONGO tables so we could have omit specifying it.

Using discovery is available. This table could have been created by:

```
create table resto
engine=connect table_type=MONGO tablename='restaurants'
data_charset=utf8 option_list='level=-1';
```

Here "depth=-1" is used to create only columns that are simple values (no array or object). Without this, with the default value "depth=0" the table had been created as:

```
CREATE TABLE `resto` (
  `_id` char(24) NOT NULL,
  `address` varchar(136) NOT NULL,
  `borough` char(13) NOT NULL,
  `cuisine` char(64) NOT NULL,
  `grades` varchar(638) NOT NULL,
  `name` char(98) NOT NULL,
  `restaurant_id` char(8) NOT NULL
) ENGINE=CONNECT DEFAULT CHARSET=latin1 `TABLE_TYPE`='MONGO' `TABNAME`='restaurants' `DATA_CHARSET`='utf8';
```

## Fixing Problems With mysqldump

In some case or some platforms, when CONNECT is set up for use with JDBC table types, this causes `mysqldump` with the `--all-databases` option to fail.

This was reported by Robert Dyas who found the cause of it and how to fix it (see [MDEV-11238](#) ).

This occurs when the Java JRE "Usage Tracker" is enabled. In that case, Java creates a directory #mysql50#.oracle\_jre\_usage in the mysql data directory that shows up as a database but cannot be accessed via MySQL Workbench nor apparently backed up by `mysqldump --all-databases`.

Per the Oracle documentation (<https://docs.oracle.com/javacomponents/usage-tracker/overview/>) the "Usage Tracker" is disabled by default. It is enabled only when creating the properties file <JRE directory>/lib/management/usagetracker.properties. This turns out to be WRONG on some platforms as the file does exist by default on a new installation, and the existence of this file enables the usage tracker.

The solution on CentOS 7 with the Oracle JVM is to rename or delete the usagetracker.properties file (to disable it) and then delete the bogus folder it created in the mysql database directory, then restart.

For example, the following works:

```
sudo mv /usr/java/default/jre/lib/management/management.properties /usr/java/default/jre/lib/management/management.properties.TR
sudo reboot
sudo rm -rf /var/lib/mysql/.oracle_jre_usage
sudo reboot
```

In this collection, the address column is a JSON object and the column grades is a JSON array. Unlike the JSON table, just specifying the column name with no Jpath result in displaying the JSON representation of them. For instance:

```
select name, address from resto limit 3;
```

name	address
Morris Park Bake Shop	{"building":"1007","coord":[-73.8561,40.8484], "street":"Morris ParkAve", "zipcode":"10462"}
Wendy'S	{"building":"469","coord":[-73.9617,40.6629], "street":"Flatbush Avenue", "zipcode":"11225"}
Reynolds Restaurant	{"building":"351","coord":[-73.9851,40.7677], "street":"West 57Street", "zipcode":"10019"}

## MongoDB Dot Notation

To address the items inside object or arrays, specify the Jpath in MongoDB syntax (if using Discovery, specify the Depth option accordingly):

From Connect 1.7.0002

```
create table newresto (
  _id varchar(24) not null,
  name varchar(64) not null,
  cuisine char(200) not null,
  borough char(16) not null,
  street varchar(65) jpath='address.street',
  building char(16) jpath='address.building',
  zipcode char(5) jpath='address.zipcode',
  grade char(1) jpath='grades.0.grade',
  score int(4) not null jpath='grades.0.score',
  `date` date jpath='grades.0.date',
  restaurant_id varchar(255) not null
engine=connect table_type=MONGO tablename='restaurants'
data_charset=utf8 connection='mongodb://localhost:27017';
```

Before Connect 1.7.0002

```
create table newresto (
  _id varchar(24) not null,
  name varchar(64) not null,
  cuisine char(200) not null,
  borough char(16) not null,
  street varchar(65) field_format='address.street',
  building char(16) field_format='address.building',
  zipcode char(5) field_format='address.zipcode',
  grade char(1) field_format='grades.0.grade',
  score int(4) not null field_format='grades.0.score',
  `date` date field_format='grades.0.date',
  restaurant_id varchar(255) not null
engine=connect table_type=MONGO tablename='restaurants'
data_charset=utf8 connection='mongodb://localhost:27017';
```

If this is not done, the Oracle JVM will start the usage tracker, which will create the hidden folder .oracle\_jre\_usage in the mysql home directory, which will cause a mysql dump of the server to fail.

```
select name, street, score, date from newresto limit 5;
```

name	street	score	date
Morris Park Bake Shop	Morris Park Ave	2	03/03/2014
Wendy'S	Flatbush Avenue	8	30/12/2014
Dj Reynolds Pub And Restaurant	West 57 Street	2	06/09/2014
Riviera Caterer	Stillwell Avenue	5	10/06/2014
Tov Kosher Kitchen	63 Road	20	24/11/2014

## MONGO Specific Options

The MongoDB syntax for Jpath does not allow the CONNECT specific items on arrays. The same effect can still be obtained by a different way. For this, additional options are used when creating MONGO tables.

Option	Type	Description
Colist	String	Options to pass to the MongoDB cursor.
Filter	String	Query used by the MongoDB cursor.
Pipeline*	Boolean	If True, Colist is a pipeline.
Fullarray*	Boolean	Used when creating with Discovery.
Driver*	String	C or Java.
Version*	Integer	The Java Driver version (defaults to 3)

\* : To be specified in the option list.

Note: For the content of these options, refer to the MongoDB documentation.

## Colist Option

Used to pass different options when making the MongoDB cursor used to retrieve the collation documents. One of them is the projection, allowing to limit the items retrieved in documents. It is hardly useful because this limitation is made automatically by CONNECT. However, it can be used when using discovery to eliminate the \_id (or another) column when you are not willing to keep it:

```
create table restest
engine=connect table_type=MONGO tablename='restaurants'
data_charset=utf8 option_list='depth=-1'
colist='{"projection":{"_id":0},"limit":5}';
```

In this example, we added another cursor option, the limit option that works like the limit SQL clause.

This additional option works only with the C driver. When using the Java driver, colist should be:

```
colist='{"_id":0}';
```

And limit would be specified with select statements.

Note: When used with a JSON table, to specify the projection list (or 'all' to get all columns) makes JPATH to be Connect Json paths, not MongoDB ones, allowing JPATH options not available to MongoDB.

## Filter Option

This option is used to specify a "filter" that works as a where clause on the table. Supposing we want to create a table restricted to the restaurant making English cuisine that are not located in the Manhattan borough, we can do it by:

```
create table english
engine=connect table_type=MONGO tablename='restaurants'
data_charset=utf8
colist='{"projection":{"cuisine":0}}'
filter='{"cuisine":"English","borough":{"$ne":"Manhattan"}}'
option_list='Depth=-1';
```

And if we ask:

```
select * from english;
```

This query will return:

_id	borough	name	restaurant_id
58ada47de5a51ddfc55ee1f3	Brooklyn	The Park Slope Chipshop	40816202
58ada47de5a51ddfc55ee999	Brooklyn	Chip Shop	41076583
58ada47ee5a51ddfc5f13d5	Brooklyn	The Monro	41660253
58ada47ee5a51ddfc5f176e	Brooklyn	Dear Bushwick	41690534
58ada47ee5a51ddfc5f1e91	Queens	Snowdonia Pub	50000290

## Pipeline Option

When this option is specified as true (by YES or 1) the Colist option contains a MongoDB pipeline applying to the table collation. This is a powerful mean for doing things such as expanding arrays like we do with JSON tables. For instance:

```
create table resto2 (
name varchar(64) not null,
borough char(16) not null,
date datetime not null,
grade char(1) not null,
score int(4) not null
engine=connect table_type=MONGO tablename='restaurants' data_charset=utf8
colist='{"pipeline":[{"$match":{"cuisine":"French"}},{"$unwind":"$grades"}, {"$project":{"_id":0,"name":1,"borough":1,"date":1,"grades":1}}]
option_list='Pipeline=1';
```

In this pipeline "\$match" is an early filter, "\$unwind" means that the grades array will be expanded (one Document for each array values) and "\$project" eliminates the \_id and cuisine columns and gives the Jpath for the date, grade and score columns.

```
select name, grade, score, date from resto2
where borough = 'Bronx';
```

This query replies:

name	grade	score	date
Bistro Sk	A	10	21/11/2014 01:00:00
Bistro Sk	A	12	19/02/2014 01:00:00
Bistro Sk	B	18	12/06/2013 02:00:00

This make possible to get things like we do with JSON tables:

```
select name, avg(score) average from resto2
group by name having average >= 25;
```

Can be used to get the average score inside the grades array.

name	average
Bouley Botanical	25,0000
Cheri	46,0000
Graine De Paris	30,0000
Le Pescadeux	29,7500

## Fullarray Option

This option, like the Depth option, is only interpreted when creating a table with Discovery (meaning not specifying the columns). It tells CONNECT to generate a column for all existing values in the array. For instance, let us see the MongoDB collection tar by:

From Connect 1.7.0002

```
create table seetar (
Collection varchar(300) not null jpath='*'
engine=CONNECT table_type=MONGO tablename=tar;
```

Before Connect 1.7.0002

```
create table seetar (
Collection varchar(300) not null field_format='*'
engine=CONNECT table_type=MONGO tablename=tar;
```

The format '\*' indicates we want to see the Json documents. This small collection is:

Collection
{"_id": {"\$oid": "58f63a5099b37d9c930f9f3b"}, "item": "journal", "prices": [87.0, 45.0, 63.0, 12.0, 78.0]}
{"_id": {"\$oid": "58f63a5099b37d9c930f9f3c"}, "item": "notebook", "prices": [123.0, 456.0, 789.0]}

The Fullarray option can be used here to generate enough columns to see all the prices of the document prices array.

```
create table tar
engine=connect table_type=MONGO
colist='{"projection":{"_id":0}}'
option_list='depth=1,Fullarray=YES';
```

The table has been created as:

From Connect 1.7.0002

```
CREATE TABLE `tar` (
`item` char(8) NOT NULL,
`prices_0` double(12,6) NOT NULL `JPATH`='prices.0',
`prices_1` double(12,6) NOT NULL `JPATH`='prices.1',
`prices_2` double(12,6) NOT NULL `JPATH`='prices.2',
`prices_3` double(12,6) DEFAULT NULL `JPATH`='prices.3',
`prices_4` double(12,6) DEFAULT NULL `JPATH`='prices.4'
) ENGINE=CONNECT DEFAULT CHARSET=latin1 `TABLE_TYPE`='MONGO' `COLIST`='{"projection":{"_id":0}}' `OPTION_LIST`='depth=1,Fullarra
```

Before Connect 1.7.0002

```
CREATE TABLE `tar` (
  `item` char(8) NOT NULL,
  `prices_0` double(12,6) NOT NULL `FIELD_FORMAT`='prices.0',
  `prices_1` double(12,6) NOT NULL `FIELD_FORMAT`='prices.1',
  `prices_2` double(12,6) NOT NULL `FIELD_FORMAT`='prices.2',
  `prices_3` double(12,6) DEFAULT NULL `FIELD_FORMAT`='prices.3',
  `prices_4` double(12,6) DEFAULT NULL `FIELD_FORMAT`='prices.4'
) ENGINE=CONNECT DEFAULT CHARSET=latin1 `TABLE_TYPE`='MONGO' `COLIST`='{"projection":{"_id":0}}' `OPTION_LIST`='level=1,Fullarray'
```

And is displayed as:

item	prices_0	prices_1	prices_2	prices_3	prices_4
journal	87.00	45.00	63.00	12.00	78.00
notebook	123.00	456.00	789.00	NULL	NULL

## Create, Read, Update and Delete Operations

All modifying operations are supported. However, inserting into arrays must be done in a specific way. Like with the Fullarray option, we must have enough columns to specify the array values. For instance, we can create a new table by:

From Connect 1.7.0002

```
create table testin (
n int not null,
m char(12) not null,
surname char(16) not null jpath='person.name.first',
name char(16) not null jpath='person.name.last',
age int(3) not null jpath='person.age',
price_1 double(8,2) jpath='d.0',
price_2 double(8,2) jpath='d.1',
price_3 double(8,2) jpath='d.2')
engine=connect table_type=MONGO tabname='tin'
connection='mongodb://localhost:27017';
```

Before Connect 1.7.0002

```
create table testin (
n int not null,
m char(12) not null,
surname char(16) not null field_format='person.name.first',
name char(16) not null field_format='person.name.last',
age int(3) not null field_format='person.age',
price_1 double(8,2) field_format='d.0',
price_2 double(8,2) field_format='d.1',
price_3 double(8,2) field_format='d.2')
engine=connect table_type=MONGO tabname='tin'
connection='mongodb://localhost:27017';
```

Now it is possible to populate it by:

```
insert into testin values
(1789, 'Welcome', 'Olivier', 'Bertrand', 56, 3.14, 2.36, 8.45),
(1515, 'Hello', 'John', 'Smith', 32, 65.17, 98.12, NULL),
(2014, 'Coucou', 'Foo', 'Bar', 20, -1.0, 74, 81356);
```

The result will be:

n	m	surname	name	age	price_1	price_2	price_3
1789	Welcome	Olivier	Bertrand	56	3,14	2,36	8,45
1515	Hello	John	Smith	32	65,17	98,12	NULL
2014	Coucou	Foo	Bar	20	-1	74	81356

Note: If the collection does not exist yet when creating the table and inserting in it, MongoDB creates it automatically.

It can be updated by queries such as:

```
update tintin set price_3 = 83.36 where n = 2014;
```

To look how the array is generated, let us create another table:

From Connect 1.7.0002

```
create table tintin (
n int not null,
name char(16) not null jpath='person.name.first',
prices varchar(255) jpath='d')
engine=connect table_type=MONGO tablename='tin';
```

Before Connect 1.7.002

```
create table tintin (
n int not null,
name char(16) not null field_format='person.name.first',
prices varchar(255) field_format='d')
engine=connect table_type=MONGO tablename='in';
```

This table is displayed as:

From Connect 1.7.0002

n	name	prices
1789	Olivier	[3.1400000000000001243,2.35999999999998757,8.44999999999992895]
1515	John	[65.17000000000001705,98.12000000000004547,null]
2014	Foo	[null,74.0,83.3599999999999432]

Before Connect 1.7.002

n	name	prices
1789	Olivier	[3.14, 2.36, 8.45]
1515	John	[65.17, 98.12]
2014	Foo	[<null>, 74.0, 83.36]

Note: This last table can be used to make array calculations like with JSON tables using the JSON UDF functions. For instance:

```
select name, jsonget_real(prices,'[+]') sum_prices, jsonget_real(prices,'[!]') avg_prices from tintin;
```

This query returns:

name	sum_prices	avg_prices
Olivier	13.95	4.65
John	163.29	81.64
Foo	157,36	78.68

Note: When calculating on arrays, null values are ignored.

## Status of MONGO Table Type

This table type is still under development. It has significant advantages over the JSON type to access MongoDB collections. Firstly, the access being direct, tables are always up to date whether the collection has been modified by another application. Performance wise, it can be faster than JSON, because most processing is done by MongoDB on BSON, its internal representation of JSON data, which is designed to optimize all operations. Note that using the MongoDB C Driver can be faster than using the MongoDB Java Driver.

## Current Restrictions

- Option “CATFUNC=tables” is not implemented yet.
- Options SRCDEF and EXECSRC do not apply to MONGO tables.

6. CONNECT MySQL versus FEDERATED
7. See also

This table type uses libmysql API to access a MySQL or MariaDB table or view. This table must be created on the current server or on another local or remote server. This is similar to what the [FederatedX](#) storage engine provides with some differences.

Currently the Federated-like syntax can be used to create such a table, for instance:

```
create table essai (
    num integer(4) not null,
    line char(15) not null)
engine=CONNECT table_type=MYSQL
connection='mysql://root@localhost/test/people';
```

The connection string can have the same syntax as that used by FEDERATED

```
scheme://username:password@hostname:port/database tablename
scheme://username@hostname/database tablename
scheme://username:password@hostname/database tablename
scheme://username:password@hostname/database tablename
```

However, it can also be mixed with connect standard options. For instance:

```
create table essai (
    num integer(4) not null,
    line char(15) not null)
engine=CONNECT table_type=MYSQL dbname=test tabname=people
connection='mysql://root@localhost';
```

It can also be specified as a reference to a federated server:

```
connection="connection_one"
connection="connection_one/table_foo"
```

The pure (deprecated) CONNECT syntax is also accepted:

```
create table essai (
    num integer(4) not null,
    line char(15) not null)
engine=CONNECT table_type=MYSQL dbname=test tabname=people
option_list='user=root,host=localhost';
```

The specific connection items are:

Option	Default value	Description
Table	The table name	The name of the table to access.
Database	The current DB name	The database where the table is located.
Host	localhost*	The host of the server, a name or an IP address.
User	The current user	The connection user name.
Password	No password	An optional user password.
Port	The currently used port	The port of the server.
Quoted	0	1 if remote Tabname must be quoted.

- - When the host is specified as "localhost", the connection is established on Linux using Linux sockets. On Windows, the connection is established by default using shared memory if it is enabled. If not, the TCP protocol is used. An alternative is to specify the host as "." to use a named pipe connection (if it is enabled). This makes possible to use these table types with server skipping networking.

**Caution:** Take care not to refer to the MYSQL table itself to avoid an infinite loop!

MYSQL table can refer to the current server as well as to another server. Views can be referred by name or directly giving a source definition, for instance:

```
create table grp engine=connect table_type=mysql  
CONNECTION='mysql://root@localhost/test/people'  
SRCDEF='select title, count(*) as cnt from employees group by title';
```

When specified, the columns of the mysql table must exist in the accessed table with the same name, but can be only a subset of them and specified in a different order. Their type must be a type supported by CONNECT and, if it is not identical to the type of the accessed table matching column, a conversion can be done according to the rules given in [Data type conversion](#).

Note: For columns prone to be targeted by a where clause, keep the column type compatible with the source table column type (numeric or character) to have a correct rephrasing of the where clause.

If you do not want to restrict or change the column definition, do not provide it and leave CONNECT get the column definition from the remote server. For instance:

```
create table essai engine=CONNECT table_type=MYSQL  
connection='mysql://root@localhost/test/people';
```

This will create the `essai` table with the same columns than the `people` table. If the target table contains CONNECT incompatible type columns, see [Data type conversion](#) to know how these columns can be converted or skipped.

## Charset Specification

When accessing the remote table, CONNECT sets the connection charset set to the default local table charset as the FEDERATED engine does.

Do not specify a column character set if it is different from the table default character set even when it is the case on the remote table. This is because the remote column is translated to the local table character set when reading it. This is the default but it can be modified by the setting the `character_set_results` variable of the target server. If it must keep its setting, for instance to UTF8 when containing Unicode characters, specify the local default charset to its character set.

This means that it is not possible to correctly retrieve a remote table if it contains columns having different character sets. A solution is to retrieve it by several local tables, each accessing only columns with the same character set.

## Indexing of MYSQL tables

Indexes are rarely useful with MYSQL tables. This is because CONNECT tries to access only the requested rows. For instance if you ask:

```
select * from essai where num = 23;
```

CONNECT will construct and send to the server the query:

```
SELECT num, line FROM people WHERE num = 23
```

If the `people` table is indexed on `num`, indexing will be used on the remote server. This, in all cases, will limit the amount of data to retrieve on the network.

However, an index can be specified for columns that are prone to be used to join another table to the MYSQL table. For instance:

```
select d.id, d.name, f.dept, f.salary  
from loc_tab d straight_join cnc_tab f on d.id = f.id  
where f.salary > 10000;
```

If the `id` column of the remote table addressed by the `cnc_tab` MYSQL table is indexed (which is likely if it is a key) you should also index the `id` column of the MYSQL `cnc_tab` table. If so, using “remote” indexing as does FEDERATED, only the useful rows of the remote table will be retrieved during the join process. However, because these rows are retrieved by separate `SELECT` statements, this will be useful only when retrieving a few rows of a big table.

In particular, you should not specify an index for columns not used for joining and above all DO NOT index a joined column if it is not indexed in the remote table. This would cause multiple scans of the remote table to retrieve the joined rows one by one.

## Data Modifying Operations

The CONNECT MYSQL type supports `SELECT` and `INSERT` and a somewhat limited form of `UPDATE` and `DELETE`. These are described below.

The MYSQL type uses similar methods than the ODBC type to implement the `INSERT`, `UPDATE` and `DELETE` commands. Refer to the ODBC chapter for the restrictions concerning them.

For the **UPDATE** and **DELETE** commands, there are fewer restrictions because the remote server being a MySQL server, the syntax of the command will be always acceptable by the remote server.

For instance, you can freely use keywords like IGNORE or LOW\_PRIORITY as well as scalar functions in the SET and WHERE clauses.

However, there is still an issue on multi-table statements. Let us suppose you have a *t1* table on the remote server and want to execute a query such as:

```
update essai as x set line = (select msg from t1 where id = x.num)
where num = 2;
```

When parsed locally, you will have errors if no *t1* table exists or if it does not have the referenced columns. When *t1* does not exist, you can overcome this issue by creating a local dummy *t1* table:

```
create table t1 (id int, msg char(1)) engine=BLACKHOLE;
```

This will make the local parser happy and permit to execute the command on the remote server. Note however that having a local MySQL table defined on the remote *t1* table does not solve the problem unless it is also names *t1* locally.

This is why, to permit to have all types of commands executed by the data source without any restriction, CONNECT provides a specific MySQL table subtype described now.

## Sending commands to a MariaDB Server

This can be done like for ODBC or JDBC tables by defining a specific table that will be used to send commands and get the result of their execution..

```
create table send (
  command varchar(128) not null,
  warnings int(4) not null flag=3,
  number int(5) not null flag=1,
  message varchar(255) flag=2)
engine=connect table_type=mysql
connection='mysql://user@host/database'
option_list='Execsrc=1,Maxerr=2';
```

The key points in this create statement are the EXECSRC option and the column definition.

The EXECSRC option tells that this table will be used to send commands to the MariaDB server. Most of the sent commands do not return result set. Therefore, the table columns are used to specify the command to be executed and to get the result of the execution. The name of these columns can be chosen arbitrarily, their function coming from the FLAG value:

**Flag=0:** The command to execute (the default)

**Flag=1:** The number of affected rows, or the result number of columns if the command would return a result set.

**Flag=2:** The returned (eventually error) message.

**Flag=3:** The number of warnings.

How to use this table and specify the command to send? By executing a command such as:

```
select * from send where command = 'a command';
```

This will send the command specified in the WHERE clause to the data source and return the result of its execution. The syntax of the WHERE clause must be exactly as shown above. For instance:

```
select * from send where command =
'CREATE TABLE people (
  num integer(4) primary key autoincrement,
  line char(15) not null';
```

This command returns:

command	warnings	number	message
CREATE TABLE people (num integer(4) primary key aut...	0	0	Affected rows

## Sending several commands in one call

It can be faster to execute because there will be only one connection for all of them. To send several commands in one call, use the following syntax:

```
select * from send where command in (
"update people set line = 'Two' where id = 2",
"update people set line = 'Three' where id = 3");
```

When several commands are sent, the execution stops at the end of them or after a command that is in error. To continue after n errors, set the option maxerr= n (0 by default) in the option list.

**Note 1:** It is possible to specify the SRCDEF option when creating an EXECSRC table. It will be the command sent by default when a WHERE clause is not specified.

**Note 2:** Backslashes inside commands must be escaped. Simple quotes must be escaped if the command is specified between simple quotes, and double quotes if it is specified between double quotes.

**Note 3:** Sent commands apply in the specified database. However, they can address any table within this database.

**Note 4:** Currently, all commands are executed in mode AUTOCOMMIT.

## Retrieving Warnings and Notes

If a sent command causes warnings to be issued, it is useless to resend a “show warnings” command because the MariaDB server is opened and closed when sending commands. Therefore, getting warnings requires a specific (and tricky) way.

To indicate that warning text must be added to the returned result, you must send a multi-command query containing “pseudo” commands that are not sent to the server but directly interpreted by the EXECSRC table. These “pseudo” commands are:

**Warning** To get warnings

**Note** To get notes

**Error** To get errors returned as warnings (?)

Note that they must be spelled (case insensitive) exactly as above, no final “s”. For instance:

```
select * from send where command in ('Warning','Note',
'drop table if exists try',
'create table try (id int key auto_increment, msg varchar(32) not
null) engine=aria',
"insert into try(msg) values('One'),(NULL),('Three') ",
"insert into try values(2,'Deux') on duplicate key update msg =
'Two'",
"insert into try(message) values('Four'),('Five'),('Six')",
'insert into try(id) values(NULL)',
"update try set msg = 'Four' where id = 4",
'select * from try');
```

This can return something like this:

command	warnings	number	message
drop table if exists try	1	0	Affected rows
Note	0	1051	Unknown table 'try'
create table try (id int key auto_increment, msg...	0	0	Affected rows
insert into try(msg) values('One'),(NULL),('Three')	1	3	Affected rows
Warning	0	1048	Column 'msg' cannot be null
insert into try values(2,'Deux') on duplicate key...	0	2	Affected rows
insert into try(msge) values('Four'),('Five'),('Six')	0	1054	Unknown column 'msge' in 'field list'
insert into try(id) values(NULL)	1	1	Affected rows
Warning	0	1364	Field 'msg' doesn't have a default value

update try set msg = 'Four' where id = 4	0	1	Affected rows
select * from try	0	2	Result set columns

The execution continued after the command in error because of the MAXERR option. Normally this would have stopped the execution.

Of course, the last “select” command is useless here because it cannot return the table contain. Another MYSQL table without the EXECSRC option and with proper column definition should be used instead.

## Connection Engine Limitations

### Data types

There is a maximum key.index length of 255 bytes. You may be able to declare the table without an index and rely on the engine condition pushdown and remote schema.

The following types can't be used:

- [BIT](#)
- [BINARY](#)
- [TINYBLOB , BLOB , MEDIUMBLOB , LONGBLOB](#)
- [TINYTEXT , MEDIUMTEXT , LONGTEXT](#)
- [ENUM](#)
- [SET](#)
- [Geometry types](#)

Note: [TEXT](#) is allowed. However, the handling depends on the values given to the [connect\\_type\\_conv](#) and [connect\\_conv\\_size](#) system variables, and by default no conversion of TEXT columns is permitted.

### SQL Limitations

The following SQL queries are not supported

- [REPLACE INTO](#)
- [INSERT ... ON DUPLICATE KEY UPDATE](#)

## CONNECT MYSQL versus FEDERATED

The CONNECT MYSQL table type should not be regarded as a replacement for the [FEDERATED\(X\)](#) engine. The main use of the MYSQL type is to access other engine tables as if they were CONNECT tables. This was necessary when accessing tables from some CONNECT table types such as [TBL](#) , [XCOL](#) , [OCCUR](#) , or [PIVOT](#) that are designed to access CONNECT tables only. When their target table is not a CONNECT table, these types are silently using internally an intermediate MYSQL table.

However, there are cases where you can use MYSQL CONNECT tables yourself, for instance:

1. When the table will be used by a [TBL](#) table. This enables you to specify the connection parameters for each sub-table and is more efficient than using a local FEDERATED sub-table.
2. When the desired returned data is directly specified by the SRCDEF option. This is great to let the remote server do most of the job, such as grouping and/or joining tables. This cannot be done with the FEDERATED engine.
3. To take advantage of the *push\_cond* facility that adds a where clause to the command sent to the remote table. This restricts the size of the result set and can be crucial for big tables.
4. For tables with the EXECSRC option on.
5. When doing tests. For instance to check a connection string.

If you need multi-table updating, deleting, or bulk inserting on a remote table, you can alternatively use the FEDERATED engine or a “send” table specifying the EXECSRC option on.

## 4.3.7.6.20 CONNECT PROXY Table Type

### Contents

1. [Proxy on non-CONNECT Tables](#)
2. [Using a PROXY Table as a View](#)
3. [Avoiding PROXY table loop](#)
4. [Modifying Operations](#)

A

PROXY

table is a table that accesses and reads the data of another table or view. For instance, to create a table based on the boys

FIX

table:

```
create table xboy engine=connect  
table_type=PROXY tabname=boys;
```

Simply,

PROXY

being the default type when

TABNAME

is specified:

```
create table xboy engine=connect tabname=boys;
```

Because the boys table can be directly used, what can be the use of a proxy table? Well, its main use is to be internally used by other table types such as **TBL** , **XCOL** , **OCCUR** , or **PIVOT** . Sure enough, PROXY tables are CONNECT tables, meaning that they can be based on tables of any engines and accessed by table types that need to access CONNECT tables.

## Proxy on non-CONNECT Tables

When the sub-table is a view or not a CONNECT table, CONNECT internally creates a temporary CONNECT table of **MYSQL** type to access it. This connection uses the same default parameters as for a

MYSQL

table. It is also possible to specify them to the

PROXY

table using in the

PROXY

declaration the same

OPTION\_LIST

options as for a

MYSQL

table. Of course, it is simpler and more natural to use directly the MYSQL type in this case.

Normally, the default parameters should enable the

PROXY

table to reconnect the server. However, an issue is when the current user was logged using a password. The security protocol prevents CONNECT to retrieve this password and requires it to be given in the

PROXY

table create statement. For instance adding to it:

```
... option_list='Password=mypass' ;
```

However, it is often not advisable to write in clear a password that can be seen by all user able to see the table declaration by show create table, in particular, if the table is used when the current user is root. To avoid this, a specific user should be created on the local host that will be used by proxy tables to retrieve local tables. This user can have minimum grant options, for instance SELECT on desired directories, and needs no password.

Supposing 'proxy' is such a user, the option list to add will be:

```
... option_list='user=proxy' ;
```

## Using a PROXY Table as a View

A

PROXY

table can also be used by itself to modify the way a table is viewed. For instance, a proxy table does not use the indexes of the object table. It is also possible to define its columns with different names or type, to use only some of them or to changes their order. For instance:

```
create table city (  
    city varchar(11),  
    boy char(12) flag=1,  
    birth date)  
engine=CONNECT tabname=boys;  
select * from city;
```

This will display:

city	boy	birth
Boston	John	1986-01-25
Boston	Henry	1987-06-07
San Jose	George	1981-08-10
Chicago	Sam	1979-11-22
Dallas	James	1992-05-13
Boston	Bill	1986-09-11

Here we did not have to specify column format or offset because data are retrieved from the boys table, not directly from the boys.txt file. The flag option of the *boy* column indicates that it correspond to the first column of the boys table, the *name* column.

## Avoiding PROXY table loop

CONNECT is able to test whether a

PROXY

, or

PROXY

-based, table refers directly or indirectly to itself. If a direct reference can be tested at table creation, an indirect reference can only be tested when executing a query on the table. However, this is possible only for local tables. When using remote tables or views, a problem can occur if the remote table or the view refers back to one of the local tables of the chain. The same caution should be used than when using

FEDERATEDX

tables.

**Note:** All

PROXY

or

PROXY

-based tables are read-only in this version.

## Modifying Operations

All **INSERT / UPDATE / DELETE** operations can be used with proxy tables. However, the same restrictions applying to the source table also apply to the proxy table.

Note: All PROXY and PROXY-based table types are not indexable.

## 4.3.7.6.21 CONNECT XCOL Table Type

### Contents

1. [Using Special Columns with XCOL](#)
2. [XCOL tables based on specified views](#)

XCOL

tables are based on another table or view, like

PROXY

tables. This type can be used when the object table has a column that contains a list of values.

Suppose we have a '*children*' table that can be displayed as:

name	childlist
Sophie	Vivian, Antony
Lisbeth	Lucy, Charles, Diana
Corinne	
Claude	Marc
Janet	Arthur, Sandra, Peter, John

We can have a different view on these data, where each child will be associated with his/her mother by creating an

XCOL

table by:

```
CREATE TABLE xchild (
    mother char(12) NOT NULL,
    child char(12) DEFAULT NULL flag=2
) ENGINE=CONNECT table_type=XCOL tablename='chlist'
option_list='colname=child';
```

The

COLNAME

option specifies the name of the column receiving the list items. This will return from:

```
select * from xchild;
```

The requested view:

mother	child
Sophia	Vivian
Sophia	Antony
Lisbeth	Lucy
Lisbeth	Charles
Lisbeth	Diana
Corinne	NULL
Claude	Marc
Janet	Arthur
Janet	Sandra
Janet	Peter
Janet	John

Several things should be noted here:

- When the original *children* field is void, what happens depends on the NULL specification of the "multiple" column. If it is nullable, like here, a void string will generate a NULL value. However, if the column is not nullable, no row will be generated at all.
- Blanks after the separator are ignored.
- No copy of the original data was done. Both tables use the same source data.
- Specifying the column definitions in the

```
CREATE TABLE  
statement is optional.
```

The "multiple" column *child* can be used as any other column. For instance:

```
select * from xchild where substr(child,1,1) = 'A';
```

This will return:

Mother	Child
Sophia	Antony
Janet	Arthur

If a query does not involve the "multiple" column, no row multiplication will be done. For instance:

```
select mother from xchild;
```

This will just return all the mothers:

mother
Sophia
Lisbeth
Corinne
Claude

Janet

The same occurs with other types of select statements, for instance:

```
select count(*) from xchild;      -- returns 5
select count(child) from xchild;  -- returns 10
select count(mother) from xchild; -- returns 5
```

Grouping also gives different result:

```
select mother, count(*) from xchild group by mother;
```

Replies:

mother	count(*)
Claude	1
Corinne	1
Janet	1
Lisbeth	1
Sophia	1

While the query:

```
select mother, count(child) from xchild group by mother;
```

Gives the more interesting result:

mother	count(child)
Claude	1
Corinne	0
Janet	4
Lisbeth	3
Sophia	2

Some more options are available for this table type:

Option	Description
Sep_char	The separator character used in the "multiple" column, defaults to the comma.
Mult	Indicates the max number of multiple items. It is used to internally calculate the max size of the table and defaults to 10. (To be specified in OPTION_LIST ).

## Using Special Columns with XCOL

Special columns can be used in XCOL tables. The mostly useful one is ROWNUM that gives the rank of the value in the list of values. For instance:

```
CREATE TABLE xchild2 (
rank int NOT NULL SPECIAL=ROWID,
mother char(12) NOT NULL,
child char(12) NOT NULL flag=2
) ENGINE=CONNECT table_type=XCOL tablename='chlist' option_list='colname=child';
```

This table will be displayed as:

rank	mother	child
1	Sophia	Vivian
2	Sophia	Antony
1	Lisbeth	Lucy
2	Lisbeth	Charles
3	Lisbeth	Diana

1	Claude	Marc
1	Janet	Arthur
2	Janet	Sandra
3	Janet	Peter
4	Janet	John

To list only the first child of each mother you can do:

```
SELECT mother, child FROM xchild2 WHERE rank = 1 ;
```

returning:

mother	child
Sophia	Vivian
Lisbeth	Lucy
Claude	Marc
Janet	Arthur

However, note the following pitfall: trying to get the names of all mothers having more than 2 children cannot be done by:

```
SELECT mother FROM xchild2 WHERE rank > 2;
```

This is because with no row multiplication being done, the rank value is always 1. The correct way to obtain this result is longer but cannot use the ROWNUM column:

```
SELECT mother FROM xchild2 GROUP BY mother HAVING COUNT(child) > 2;
```

## XCOL tables based on specified views

Instead of specifying a source table name via the TABNAME option, it is possible to retrieve data from a “view” whose definition is given in a new option SRCDEF . For instance:

```
CREATE TABLE xsvars ENGINE=CONNECT TABLE_TYPE=XCOL
SRCDEF='SHOW VARIABLES LIKE "optimizer_switch"'
OPTION_LIST='Colname=Value';
```

Then, for instance:

```
SELECT value FROM xsvars LIMIT 10;
```

This will display something like:

value
index_merge=on
index_merge_union=on
index_merge_sort_union=on
index_merge_intersection=on
index_merge_sort_intersection=off
engine_condition_pushdown=off
index_condition_pushdown=on
derived_merge=on
derived_with_keys=on
firstmatch=on

Note: All XCOL tables are read only.

## 4.3.7.6.22 CONNECT OCCUR Table Type

Similarly to the

## XCOL

table type,  
OCCUR  
is an extension to the

## PROXY

type when referring to a table or view having several columns containing the same kind of data. It enables having a different view of the table where the data from these columns are put in a single column, eventually causing several rows to be generated from one row of the object table. For example, supposing we have a *pets* table:

name	dog	cat	rabbit	bird	fish
John	2	0	0	0	0
Bill	0	1	0	0	0
Mary	1	1	0	0	0
Lisbeth	0	0	2	0	0
Kevin	0	2	0	6	0
Donald	1	0	0	0	3

We can create an occur table by:

```
create table xpet (
    name varchar(12) not null,
    race char(6) not null,
    number int not null
engine=connect table_type=occur tabname=pets
option_list='OccurCol=number,RankCol=race'
Colist='dog,cat,rabbit,bird,fish';
```

When displaying it by

```
select * from xpet;
```

We will get the result:

name	race	number
John	dog	2
Bill	cat	1
Mary	dog	1
Mary	cat	1
Lisbeth	rabbit	2
Kevin	cat	2
Kevin	bird	6
Donald	dog	1
Donald	fish	3

First of all, the values of the column listed in the Colist option have been put in a unique column whose name is given by the OccurCol option. When several columns have non null (or pseudo-null) values, several rows are generated, with the other normal columns values repeated.

In addition, an optional special column was added whose name is given by the RankCol option. This column contains the name of the source column from which the value of the OccurCol column comes from. It permits here to know the race of the pets whose number is given in *number*.

This table type permit to make queries that would be more complicated to make on the original tables. For instance to know who has more than 1 pet of a kind, you can simply ask:

```
select * from xpet where number > 1;
```

You will get the result:

name	race	number
John	dog	2

Lisbeth	rabbit	2
Kevin	cat	2
Kevin	bird	6
Donald	fish	3

**Note 1:** Like for [XCOL tables](#), no row multiplication for queries not implying the Occur column.

**Note 2:** Because the OccurCol was declared "not null" no rows were generated for null or pseudo-null values of the column list. If the OccurCol is declared as nullable, rows are also generated for columns containing null or pseudo-null values.

Occur tables can be also defined from views or source definition. Also, CONNECT is able to generate the column definitions if not specified. For example:

```
create table ocsrc engine=connect table_type=occur
colist='january,february,march,april,may,june,july,august,september,
october,november,december' option_list='rankcol=month,occurcol=day'
srcdef='select ''Foo'' name, 8 january, 7 february, 2 march, 1 april,
8 may, 14 june, 25 july, 10 august, 13 september, 22 october, 28
november, 14 december';
```

This table is displayed as:

name	month	day
Foo	january	8
Foo	february	7
Foo	march	2
Foo	april	1
Foo	may	8
Foo	june	14
Foo	july	25
Foo	august	10
Foo	september	13
Foo	october	22
Foo	november	28
Foo	december	14

## 4.3.7.6.23 CONNECT PIVOT Table Type

### Contents

1. [Using the PIVOT Tables Type](#)
2. [Restricting the Columns in a Pivot Table](#)
3. [PIVOT Create Table Syntax](#)
  1. [Additional Access Options](#)
4. [Defining a Pivot Table](#)
  1. [Defining a Pivot Table from a Source Table](#)
  2. [Directly Defining the Source of a Pivot Table in SQL](#)
5. [Specifying the Columns Corresponding to the Pivot Column](#)
6. [Pivoting Big Source Tables](#)

This table type can be used to transform the result of another table or view (called the source table) into a pivoted table along “pivot” and “facts” columns. A pivot table is a great reporting tool that sorts and sums (by default) independent of the original data layout in the source table.

For example, let us suppose you have the following “Expenses” table:

Who	Week	What	Amount
Joe	3	Beer	18.00
Beth	4	Food	17.00
Janet	5	Beer	14.00
Joe	3	Food	12.00

Joe	4	Beer	19.00
Janet	5	Car	12.00
Joe	3	Food	19.00
Beth	4	Beer	15.00
Janet	5	Beer	19.00
Joe	3	Car	20.00
Joe	4	Beer	16.00
Beth	5	Food	12.00
Beth	3	Beer	16.00
Joe	4	Food	17.00
Joe	5	Beer	14.00
Janet	3	Car	19.00
Joe	4	Food	17.00
Beth	5	Beer	20.00
Janet	3	Food	18.00
Joe	4	Beer	14.00
Joe	5	Food	12.00
Janet	3	Beer	18.00
Janet	4	Car	17.00
Janet	5	Food	12.00

Pivoting the table contents using the 'Who' and 'Week' fields for the left columns, and the 'What' field for the top heading and summing the 'Amount' fields for each cell in the new table, gives the following desired result:

Who	Week	Beer	Car	Food
Beth	3	16.00	0.00	0.00
Beth	4	15.00	0.00	17.00
Beth	5	20.00	0.00	12.00
Janet	3	18.00	19.00	18.00
Janet	4	0.00	17.00	0.00
Janet	5	33.00	12.00	12.00
Joe	3	18.00	20.00	31.00
Joe	4	49.00	0.00	34.00
Joe	5	14.00	0.00	12.00

Note that SQL enables you to get the same result presented differently by using the "group by" clause, namely:

```
select who, week, what, sum(amount) from expenses
group by who, week, what;
```

However there is no way to get the pivoted layout shown above just using SQL. Even using embedded SQL programming for some DBMS is not quite simple and automatic.

The Pivot table type of CONNECT makes doing this much simpler.

## Using the PIVOT Tables Type

To get the result shown in the example above, just define it as a new table with the statement:

```
create table pivex
engine=connect table_type=pivot tablename=expenses;
```

You can now use it as any other table, for instance to display the result shown above, just say:

```
select * from pivex;
```

The CONNECT implementation of the PIVOT table type does much of the work required to transform the source table:

1. Finding the “Facts” column, by default the last column of the source table. Finding “Facts” or “Pivot” columns work only for table based pivot tables. They do not for view or srcdef based pivot tables, for which they must be explicitly specified.
2. Finding the “Pivot” column, by default the last remaining column.
3. Choosing the aggregate function to use, “SUM” by default.
4. Constructing and executing the “Group By” on the “Facts” column, getting its result in memory.
5. Getting all the distinct values in the “Pivot” column and defining a “Data” column for each.
6. Spreading the result of the intermediate memory table into the final table.

The source table “Pivot” column must not be nullable (there are no such things as a “null” column) The creation will be refused even if this nullable column actually does not contain null values.

If a different result is desired, Create Table options are available to change the defaults used by Pivot. For instance if we want to display the average expense for each person and product, spread in columns for each week, use the following statement:

```
create table pivex2  
engine=connect table_type=pivot tablename=expenses  
option_list='PivotCol=Week,Function=AVG';
```

Now saying:

```
select * from pivex2;
```

Will display the resulting table:

Who	What	3	4	5
Beth	Beer	16.00	15.00	20.00
Beth	Food	0.00	17.00	12.00
Janet	Beer	18.00	0.00	16.50
Janet	Car	19.00	17.00	12.00
Janet	Food	18.00	0.00	12.00
Joe	Beer	18.00	16.33	14.00
Joe	Car	20.00	0.00	0.00
Joe	Food	15.50	17.00	12.00

## Restricting the Columns in a Pivot Table

Let us suppose that we want a Pivot table from expenses summing the expenses for all people and products whatever week it was bought. We can do this just by removing from the pivex table the week column from the column list.

```
alter table pivex drop column week;
```

The result we get from the new table is:

Who	Beer	Car	Food
Beth	51.00	0.00	29.00
Janet	51.00	48.00	30.00
Joe	81.00	20.00	77.00

Note: Restricting columns is also needed when the source table contains extra columns that should not be part of the pivot table. This is true in particular for key columns that prevent a proper grouping.

## PIVOT Create Table Syntax

The Create Table statement for PIVOT tables uses the following syntax:

```

create table pivot_table_name
[(column_definition)]
engine=CONNECT table_type=PIVOT
{tablename='source_table_name' | srcdef='source_table_def'}
[option_list='pivot_table_option_list'];

```

The column definition has two sets of columns:

1. A set of columns belonging to the source table, not including the “facts” and “pivot” columns.
2. “Data” columns receiving the values of the aggregated “facts” columns named from the values of the “pivot” column. They are indicated by the “flag” option.

The **options** and **sub-options** available for Pivot tables are:

Option	Type	Description
<b>Tabname</b>	<i>[DB.]Name</i>	The name of the table to “pivot”. If not set SrcDef must be specified.
<b>SrcDef</b>	<i>SQL_statement</i>	The statement used to generate the intermediate mysql table.
<b>DBname</b>	<i>name</i>	The name of the database containing the source table. Defaults to the current database.
<b>Function*</b>	<i>name</i>	The name of the aggregate function used for the data columns, SUM by default.
<b>PivotCol*</b>	<i>name</i>	Specifies the name of the Pivot column whose values are used to fill the “data” columns having the flag option.
<b>FncCol*</b>	<i>[func([name])]</i>	Specifies the name of the data “Facts” column. If the form func(name) is used, the aggregate function name is set to func.
<b>Groupby*</b>	<i>Boolean</i>	Set it to True (1 or Yes) if the table already has a GROUP BY format.
<b>Accept*</b>	<i>Boolean</i>	To accept non matching Pivot column values.

- : These options must be specified in the OPTION\_LIST.

## Additional Access Options

There are four cases where pivot must call the server containing the source table or on which the SrcDef statement must be executed:

1. The source table is not a CONNECT table.
2. The SrcDef option is specified.
3. The source table is on another server.
4. The columns are not specified.

By default, pivot tries to call the currently used server using host=localhost, user=root not using password, and port=3306. However, this may not be what is needed, in particular if the local root user has a password in which case you can get an “access denied” error message when creating or using the pivot table.

Specify the host, user, password and/or port options in the option\_list to override the default connection options used to access the source table, get column specifications, execute the generated group by or SrcDef query.

## Defining a Pivot Table

There are principally two ways to define a PIVOT table:

1. From an existing table or view.
2. Directly giving the SQL statement returning the result to pivot.

### Defining a Pivot Table from a Source Table

The **tablename** standard table option is used to give the name of the source table or view.

For tables, the internal Group By will be internally generated, except when the GROUPBY option is specified as true. Do it only when the table or view has a valid GROUP BY format.

### Directly Defining the Source of a Pivot Table in SQL

Alternatively, the internal source can be directly defined using the **SrcDef** option that must have the proper group by format.

As we have seen above, a proper Pivot Table is made from an internal intermediate table resulting from the execution of a

GROUP BY

statement. In many cases, it is simpler or desirable to directly specify this when creating the pivot table. This may be because the source is the result of a complex process including filtering and/or joining tables.

To do this, use the **SrcDef** option, often replacing all other options. For instance, suppose that in the first example we are only interested in weeks 4 and 5. We could of course display it by:

```
select * from pivex where week in (4,5);
```

However, what if this table is a huge table? In this case, the correct way to do it is to define the pivot table as this:

```

create table pivex4
engine=connect table_type=pivot
option_list='PivotCol=what,FncCol=amount'
SrcDef='select who, week, what, sum(amount) from expenses
where week in (4,5) group by who, week, what';

```

If your source table has millions of records and you plan to pivot only a small subset of it, doing so will make a lot of a difference performance wise. In addition, you have entire liberty to use expressions, scalar functions, aliases, join, where and having clauses in your SQL statement. The only constraint is that you are responsible for the result of this statement to have the correct format for the pivot processing.

Using SrcDef also permits to use expressions and/or scalar functions. For instance:

```

create table xpivot (
Who char(10) not null,
What char(12) not null,
First double(8,2) flag=1,
Middle double(8,2) flag=1,
Last double(8,2) flag=1
engine=connect table_type=PIVOT
option_list='PivotCol=wk,FncCol=amnt'
Srcdef='select who, what, case when week=3 then ''First'' when
week=5 then ''Last'' else ''Middle'' end as wk, sum(amount) *
6.56 as amnt from expenses group by who, what, wk';

```

Now the statement:

```
select * from xpivot;
```

Will display the result:

Who	What	First	Middle	Last
Beth	Beer	104.96	98.40	131.20
Beth	Food	0.00	111.52	78.72
Janet	Beer	118.08	0.00	216.48
Janet	Car	124.64	111.52	78.72
Janet	Food	118.08	0.00	78.72
Joe	Beer	118.08	321.44	91.84
Joe	Car	131.20	0.00	0.00
Joe	Food	203.36	223.04	78.72

**Note 1:** to avoid multiple lines having the same fixed column values, it is mandatory in **SrcDef** to place the pivot column at the end of the group by list.

**Note 2:** in the create statement **SrcDef**, it is mandatory to give aliases **to** the columns containing expressions so they are recognized by the other options.

**Note 3:** in the **SrcDef** select statement, quotes must be escaped because the entire statement is passed to MariaDB between quotes. Alternatively, specify it between double quotes.

**Note 4:** We could have left CONNECT do the column definitions. However, because they are defined from the sorted names, the Middle column had been placed at the end of them.

## Specifying the Columns Corresponding to the Pivot Column

These columns must be named from the values existing in the “pivot” column. For instance, supposing we have the following *pet* table:

name	race	number
John	dog	2
Bill	cat	1
Mary	dog	1
Mary	cat	1
Lisbeth	rabbit	2
Kevin	cat	2
Kevin	bird	6

Donald	dog	1
Donald	fish	3

Pivoting it using `race` as the pivot column is done with:

```
create table pivot
engine=connect table_type=pivot tablename=pet
option_list='PivotCol=race,groupby=1';
```

This gives the result:

name	dog	cat	rabbit	bird	fish
John	2	0	0	0	0
Bill	0	1	0	0	0
Mary	1	1	0	0	0
Lisbeth	0	0	2	0	0
Kevin	0	2	0	6	0
Donald	1	0	0	0	3

By the way, does this ring a bell? It shows that in a way PIVOT tables are doing the opposite of what OCCUR tables do.

We can alternatively define specifically the table columns but what happens if the Pivot column contains values that is not matching a “data” column? There are three cases depending on the specified options and flags.

**First case:** If no specific options are specified, this is an error an when trying to display the table. The query will abort with an error message stating that a non-matching value was met. Note that because the column list is established when creating the table, this is prone to occur if some rows containing new values for the pivot column are inserted in the source table. If this happens, you should re-create the table or manually add the new columns to the pivot table.

**Second case:** The accept option was specified. For instance:

```
create table xpivot2 (
name varchar(12) not null,
dog int not null default 0 flag=1,
cat int not null default 0 flag=1)
engine=connect table_type=pivot tablename=pet
option_list='PivotCol=race,groupby=1,Accept=1';
```

No error will be raised and the non-matching values will be ignored. This table will be displayed as:

name	dog	cat
John	2	0
Bill	0	1
Mary	1	1
Lisbeth	0	0
Kevin	0	2
Donald	1	0

**Third case:** A “dump” column was specified with the flag value equal to 2. All non-matching values will be added in this column. For instance:

```
create table xpivot (
name varchar(12) not null,
dog int not null default 0 flag=1,
cat int not null default 0 flag=1,
other int not null default 0 flag=2)
engine=connect table_type=pivot tablename=pet
option_list='PivotCol=race,groupby=1';
```

This table will be displayed as:

name	dog	cat	other
John	2	0	0
Bill	0	1	0
Mary	1	1	0

Lisbeth	0	0	2
Kevin	0	2	6
Donald	1	0	3

It is a good idea to provide such a “dump” column if the source table is prone to be inserted new rows that can have a value for the pivot column that did not exist when the pivot table was created.

## Pivoting Big Source Tables

This may sometimes be risky. If the pivot column contains too many distinct values, the resulting table may have too many columns. In all cases the process involved, finding distinct values when creating the table or doing the group by when using it, can be very long and sometimes can fail because of exhausted memory.

Restrictions by a where clause should be applied to the source table when creating the pivot table rather than to the pivot table itself. This can be done by creating an intermediate table or using as source a view or a srcdef option.

All PIVOT tables are read only.

### 4.3.7.6.24 CONNECT TBL Table Type: Table List

#### Contents

1. Sub-tables of not CONNECT engines
2. Using the TABID special column
3. Parallel Execution

This type allows defining a table as a list of tables of any engine and type. This is more flexible than multiple tables that must be all of the same file type. This type does, but is more powerful than, what is done with the **MERGE** engine.

The list of the columns of the TBL table may not necessarily include all the columns of the tables of the list. If the name of some columns is different in the sub-tables, the column to use can be specified by its position given by the

FLAG

option of the column. If the

ACCEPT

option is set to true (Y or 1) columns that do not exist in some of the sub-tables are accepted and their value will be null or pseudo-null (this depends on the nullability of the column) for the tables not having this column. The column types can also be different and an automatic conversion will be done if necessary.

**Note:** If not specified, the column definitions are retrieved from the first table of the table list.

The default database of the sub-tables is the current database or if not, can be specified in the DBNAME option. For the tables that are not in the default database, this can be specified in the table list. For instance, to create a table based on the French table *employe* in the current database and on the English table *employee* of the *db2* database, the syntax of the create statement can be:

```
CREATE TABLE allemp (
  SERIALNO char(5) NOT NULL flag=1,
  NAME varchar(12) NOT NULL flag=2,
  SEX smallint(1),
  TITLE varchar(15) NOT NULL flag=3,
  MANAGER char(5) DEFAULT NULL flag=4,
  DEPARTMENT char(4) NOT NULL flag=5,
  SECRETARY char(5) DEFAULT NULL flag=6,
  SALARY double(8,2) NOT NULL flag=7)
ENGINE=CONNECT table_type=TBL
table_list='employe,db2.employee' option_list='Accept=1';
```

The search for columns in sub tables is done by name and, if they exist with a different name, by their position given by a not null

FLAG

option. Column sex exists only in the English table (

FLAG

is

0

). Its values will null value for the French table.

For instance, the query:

```
select name, sex, title, salary from allemp where department = 318;
```

Can reply:

NAME	SEX	TITLE	SALARY
BARBOUD	NULL	VENDEUR	9700.00
MARCHANT	NULL	VENDEUR	8800.00
MINIARD	NULL	ADMINISTRATIF	7500.00
POUPIN	NULL	INGENIEUR	7450.00
ANTERPE	NULL	INGENIEUR	6850.00
LOULOUTE	NULL	SECRETAIRE	4900.00
TARTINE	NULL	OPERATRICE	2800.00
WERTHER	NULL	DIRECTEUR	14500.00
VOITURIN	NULL	VENDEUR	10130.00
BANCROFT	2	SALESMAN	9600.00
MERCHANT	1	SALESMAN	8700.00
SHRINKY	2	ADMINISTRATOR	7500.00
WALTER	1	ENGINEER	7400.00
TONGHO	1	ENGINEER	6800.00
HONEY	2	SECRETARY	4900.00
PLUMHEAD	2	TYPIST	2800.00
WERTHER	1	DIRECTOR	14500.00
WHEELFOR	1	SALESMAN	10030.00

The first 9 rows, coming from the French table, have a null for the sex value. They would have 0 if the sex column had been created NOT NULL.

## Sub-tables of not CONNECT engines

Sub-tables are accessed as

PROXY

tables. For not CONNECT sub-tables that are accessed via the MySQL API, it is possible like with

PROXY

to change the MYSQL default options. Of course, this will apply to all not CONNECT tables of the list.

## Using the TABID special column

The TABID special column can be used to see from which table the rows come from and to restrict the access to only some of the sub-tables.

Let us see the following example where t1 and t2 are MyISAM tables similar to the ones given in the

MERGE

description:

```
create table xt1 (
  a int(11) not null,
  message char(20))
engine=CONNECT table_type=MYSQL tablename='t1'
option_list='database=test,user=root';

create table xt2 (
  a int(11) not null,
  message char(20))
engine=CONNECT table_type=MYSQL tablename='t2'
option_list='database=test,user=root';

create table toto (
  tablename char(8) not null special='TABID',
  a int(11) not null,
  message char(20))
engine=CONNECT table_type=TBL table_list='xt1,xt2';

select * from total;
```

The result returned by the SELECT statement is:

tablename	a	message
xt1	1	Testing
xt1	2	table
xt1	3	t1
xt2	1	Testing
xt2	2	table
xt2	3	t2

Now if you send the query:

```
select * from total where tablename = 'xt2';
```

CONNECT will analyze the where clause and only read the xt1 table. This can save time if you want to retrieve only a few sub-tables from a TBL table containing many sub-tables.

## Parallel Execution

Parallel Execution is currently unavailable until some bugs are fixed.

When the sub-tables are located on different servers, it is possible to execute the remote queries simultaneously instead of sequentially. To enable this, set the thread option to yes.

Additional options available for this table type:

Option	Description
Maxerr	The max number of missing tables in the table list before an error is raised. Defaults to 0.
Accept	If true, missing columns are accepted and return null values. Defaults to false.
Thread	If true, enables parallel execution of remote sub-tables.

These options can be specified in the

OPTION\_LIST

## 4.3.7.6.25 CONNECT - Using the TBL and MYSQL Table Types Together

### Contents

1. [Remotely executing complex queries](#)
2. [Providing a list of servers](#)

Used together, these types lift all the limitations of the [FEDERATED](#) and [MERGE](#) engines.

**MERGE:** Its limitation is obvious, the merged tables must be identical [MyISAM](#) tables, and MyISAM is not even the default engine for MariaDB. However, [TBL](#) accesses a collection of CONNECT tables, but because these tables can be user specified or internally created [MYSQL](#) tables, there is no limitation to the type of the tables that can be merged.

TBL is also much more flexible. The merged tables must not be "identical", they just should have the columns defined in the TBL table. If the type of one column in a merged table is not the one of the corresponding column of the TBL table, the column value will be converted. As we have seen, if one column of the TBL table of the TBL column does not exist in one of the merged table, the corresponding value will be set to null. If columns in a sub-table have a different name, they can be accessed by position using the FLAG column option of CONNECT.

However, one limitation of the TBL type regarding MERGE is that TBL tables are currently read-only; INSERT is not supported by TBL. Also, keep using MERGE to access a list of identical MyISAM tables because it will be faster, not passing by the MySQL API.

**FEDERATED(X):** The main limitation of FEDERATED is to access only MySQL/MariaDB tables. The MYSQL table type of CONNECT has the same limitation but CONNECT provides the [ODBC table type](#) and [JDBC table type](#) that can access tables of any RDBS providing an ODBC or JDBC driver (including MySQL even it is not really useful!)

Another major limitation of FEDERATED is to access only one table. By combining TBL and MYSQL tables, CONNECT enables to access a collection of local or remote tables as one table. Of course the sub-tables can be on different servers. With one SELECT statement, a company manager will be able to interrogate results coming from all of his subsidiary computers. This is great for distribution, banking, and many other industries.

### Remotely executing complex queries

Many companies or administrations must deal with distributed information. CONNECT enables to deal with it efficiently without having to copy it to a centralized database. Let us suppose we have on some remote network machines  $m_1, m_2, \dots, m_n$  some information contained in two tables  $t_1$  and  $t_2$ .

Suppose we want to execute on all servers a query such as:

```
select c1, sum(c2) from t1 a, t2 b where a.id = b.id group by c1;
```

This raises many problems. Returning the column values of the  $t_1$  and  $t_2$  tables from all servers can be a lot of network traffic. The group by on the possibly huge resulting tables can be a long process. In addition, the join on the  $t_1$  and  $t_2$  tables may be relevant only if the joined tuples belong to the same machine, obliging to add a condition on an additional tabid or servid special column.

All this can be avoided and optimized by forcing the query to be locally executed on each server and retrieving only the small results of the group by queries. Here is how to do it. For each remote machine, create a table that will retrieve the locally executed query. For instance for  $m_1$ :

```
create table rt1 engine=connect option_list='host=m1'
srcdef='select c1, sum(c2) as sc2 from t1 a, t2 b where a.id = b.id group by c1';
```

Note the alias for the functional column. An alias would be required for the  $c1$  column if its name was different on some machines. The  $t1$  and  $t2$  table names can also be eventually different on the remote machines. The true names must be used in the

SRCDEF

parameter. This will create a set of tables with two columns named  $c1$  and  $sc2$ <sup>[1]</sup>.

Then create the table that will retrieve the result of all these tables:

```
create table rtall engine=connect table_type=tbl
table_list='rt1,rt2,...,rtn' option_list='thread=yes';
```

Now you can retrieve the desired result by:

```
select c1, sum(sc2) from rtall;
```

Almost all the work will be done on the remote machines, simultaneously thanks to the thread option, making this query super-fast even on big tables placed on many remote machines.

Thread is currently experimental. Use it only for test and report any malfunction on [JIRA](#).

## Providing a list of servers

An interesting case is when the query to run on remote machines is the same for all of them. It is then possible to avoid declaring all sub-tables. In this case, the table list option will be used to specify the list of servers the

SRCDEF

query must be sent. This will be a list of URL's and/or Federated server names.

For instance, supposing that federated servers  $srv_1, srv_2, \dots, srv_n$  were created for all remote servers, it will be possible to create a  $tbl$  table allowing getting the result of a query executed on all of them by:

```
create table qall [column definition]
engine=connect table_type=TBL srcdef='a query'
table_list='srv1,srv2,...,srvn' [option_list='thread=yes'];
```

For instance:

```
create table verall engine=connect table_type=TBL srcdef='select @@version' table_list=',server_one';
select * from verall;
```

This reply:

@@version
10.0.3-MariaDB-debug
10.0.2-MariaDB

Here the server list specifies a void server corresponding to the local running MariaDB and a federated server named `server_one`.

1. ↑ To generate the columns from the

SRCDEF

query, CONNECT must execute it. This will make sure it is ok. However, if the remote server is not connected yet, or the remote table not existing yet, you can alternatively specify the columns in the create table statement.

## 4.3.7.6.26 CONNECT Table Types - Special "Virtual" Tables

### Contents

- 1. [DIR Type](#)
  - 1. [The Subdir option](#)
  - 2. [The Nodir option \(Windows\)](#)
- 2. [Windows Management Instrumentation](#)
  - Table Type "WMI"
    - 1. [Getting column information](#)
    - 2. [Performance Consideration](#)
    - 3. [Syntax of WMI queries](#)
  - 3. [MAC Address Table Type "MAC"](#)

The special table types supported by CONNECT are the Virtual table type ( VIR - introduced in [MariaDB 10.0.15](#) ), Directory Listing table type (DIR), the Windows Management Instrumentation Table Type (WMI), and the "Mac Address" type (MAC).

These tables are "virtual tables", meaning they have no physical data but rather produce result data using specific algorithms. Note that this is close to what Views are, so they could be regarded as special views.

### DIR Type

A table of type DIR returns a list of file name and description as a result set. To create a DIR table, use a Create Table statement such as:

```
create table source (
    DRIVE char(2) NOT NULL,
    PATH varchar(256) NOT NULL,
    FNAME varchar(256) NOT NULL,
    FTYPE char(4) NOT NULL,
    SIZE double(12,0) NOT NULL flag=5,
    MODIFIED datetime NOT NULL)
engine=CONNECT table_type=DIR file_name='..\*.cc';
```

When used in a query, the table returns the same file information listing than the system "DIR

```
*.cc
" statement would return if executed in the same current directory (here supposedly ..\)
```

For instance, the query:

```
select fname, size, modified from source
where fname like '%handler%';
```

Displays:

fname	size	modified
handler	152177	2011-06-13 18:08:29
sql_handler	25321	2011-06-13 18:08:31

**Note:** the important item in this table is the flag option value (set sequentially from 0 by default) because it determines which particular information item is returned in the column:

Flag value	Information
0	The disk drive (Windows)
1	The file path
2	The file name
3	The file type
4	The file attribute
5	The file size
6	The last write access date
7	The last read access date
8	The file creation date

## The Subdir option

When specified in the create table statement, the subdir option indicates to list, in addition to the files contained in the specified directory, all the files verifying the filename pattern that are contained in sub-directories of the specified directory. For instance, using:

```
create table data (
    PATH varchar(256) NOT NULL flag=1,
    FNAME varchar(256) NOT NULL,
    FTYPE char(4) NOT NULL,
    SIZE double(12,0) NOT NULL flag=5)
engine=CONNECT table_type=DIR file_name='*.frm'
option_list='subdir=1';

select path, count(*), sum(size) from data group by path;
```

You will get the following result set showing how many tables are created in the MariaDB databases and what is the total length of the FRM files:

path	count(*)	sum(size)
\CommonSource\mariadb-5.2.7\sql\data\connect\	30	264469
\CommonSource\mariadb-5.2.7\sql\data\mysql\	23	207168
\CommonSource\mariadb-5.2.7\sql\data\test\	22	196882

## The Nodir option (Windows)

The Boolean Nodir option can be set to false (0 or no) to add directories that match the file name pattern from the listed files (it is true by default). This is an addition to CONNECT version 1.6. Previously, directory names matching pattern were listed on Windows. Directories were and are never listed on Linux.

Note: The way file names are retrieved makes positional access to them impossible. Therefore, DIR tables cannot be indexed or sorted when it is done using positions.

Be aware, in particular when using the subdir option, that queries on DIR tables are slow and can last almost forever if made on a directory that contains a great number of files in it and its sub-directories.

dir tables can be used to populate a list of files used to create a multiple=2 table. However, this is not as useful as it was when the multiple 3 did not exist.

## Windows Management Instrumentation Table Type “WMI”

**Note:** This table type is available on Windows only.

WMI provides an operating system interface through which instrumented components provide information. Some Microsoft tools to retrieve information through WMI are the WMIC console command and the WMI CMI Studio application.

The CONNECT WMI table type enables administrators and operators not capable of scripting or programming on top of WMI to enjoy the benefit of WMI without even learning about it. It permits to present this information as tables that can be queried, transformed, copied in documents or other tables.

To create a WMI table displaying information coming from a WMI provider, you must provide the namespace and the class name that characterize the information you want to retrieve. The best way to find them is to use the WMI CIM Studio that have tools to browse namespaces and classes and that can display the names of the properties of that class.

The column names of the tables must be the names (case insensitive) of the properties you want to retrieve. For instance:

```
create table alias (
    friendlyname char(32) not null,
    target char(50) not null)
engine=CONNECT table_type='WMI'
option_list='Namespace=root\cli,Class=Msft_CliAlias';
```

WMI tables returns one row for each instance of the related information. The above example is handy to get the class equivalent of the alias of the WMIC command and also to have a list of many classes commonly used.

Because most of the useful classes belong to the 'root\cimv2' namespace, this is the default value for WMI tables when the namespace is not specified. Some classes have many properties whose name and type may not be known when creating the table. To find them, you can use the WMI CMI Studio application but this will be rarely required because CONNECT is able to retrieve them.

Actually, the class specification also has default values for some namespaces. For the 'root\cli' namespace the class name defaults to 'Msft\_CliAlias' and for the 'root\_cimv2' namespace the class default value is 'Win32\_ComputerSystemProduct'. Because many class names begin with 'Win32\_' it is not necessary to say it and specifying the class as 'Product' will effectively use class 'Win32\_Product'.

For example if you define a table as:

```
create table CSPROD engine=CONNECT table_type='WMI';
```

It will return the information on the current machine, using the class ComputerSystemProduct of the CIMV2 namespace. For instance:

```
select * from csprod;
```

Will return a result such as:

Column	Row 1
Caption	Computer system product
Description	Computer system product
IdentifyingNumber	LXAP50X32982327A922300
Name	Aspire 8920
SKUNumber	
UUID	00FC523D-B8F7-DC12-A70E-00B0D1A46136
Vendor	Acer
Version	Aspire 8920

**Note:** This is a transposed display that can be obtained with some GUI.

## Getting column information

An issue, when creating a WMI table, is to make its column definition. Indeed, even when you know the namespace and the class for the wanted information, it is not easy to find what are the names and types of its properties. However, because CONNECT can retrieve this information from the WMI provider, you can simply omit defining columns and CONNECT will do the job.

Alternatively, you can get this information using a catalog table (see below).

## Performance Consideration

Some WMI providers can be very slow to answer. This is not an issue for those that return few object instances, such as the ones returning computer, motherboard, or Bios information. They generally return only one row (instance). However, some can return many rows, in particular the "CIM\_DataFile" class. This is why care must be taken about them.

Firstly, it is possible to limit the allocated result size by using the 'Estimate' create table option. To avoid result truncation, CONNECT allocates a result of 100 rows that is enough for almost all tables. The 'Estimate' option permits to reduce this size for all classes that return only a few rows, and in some rare case to increase it to avoid truncation.

However, it is not possible to limit the time taken by some WMI providers to answer, in particular the CIM\_DATAFILE class. Indeed the Microsoft documentation says about it:

"Avoid enumerating or querying for all instances of CIM\_DataFile on a computer because the volume of data is likely to either affect performance or cause the computer to stop responding."

Sure enough, even a simple query such as:

```
select count(*) from cim where drive = 'D:' and path like '\\MariaDB\\%';
```

is prone to last almost forever (probably due to the LIKE clause). This is why, when not asking for some specific items, you should consider using the DIR table type instead.

## Syntax of WMI queries

Queries to WMI providers are done using the WQL language, not the SQL language. CONNECT does the job of making the WQL query. However, because of the restriction of the WQL syntax, the WHERE clause will be generated only when respecting the following restrictions:

1. No function.
2. No comparison between two columns.
3. No expression (currently a CONNECT restriction)
4. No BETWEEN and IN predicates.

Filtering with WHERE clauses not respecting these conditions will still be done by MariaDB only, except in the case of CIM\_Datafile class for the reason given above.

However, there is one point that is not covered yet, the syntax used to specify dates in queries. WQL does not recognize dates as number items but translates them to its internal format dates specified as text. Many formats are recognized as described in the Microsoft documentation but only one is useful because common to WQL and MariaDB SQL. Here is an example of a query on a table named "cim" created by:

```

create table cim (
    Name varchar(255) not null,
    LastModified datetime not null)
engine=CONNECT table_type='WMI'
option_list='class=CIM_DataFile,estimate=5000';

```

The date must be specified with the format in which CIM DATETIME values are stored (WMI uses the date and time formats defined by the Distributed Management Task Force).

```

select * from cim where drive = 'D:' and path = '\\PlugDB\\Bin\\'
    and lastmodified > '2012041500000.00000+120';

```

This syntax must be strictly respected. The text has the format:

```
yyyymmddHHMMSS.mmmmmmsUUU
```

It is: year, month, day, hour, minute, second, millisecond, and signed minute deviation from UTC . This format is locale-independent so you can write a query that runs on any machine.

**Note 1:** The WMI table type is available only in Windows versions of CONNECT.

**Note 2:** WMI tables are read only.

**Note 3:** WMI tables are not indexable.

**Note 4:** WMI consider all strings as case insensitive.

## MAC Address Table Type “MAC”

**Note:** This table type is available on Windows only.

This type is used to display various general information about the computer and, in particular, about its network cards. To create such a table, the syntax to use is:

```

create table tablename (column definition)
engine=CONNECT table_type=MAC;

```

Column names can be freely chosen because their signification, i.e. the values they will display, comes from the specified Flag option. The valid values for Flag are:

Flag	Valeur	Type
1	Host name	varchar(132)
2	Domain	varchar(132)
3	DNS address	varchar(24)
4	Node type	int(1)
5	Scope ID	varchar(256)
6	Routing	int(1)
7	Proxy	int(1)
8	DNS	int(1)
10	Name	varchar(260)
11	Description	varchar(132)
12	MAC address	char(24)
13	Type	int(3)
14	DHCP	int(1)
15	IP address	char(16)
16	SUBNET mask	char(16)
17	GATEWAY	char(16)
18	DHCP server	char(16)
19	Have WINS	int(1)

20	Primary WINS	char(16)
21	Secondary WINS	char(16)
22	Lease obtained	datetime
23	Lease expires	datetime

**Note:** The information of columns having a Flag value less than 10 are unique for the computer, the other ones are specific to the network cards of the computer.

For instance, you can define the table `macaddr` as:

```
create table macaddr (
  Host varchar(132) flag=1,
  Card varchar(132) flag=11,
  Address char(24) flag=12,
  IP char(16) flag=15,
  Gateway char(16) flag=17,
  Lease datetime flag=23)
engine=CONNECT table_type=MAC;
```

If you execute the query:

```
select host, address, ip, gateway, lease from macaddr;
```

It will return, for example:

Host	Address	IP	Gateway	Lease
OLIVIER	00-A0-D1-A4-61-36	0.0.0.0	0.0.0.0	1970-01-01 00:00:00
OLIVIER	00-1D-E0-9B-90-0B	192.168.0.10	192.168.0.254	2011-09-18 10:28:5

## 4.3.7.6.27 CONNECT Table Types - VIR

### Contents

1. [VIR Type](#)
2. [Displaying constants or expressions](#)
3. [Generating a Table filled with constant values](#)
4. [VIR tables vs. SEQUENCE tables](#)

## VIR Type

A VIR table is a virtual table having only Special or Virtual columns. Its only property is its “size”, or cardinality, meaning the number of virtual rows it contains. It is created using the syntax:

```
CREATE TABLE name [coldef] ENGINE=CONNECT TABLE_TYPE=VIR
[BLOCK_SIZE=n];
```

The optional

`BLOCK_SIZE`

option gives the size of the table, defaulting to 1 if not specified. When its columns are not specified, it is almost equivalent to a [SEQUENCE](#) table “seq\_1\_to\_Size”.

### Displaying constants or expressions

Many DBMS use a no-column one-line table to do this, often call “dual”. MySQL and MariaDB use syntax where no table is specified. With CONNECT, you can achieve the same purpose with a virtual table, with the noticeable advantage of being able to display several lines. For example:

```
create table virt engine=connect table_type=VIR block_size=10;
select concat('The square root of ', n, ' is') what,
round(sqrt(n),16) value from virt;
```

This will return:

what	value
The square root of 1 is	1.0000000000000000
The square root of 2 is	1.4142135623730951

The square root of 3 is	1.7320508075688772
The square root of 4 is	2.0000000000000000
The square root of 5 is	2.2360679774997898
The square root of 6 is	2.4494897427831779
The square root of 7 is	2.6457513110645907
The square root of 8 is	2.8284271247461903
The square root of 9 is	3.0000000000000000
The square root of 10 is	3.1622776601683795

What happened here? First of all, unlike Oracle “dual” tableS that have no columns, a MariaDB table must have at least one column. By default, CONNECT creates VIR tables with one special column. This can be seen with the SHOW CREATE TABLE statement:

```
CREATE TABLE `virt` (
`n` int(11) NOT NULL `SPECIAL`=ROWID,
PRIMARY KEY (`n`)
) ENGINE=CONNECT DEFAULT CHARSET=latin1 `TABLE_TYPE`='VIR'
`BLOCK_SIZE`=10
```

This special column is called “n” and its value is the row number starting from 1. It is purely a virtual table and no data file exists corresponding to it and to its index. It is possible to specify the columns of a VIR table but they must be CONNECT special columns or virtual columns. For instance:

```
create table virt2 (
n int key not null special=rowid,
sig1 bigint as ((n*(n+1))/2) virtual,
sig2 bigint as(((2*n+1)*(n+1)*n)/6) virtual)
engine=connect table_type=VIR block_size=10000000;
select * from virt2 limit 995, 5;
```

This table shows the sum and the sum of the square of the n first integers:

n	sig1	sig2
996	496506	329845486
997	497503	330839495
998	498501	331835499
999	499500	332833500
1000	500500	333833500

Note that the size of the table can be made very big as there no physical data. However, the result should be limited in the queries. For instance:

```
select * from virt2 where n = 1664510;
```

Such a query could last very long if the rowid column were not indexed. Note that by default, CONNECT declares the “n” column as a primary key. Actually, VIR tables can be indexed but only on the ROWID (or ROWNUM) columns of the table. This is a virtual index for which no data is stored.

## Generating a Table filled with constant values

An interesting use of virtual tables, which often cannot be achieved with a table of any other type, is to generate a table containing constant values. This is easily done with a virtual table. Let us define the table FILLER as:

```
create table filler engine=connect table_type=VIR block_size=5000000;
```

Here we choose a size larger than the biggest table we want to generate. Later if we need a table pre-filled with default and/or null values, we can do for example:

```
create table tp (
id int(6) key not null,
name char(16) not null,
salary float(8,2));
insert into tp select n, 'unknown', NULL from filler where n <= 10000;
```

This will generate a table having 10000 rows that can be updated later when needed. Note that a [SEQUENCE](#) table could have been used here instead of FILLING .

## VIR tables vs. SEQUENCE tables

With just its default column, a VIR table is almost equivalent to a [SEQUENCE](#) table. The syntax used is the main difference, for instance:

```
select * from seq_100_to_150_step_10;
```

can be obtained with a VIR table (of size  $\geq 15$ ) by:

```
select n*10 from vir where n between 10 and 15;
```

Therefore, the main difference is to be able to define the columns of VIR tables. Unfortunately, there are currently many limitations to virtual columns that hopefully should be removed in the future.

## 4.3.7.6.28 CONNECT Table Types - OEM: Implemented in an External LIB

### Contents

- 1. [An OEM Table Example](#)
- 1. [Some Currently Available OEM Table Modules and Subtypes](#)

Although CONNECT provides a rich set of table types, specific applications may need to access data organized in a way that is not handled by its existing foreign data wrappers (FDW). To handle these cases, CONNECT features an interface that enables developers to implement in C++ the required table wrapper and use it as if it were part of the standard CONNECT table type list. CONNECT can use these additional handlers providing the corresponding external module (dll or shared lib) be available.

To create such a table on an existing handler, use a Create Table statement as shown below.

```
create table xtab (column definitions)
engine=CONNECT table_type=OEM module='libname'
subtype='MYTYPE' [standard table options]
Option_list='Myopt=foo';
```

The option module gives the name of the DLL or shared library implementing the OEM wrapper for the table type. This library must be located in the plugin directory like all other plugins or UDF's.

This library must export a function `GetMYTYPE`. The option subtype enables CONNECT to have the name of the exported function and to use the new table type. Other options are interpreted by the OEM type and can also be specified within the `option_list` option.

Column definitions can be unspecified only if the external wrapper is able to return this information. For this it must export a function `ColMYTYPE` returning these definitions in a format acceptable by the CONNECT discovery function.

Which and how options must be specified and the way columns must be defined may vary depending on the OEM type used and should be documented by the OEM type implementer(s).

## An OEM Table Example

The OEM table REST described in [Adding the REST Feature as a Library Called by an OEM Table](#) permits using REST-like tables with MariaDB binary distributions containing but not enabling the [REST table type](#)

Of course, the mongo (dll or so) exporting the `GetREST` and `colREST` functions must be available in the plugin directory for all this to work.

## Some Currently Available OEM Table Modules and Subtypes

Module	Subtype	Description
libhello	HELLO	A sample OEM wrapper displaying a one line table saying "Hello world"
mongo	MONGO	Enables using tables based on MongoDB collections.
Tabfic	FIC	Handles files having the Windev HyperFile format.
Tabofx	OFC	Handles Open Financial Connectivity files.
Tabofx	QIF	Handles Quicken Interchange Format files.
Cirpack	CRPK	Handles CDR's from Cirpack UTP's.
Tabplg	PLG	Access tables from the PlugDB DBMS.

How to implement an OEM handler is out of the scope of this document.

## 4.3.7.6.29 CONNECT Table Types - Catalog Tables

A catalog table is one that returns information about another table, or data source. It is similar to what MariaDB commands such as

DESCRIBE  
or  
SHOW

do. Applied to local tables, this just duplicates what these commands do, with the noticeable difference that they are tables and can be used inside queries as joined tables or inside sub-selects.

But their main interest is to enable querying the structure of external tables that cannot be directly queried with description commands. Let's see an example:

Suppose we want to access the tables from a Microsoft Access database as an ODBC type table. The first information we must obtain is the list of tables existing in this data source. To get it, we will create a catalog table that will return it extracted from the result set of the SQLTables ODBC function:

```
create table tabinfo (
    table_name varchar(128) not null,
    table_type varchar(16) not null)
engine=connect table_type=ODBC catfunc=tables
Connection='DSN=MS Access Database;DBQ=C:/Program
Files/Microsoft Office/Office/1033/FPNWIND.MDB';
```

The SQLTables function returns a result set having the following columns:

Field	Data Type	Null	Info Type	Flag Value
Table_Cat	char(128)	NO	FLD_CAT	17
Table_Name	char(128)	NO	FLD_SCHEM	18
Table_Name	char(128)	NO	FLD_NAME	1
Table_Type	char(16)	NO	FLD_TYPE	2
Remark	char(128)	NO	FLD_Rem	5

**Note:** The Info Type and Flag Value are CONNECT interpretations of this result.

Here we could have omitted the column definitions of the catalog table or, as in the above example, chose the columns returning the name and type of the tables. If specified, the columns must have the exact name of the corresponding SQLTables result set, or be given a different name with the matching flag value specification.

(The Table\_Type can be TABLE, SYSTEM TABLE, VIEW, etc.)

For instance, to get the tables we want to use we can ask:

```
select table_name from tabinfo where table_type = 'TABLE';
```

This will return:

table_name
Categories
Customers
Employees
Products
Shippers
Suppliers

Now we want to create the table to access the CUSTOMERS table. Because CONNECT can retrieve the column description of ODBC tables, it is not necessary to specify them in the create table statement:

```
create table Customers engine=connect table_type=ODBC
Connection='DSN=MS Access Database;DBQ=C:/Program
Files/Microsoft Office/Office/1033/FPNWIND.MDB';
```

However, if we prefer to specify them (to eventually modify them) we must know what the column definitions of that table are. We can get this information with a catalog table. This is how to do it:

```
create table custinfo engine=connect table_type=ODBC
tabname=customers catfunc=columns
Connection='DSN=MS Access Database;DBQ=C:/Program
Files/Microsoft Office/Office/1033/FPNWIND.MDB';
```

Alternatively it is possible to specify what columns of the catalog table we want:

```
create table custinfo (
    column_name char(128) not null,
    type_name char(20) not null,
    length int(10) not null flag=7,
    prec smallint(6) not null flag=9
    nullable smallint(6) not null)
engine=connect table_type=ODBC tablename=customers
catfunc=columns
Connection='DSN=MS Access Database;DBQ=C:/Program
Files/Microsoft Office/Office/1033/FPNWIND.MDB';
```

To get the column info:

```
select * from custinfo;
```

which results in this table:

column_name	type_name	length	prec	nullable
CustomerID	VARCHAR	5	0	1
CompanyName	VARCHAR	40	0	1
ContactName	VARCHAR	30	0	1
ContactTitle	VARCHAR	30	0	1
Address	VARCHAR	60	0	1
City	VARCHAR	15	0	1
Region	VARCHAR	15	0	1
PostalCode	VARCHAR	10	0	1
Country	VARCHAR	15	0	1
Phone	VARCHAR	24	0	1
Fax	VARCHAR	24	0	1

Now you can create the CUSTOMERS table as:

```
create table Customers (
    CustomerID varchar(5),
    CompanyName varchar(40),
    ContactName varchar(30),
    ContactTitle varchar(30),
    Address varchar(60),
    City varchar(15),
    Region varchar(15),
    PostalCode varchar(10),
    Country varchar(15),
    Phone varchar(24),
    Fax varchar(24))
engine=connect table_type=ODBC block_size=10
Connection='DSN=MS Access Database;DBQ=C:/Program
Files/Microsoft Office/Office/1033/FPNWIND.MDB';
```

Let us explain what we did here: First of all, the creation of the catalog table. This table returns the result set of an ODBC SQLColumns function sent to the ODBC data source. Columns functions always return a data set having some of the following columns, depending on the table type:

Field	Data Type	Null	Info Type	Flag Value	Returned by
Table_Cat*	char(128)	NO	FLD_CAT	17	ODBC, JDBC
Table_Schema*	char(128)	NO	FLD_SCEM	18	ODBC, JDBC
Table_Name	char(128)	NO	FLD_TABNAME	19	ODBC, JDBC
Column_Name	char(128)	NO	FLD_NAME	1	ALL
Data_Type	smallint(6)	NO	FLD_TYPE	2	ALL
Type_Name	char(30)	NO	FLD_TYPENAME	3	ALL
Column_Size*	int(10)	NO	FLD_PREC	4	ALL

Buffer_Length*	int(10)	NO	FLD_LENGTH	5	ALL
Decimal_Digits*	smallint(6)	NO	FLD_SCALE	6	ALL
Radix	smallint(6)	NO	FLD_RADIX	7	ODBC, JDBC, MYSQL
Nullable	smallint(6)	NO	FLD_NULL	8	ODBC, JDBC, MYSQL
Remarks	char(255)	NO	FLD_REM	9	ODBC, JDBC, MYSQL
Collation	char(32)	NO	FLD_CHARSET	10	MYSQL
Key	char(4)	NO	FLD_KEY	11	MYSQL
Default_value	N.A.		FLD_DEFAULT	12	
Privilege	N.A.		FLD_PRIV	13	
Date_fmt	char(32)	NO	FLD_DATEFMT	15	MYSQL
Xpath/Jxpath	Varchar(256)	NO	FLD_FORMAT	16	XML/JSON

\*\*: These names have changed since earlier versions of CONNECT.

**Note:** ALL includes the ODBC, JDBC, MYSQL, DBF, CSV, PROXY, TBL, XML, JSON, XCOL, and WMI table types. More could be added later.

We chose among these columns the ones that were useful for our create statement, using the flag value when we gave them a different name (case insensitive).

The options used in this definition are the same as the one used later for the actual CUSTOMERS data tables except that:

1. The

TABNAME

option is mandatory here to specify what the queried table name is.

2. The

CATFUNC

option was added both to indicate that this is a catalog table, and to specify that we want column information.

**Note:** If the

TABNAME

option had not been specified, this table would have returned the columns of all the tables defined in the connected data source.

Currently the available

CATFUNC

are:

Function	Specified as:	Applies to table types:
FNC_TAB	<b>tab les</b>	ODBC, JDBC, MYSQL
FNC_COL	<b>col umns</b>	ODBC, JDBC, MYSQL, DBF, CSV, PROXY, XCOL, TBL, WMI
FNC_DSN	<b>datasource s</b> <b>dsn</b> <b>sqldatasource s</b>	ODBC
FNC_DRIVER	<b>driver s</b> <b>sqldrivers</b>	ODBC, JDBC

**Note:** Only the bold part of the function name specification is required.

The

DATASOURCE

and

DRIVERS

functions respectively return the list of available data sources and ODBC drivers available on the system.

The SQLDataSources function returns a result set having the following columns:

Field	Data Type	Null	Info Type	Flag value
Name	varchar(256)	NO	FLD_NAME	1
Description	varchar(256)	NO	FLD_REM	9

To get the data source, you can do for instance:

```
create table datasources (
  engine=CONNECT table_type=ODBC catfunc=DSN;
```

The SQLDrivers function returns a result set having the following columns:

Field	Type	Null	Info Type	Flag value
Description	varchar(128)	YES	FLD_NAME	1
Attributes	varchar(256)	YES	FLD_Rem	9

You can get the driver list with:

```
create table drivers
engine=CONNECT table_type=ODBC catfunc=drivers;
```

## Another example, WMI table

To create a catalog table returning the attribute names of a WMI class, use the same table options as the ones used with the normal WMI table plus the additional option 'catfunc=columns'. If specified, the columns of such a catalog table can be chosen among the following:

Name	Type	Flag	Description
Column_Name	CHAR	1	The name of the property
Data_Type	INT	2	The SQL data type
Type_Name	CHAR	3	The SQL type name
Column_Size	INT	4	The field length in characters
Buffer_Length	INT	5	Depends on the coding
Scale	INT	6	Depends on the type

If you wish to use a different name for a column, set the Flag column option.

For example, before creating the "csprod" table, you could have created the info table:

```
create table CSPRODCOL (
  Column_name char(64) not null,
  Data_Type int(3) not null,
  Type_name char(16) not null,
  Length int(6) not null,
  Prec int(2) not null flag=6
engine=CONNECT table_type='WMI' catfunc=col;
```

Now the query:

```
select * from csprodcol;
```

will display the result:

Column_name	Data_Type	Type_name	Length	Prec
Caption	1	CHAR	255	1
Description	1	CHAR	255	1
IdentifyingNumber	1	CHAR	255	1
Name	1	CHAR	255	1
SKUNumber	1	CHAR	255	1
UUID	1	CHAR	255	1
Vendor	1	CHAR	255	1
Version	1	CHAR	255	1

This can help to define the columns of the matching normal table.

**Note 1:** The column length, for the Info table as well as for the normal table, can be chosen arbitrarily, it just must be enough to contain the returned information.

**Note 2:** The Scale column returns 1 for text columns (meaning case insensitive); 2 for float and double columns; and 0 for other numeric columns.

## Catalog Table result size limit

Because catalog tables are processed like the information retrieved by "Discovery" when table columns are not specified in a Create Table statement, their result set is entirely retrieved and memory allocated.

By default, this allocation is done for a maximum return line number of:

Catfunc	Max lines
Drivers	256
Data Sources	512
Columns	20,000
Tables	10,000

When the number of lines retrieved for a table is more than this maximum, a warning is issued by CONNECT. This is mainly prone to occur with columns (and also tables) with some data sources having many tables when the table name is not specified.

If this happens, it is possible to increase the default limit using the MAXRES option, for instance:

```
create table allcols engine=connect table_type=odbc
connection='DSN=ORACLE_TEST;UID=system;PWD=manager'
option_list='Maxres=110000' catfunc=columns;
```

Indeed, because the entire table result is memorized before the query is executed; the returned value would be limited even on a query such as:

```
select count(*) from allcols;
```

## 4.3.7.7 CONNECT - Security

The use of the CONNECT engine requires the

FILE

privilege for "outward" tables. This should not be an important restriction. The use of CONNECT "outward" tables on a remote server seems of limited interest without knowing the files existing on it and must be protected anyway. On the other hand, using it on the local client machine is not an issue because it is always possible to create locally a user with the

FILE  
privilege.

## 4.3.7.8 CONNECT - OEM Table Example

This is an example showing how an OEM table can be implemented.

The header File

```
my_global.h
:
```

```

/***********************/
/* Definitions needed by the included files. */
/***********************/

#ifndef !defined(MY_GLOBAL_H)
#define MY_GLOBAL_H

typedef unsigned int uint;
typedef unsigned int uint32;
typedef unsigned short ushort;
typedef unsigned long ulong;
typedef unsigned long DWORD;
typedef char *LPSTR;
typedef const char *LPCSTR;
typedef int BOOL;
#if defined(_WIN_)
typedef void *HANDLE;
#else
typedef int HANDLE;
#endif
typedef char *PSZ;
typedef const char *PCSZ;
typedef unsigned char BYTE;
typedef unsigned char uchar;
typedef long long longlong;
typedef unsigned long long ulonglong;
typedef char my_bool;
struct charset_info_st {};
typedef const charset_info_st CHARSET_INFO;
#define FALSE 0
#define TRUE 1
#define Item char
#define MY_MAX(a,b) ((a>b)?(a):(b))
#define MY_MIN(a,b) ((a<b)?(a):(b))
#endif // MY_GLOBAL_H

```

Note: This is a fake

```

my_global.h
that just contains what is useful for the
jmgoem.cpp
source file.

```

The source File

```

jmgoem.cpp
:
```

```

/****************** jmgoem C++ Program Source Code File (.CPP) *****/
/* PROGRAM NAME: jmgoem Version 1.0 */
/* (C) Copyright to the author Olivier BERTRAND 2017 */

```

## Compiling this OEM

To compile this OEM module, first make the two or three required files by copy/pasting from the above listings.

Even if this module is to be used with a binary distribution, you need some source files in order to successfully compile it. At least the CONNECT header files that are included in

`jmgem.cpp`

and the ones they can include. This can be obtained by downloading the MariaDB source file tar.gz and extracting from it the CONNECT sources files in a directory that will be added to the additional source directories if it is not the directory containing the above files.

The module must be linked to the

`ha_connect.lib`

of the binary version it will be used with. Recent distributions add this lib in the plugin directory.

The resulting module, for instance

`mongo.so`

or

`mongo.dll`

, must be placed in the plugin directory of the MariaDB server. Then, you will be able to use MONGO like tables simply replacing in the CREATE TABLE statement the option

`TABLE_TYPE=MONGO`

with

`TABLE_TYPE=OEM SUBTYPE=MONGO MODULE='mongo.(so|dll)'`

. Actually, the module name, here supposedly 'mongo', can be anything you like.

This will work with the last (not yet) distributed versions of [MariaDB 10.0](#) and 10.1 because, even if it is not enabled, the MONGO type is included in them. This is also the case for [MariaDB 10.2.9](#) but then, on Windows, you will have to define NOEXP and NOMGOCOL because these functions are not exported by this version.

To implement for older versions that do not contain the MONGO type, you can add the corresponding source files, namely

`javaconn.cpp`

,

`jmgfam.cpp`

,

`jmgconn.cpp`

,

`mongo.cpp`

and

`tabjmg.cpp`

that you should find in the CONNECT extracted source files if you downloaded a recent version. As they include

`my_global.h`

, this is the reason why the included file was named this way. In addition, your compiling should define

`HAVE_JMGO`

and

`HAVE_JAVACONN`

. Of course, this is possible only if

`ha_connect.lib`

is available.

# 4.3.7.9.1 Using CONNECT - General Information

## Contents

- 1. [Performance](#)
- 2. [Create Table statement](#)
- 3. [Drop Table statement](#)
- 4. [Alter Table statement](#)
- 5. [Update and Delete for File Tables](#)

The main characteristic of CONNECT is to enable accessing data scattered on a machine as if it was a centralized database. This, and the fact that locking is not used by connect (data files are open and closed for each query) makes CONNECT very useful for importing or exporting data into or from a MariaDB database and also for all types of Business Intelligence applications. However, it is not suited for transactional applications.

For instance, the index type used by CONNECT is closer to bitmap indexing than to B-trees. It is very fast for retrieving result but not when updating is done. In fact, even if only one indexed value is modified in a big table, the index is entirely remade (yet this being four to five times faster than for a b-tree index). But normally in Business Intelligence applications, files are not modified so often.

If you are using CONNECT to analyze files that can be modified by an external process, the indexes are of course not modified by it and become outdated. Use the OPTIMIZE TABLE command to update them before using the tables based on them.

This means also that CONNECT is not designed to be used by centralized servers, which are mostly used for transactions and often must run a long time without human intervening.

## Performance

Performances vary a great deal depending on the table type. For instance, ODBC tables are only retrieved as fast as the other DBMS can do. If you have a lot of queries to execute, the best way to optimize your work can be sometime to translate the data from one type to another. Fortunately this is very simple with CONNECT. Fixed formats like FIX, BIN or VEC tables can be created from slower ones by commands such as:

```
Create table fastable table_specs select * from slowtable;
```

FIX

and

BIN

are often the better choice because the I/O functions are done on blocks of

BLOCK\_SIZE

ROWS.

VEC

tables can be very efficient for tables having many columns only a few being used in each query. Furthermore, for tables of reasonable size, the

MAPPED

option can very often speed up many queries.

## Create Table statement

Be aware of the two broad kinds of CONNECT tables:

**Inward** They are table whose file name is not specified at create. An empty file will be given a default name ( `tablename.tabtype` ) and will be populated like for other engines. They do not require the FILE privilege and can be used for testing purpose.

They are all other

CONNECT

**Outward** tables and access external data sources or files. They are the true useful tables but require the FILE privilege.

## Drop Table statement

For outward tables, the `DROP TABLE` statement just removes the table definition but does not erase the table data. However, dropping an inward tables also erase the table data as well.

## Alter Table statement

Be careful using the `ALTER TABLE` statement. Currently the data compatibility is not tested and the modified definition can become incompatible with the data. In particular, Alter modifies the table definition only but does not modify the table data. Consequently, the table type should not be modified this way, except to correct an incorrect definition. Also adding, dropping or modifying columns may be wrong because the default offset values (when not explicitly given by the FLAG option) may be wrong when recompiled with missing columns.

Safe use of ALTER is for indexing, as we have seen earlier, and to change options such as MAPPED or HUGE those do not impact the data format but just the way the data file is accessed. Modifying the BLOCK\_SIZE option is all right with FIX, BIN, DBF, split VEC tables; however it is unsafe for VEC tables that are not split (only one data file) because at their creation the estimate size has been made a multiple of the block size. This can cause errors if this estimate is not a multiple of the new value of the block size.

In all cases, it is safer to drop and re-create the table (outward tables) or to make another one from the table that must be modified.

## Update and Delete for File Tables

CONNECT can execute these commands using two different algorithms:

- It can do it in place, directly modifying rows (update) or moving rows (delete) within the table file. This is a fast way to do it in particular when indexing is used.
- It can do it using a temporary file to make the changes. This is required when updating variable record length tables and is more secure in all cases.

The choice between these algorithms depends on the session variable `connect_use_tempfile`.

### 4.3.7.9.2 Using CONNECT - Virtual and Special Columns

CONNECT supports MariaDB [virtual and persistent columns](#). It is also possible to declare a column as being a CONNECT special column. Let us see on an example how this can be done. The boys table we have seen previously can be recreated as:

```
create table boys (
    linenum int(6) not null default 0 special=rowid,
    name char(12) not null,
    city char(12) not null,
    birth date not null date_format='DD/MM/YYYY',
    hired date not null date_format='DD/MM/YYYY' flag=36,
    agehired int(3) as (floor(datediff(hired,birth)/365.25))
    virtual,
    fn char(100) not null default '' special=FILEID)
engine=CONNECT table_type=FIX file_name='boys.txt' mapped=YES lrecl=47;
```

We have defined two CONNECT special columns. You can give them any name; it is the field SPECIAL option that specifies the special column functional name.

**Note:** the default values specified for the special columns do not mean anything. They are specified just to prevent getting warning messages when inserting new rows.

For the definition of the `agehired` virtual column, no CONNECT options can be specified as it has no offset or length, not being stored in the file.

The command:

```
select * from boys where city = 'boston';
```

will return:

linenum	name	city	birth	hired	agehired	fn
1	John	Boston	1986-01-25	2010-06-02	24	d:\mariadb\sql\data\boys.txt
2	Henry	Boston	1987-06-07	2008-04-01	20	d:\mariadb\sql\data\boys.txt
6	Bill	Boston	1986-09-11	2008-02-10	21	d:\mariadb\sql\data\boys.txt

Existing special columns are listed in the following table:

Special Name	Type	Description of the column value
ROWID	Integer	The row ordinal number in the table. This is not quite equivalent to a virtual column with an auto increment of 1 because rows are renumbered when deleting rows.
ROWNUM	Integer	The row ordinal number in the file. This is different from ROWID for multiple tables, TBL/XCOL/OCCUR/PIVOT tables, XML tables with a multiple column, and for DBF tables where ROWNUM includes soft deleted rows.
FILEID FDISK FPATH FNAME FTYPE	String	FILEID returns the full name of the file this row belongs to. Useful in particular for multiple tables represented by several files. The other special columns can be used to retrieve only one part of the full name.

TABID	String	The name of the table this row belongs to. Useful for TBL tables.
PARTID	String	The name of the partition this row belongs to. Specific to partitioned tables.
SERVID	String	The name of the federated server or server host used by a MYSQL table. "ODBC" for an ODBC table, "JDBC" for a JDBC table and "Current" for all other tables.

**Note:** CONNECT does not currently support auto incremented columns. However, a

ROWID

special column will do the job of a column auto incremented by 1.

### 4.3.7.9.3 Using CONNECT - Importing File Data Into MariaDB Tables

Directly using external (file) data has many advantages, such as to work on "fresh" data produced for instance by cash registers, telephone switches, or scientific apparatus. However, you may want in some case to import external data into your MariaDB database. This is extremely simple and flexible using the CONNECT handler. For instance, let us suppose you want to import the data of the xsample.xml XML file previously given in example into a MyISAM table called *biblio* belonging to the connect database. All you have to do is to create it by:

```
create table biblio engine=myisam select * from xsampall2;
```

This last statement creates the MyISAM table and inserts the original XML data, translated to tabular format by the xsampall2 CONNECT table, into the MariaDB *biblio* table. Note that further transformation on the data could have been achieved by using a more elaborate Select statement in the Create statement, for instance using filters, alias or applying functions to the data. However, because the Create Table process copies table data, later modifications of the xsample.xml file will not change the *biblio* table and changes to the *biblio* table will not modify the xsample.xml file.

All these can be combined or transformed by further SQL operations. This makes working with CONNECT much more flexible than just using the LOAD statement.

### 4.3.7.9.4 Using CONNECT - Exporting Data From MariaDB

Exporting data from MariaDB is obviously possible with CONNECT in particular for all formats not supported by the

SELECT INTO OUTFILE

statement. Let us consider the query:

```
select plugin_name handler, plugin_version version, plugin_author
author, plugin_description description, plugin_maturity maturity
from information_schema.plugins where plugin_type = 'STORAGE ENGINE';
```

Supposing you want to get the result of this query into a file handlers.htm in XML/HTML format, allowing displaying it on an Internet browser, this is how you can do it:

Just create the CONNECT table that will be used to make the file:

```
create table handout
engine=CONNECT table_type=XML file_name='handout.htm' header=yes
option_list='name=TABLE,coltype=HTML,attribute=border=1;cellpadding=5
,headattr=bgcolor=yellow'
select plugin_name handler, plugin_version version, plugin_author
author, plugin_description description, plugin_maturity maturity
from information_schema.plugins where plugin_type = 'STORAGE ENGINE';
```

Here the column definition is not given and will come from the Select statement following the Create. The CONNECT options are the same we have seen previously. This will do both actions, creating the matching *handlers* CONNECT table and 'filling' it with the query result.

**Note 1:** This could not be done in only one statement if the table type had required using explicit CONNECT column options. In this case, firstly create the table, and then populate it with an Insert statement.

**Note 2:** The source "plugins" table column "description" is a long text column, data type not supported for CONNECT tables. It has been silently internally replaced by varchar(256).

### 4.3.7.9.5 Using CONNECT - Indexing

## Contents

1. Standard Indexing
  1. Handling index errors
  2. Index file mapping
2. Block Indexing
  1. Difference between standard indexing and block indexing
  2. Notes for this Release:
3. Remote Indexing
4. Dynamic Indexing
5. Virtual Indexing

[Indexing](#) is one of the main ways to optimize queries. Key columns, in particular when they are used to join tables, should be indexed. But what should be done for columns that have only few distinct values? If they are randomly placed in the table they should not be indexed because reading many rows in random order can be slower than reading the entire table sequentially. However, if the values are sorted or clustered, indexing can be acceptable because [CONNECT](#) indexes store the values in the order they appear into the table and this will make retrieving them almost as fast as reading them sequentially.

[CONNECT](#) provides four indexing types:

1. Standard Indexing
2. Block Indexing
3. Remote Indexing
4. Dynamic Indexing

## Standard Indexing

[CONNECT](#) standard indexes are created and used as the ones of other storage engines although they have a specific internal format. The [CONNECT](#) handler supports the use of standard indexes for most of the file based table types.

You can define them in the [CREATE TABLE](#) statement, or either using the [CREATE INDEX](#) statement or the [ALTER TABLE](#) statement. In all cases, the index files are automatically made. They can be dropped either using the [DROP INDEX](#) statement or the [ALTER TABLE](#) statement, and this erases the index files.

Indexes are automatically reconstructed when the table is created, modified by [INSERT](#), [UPDATE](#) or [DELETE](#) commands, or when the [SEPINDEX](#) option is changed. If you have a lot of changes to do on a table at one moment, you can use table locking to prevent indexes to be reconstructed after each statement. The indexes will be reconstructed when unlocking the table. For instance:

```
lock table t1 write;
insert into t1 values(...);
insert into t1 values(...);
...
unlock tables;
```

If a table was modified by an external application that does not handle indexing, the indexes must be reconstructed to prevent returning false or incomplete results. To do this, use the [OPTIMIZE TABLE](#) command.

For outward tables, index files are not erased when dropping the table. This is the same as for the data file and preserves the possibility of several users using the same data file via different tables.

Unlike other storage engines, [CONNECT](#) constructs the indexes as files that are named by default from the data file name, not from the table name, and located in the data file directory. Depending on the [SEPINDEX](#) table option, indexes are saved in a unique file or in separate files (if [SEPINDEX](#) is true). For instance, if indexes are in separate files, the primary index of the table *dept.dat* of type DOS is a file named *dept\_PRIMARY.dnx*. This makes possible to define several tables on the same data file, with eventual different options such as mapped or not mapped, and to share the index files as well.

If the index file should have a different name, for instance because several tables are created on the same data file with different indexes, specify the base index file name with the [XFILE\\_NAME](#) option.

**Note1:** Indexed columns must be declared NOT NULL; [CONNECT](#) doesn't support indexes containing null values.

**Note 2:** MRR is used by standard indexing if it is enabled.

**Note 3:** Prefix indexing is not supported. If specified, the [CONNECT](#) engine ignores the prefix and builds a whole index.

## Handling index errors

The way [CONNECT](#) handles indexing is very specific. All table modifications are done regardless of indexing. Only after a table has been modified, or when an

[OPTIMIZE TABLE](#)

command is sent are the indexes made. If an error occurs, the corresponding index is not made. However, [CONNECT](#) being a non-transactional engine, it is unable to roll back the changes made to the table. The main causes of indexing errors are:

- Trying to index a nullable column. In this case, you can alter the table to declare the column as not nullable or, if the column is nullable indeed, make it not indexed.

- Entering duplicate values in a column indexed by a unique index. In this case, if the index was wrongly declared as unique, alter is declaration to reflect this. If the column should really contain unique values, you must manually remove or update the duplicate values.

In both cases, after correcting the error, remake the indexes with the [OPTIMIZE TABLE](#) command.

## Index file mapping

To accelerate the indexing process, CONNECT makes an index structure in memory from the index file. This can be done by reading the index file or using it as if it was in memory by “file mapping”. On enabled versions, file mapping is used according to the boolean [connect\\_idx\\_map](#) system variable. Set it to 0 (file read) or 1 (file mapping).

## Block Indexing

To accelerate input/output, CONNECT uses when possible a read/write mode by blocks of n rows, n being the value given in the BLOCK \_ SIZE option of the Create Table, or a default value depending on the table type. This is automatic for fixed files ([FIX](#) , [BIN](#) , [DBF](#) or [VEC](#) ), but must be specified for variable files ([DOS](#) , [CSV](#) or [FMT](#) ).

For blocked tables, further optimization can be achieved if the data values for some columns are “clustered” meaning that they are not evenly scattered in the table but grouped in some consecutive rows. Block indexing permits to skip blocks in which no rows fulfill a conditional predicate without having even to read the block. This is true in particular for sorted columns.

You indicate this when creating the table by using the [DISTRIB =d](#) column option. The enum value d can be *scattered* , *clustered* , or *sorted* . In general only one column can be sorted. Block indexing is used only for clustered and sorted columns.

## Difference between standard indexing and block indexing

- Block indexing is internally handled by CONNECT while reading sequentially a table data. This means in particular that when standard indexing is used on a table, block indexing is not used.
- In a query, only one standard index can be used. However, block indexing can combine the restrictions coming from a where clause implying several clustered/sorted columns.
- The block index files are faster to make and much smaller than standard index files.

## Notes for this Release:

- On all operations that create or modify a table, CONNECT automatically calculates or recalculates and saves the mini/maxi or bitmap values for each block, enabling it to skip block containing no acceptable values. In the case where the optimize file does not correspond anymore to the table, because it has been accidentally destroyed, or because some column definitions have been altered, you can use the [OPTIMIZE TABLE](#) command to reconstruct the optimization file.
- Sorted column special processing is currently restricted to ascending sort. Column sorted in descending order must be flagged as clustered. Improper sorting is not checked in Update or Insert operations but is flagged when optimizing the table.
- Block indexing can be done in two ways. Keeping the min/max values existing for each block, or keeping a bitmap allowing knowing what column distinct values are met in each blocks. This second ways often gives a better optimization, except for sorted columns for which both are equivalent. The bitmap approach can be done only on columns having not too many distinct values. This is estimated by the MAX \_ DIST option value associated to the column when creating the table. Bitmap block indexing will be used if this number is not greater than the MAXBMP setting for the database.
- CONNECT cannot perform block indexing on case insensitive character columns. To force block indexing on a character column, specify its charset as not case insensitive, for instance as binary. However this will also apply to all other clauses, this column being now case sensitive.

## Remote Indexing

Remote indexing is specific to the [MYSQL](#) table type. It is equivalent to what the [FEDERATED](#) storage does. A MYSQL table does not support indexes per se. Because access to the table is handled remotely, it is the remote table that supports the indexes. What the MYSQL table does is just to add a WHERE clause to the [SELECT](#) command sent to the remote server allowing the remote server to use indexing when applicable. Note however that because CONNECT adds when possible all or part of the where clause of the original query, this happens often even if the remote indexed column is not declared locally indexed. The only, but very important, case a column should be locally declared indexed is when it is used to join tables. Otherwise, the required where clause would not be added to the sent SELECT query.

See [Indexing of MYSQL tables](#) for more.

## Dynamic Indexing

An indexed created as “dynamic” is a standard index which, in some cases, can be reconstructed for a specific query. This happens in particular for some queries where two tables are joined by an indexed key column. If the “from” table is big and the “to” big table reduced in size because of a where clause, it can be worthwhile to reconstruct the index on this reduced table.

Because of the time added by reconstructing the index, this will be valuable only if the time gained by reducing the index size if more than this reconstruction time. This is why this should not be done if the “from” table is small because there will not be enough row joining to compensate for the additional time. Otherwise, the gain of using a dynamic index is:

- Indexing time is a little faster if the index is smaller.
- The join process will return only the rows fulfilling the where clause.
- Because the table is read sequentially when reconstructing the index there no need for MRR.

- Constructing the index can be faster if the table is reduced by block indexing.
- While constructing the index, CONNECT also stores in memory the values of other used columns.

This last point is particularly important. It means that after the index is reconstructed, the join is done on a temporary memory table.

Unfortunately, storage engines being called independently by MariaDB for each table, CONNECT has no global information to decide when it is good to use dynamic indexing. This is why you should use it only on cases where you see that some important join queries take a very long time and only on columns used for joining the table. How to declare an index to be dynamic is by using the Boolean DYNAM index option. For instance, the query:

```
select d.diag, count(*) cnt from diag d, patients p where d.pnb =
p.pnb and ageyears < 17 and county = 30 and drg >> 11 and d.diag
between 4296 and 9434 group by d.diag order by cnt desc;
```

Such a query joining the diag table to the patients table may last a very long time if the tables are big. To declare the primary key on the pnb column of the patients table to be dynamic:

```
alter table patients drop primary key;
alter table patients add primary key (pnb) comment 'DYNAMIC' dynam=1;
```

Note 1: The comment is not mandatory here but useful to see that the index is dynamic if you use the [SHOW INDEX](#) command.

Note 2: There is currently no way to just change the DYNAM option without dropping and adding the index. This is unfortunate because it takes time.

## Virtual Indexing

It applies only to the virtual tables of type [VIR](#) and must be made on a column specifying

SPECIAL=ROWID

or

SPECIAL=ROWNUM

## 4.3.7.9.6 Using CONNECT - Condition Pushdown

The [ODBC](#) , [JDBC](#) , [MYSQL](#) , [TBL](#) and WMI table types use engine condition pushdown in order to restrict the number of rows returned by the RDBS source or the WMI component.

The CONDITION\_PUSHDOWN argument used in old versions of CONNECT is no longer needed because CONNECT uses condition pushdown unconditionally.

CONNECT supports the MySQL/MariaDB partition specification. It is done similar to the way [MyISAM](#) or [InnoDB](#) do by using the PARTITION engine that must be enabled for this to work. This type of partitioning is sometimes referred as "horizontal partitioning".

Partitioning enables you to distribute portions of individual tables across a file system according to rules which you can set largely as needed. In effect, different portions of a table are stored as separate tables in different locations. The user-selected rule by which the division of data is accomplished is known as a partitioning function, which in MariaDB can be the modulus, simple matching against a set of ranges or value lists, an internal hashing function, or a linear hashing function.

CONNECT takes this notion a step further, by providing two types of partitioning:

1. File partitioning. Each partition is stored in a separate file like in multiple tables.

2. Table partitioning. Each partition is stored in a separate table like in TBL tables.

## Partition engine issues

Using partitions sometimes requires creating the tables in an unnatural way to avoid some error due to several partition engine bugs:

1. Engine specific column and index options are not recognized and cause a syntax error when the table is created. The workaround is to create the table in two steps, a CREATE TABLE statement followed by an ALTER TABLE statement.
2. The connection string, when specified for the table, is lost by the partition engine. The workaround is to specify the connection string in the `option_list`.
3. [MySQL upstream bug #71095](#). In case of list columns partitioning it sometimes causes a false “impossible where” clause to be raised. This makes a wrong void result returned when it should not be void. There is no workaround but this bug should be hopefully fixed.

The following examples are using the above workaround syntax to address these issues.

## File Partitioning

File partitioning applies to file-based CONNECT table types. As with multiple tables, physical data is stored in several files instead of just one. The differences to multiple tables are:

1. Data is distributed amongst the different files following the partition rule.
2. Unlike multiple tables, partitioned tables are not read only.
3. Unlike multiple tables, partitioned tables can be indexable.
4. The file names are generated from the partition names.
5. Query pruning is automatically made by the partition engine.

The table file names are generated differently depending on whether the table is an inward or outward table. For inward tables, for which the file name is not specified, the partition file names are:

```
Data file name: table_name#P#partition_name.table_file_type  
Index file name: table_name#P#partition_name.index_file_type
```

For instance for the table:

```
CREATE TABLE t1 (  
    id INT KEY NOT NULL,  
    msg VARCHAR(32))  
ENGINE=CONNECT TABLE_TYPE=FIX  
partition by range(id) (  
    partition first values less than(10),  
    partition middle values less than(50),  
    partition last values less than(MAXVALUE));
```

CONNECT will generate in the current data directory the files:

```
| t1#P#first.fix  
| t1#P#first.fnx  
| t1#P#middle.fix  
| t1#P#middle.fnx  
| t1#P#last.fix  
| t1#P#last.fnx
```

This is similar to what the partition engine does for other engines - CONNECT partitioned inward tables behave like other engines partition tables do. Just the data format is different.

Note: If sub-partitioning is used, inward table files and index files are named:

```
| table_name#P#partition_name#SP#subpartition_name.type  
| table_name#P#partition_name#SP#subpartition_name.index_type
```

## Outward Tables

The real problems occur with outward tables, in particular when they are created from already existing files. The first issue is to make the partition table use the correct existing file names. The second one, only for already existing not void tables, is to be sure the partitioning function match the distribution of the data already existing in the files.

The first issue is addressed by the way data file names are constructed. For instance let us suppose we want to make a table from the fixed formatted files:

```
E:\Data\part1.txt  
E:\Data\part2.txt  
E:\Data\part3.txt
```

This can be done by creating a table such as:

```
create table t2 (
id int not null,
msg varchar(32),
index XID(id))
engine=connect table_type=FIX file_name='E:/Data/part%s.txt'
partition by range(id) (
partition `1` values less than(10),
partition `2` values less than(50),
partition `3` values less than(MAXVALUE));
```

The rule is that for each partition the matching file name is internally generated by replacing in the given FILE\_NAME option value the "%s" part by the partition name.

If the table was initially void, further inserts will populate it according to the partition function. However, if the files did exist and contained data, this is your responsibility to determine what partition function actually matches the data distribution in them. This means in particular that partitioning by key or by hash cannot be used (except in exceptional cases) because you have almost no control over what the used algorithm does.

In the example above, there is no problem if the table is initially void, but if it is not, serious problems can be met if the initial distribution does not match the table distribution. Supposing a row in which "id" as the value 12 was initially contained in the part1.txt file, it will be seen when selecting the whole table but if you ask:

```
select * from t2 where id = 12;
```

The result will have 0 rows. This is because according to the partition function query pruning will only look inside the second partition and will miss the row that is in the wrong partition.

One way to check for wrong distribution if for instance to compare the results from queries such as:

```
SELECT partition_name, table_rows FROM
information_schema.partitions WHERE table_name = 't2';
```

And

```
SELECT CASE WHEN id < 10 THEN 1 WHEN id < 50 THEN 2 ELSE 3 END
AS pn, COUNT(*) FROM part3 GROUP BY pn;
```

If they match, the distribution can be correct although this does not prove it. However, if they do not match, the distribution is surely wrong.

## Partitioning on a Special Column

There are some cases where the files of a multiple table do not contain columns that can be used for range or list partitioning. For instance, let's suppose we have a multiple table based on the following files:

```
tmp/boston.txt
tmp/chicago.txt
tmp/atlanta.txt
```

Each of them containing the same kind of data:

```
ID: int
First_name: varchar(16)
Last_name: varchar(30)
Birth: date
Hired: date
Job: char(10)
Salary: double(8,2)
```

A multiple table can be created on them, for instance by:

```
create table mulemp (
id int NOT NULL,
first_name varchar(16) NOT NULL,
last_name varchar(30) NOT NULL,
birth date NOT NULL date_format='DD/MM/YYYY',
hired date NOT NULL date_format='DD/MM/YYYY',
job char(10) NOT NULL,
salary double(8,2) NOT NULL
) engine=CONNECT table_type=FIX file_name='tmp/*.txt' multiple=1;
```

The issue is that if we want to create a partitioned table on these files, there are no columns to use for defining a partition function. Each city file can have

the same kind of column values and there is no way to distinguish them.

However, there is a solution. It is to add to the table a special column that will be used by the partition function. For instance, the new table creation can be done by:

```
create table partemp (
id int NOT NULL,
first_name varchar(16) NOT NULL,
last_name varchar(30) NOT NULL,
birth date NOT NULL date_format='DD/MM/YYYY',
hired date NOT NULL date_format='DD/MM/YYYY',
job char(16) NOT NULL,
salary double(10,2) NOT NULL,
city char(12) default 'boston' special=PARTID,
index XID(id)
) engine=CONNECT table_type=FIX file_name='E:/Data/Test/%s.txt';
alter table partemp
partition by list columns(city) (
partition `atlanta` values in('atlanta'),
partition `boston` values in('boston'),
partition `chicago` values in('chicago'));
```

Note 1: we had to do it in two steps because of the column CONNECT options.

Note 2: the special column PARTID returns the name of the partition in which the row is located.

Note 3: here we could have used the FNAME special column instead because the file name is specified as being the partition name.

This may seem rather stupid because it means for instance that a row will be in partition boston if it belongs to the partition boston! However, it works because the partition engine doesn't know about special columns and behaves as if the city column was a real column.

What happens if we populate it by?

```
insert into partemp(id,first_name,last_name,birth,hired,job,salary) values
(1205,'Harry','Cover','1982-10-07','2010-09-21','MANAGEMENT',125000.00);
insert into partemp values
(1524,'Jim','Beams','1985-06-18','2012-07-25','SALES',52000.00,'chicago'),
(1431,'Johnny','Walker','1988-03-12','2012-08-09','RESEARCH',46521.87,'boston'),
(1864,'Jack','Daniels','1991-12-01','2013-02-16','DEVELOPMENT',63540.50,'atlanta');
```

The value given for the city column (explicitly or by default) will be used by the partition engine to decide in which partition to insert the rows. It will be ignored by CONNECT (a special column cannot be given a value) but later will return the matching value. For instance:

```
select city, first_name, job from partemp where id in (1524,1431);
```

This query returns:

city	first_name	job
boston	Johnny	RESEARCH
chicago	Jim	SALES

Everything works as if the city column was a real column contained in the table data files.

### Partitioning of zipped tables

Two cases are currently supported:

If a table is based on several zipped files, portioning is done the standard way as above. This is the *file\_name* option specifying the name of the zip files that shall contain the '%s' part used to generate the file names.

If a table is based on only one zip file containing several entries, this will be indicated by placing the '%s' part in the entry option value.

Note: If a table is based on several zipped files each containing several entries, only the first case is possible. Using sub-partitioning to make partitions on each entries is not supported yet.

## Table Partitioning

With table partitioning, each partition is physically represented by a sub-table. Compared to standard partitioning, this brings the following features:

1. The partitions can be tables driven by different engines. This relieves the current existing limitation of the partition engine.
2. The partitions can be tables driven by engines not currently supporting partitioning.
3. Partition tables can be located on remote servers, enabling table sharding.
4. Like for TBL tables, the columns of the partition table do not necessarily match the columns of the sub-tables.

The way it is done is to create the partition table with a table type referring to other tables, [PROXY](#), [MYSQL ODBC](#) or [JDBC](#). Let us see how this is done on a simple example. Supposing we have created the following tables:

```

create table xt1 (
id int not null,
msg varchar(32))
engine=myisam;

create table xt2 (
id int not null,
msg varchar(32)); /* engine=innnoDB */

create table xt3 (
id int not null,
msg varchar(32))
engine=connect table_type=CSV;

```

We can for instance create a partition table using these tables as physical partitions by:

```

create table t3 (
id int not null,
msg varchar(32))
engine=connect table_type=PROXY tablename='xt%';
partition by range columns(id) (
partition `1` values less than(10),
partition `2` values less than(50),
partition `3` values less than(MAXVALUE));

```

Here the name of each partition sub-table will be made by replacing the '%s' part of the tablename option value by the partition name. Now if we do:

```

insert into t3 values
(4, 'four'),(7, 'seven'),(10, 'ten'),(40, 'forty'),
(60, 'sixty'),(81, 'eighty one'),(72, 'seventy two'),
(11, 'eleven'),(1, 'one'),(35, 'thirty five'),(8, 'eight');

```

The rows will be distributed in the different sub-tables according to the partition function. This can be seen by executing the query:

```

select partition_name, table_rows from
information_schema.partitions where table_name = 't3';

```

This query replies:

partition_name	table_rows
1	4
2	4
3	3

Query pruning is of course automatic, for instance:

```

explain partitions select * from t3 where id = 81;

```

This query replies:

id	select_type	table	partitions	type	possible_keys	key	key_len	ref	rows	Extra
1	SIMPLE	part5	3	ALL	<null>	<null>	<null>	<null>	22	Using where

When executing this select query, only sub-table xt3 will be used.

## Indexing with Table Partitioning

Using the **PROXY** table type seems natural. However, in this current version, the issue is that PROXY (and **ODBC**) tables are not indexable. This is why, if you want the table to be indexed, you must use the **MYSQL** table type. The CREATE TABLE statement will be almost the same:

```

create table t4 (
id int key not null,
msg varchar(32))
engine=connect table_type=MYSQL tablename='xt%';
partition by range columns(id) (
partition `1` values less than(10),
partition `2` values less than(50),
partition `3` values less than(MAXVALUE));

```

The column `id` is declared as a key, and the table type is now MYSQL. This makes Sub-tables accessed by calling a MariaDB server as MYSQL tables do. Note that this modifies only the way CONNECT sub-tables are accessed.

However, indexing just make the partitioned table use “remote indexing” the way FEDERATED tables do. This means that when sending the query to retrieve the table data, a where clause will be added to the query. For instance, let's suppose you ask:

```
select * from t4 where id = 7;
```

The query sent to the server will be:

```
SELECT `id`, `msg` FROM `xt1` WHERE `id` = 7
```

On a query like this one, it does not change much because the where clause could have been added anyway by the cond\_push function, but it does make a difference in case of joins. The main thing to understand is that real indexing is done by the called table and therefore that it should be indexed.

This also means that the `xt1`, `xt2`, and `xt3` table indexes should be made separately because creating the `t2` table as indexed does not make the indexes on the sub-tables.

## Sharding with Table Partitioning

Using table partitioning can have one more advantage. Because the sub-tables can address a table located on another server, it is possible to shard a table on separate servers and hardware machines. This may be required to access as one table data already located on several remote machines, such as servers of a company branches. Or it can be just used to split a huge table for performance reason. For instance, supposing we have created the following tables:

```
create table rt1 (id int key not null, msg varchar(32))
engine=federated connection='mysql://root@host1/test/sales';

create table rt2 (id int key not null, msg varchar(32))
engine=federated connection='mysql://root@host2/test/sales';

create table rt3 (id int key not null, msg varchar(32))
engine=federated connection='mysql://root@host3/test/sales';
```

Creating the partition table accessing all these will be almost like what we did with the `t4` table:

```
create table t5 (
id int key not null,
msg varchar(32))
engine=connect table_type=MYSQL tablename='rt%'
partition by range columns(id) (
partition `1` values less than(10),
partition `2` values less than(50),
partition `3` values less than(MAXVALUE));
```

The only difference is the `tablename` option now referring to the `rt1`, `rt2`, and `rt3` tables. However, even if it works, this is not the best way to do it. This is because accessing a table via the MySQL API is done twice per table. Once by CONNECT to access the FEDERATED table on the local server, then a second time by FEDERATED engine to access the remote table.

The CONNECT MYSQL table type being used anyway, you'd rather use it to directly access the remote tables. Indeed, the partition names can also be used to modify the connection URL's. For instance, in the case shown above, the partition table can be created as:

```
create table t6 (
id int key not null,
msg varchar(32))
engine=connect table_type=MYSQL
option_list='connect=mysql://root@host%_test/sales'
partition by range columns(id) (
partition `1` values less than(10),
partition `2` values less than(50),
partition `3` values less than(MAXVALUE));
```

Several things can be noted here:

1. As we have seen before, the partition engine currently loses the connection string. This is why it was specified as “connect” in the option list.
2. For each partition sub-tables, the “%s” part of the connection string has been replaced by the partition name.
3. It is not needed anymore to define the `rt1`, `rt2`, and `rt3` tables (even it does not harm) and the FEDERATED engine is no more used to access the remote tables.

This is a simple case where the connection string is almost the same for all the sub-tables. But what if the sub-tables are accessed by very different connection strings? For instance:

```

For rt1: connection='mysql://root:tinono@127.0.0.1:3307/test/xt1'
For rt2: connection='mysql://foo:foopass@denver/dbemp/xt2'
For rt3: connection='mysql://root@houston :5505/test/tabc'

```

There are two solutions. The first one is to use the parts of the connection string to differentiate as partition names:

```

create table t7 (
id int key not null,
msg varchar(32))
engine=connect table_type=MYSQL
option_list='connect=mysql://%s'
partition by range columns(id) (
partition `root:tinono@127.0.0.1:3307/test/xt1` values less than(10),
partition `foo:foopass@denver/dbemp/xt2` values less than(50),
partition `root@houston :5505/test/tabc` values less than(MAXVALUE));

```

The second one, allowing avoiding too complicated partition names, is to create federated servers to access the remote tables (if they do not already exist, else just use them). For instance the first one could be:

```

create server `server_one` foreign data wrapper 'mysql'
options
(host '127.0.0.1',
database 'test',
user 'root',
password 'tinono',
port 3307);

```

Similarly, "server\_two" and "server\_three" would be created and the final partition table would be created as:

```

create table t8 (
id int key not null,
msg varchar(32))
engine=connect table_type=MYSQL
option_list='connect=server_%s'
partition by range columns(id) (
partition `one/xt1` values less than(10),
partition `two/xt2` values less than(50),
partition `three/tabc` values less than(MAXVALUE));

```

It would be even simpler if all remote tables had the same name on the remote databases, for instance if they all were named xt1, the connection string could be set as "server\_%s/xt1" and the partition names would be just "one", "two", and "three".

## Sharding on a Special Column

The technique we have seen above with file partitioning is also available with table partitioning. Companies willing to use as one table data sharded on the company branch servers can, as we have seen, add to the table create definition a special column. For instance:

```

create table t9 (
id int not null,
msg varchar(32),
branch char(16) default 'main' special=PARTID,
index XID(id))
engine=connect table_type=MYSQL
option_list='connect=server_%s/sales'
partition by range columns(id) (
partition `main` values in('main'),
partition `east` values in('east'),
partition `west` values in('west'));

```

This example assumes that federated servers had been created named "server\_main", "server\_east" and "server\_west" and that all remote tables are named "sales". Note also that in this example, the column id is no more a key.

## Current Partition Limitations

Because the partition engine was written before some other engines were added to MariaDB, the way it works is sometime incompatible with these engines, in particular with CONNECT.

## Update statement

With the sample tables above, you can do update statements such as:

```
update t2 set msg = 'quatre' where id = 4;
```

It works perfectly and is accepted by CONNECT. However, let us consider the statement:

```
update t2 set id = 41 where msg = 'four';
```

This statement is not accepted by CONNECT. The reason is that the column id being part of the partition function, changing its value may require the modified row to be moved to another partition. The way it is done by the partition engine is to delete the old row and to re-insert the new modified one. However, this is done in a way that is not currently compatible with CONNECT (remember that CONNECT supports UPDATE in a specific way, in particular for the table type MYSQL) This limitation could be temporary. Meanwhile the workaround is to manually do what is done above,

Deleting the row to modify and inserting the modified row:

```
delete from t2 where id = 4;
insert into t2 values(41, 'four');
```

## Alter Table statement

For all CONNECT outward tables, the ALTER TABLE statement does not make any change in the table data. This is why ALTER TABLE should not be used; in particular to modify the partition definition, except of course to correct a wrong definition. Note that using ALTER TABLE to create a partition table in two steps because column options would be lost is valid as it applies to a table that is not yet partitioned.

As we have seen, it is also safe to use it to create or drop indexes. Otherwise, a simple rule of thumb is to avoid altering a table definition and better drop and re-create a table whose definition must be modified. Just remember that for outward CONNECT tables, dropping a table does not erase the data and that creating it does not modify existing data.

## Rowid special column

Each partition being handled separately as one table, the ROWID special column returns the rank of the row in its partition, not in the whole table. This means that for partition tables ROWID and ROWNUM are equivalent.

## 4.3.7.10 CONNECT - Making the GetRest Library

To enable the REST feature with binary distributions of MariaDB, the function calling the cpprestsdk package is not included in CONNECT, thus allowing CONNECT normal operation when the cpprestsdk package is not installed. Therefore, it must be compiled separately as a library (so or dll) that will be loaded by CONNECT when needed.

This library will contain only one file shown here:

```
***** Restget C++ Program Source Code File (.CPP) *****/
/* Adapted from the sample program of the Casablanca tutorial. */
/* Copyright Olivier Bertrand 2019. */
/*****
#include <cpprest/filestream.h>
#include <cpprest/http_client.h>

using namespace utility::conversions; // String conversions utilities
using namespace web; // Common features like URIs.
using namespace web::http; // Common HTTP functionality
using namespace web::http::client; // HTTP client features
using namespace concurrency::streams; // Asynchronous streams

typedef const char* PCSZ;

extern "C" int restGetFile(char* m, bool xt, PCSZ http, PCSZ uri, PCSZ fn);

/*****
/* Make a local copy of the requested file. */
/*****
int restGetFile(char *m, bool xt, PCSZ http, PCSZ uri, PCSZ fn)
{
    int rc = 0;
    auto fileStream = std::make_shared<ostream>();

    if (!http || !fn) {
        strcpy(m, "Missing http or filename");
        return 2;
    } // endif

    if (xt)
        fprintf(stderr, "restGetFile: fn=%s\n", fn);

    // Open stream to output file.
    only::task<void> requestTask = fileStream->open_outstream(to_string(t(fn))
```

```

    .then([=](ostream outFile) {
        *fileStream= outFile;

        if (xt)
            fprintf(stderr, "Outfile isopen=%d\n", outFile.is_open());

        // Create http_client to send the request.
        http_client client(to_string_t(http));

        if (uri) {
            // Build request URI and start the request.
            uri_builder builder(to_string_t(uri));
            return client.request(methods::GET, builder.to_string());
        } else
            return client.request(methods::GET);
    })

    // Handle response headers arriving.
    .then([=](http_response response) {
        if (xt)
            fprintf(stderr, "Received response status code:%u\n",
                    response.status_code());

        // Write response body into the file.
        return response.body().read_to_end(fileStream->streambuf());
    })

    // Close the file stream.
    .then([=](size_t n) {
        if (xt)
            fprintf(stderr, "Return size=%zu\n", n);

        return fileStream->close();
    });

    // Wait for all the outstanding I/O to complete and handle any exceptions
    try {
        if (xt)
            fprintf(stderr, "Waiting\n");

        requestTask.wait();
    } catch (const std::exception &e) {
        if (xt)
            fprintf(stderr, "Error exception: %s\n", e.what());

        sprintf(m, "Error exception: %s", e.what());
        rc= 1;
    } // end try/catch

    if (xt)
        fprintf(stderr, "restget done: rc=%d\n", rc);

    return rc;
} // end of restGetFile

```

This file exists in the source of CONNECT as

`restget.cpp`

. If you have no access to the source, use your favorite editor to make it by copy/pasting from the above.

Then, on Linux, compile the GetRest.so library:

```
g++ -o GetRest.so -O3 -Wall -std=c++11 -fPIC -shared restget.cpp -lcpprest
```

Note: You can replace

-O3

by

-g

to make a debug version.

This library should be placed where it can be accessed. A good place is the directory where the

`libcpprest.so`

is, for instance

`/usr/lib64`

. You can move or copy it there.

On windows, using Visual Studio, make an empty win32 dll project named GetRest and add it the above file. Also add it the module definition file

```
restget.def
```

```
:
```

```
LIBRARY REST
EXPORTS
    restGetFile    @1
```

Important: This file must be specified in the property linker input page.

Once compiled, the release or debug versions can be copied in the

```
cpprestsdk
```

```
corresponding directories, bin or debug\bin.
```

That is all. It is a once-off job. Once done, it will work with all new MariaDB versions featuring CONNECT version 1.07.

Note: the xt tracing variable is true when connect\_xtrace setting includes the value "MONGO" (512).

Caution: If your server crashes when using this feature, this is likely because the GetRest lib is linked to the wrong cpprestsdk lib (this may only apply on Windows)

A Release version of GetRest must be linked to the release version of the cpprestsdk lib (cpprest\_2\_10.dll) but if you make a Debug version of GetRest, make sure it is linked to the Debug version of cpprestsdk lib (cpprest\_2\_10d.dll)

This may be automatic if you use Visual Studio to make the GetRest.dll.

## 4.3.7.11 CONNECT - Adding the REST Feature as a Library Called by an OEM Table

If you are using a version of MariaDB that does not support REST, this is how the REST feature can be added as a library called by an OEM table.

Before making the REST OEM module, the Microsoft Casablanca package must be installed as for compiling MariaDB from source.

Even if this module is to be used with a binary distribution, you need some CONNECT source files in order to successfully make it. It is made with four files existing in the version 1.06.0010 of CONNECT: tabrest.cpp, restget.cpp, tabrest.h and mini-global.h. It also needs the CONNECT header files that are included in tabrest.cpp and the ones they can include. This can be obtained by going to a recent download site of a version of MariaDB that includes the REST feature, downloading the MariaDB source file tar.gz and extracting from it the CONNECT sources files in a directory that will be added to the additional source directories if it is not the directory containing the above files.

On Windows, use a recent version of Visual Studio. Make a new empty DLL project and add the source files tabrest.cpp and restget.cpp. Visual studio should automatically generate all necessary connections to the cpprest SDK. Just edit the properties of the project to add the additional include directory (the one where the CONNECT source was downloaded) et the link to the ha\_connect.lib of the binary version of MariaDB (in the same directory than ha\_connect.dll in your binary distribution). Add the preprocessor definition XML\_SUPPORT. Also set in the linker input page of the project property the Module definition File to the rest.def file (with its full path) also existing in the CONNECT source files. If you are making a debug configuration, make sure that in the C/C++ Code generation page the Runtime library line specifies Multi-threaded Debug DLL (/MDd) or your server will crash when using the feature.

This is not really simple but it is nothing compared with Linux! Someone having made an OEM module for its own application have written:

For whatever reason, g++ / ld on Linux are both extremely picky about what they will and won't consider a \*\*library\*\* for linking purposes. In order to get them to recognize and therefore find `ha\_connect.so` as a "valid" linkable library, `ha\_connect.so` must exist in a directory whose path is in `/etc/ld.so.conf` or `/etc/ld.so.conf.d/ha\_connect.conf` \*AND\* its filename must begin with "lib".

On Fedora, you can make a link to ha\_connect.so by:

```
$ sudo ln -s ..path to../ha_connect.so /usr/lib64/libconnect.so
```

This provides a library whose name begins with "lib". It was made in /usr/lib64/ because it was the directory of the libcpprest.so Casablanca library. This solved the need of a file in /etc/ld.so.conf.d as this was already done for the cpprest library. Note that the -s parameter is a must, without it all sort of nasty errors are met when using the feature.

Then compile and install the OEM module with:

```
$ mkdir oem
$ cd oem
$ makedir Release
$ make -f oemrest.mak
$ sudo cp rest.so /usr/local/mysql/lib/plugin
```

The oemrest.mak file:

```

#LINUX
CPP = g++
LD = g++
OD = ./Release/
SD = /home/olivier/MariaDB/server/storage/connect/
CD =/usr/lib64
# flags to compile object files that can be used in a dynamic library
CFLAGS= -Wall -c -O3 -std=c++11 -fPIC -fno-rtti -I$(SD) -DXML_SUPPORT
# Replace -O3 by -g for debug
LDFLAGS = -L$(CD) -lcpprest -lconnect

# Flags to create a dynamic library.
DYNLINKFLAGS = -shared
# on some platforms, use '-G' instead.

# REST library's archive file
OEMREST = rest.so

SRCS_CPP = $(SD)tabrest.cpp $(SD)restget.cpp
OBJS_CPP = $(OD)tabrest.o $(OD)restget.o

# top-level rule
all: $(OEMREST)

$(OEMREST): $(OBJS_CPP)
    $(LD) $(OBJS_CPP) $(LDFLAGS) $(DYNLINKFLAGS) -o $@

#CPP Source files
$(OD)tabrest.o: $(SD)tabrest.cpp $(SD)mini-global.h $(SD)global.h $(SD)plgdbsem.h $(SD)xtable.h $(SD)filamtxt.h $(SD)plgxml.h
    $(CPP) $(CFLAGS) -o $@ $(SD)$(*F).cpp
$(OD)restget.o: $(SD)restget.cpp $(SD)mini-global.h $(SD)global.h
    $(CPP) $(CFLAGS) -o $@ $(SD)$(*F).cpp

# clean everything
clean:
    $(RM) $(OBJS_CPP) $(OEMREST)

```

The SD and CD variables are the directories of the CONNECT source files and the one containing the libcpprest.so lib. They can be edited to match those on your machine OD is the directory that was made to contain the object files.

A very important flag is -fno-rtti. Without it you would be in big trouble.

The resulting module, for instance rest.so or rest.dll, must be placed in the plugin directory of the MariaDB server. Then, you will be able to use NoSQL tables simply replacing in the CREATE TABLE statement the TABLE\_TYPE option =JSON or XML by TABLE\_TYPE=OEM SUBTYPE=REST MODULE='rest.(so|dll)'. Actually, the module name, here supposedly 'rest', can be anything you like.

The file type is JSON by default. If not, it must be specified like this:

```
OPTION_LIST='Ftype=XML'
```

To be added to the create table statement. For instance:

```

CREATE TABLE webw
ENGINE=CONNECT TABLE_TYPE=OEM MODULE='Rest.dll' SUBTYPE=REST
FILE_NAME='weatherdata.xml'
HTTP='https://samples.openweathermap.org/data/2.5/forecast?q=London,us&mode=xml&appid=b6907d289e10d714a6e88b30761fae22'
OPTION_LIST='Ftype=XML,Depth=3,Rownode=weatherdata';

```

Note: this last example returns an XML file whose format was not recognized by old CONNECT versions. It is here the reason of the option 'Rownode=weatherdata'.

If you have trouble making the module, you can post an issue on [JIRA](#).

## 4.3.7.12 CONNECT - Compiling JSON UDFs in a Separate Library

Although the JSON UDFs can be nicely included in the CONNECT library module, there are cases when you may need to have them in a separate library.

This is when CONNECT is compiled embedded, or if you want to test or use these UDFs with other MariaDB versions not including them.

To make it, you need to have access to the most recent MariaDB source code. Then, make a project containing these files:

1. jsonudf.cpp
2. json.cpp
3. value.cpp

4. osutil.c
5. plugutil.cpp
6. maputil.cpp
7. jsonutil.cpp

jsonutil.cpp

is not distributed with the source code, you will have to make it from the following:

```

#include "my_global.h"
#include "mysqld.h"
#include "plugin.h"
#include <stdlib.h>
#include <string.h>
#include <stdio.h>
#include <errno.h>

#include "global.h"

extern "C" int GetTraceValue(void) { return 0; }
uint GetJsonGrpSize(void) { return 100; }

/***/
/* These replace missing function of the (not used) DTVAL class. */
/***/
typedef struct _datpar *PDTp;
PDTp MakeDateFormat(PGLOBAL, PSZ, bool, bool, int) { return NULL; }
int ExtractDate(char*, PDTp, int, int val[6]) { return 0; }

#ifndef __WIN__
my_bool CloseFileHandle(HANDLE h)
{
    return !CloseHandle(h);
} /* end of CloseFileHandle */

#else /* UNIX */
my_bool CloseFileHandle(HANDLE h)
{
    return (close(h)) ? TRUE : FALSE;
} /* end of CloseFileHandle */

int GetLastError()
{
    return errno;
} /* end of GetLastError */

#endif // UNIX

/***/
/* Program for sub-allocating one item in a storage area. */
/* Note: This function is equivalent to PlugSubAlloc except that in */
/* case of insufficient memory, it returns NULL instead of doing a */
/* long jump. The caller must test the return value for error. */
/***/
void *PlgDBSubAlloc(PGLOBAL g, void *memp, size_t size)
{
    PPOOLHEADER pph;           // Points on area header.

    if (!memp) // Allocation is to be done in the Sarea
        memp = g->Sarea;

    size = ((size + 7) / 8) * 8; /* Round up size to multiple of 8 */
    pph = (PPOOLHEADER)memp;

    if ((uint)size > pph->FreeBlk) { /* Not enough memory left in pool */
        sprintf(g->Message,
            "Not enough memory in Work area for request of %d (used=%d free=%d)",
            (int)size, pph->To_Free, pph->FreeBlk);
        return NULL;
    } // endif size

    // Do the suballocation the simplest way
    memp = MakePtr(memp, pph->To_Free); // Points to sub_allocated block
    pph->To_Free += size;               // New offset of pool free block
    pph->FreeBlk -= size;              // New size of pool free block

    return (memp);
} // end of PlgDBSubAlloc

```

You can create the file by copy/paste from the above.

Set all the additional include directories to the MariaDB include directories used in plugin compiling plus the reference of the storage/connect directories, and compile like any other UDF giving any name to the made library module (I used

jsonudf.dll

on Windows).

Then you can create the functions using this name as the soname parameter.

There are some restrictions when using the UDFs this way:

- The `connect_json_grp_size` variable cannot be accessed. The group size is set and retrieved using the `jsonset_grp_size` and `jsonget_grp_size` functions (previously 100).
- In case of error, warnings are replaced by messages sent to stderr.
- No trace.

## 4.3.7.13 CONNECT System Variables

### Contents

1. [connect\\_class\\_path](#)
2. [connect\\_cond\\_push](#)
3. [connect\\_conv\\_size](#)
4. [connect\\_default\\_depth](#)

15. [connect\\_type\\_conv](#)
16. [connect\\_use\\_tempfile](#)
17. [connect\\_work\\_size](#)
18. [connect\\_xtrace](#)

This page documents system variables related to the [CONNECT storage engine](#). See [Server System Variables](#) for a complete list of system variables and instructions on setting them.

See also the [Full list of MariaDB options, system and status variables](#).

#### connect\_class\_path

- **Description:** Java class path
- **Commandline:**  
`--connect-class-path=value`
- **Scope:** Global
- **Dynamic:**
- **Data Type:**  
`string`
- **Default Value:**

---

#### connect\_cond\_push

- **Description:** Enable condition pushdown
- **Commandline:**  
`--connect-cond-push={0|1}`
- **Scope:** Global, Session
- **Dynamic:** Yes
- **Data Type:**  
`boolean`
- **Default Value:**  
`ON`
- **Introduced:** [MariaDB 10.3.6](#) , [MariaDB 10.2.14](#)

## connect\_conv\_size

- **Description:** The size of the `VARCHAR` created when converting from a `TEXT` type. See `connect_type_conv`.

- **Commandline:**

--connect-conv-size=#

- **Scope:** Global, Session

- **Dynamic:** Yes

- **Data Type:**

numeric

- **Default Value:**

◦ >= MariaDB 10.4.8 , MariaDB 10.3.18 , MariaDB 10.2.27 :

1024

◦ <= MariaDB 10.4.7 , MariaDB 10.3.17 , MariaDB 10.2.26 :

8192

- **Range:**

0

to

65500

## connect\_default\_depth

- **Description:** Default depth used by Json, XML and Mongo discovery.

- **Commandline:**

--connect-default-depth=#

- **Scope:** Global, Session

- **Dynamic:** Yes

- **Data Type:**

numeric

- **Default Value:**

5

- **Range:**

-1

to

16

- **Introduced:** MariaDB 10.5.7 , MariaDB 10.4.16 , MariaDB 10.3.26 , MariaDB 10.2.35

## connect\_default\_prec

- **Description:** Default precision used for doubles.

- **Commandline:**

--connect-default-prec=#

- **Scope:** Global, Session

- **Dynamic:** Yes

- **Data Type:**

numeric

- **Default Value:**

6

- **Range:**

0

to

16

- **Introduced:** MariaDB 10.5.9 , MariaDB 10.4.18 , MariaDB 10.3.28 , MariaDB 10.2.37
- 

connect\_enable\_mongo

- **Description:** Enable the [Mongo table type](#) .

- **Commandline:**

    --connect-enable-mongo={0|1}

- **Scope:** Global, Session

- **Dynamic:**

- **Data Type:**

    boolean

- **Default Value:**

    OFF

- **Introduced:** MariaDB 10.3.2 , MariaDB 10.2.9

- **Removed:** MariaDB 10.3.3
- 

connect\_exact\_info

- **Description:** Whether the CONNECT engine should return an exact record number value to information queries. It is OFF by default because this information can take a very long time for large variable record length tables or for remote tables, especially if the remote server is not available. It can be set to ON when exact values are desired, for instance when querying the repartition of rows in a partition table.

- **Commandline:**

    --connect-exact-info={0|1}

- **Scope:** Global, Session

- **Dynamic:** Yes

- **Data Type:**

    boolean

- **Default Value:**

    OFF

---

connect\_force\_bson

- **Description:** Force using BSON for JSON tables. Starting with these releases, the internal way JSON was parsed and handled was changed. The main advantage of the new way is to reduce the memory required to parse JSON (from 6 to 10 times the size of the JSON source to now only 2 to 4 times). However, this is in Beta mode and JSON tables are still handled using the old mode. To use the new mode, tables should be created with TABLE\_TYPE=BSON, or by setting this session variable to 1 or ON. Then, all JSON tables will be handled as BSON. This is temporary until the new way replaces the old way by default.

- **Commandline:**

    --connect-force-bson={0|1}

- **Scope:** Global, Session

- **Dynamic:** Yes

- **Data Type:**

    boolean

- **Default Value:**

    OFF

- **Introduced:** MariaDB 10.5.9 , MariaDB 10.4.18 , MariaDB 10.3.28 , MariaDB 10.2.37
- 

connect\_idx\_map

- **Description:** Enable file mapping for index files. To accelerate the indexing process, CONNECT makes an index structure in memory from the

index file. This can be done by reading the index file or using it as if it was in memory by “file mapping”. Set to 0 (file read, the default) or 1 (file mapping).

- **Commandline:**

```
--connect-idx-map=#
```

- **Scope:** Global

- **Dynamic:** Yes

- **Data Type:**

boolean

- **Default Value:**

OFF

---

connect\_java\_wrapper

- **Description:** Java wrapper.

- **Commandline:**

```
--connect-java-wrapper=val
```

- **Scope:** Global, Session

- **Dynamic:** Yes

- **Data Type:**

string

- **Default Value:**

wrappers/JdbcInterface

- **Introduced:** Connect 1.05.0001, [MariaDB 10.2.4](#)

---

connect\_json\_all\_path

- **Description:** Discovery to generate json path for all columns if ON (the default) or do not when the path is the column name.

- **Commandline:**

```
--connect-json-all-path={0|1}
```

- **Scope:** Global, Session

- **Dynamic:** Yes

- **Data Type:**

numeric

- **Data Type:**

boolean

- **Default Value:**

ON

- **Introduced:** [MariaDB 10.5.7](#) , [MariaDB 10.4.16](#) , [MariaDB 10.3.26](#) , [MariaDB 10.2.35](#)

---

connect\_json\_grp\_size

- **Description:** Max number of rows for JSON aggregate functions.

- **Commandline:**

```
--connect-json-grp-size=#
```

- **Scope:** Global, Session

- **Dynamic:** Yes

- **Data Type:**

numeric

- **Default Value:**

50

```
(>= Connect 1.7.0003),  
10  
(<= Connect 1.7.0002)  
• Range:  
1  
to  
2147483647
```

---

### connect\_json\_null

- **Description:** Representation of JSON null values.

- **Commandline:**

```
--connect-json-null=value
```

- **Scope:** Global, Session

- **Dynamic:** Yes

- **Data Type:**

```
string
```

- **Default Value:**

```
<null>
```

- **Introduced:** MariaDB 10.2.8
- 

### connect\_jvm\_path

- **Description:** Path to JVM library.

- **Commandline:**

```
--connect-jvm_path=value
```

- **Scope:** Global

- **Dynamic:**

- **Data Type:**

```
string
```

- **Default Value:**

- **Introduced:** Connect 1.04.0006
- 

### connect\_type\_conv

- **Description:** Determines the handling of TEXT columns.

```
◦
```

```
NO
```

: The default until Connect 1.06.005, no conversion takes place, and a TYPE\_ERROR is returned, resulting in a "not supported" message.

```
◦
```

```
YES
```

: The default from Connect 1.06.006. The column is internally converted to a column declared as VARCHAR(n), n being the value of connect\_conv\_size .

```
◦
```

```
FORCE
```

(>= Connect 1.06.006): Also convert ODBC blob columns to TYPE\_STRING.

```
◦
```

```
SKIP
```

: No conversion. When the column declaration is provided via Discovery (meaning the CONNECT table is created without a column description), this column is not generated. Also applies to ODBC tables.

- **Commandline:**

```
--connect-type-conv=#
```

- **Scope:** Global, Session

- **Dynamic:** Yes

- **Data Type:**

enum

- **Valid Values:**

NO

,

YES

,

FORCE

or

SKIP

- **Default Value:**

YES

---

## connect\_use\_tempfile

- **Description:**

◦

NO

: The first algorithm is always used. Because it can cause errors when updating variable record length tables, this value should be set only for testing.

◦

AUTO

: This is the default value. It leaves CONNECT to choose the algorithm to use. Currently it is equivalent to

NO

, except when updating variable record length tables ( [DOS](#) , [CSV](#) or [FMT](#) ) with file mapping forced to OFF.

◦

YES

: Using a temporary file is chosen with some exceptions. These are when file mapping is ON, for [VEC](#) tables and when deleting from [DBF](#) tables (soft delete). For variable record length tables, file mapping is forced to OFF.

◦

FORCE

: Like YES but forces file mapping to be OFF for all table types.

◦

TEST

: Reserved for CONNECT development.

- **Commandline:**

--connect-use-tempfile=#

- **Scope:** Session

- **Dynamic:** Yes

- **Data Type:**

enum

- **Default Value:**

AUTO

---

## connect\_work\_size

- **Description:** Size of the CONNECT work area used for memory allocation. Permits allocating a larger memory sub-allocation space when dealing with very large if sub-allocation fails. If the specified value is too big and memory allocation fails, the size of the work area remains but the variable value is not modified and should be reset.

- **Commandline:**

--connect-work-size=#

- **Scope:** Global, Session (Session-only from CONNECT 1.03.005)

- **Dynamic:** Yes

- **Data Type:**

numeric

- **Default Value:**

67108864

- **Range:**

4194304

upwards, depending on the physical memory size

---

connect\_xtrace

- **Description:** Console trace value. Set to

0

(no trace), or to other values if a console tracing is desired. Note that to test this handler, MariaDB should be executed with the `--console` parameter because CONNECT prints some error and trace messages on the console. In some Linux versions, this is re-routed into the error log file. Console tracing can be set on the command line or later by names or values. Valid values (from Connect 1.06.006) include:

◦

0

: No trace

◦

YES

or

1

: Basic trace

◦

MORE

or

2

: More tracing

◦

INDEX

or

4

: Index construction

◦

MEMORY

or

8

: Allocating and freeing memory

◦

SUBALLOC

or

16

: Sub-allocating in work area

◦

QUERY

or

32

: Constructed query sent to external server

◦

STMT

or

64

: Currently executing statement

◦

HANDLER

or

128

: Creating and dropping CONNECT handlers

◦

BLOCK

or

256

: Creating and dropping CONNECT objects

◦

MONGO

or

512

: Mongo and REST (from Connect 1.06.0010 ) tracing

- For example:

◦

`set global connect_xtrace=0;`

```

No trace

o
    set global connect_xtrace='YES';

By name

o
    set global connect_xtrace=1;

By value

o
    set global connect_xtrace='QUERY,STMT';

By name

o
    set global connect_xtrace=96;

By value

o
    set global connect_xtrace=1023;

Trace all

```

- **Commandline:**

--connect-xtrace=#

- **Scope:** Global
- **Dynamic:** Yes
- **Data Type:**

set

- **Default Value:**

0

- **Valid Values:** See description

                }
            ]
        }
    ]
}
]
```

## OEM example

This is an example showing how an OEM table can be implemented. It is out of the scope of this document to explain how it works and to be a full guide on writing OEM tables for CONNECT.

The header File tabfic.h:

```
// TABFIC.H      Olivier Bertrand    2008-2010
// External table type to read FIC files

#define TYPE_AM_FIC  (AMT)129

typedef class FICDEF *PFICDEF;
typedef class TDBFIC *PTDBFIC;
typedef class FICCOL *PFICCOL;

/* ----- FIC classes ----- */

/***
/* FIC: OEM table to read FIC files.          */
/**/

/***
/* This function is exported from the Tabfic.dll   */
/**/

extern "C" PTABDEF __stdcall GetFIC(PGLOBAL g, void *memp);

/***
/* FIC table definition class.                  */
/**/

class FICDEF : public DOSDEF {           /* Logical table description */
public:
    friend class TDBFIC;
    // Constructor
    FICDEF(void) {Pseudo = 3;}

    // Implementation
    virtual const char *GetType(void) {return "FIC";}

    // Methods
    virtual BOOL DefineAM(PGLOBAL g, LPCSTR am, int poff);
    virtual PTDB GetTable(PGLOBAL g, MODE m);

protected:
    // No Members
}; // end of class FICDEF

/***
/* This is the class declaration for the FIC table. */
/**/

class TDBFIC : public TDBFIX {
public:
    friend class FICCOL;
    // Constructor
    TDBFIC(PFICDEF tdp);

    // Implementation
    virtual AMT GetAmType(void) {return TYPE_AM_FIC;}

    // Methods
    virtual void ResetDB(void);
    virtual int RowNumber(PGLOBAL g, BOOL b = FALSE);

    // Database routines
    virtual PCOL MakeCol(PGLOBAL g, PCOLDEF cdp, PCOL cprec, int n);
    virtual BOOL OpenDB(PGLOBAL g, PSQL sqlp);
    virtual int ReadDB(PGLOBAL g);
    virtual int WriteDB(PGLOBAL g);
    virtual int DeleteDB(PGLOBAL g, int irc);

protected:
    // Members
    int ReadMode;      // To read soft deleted lines
    int Rows;           // Used for RowID
}; // end of class TDBFIC

/***
/* Class FICCOL: for Monetary columns.          */
/**/

class FICCOL : public DOSCOL {
public:
    // Constructors
    FICCOL(PGLOBAL g, PCOLDEF cd, PTDB tdp, int n)
```

```

FICCOL(PGLOBAL g, PCOLDEF cdp, PTDB tdp,
       PCOL cprec, int i, PSZ am = "FIC");

// Implementation
virtual int GetAmType(void) {return TYPE_AM_FIC;}

// Methods
virtual void ReadColumn(PGLOBAL g);

protected:
    // Members
    char Fmt;           // The column format
}; // end of class FICCOL

```

## tabfic.cpp

The source File tabfic.cpp:

```

/**
 * FIC: OEM table to read FIC files.                                     */

} // end of ReadColumn

```

## tabfic.def

The file tabfic.def: (required only on Windows)

```

LIBRARY      TABFIC
DESCRIPTION 'FIC files'
EXPORTS
    GetFIC      @1

```

## JSON UDFs in a separate library

Although the JSON UDF's can be nicely included in the CONNECT library module, there are cases when you may need to have them in a separate library.

This is when CONNECT is compiled embedded, or if you want to test or use these UDF's with other MariaDB versions not including them.

To make it, you need to have access to the last MariaDB source code. Then, make a project containing these files:

1. jsonudf.cpp
2. json.cpp
3. value.cpp
4. osutil.c
5. plugutil.c
6. maputil.cpp
7. jsonutil.cpp

jsonutil.cpp is not distributed with the source code, you will have to make it from the following:

```

#include "my_global.h"
#include "mysqld.h"
#include "plugin.h"
#include <stdlib.h>
#include <string.h>
#include <stdio.h>
#include <errno.h>

#include "global.h"

extern "C" int GetTraceValue(void) { return 0; }
uint GetJsonGrpSize(void) { return 100; }

/***/
/* These replace missing function of the (not used) DTVAL class. */
/***/
typedef struct _datpar *PDTp;
PDTp MakeDateFormat(PGLOBAL, PSZ, bool, bool, int) { return NULL; }
int ExtractDate(char*, PDTp, int, int val[6]) { return 0; }

#ifndef __WIN__
my_bool CloseFileHandle(HANDLE h)
{
    return !CloseHandle(h);
} /* end of CloseFileHandle */

#else /* UNIX */
my_bool CloseFileHandle(HANDLE h)
{
    return (close(h)) ? TRUE : FALSE;
} /* end of CloseFileHandle */

int GetLastError()
{
    return errno;
} /* end of GetLastError */

#endif // UNIX

/***/
/* Program for sub-allocating one item in a storage area. */
/* Note: This function is equivalent to PlugSubAlloc except that in */
/* case of insufficient memory, it returns NULL instead of doing a */
/* long jump. The caller must test the return value for error. */
/***/
void *PlgDBSubAlloc(PGLOBAL g, void *memp, size_t size)
{
    PPOOLHEADER pph;           // Points on area header.

    if (!memp) // Allocation is to be done in the Sarea
        memp = g->Sarea;

    size = ((size + 7) / 8) * 8; /* Round up size to multiple of 8 */
    pph = (PPOOLHEADER)memp;

    if ((uint)size > pph->FreeBlk) { /* Not enough memory left in pool */
        sprintf(g->Message,
            "Not enough memory in Work area for request of %d (used=%d free=%d)",
            (int)size, pph->To_Free, pph->FreeBlk);
        return NULL;
    } // endif size

    // Do the suballocation the simplest way
    memp = MakePtr(memp, pph->To_Free); // Points to sub_allocated block
    pph->To_Free += size;               // New offset of pool free block
    pph->FreeBlk -= size;              // New size of pool free block

    return (memp);
} // end of PlgDBSubAlloc

```

You can create the file by copy/paste from the above.

Set all the additional include directories to the MariaDB include directories used in plugin compiling plus the reference of the storage/connect directories, and compile like any other UDF giving any name to the made library module (I used jsonudf.dll on Windows)

Then you can create the functions using this name as the soname parameter.

There are some restrictions when using the UDF's this way:

- The connect\_json\_grp\_size variable cannot be accessed. The group size is set to 100.
- In case of error, warnings are replaced by messages sent to stderr.
- No trace.

## 4.3.8 CSV

### 4.3.8.1 CSV Overview

#### Contents

1. [The CSV storage engine and logging to tables](#)
2. [CSV Storage Engine files](#)
3. [Limitations](#)
4. [Examples](#)
5. [See Also](#)

The CSV Storage Engine can read and append to files stored in CSV (comma-separated-values) format.

However, since [MariaDB 10.0](#), a better storage engine is able to read and write such files: [CONNECT](#).

## The CSV storage engine and logging to tables

The CSV storage engine is the default storage engine when using [logging of SQL queries](#) to tables.

```
mysqld --log-output=table
```

## CSV Storage Engine files

When you create a table using the CSV storage engine, three files are created:

- `<table_name>.frm`
- `<table_name>.CSV`
- `<table_name>.CSM`

The

`.frm`  
file is the table format file.

The

`.CSV`  
file is a plain text file. Data you enter into the table is stored as plain text in comma-separated-values format.

The

`.CSM`  
file stores metadata about the table such as the state and the number of rows in the table.

## Limitations

- CSV tables do not support indexing.
- CSV tables cannot be partitioned.
- Columns in CSV tables must be declared as NOT NULL.
- No [transactions](#).
- The original CSV-format does not enable IETF-compatible parsing of embedded quote and comma characters. From [MariaDB 10.1.8](#), it is possible to do so by setting the [IETF\\_QUOTES](#) option when creating a table.

## Examples

Forgetting to add NOT NULL:

```
CREATE TABLE csv_test (x INT, y DATE, z CHAR(10)) ENGINE=CSV;
ERROR 1178 (42000): The storage engine for the table doesn't support nullable columns
```

Creating, inserting and selecting:

```
CREATE TABLE csv_test (
  x INT NOT NULL, y DATE NOT NULL, z CHAR(10) NOT NULL
) ENGINE=CSV;
```

```
INSERT INTO csv_test VALUES
(1,CURDATE(),'one'),
(2,CURDATE(),'two'),
(3,CURDATE(),'three');
```

```
SELECT * FROM csv_test;
+---+-----+-----+
| x | y      | z      |
+---+-----+-----+
| 1 | 2011-11-16 | one   |
| 2 | 2011-11-16 | two   |
| 3 | 2011-11-16 | three |
+---+-----+-----+
```

Viewing in a text editor:

```
$ cat csv_test.CSV
1,"2011-11-16","one"
2,"2011-11-16","two"
3,"2011-11-16","three"
```

## See Also

- [Checking and Repairing CSV Tables](#)

### 4.3.8.2 Checking and Repairing CSV Tables

CSV tables support the [CHECK TABLE](#) and [REPAIR TABLE](#) statements.

CHECK TABLE will mark the table as corrupt if it finds a problem, while REPAIR TABLE will restore rows until the first corrupted row, discarding the rest.

## Examples

```
CREATE TABLE csv_test (
  x INT NOT NULL, y DATE NOT NULL, z CHAR(10) NOT NULL
) ENGINE=CSV;

INSERT INTO csv_test VALUES
(1,CURDATE(),'one'),
(2,CURDATE(),'two'),
(3,CURDATE(),'three');
```

```
SELECT * FROM csv_test;
+---+-----+-----+
| x | y      | z      |
+---+-----+-----+
| 1 | 2013-07-08 | one   |
| 2 | 2013-07-08 | two   |
| 3 | 2013-07-08 | three |
+---+-----+-----+
```

Using an editor, the actual file will look as follows

```
$ cat csv_test.CSV
1,"2013-07-08","one"
2,"2013-07-08","two"
3,"2013-07-08","three"
```

Let's introduce some corruption with an unwanted quote in the 2nd row:

```
1,"2013-07-08","one"
2,"2013-07-08","two"
3,"2013-07-08","three"
```

```
CHECK TABLE csv_test;
+-----+-----+-----+
| Table | Op   | Msg_type | Msg_text |
+-----+-----+-----+
| test.csv_test | check | error    | Corrupt  |
+-----+-----+-----+
```

We can repair this, but all rows from the corrupt row onwards will be lost:

```
REPAIR TABLE csv_test;
+-----+-----+-----+
| Table | Op   | Msg_type | Msg_text |
+-----+-----+-----+
| test.csv_test | repair | Warning  | Data truncated for column 'x' at row 2 |
| test.csv_test | repair | status   | OK        |
+-----+-----+-----+

SELECT * FROM csv_test;
+---+---+
| x | y      | z   |
+---+---+
| 1 | 2013-07-08 | one |
+---+---+
```

## 4.3.9 FederatedX

### 4.3.9.1 About FederatedX

MariaDB starting with [5.1](#)

The FederatedX storage engine was first released in [MariaDB 5.1](#).

The FederatedX storage engine is a fork of MySQL's [Federated storage engine](#), which is no longer being developed by Oracle. The original purpose of FederatedX was to keep this storage engine's development progressing-- to both add new features as well as fix old bugs.

Since [MariaDB 10.0](#), the `CONNECT` storage engine also allows access to a remote database via MySQL or ODBC connection (table types: [MYSQL](#), [ODBC](#)). However, in the current implementation there are several limitations.

  1. [What are the plans for FederatedX?](#)

## What is the FederatedX storage engine?

The FederatedX Storage Engine is a storage engine that works with both MariaDB and MySQL. Where other storage engines are built as interfaces to lower-level file-based data stores, FederatedX uses libmysql to talk to the data source, the data source being a remote RDBMS. Currently, since FederatedX only uses libmysql, it can only talk to another MySQL RDBMS. The plan is of course to be able to use other RDBMS systems as a data

source. There is an existing project Federated ODBC which was able to use PostgreSQL as a remote data source, and it is this type of functionality which will be brought to FederatedX in subsequent versions.

## History

The history of FederatedX is derived from the History of Federated. Cisco needed a MySQL storage engine that would allow them to consolidate remote tables on some sort of routing device, being able to interact with these remote tables as if they were local to the device, but not actually on the device, since the routing device had only so much storage space. The first prototype of the Federated Storage Engine was developed by JD (need to check on this- Brian Aker can verify) using the HANDLER interface. Brian handed the code to Patrick Galbraith and explained how it needed to work, and with Brian and Monty's tutelage and Patrick had a working Federated Storage Engine with MySQL 5.0. Eventually, Federated was released to the public in a MySQL 5.0 release.

When MySQL 5.1 became the production release of MySQL, Federated had more features and enhancements added to it, namely:

- New Federated SERVER added to the parser. This was something Cisco needed that made it possible to change the connection parameters for numerous Federated tables at once without having to alter or re-create the Federated tables.
- Basic Transactional support-- for supporting remote transactional tables
- Various bugs that needed to be fixed from MySQL 5.0
- Plugin capability

In [MariaDB 10.0.2](#) FederatedX got support for assisted [table discovery](#).

## Installing the Plugin

Although the plugin's shared library is distributed with MariaDB by default, the plugin is not actually installed by MariaDB by default. There are two methods that can be used to install the plugin with MariaDB.

The first method can be used to install the plugin without restarting the server. You can install the plugin dynamically by executing

```
INSTALL SONAME
```

or

```
INSTALL PLUGIN
```

. For example:

```
INSTALL SONAME 'ha_federatedx';
```

The second method can be used to tell the server to load the plugin when it starts up. The plugin can be installed this way by providing the

```
--plugin-load
```

or the

```
--plugin-load-add
```

options. This can be specified as a command-line argument to

```
mysqld
```

or it can be specified in a relevant server [option group](#) in an [option file](#). For example:

```
[mariadb]
...
plugin_load_add = ha_federatedx
```

## Uninstalling the Plugin

You can uninstall the plugin dynamically by executing

```
UNINSTALL SONAME
```

or

```
UNINSTALL PLUGIN
```

. For example:

```
UNINSTALL SONAME 'ha_federatedx';
```

If you installed the plugin by providing the

```
--plugin-load
```

or the

```
--plugin-load-add
```

options in a relevant server [option group](#) in an [option file](#), then those options should be removed to prevent the plugin from being loaded the next time the server is restarted.

## How FederatedX works

Every storage engine has to implement derived standard handler class API methods for a storage engine to work. FederatedX is no different in that regard. The big difference is that FederatedX needs to implement these handler methods in such as to construct SQL statements to run on the remote server and if there is a result set, process that result set into the internal handler format so that the result is returned to the user.

### Internal workings of FederatedX

Normal database files are local and as such: You create a table called 'users', a file such as 'users.MYD' is created. A handler reads, inserts, deletes, updates data in this file. The data is stored in particular format, so to read, that data has to be parsed into fields, to write, fields have to be stored in this format to write to this data file.

With the FederatedX storage engine, there will be no local files for each table's data (such as .MYD). A foreign database will store the data that would normally be in this file. This will necessitate the use of MySQL client API to read, delete, update, insert this data. The data will have to be retrieved via an SQL call "

```
SELECT
```

```
*
```

```
FROM
```

```
users
```

". Then, to read this data, it will have to be retrieved via

```
mysql_fetch_row
```

one row at a time, then converted from the column in this select into the format that the handler expects.

The basic functionality of how FederatedX works is:

- The user issues an SQL statement against the local federatedX table. This statement is parsed into an item tree
- FederatedX uses the mysql handler API to implement the various methods required for a storage engine. It has access to the item tree for the SQL statement issued, as well as the Table object and each of its Field members. At
- With this information, FederatedX constructs an SQL statement
- The constructed SQL statement is sent to the Foreign data source through libmysql using the mysql client API
- The foreign database reads the SQL statement and sends the result back through the mysql client API to the origin
- If the original SQL statement has a result set from the foreign data source, the FederatedX storage engine iterates through the result set and converts each row and column to the internal handler format
- If the original SQL statement only returns the number of rows returned (affected\_rows), that number is added to the table stats which results in the user seeing how many rows were affected.

### FederatedX table creation

The create table will simply create the .frm file, and within the

```
CREATE
```

```
TABLE
```

SQL statement, there SHALL be any of the following :

```
connection=scheme://username:password@hostname:port/database tablename  
connection=scheme://username@hostname/database tablename  
connection=scheme://username:password@hostname/database tablename  
connection=scheme://username:password@hostname/database tablename
```

Or using the syntax introduced in MySQL versions 5.1 for a Federated server (SQL/MED Spec xxxx)

```
connection="connection_one"  
connection="connection_one/table_foo"
```

An example of a connect string specifying all the connection parameters would be:

```
connection=mysql://username:password@hostname:port/database tablename
```

Or, using a Federated server, first a server is created:

```
create server 'server_one' foreign data wrapper 'mysql' options  
(HOST '127.0.0.1',  
DATABASE 'db1',  
USER 'root',  
PASSWORD '',  
PORT 3306,  
SOCKET '',  
OWNER 'root');
```

Then the FederatedX table is created specifying the newly created Federated server:

```
CREATE TABLE federatedx.t1 (  
`id` int(20) NOT NULL,  
`name` varchar(64) NOT NULL default ''  
)  
ENGINE="FEDERATED" DEFAULT CHARSET=latin1  
CONNECTION='server_one';
```

(Note that in MariaDB, the original Federated storage engine is replaced with the new FederatedX storage engine. And for backward compatibility, the old name "FEDERATED" is used in create table. So in MariaDB, the engine type should be given as "FEDERATED" without an extra "X", not "FEDERATEDX").

The equivalent of above, if done specifying all the connection parameters

```
CONNECTION="mysql://root@127.0.0.1:3306/db1/t1"
```

You can also change the server to point to a new schema:

```
ALTER SERVER 'server_one' options(DATABASE 'db2');
```

All subsequent calls to any FederatedX table using the 'server\_one' will now be against db2.t1! Guess what? You no longer have to perform an alter table in order to point one or more FederatedX tables to a new server!

This

```
connection="connection string"  
is necessary for the handler to be able to connect to the foreign server, either by URL, or by server name.
```

## Method calls

One way to see how the FederatedX storage engine works is to compile a debug build of MariaDB and turn on a trace log. Using a two column table, with one record, the following SQL statements shown below, can be analyzed for what internal methods they result in being called.

**SELECT**

If the query is for instance "

```
SELECT
```

```
*
```

```
FROM
```

```
foo
```

", then the primary methods you would see with debug turned on would be first:

```
ha_federatedx::info
ha_federatedx::scan_time:
ha_federatedx::rnd_init: share->select_query SELECT * FROM foo
ha_federatedx::extra
```

Then for every row of data retrieved from the foreign database in the result set:

```
ha_federatedx::rnd_next
ha_federatedx::convert_row_to_internal_format
ha_federatedx::rnd_next
```

After all the rows of data that were retrieved, you would see:

```
ha_federatedx::rnd_end
ha_federatedx::extra
ha_federatedx::reset
```

## INSERT

If the query was "

```
INSERT
```

```
INTO
```

```
foo
```

```
(
```

```
id
```

```
,
```

```
ts
```

```
)
```

```
VALUES
```

```
(
```

```
2
```

```
,
```

```
now
```

```
());
```

", the trace would be:

```
ha_federatedx::write_row  
ha_federatedx::reset
```

## UPDATE

If the query was "

```
UPDATE
```

```
    foo
```

```
    SET
```

```
        ts
```

```
        =
```

```
        now
```

```
    ()
```

```
WHERE
```

```
    id
```

```
    =
```

```
    1
```

```
;
```

", the resultant trace would be:

```
ha_federatedx::index_init  
ha_federatedx::index_read  
ha_federatedx::index_read_idx  
ha_federatedx::rnd_next  
ha_federatedx::convert_row_to_internal_format  
ha_federatedx::update_row  
  
ha_federatedx::extra  
ha_federatedx::extra  
ha_federatedx::extra  
ha_federatedx::external_lock  
ha_federatedx::reset
```

## FederatedX capabilities and limitations

- Tables MUST be created on the foreign server prior to any action on those tables via the handler, first version. IMPORTANT: IF you MUST use the FederatedX storage engine type on the REMOTE end, make sure that the table you connect to IS NOT a table pointing BACK to your ORIGINAL table! You know and have heard the screeching of audio feedback? You know putting two mirrors in front of each other how the reflection continues for eternity? Well, need I say more?!
- There is no way for the handler to know if the foreign database or table has changed. The reason for this is that this database has to work like a data file that would never be written to by anything other than the database. The integrity of the data in the local table could be breached if there was any change to the foreign database.
- Support for SELECT, INSERT, UPDATE, DELETE indexes.
- No ALTER TABLE, DROP TABLE or any other Data Definition Language calls.
- Prepared statements will not be used in the first implementation, it remains to be seen whether the limited subset of the client API for the server

supports this.

- This uses SELECT, INSERT, UPDATE, DELETE and not HANDLER for its implementation.
- This will not work with the query cache.

## How do you use FederatedX?

To use this handler, it's very simple. You must have two databases running, either both on the same host, or on different hosts.

First, on the foreign database you create a table, for example:

```
CREATE TABLE test_table (
    id      int(20) NOT NULL auto_increment,
    name    varchar(32) NOT NULL default '',
    other   int(20) NOT NULL default '0',
    PRIMARY KEY (id),
    KEY name (name),
    KEY other_key (other)
) ENGINE=InnoDB DEFAULT CHARSET=latin1;
```

Then, on the server that will be connecting to the foreign host (client), you create a federated table without specifying the table structure:

```
CREATE TABLE test_table ENGINE=FEDERATED CONNECTION='mysql://root@127.0.0.1:9306/federatedx/test_federatedx';
```

Notice the "ENGINE" and "CONNECTION" fields? This is where you respectively set the engine type, "FEDERATED" and foreign host information, this being the database your 'client' database will connect to and use as the "data file". Obviously, the foreign database is running on port 9306, so you want to start up your other database so that it is indeed on port 9306, and your FederatedX database on a port other than that. In my setup, I use port 5554 for FederatedX, and port 5555 for the foreign database.

Alternatively (or if you're using MariaDB before version 10.0.2) you specify the federated table structure explicitly:

```
CREATE TABLE test_table (
    id      int(20) NOT NULL auto_increment,
    name    varchar(32) NOT NULL default '',
    other   int(20) NOT NULL default '0',
    PRIMARY KEY (id),
    KEY name (name),
    KEY other_key (other)
) ENGINE=FEDERATED
DEFAULT CHARSET=latin1
CONNECTION='mysql://root@127.0.0.1:9306/federatedx/test_federatedx';
```

In this case the table structure must match exactly the table on the foreign server.

## How to see the storage engine in action

When developing this handler, I compiled the FederatedX database with debugging:

```
./configure --with-federatedx-storage-engine \
--prefix=/home/mysql/mysql-build/federatedx/ --with-debug
```

Once compiled, I did a 'make install' (not for the purpose of installing the binary, but to install all the files the binary expects to see in the directory I specified in the build with

```
--prefix=/home/code-dev/maria
```

Then, I started the foreign server:

```
/usr/local/mysql/bin/mysqld_safe \
--user=mysql --log=/tmp/mysqld.5555.log -P 5555
```

Then, I went back to the directory containing the newly compiled mysqld

```
<builddir>/sql/
, started up gdb:
```

```
gdb ./mysqld
```

Then, within the (gdb) prompt:

```
(gdb) run --gdb --port=5554 --socket=/tmp/mysqld.5554 --skip-innodb --debug
```

Next, I open several windows for each:

1. Tail the debug trace: tail -f /tmp/mysql.trace|grep ha\_fed
2. Tail the SQL calls to the foreign database: tail -f /tmp/mysql.5555.log
3. A window with a client open to the federatedx server on port 5554
4. A window with a client open to the federatedx server on port 5555

I would create a table on the client to the foreign server on port 5555, and then to the FederatedX server on port 5554. At this point, I would run whatever queries I wanted to on the FederatedX server, just always remembering that whatever changes I wanted to make on the table, or if I created new tables, that I would have to do that on the foreign server.

Another thing to look for is 'show variables' to show you that you have support for FederatedX handler support:

```
show variables like '%federat%'
```

and:

```
show storage engines;
```

Both should display the federatedx storage handler.

## How do I create a federated server?

A federated server is a way to have a foreign data source defined-- with all connection parameters-- so that you don't have to specify explicitly the connection parameters in a string.

For instance, say if you wanted to create a table, t1, that you would specify with

```
connection="mysql://patg@192.168.1.123/first_db/t1"
```

You could instead create this with a server:

```
create server 'server_one' foreign data wrapper 'mysql' options
(HOST '192.168.1.123',
DATABASE 'first_db',
USER 'patg',
PASSWORD '',
PORT 3306,
SOCKET '',
OWNER 'root');
```

You could now instead specify the server instead of the full URL connection string

```
connect="server_one"
```

## How does FederatedX differ from the old Federated Engine?

FederatedX from a user point of view is the same for the most part. What is different with FederatedX and Federated is the following:

- Rewrite of the main Federated source code from one single ha\_federated.cc file into three main abstracted components:
  - ha\_federatedx.cc - Core implementation of FederatedX
  - federated\_io.cc - Parent connection class to be over-written by derived classes for each RDBMS/client lib
  - federated\_io\_<driver>.cc - derived federated\_io class for a given RDBMS
  - federated\_txn.cc - New support for using transactional engines on the foreign server using a connection poll
- Various bugs fixed (need to look at opened bugs for Federated)

## Where can I get FederatedX

FederatedX is part of [MariaDB 5.1](#) and later. MariaDB merged with the latest FederatedX when there is a need to get a bug fixed. You can get the latest code/follow/participate in the project from the [FederatedX home page](#).

## What are the plans for FederatedX?

- Support for other RDBMS vendors using ODBC
- Support for pushdown conditions
- Ability to limit result set sizes

## 4.3.9.2 Differences Between FederatedX and Federated

The main differences are:

# New features in FederatedX

- Transactions (beta feature)
- Supports partitions (alpha feature)
- New class structure which allows developers to write connection classes for other RDBMSs without having to modify base classes for FederatedX
- Actively developed!

## Different behavior

- FederatedX is statically compiled into MariaDB by default.
- When you create a table with FederatedX, the connection will be tested. The

CREATE  
will fail if MariaDB can't connect to the remote host or if the remote table doesn't exist.

## 4.3.10 MEMORY Storage Engine

### Contents

1. [Index Type](#)
2. [See Also](#)
3. [Example](#)

Contents of the MEMORY storage engine (previously known as HEAP) are stored in memory rather than on disk.

It is best-used for read-only caches of data from other tables, or for temporary work areas.

Since the data is stored in memory, it is highly vulnerable to power outages or hardware failure, and is unsuitable for permanent data storage. In fact, after a server restart,

MEMORY

tables will be recreated (because the definition file is stored on disk), but they will be empty. It is possible to re-populate them with a query using the

--init-file

server startup option.

Variable-length types like

VARCHAR

can be used in MEMORY tables.

BLOB

or

TEXT

columns are not supported for MEMORY tables.

The maximum total size of MEMORY tables cannot exceed the

max\_heap\_table\_size

system server variable. When a table is created this value applies to that table, and when the server is restarted this value applies to existing tables. Changing this value has no effect on existing tables. However, executing a

ALTER TABLE ... ENGINE=MEMORY

statement applies the current value of

max\_heap\_table\_size

to the table. Also, it is possible to change the session value of

max\_heap\_table\_size

before creating a table, to make sure that tables created by other sessions are not affected.

The

MAX\_ROWS

table option provides a hint about the number of rows you plan to store in them. This is not a hard limit that cannot be exceeded, and does not allow to exceed

max\_heap\_table\_size

. The storage engine uses max\_heap\_table\_size and MAX\_ROWS to calculate the maximum memory that could be allocated for the table.

When rows are deleted, space is not automatically freed. The only way to free space without dropping the table is using

ALTER TABLE tbl\_name ENGINE = MEMORY

TRUNCATE TABLE

frees the memory too.

## Index Type

The MEMORY storage engine permits indexes to be either B-tree or Hash. Hash is the default type for MEMORY. See [Storage Engine index types](#) for more on their characteristics.

A MEMORY table can have up to 64 indexes, 16 columns for each index and a maximum key length of 3072 bytes.

## See Also

- [Performance of MEMORY tables](#)

## Example

The following example shows how to create a

MEMORY  
table with a given maximum size, as described above.

```
SET max_heap_table_size = 1024*516;  
  
CREATE TABLE t (a VARCHAR(10), b INT) ENGINE = MEMORY;  
  
SET max_heap_table_size = @@max_heap_table_size;
```

## 4.3.11 MERGE

### Contents

1. [Description](#)
2. [Examples](#)

## Description

The MERGE storage engine, also known as the MRG\_MyISAM engine, is a collection of identical MyISAM tables that can be used as one. "Identical" means that all tables have identical column and index information. You cannot merge MyISAM tables in which the columns are listed in a different order, do not have exactly the same columns, or have the indexes in different order. However, any or all of the MyISAM tables can be compressed with [myisampack](#). Column names and indexes names can be different, as long as data types and NULL/NOT NULL clauses are the same. Differences in table options such as AVG\_ROW\_LENGTH, MAX\_ROWS, or PACK\_KEYS do not matter.

Each index in a MERGE table must match an index in underlying MyISAM tables, but the opposite is not true. Also, a MERGE table cannot have a PRIMARY KEY or UNIQUE indexes, because it cannot enforce uniqueness over all underlying tables.

The following options are meaningful for MERGE tables:

- UNION  
. This option specifies the list of the underlying MyISAM tables. The list is enclosed between parentheses and separated with commas.
- INSERT\_METHOD  
. This option specifies whether, and how, INSERTs are allowed for the table. Allowed values are:  
NO  
(INSERTs are not allowed),  
FIRST  
(new rows will be written into the first table specified in the  
UNION  
list),  
LAST  
(new rows will be written into the last table specified in the  
UNION  
list). The default value is  
NO

If you define a MERGE table with a definition which is different from the underlying MyISAM tables, or one of the underlying tables is not MyISAM, the CREATE TABLE statement will not return any error. But any statement which involves the table will produce an error like the following:

```
ERROR 1168 (HY000): Unable to open underlying table which is differently defined  
or of non-MyISAM type or doesn't exist
```

CHECK TABLE

will show more information about the problem.

The error is also produced if the table is properly defined, but an underlying table's definition changes at some point in time.

If you try to insert a new row into a MERGE table with INSERT\_METHOD=NO, you will get an error like the following:

```
ERROR 1036 (HY000): Table 'tbl_name' is read only
```

It is possible to build a MERGE table on MyISAM tables which have one or more [virtual columns](#). MERGE itself does not support virtual columns, thus such columns will be seen as regular columns. The data types and sizes will still need to be identical, and they cannot be NOT NULL.

## Examples

```
CREATE TABLE t1 (
    a INT NOT NULL AUTO_INCREMENT PRIMARY KEY,
    message CHAR(20) ENGINE=MyISAM;

CREATE TABLE t2 (
    a INT NOT NULL AUTO_INCREMENT PRIMARY KEY,
    message CHAR(20) ENGINE=MyISAM;

INSERT INTO t1 (message) VALUES ('Testing'),('table'),('t1');

INSERT INTO t2 (message) VALUES ('Testing'),('table'),('t2');

CREATE TABLE total (
    a INT NOT NULL AUTO_INCREMENT,
    message CHAR(20), INDEX(a)
    ENGINE=MERGE UNION=(t1,t2) INSERT_METHOD=LAST;

SELECT * FROM total;
+-----+
| a | message |
+-----+
| 1 | Testing |
| 2 | table   |
| 3 | t1      |
| 1 | Testing |
| 2 | table   |
| 3 | t2      |
+-----+
```

In the following example, we'll create three MyISAM tables, and then a MERGE table on them. However, one of them uses a different data type for the column b, so a SELECT will produce an error:

```
CREATE TABLE t1 (
    a INT,
    b INT
) ENGINE = MyISAM;

CREATE TABLE t2 (
    a INT,
    b INT
) ENGINE = MyISAM;

CREATE TABLE t3 (
    a INT,
    b TINYINT
) ENGINE = MyISAM;

CREATE TABLE t_mrg (
    a INT,
    b INT
) ENGINE = MERGE,UNION=(t1,t2,t3);

SELECT * FROM t_mrg;
ERROR 1168 (HY000): Unable to open underlying table which is differently defined
or of non-MyISAM type or doesn't exist
```

To find out what's wrong, we'll use a CHECK TABLE:

CHECK TABLE t_mrg;			
Table	Op	Msg_type	Msg_text
test.t_mrg	check	Error	Table 'test.t3' is differently defined or of non-MyISAM type or doesn't exist
test.t_mrg	check	Error	Unable to open underlying table which is differently defined or of non-MyISAM type or doesn't
test.t_mrg	check	error	Corrupt

Now, we know that the problem is in

t3  
's definition.

## 4.3.12 Mroonga

### 4.3.12.1 About Mroonga

#### Contents

1. [How to Install](#)
2. [Limitations](#)
3. [Available Character Sets](#)
4. [More Information](#)

Mroonga Version	Introduced	Maturity
7.07	<a href="#">MariaDB 10.2.11</a> , <a href="#">MariaDB 10.1.29</a>	Stable
5.04	<a href="#">MariaDB 10.1.6</a>	Stable
5.02	<a href="#">MariaDB 10.0.18</a> , <a href="#">MariaDB 10.1.5</a>	Stable
5.0	<a href="#">MariaDB 10.0.17</a>	Stable
4.06	<a href="#">MariaDB 10.0.15</a>	Stable

Mroonga is a full text search storage engine based on Groonga, which is an open-source CJK-ready (Chinese, Japanese, and Korean) fulltext search engine using column base. See <http://groonga.org> for more.

With Mroonga, you can have a CJK-ready full text search feature, and it is faster than the [MyISAM](#) and [InnoDB full text search](#) for both updating and searching.

Mroonga also supports Groonga's fast geolocation search by using MariaDB's geolocation SQL syntax.

Mroonga currently only supports Linux x86\_64 (Intel64/AMD64).

## How to Install

Enable Mroonga with the following statement:

```
INSTALL SONAME 'ha_mroonga';
```

On Debian and Ubuntu mroonga engine will be installed with

```
sudo apt-get install mariadb-plugin-mroonga
```

See [Plugin overview](#) for details on installing and uninstalling plugins.

`SHOW ENGINES` can be used to check whether Mroonga is installed correctly:

```
SHOW ENGINES;
...
***** 8. row *****
  Engine: Mroonga
  Support: YES
  Comment: CJK-ready fulltext search, column store
Transactions: NO
      XA: NO
  Savepoints: NO
...
```

Once the plugin is installed, add a UDF (User-Defined Function) named "last\_insert\_grn\_id", that returns the record ID assigned by groonga in INSERT, by the following SQL.

```
mysql> CREATE FUNCTION last_insert_grn_id RETURNS INTEGER SONAME 'ha_mroonga.so';
```

## Limitations

- The maximum size of a single key is 4096 bytes.
- The maximum size of all keys is 4GB.
- The maximum number of records in a fulltext index is 268,435,455
- The maximum number of distinct terms in a fulltext index is 268,435,455
- The maximum size of a fulltext index is 256GB

Note that the maximum sizes are not hard limits, and may vary according to circumstance.

For more details, see <http://mroonga.org/docs/reference/limitations.html>.

## Available Character Sets

Mroonga supports a limited number of [character sets](#). These include:

- ASCII
- BINARY
- CP932
- EUCJPMS
- KOI8R
- LATIN1
- SJIS
- UJIS
- UTF8
- UTF8MB4

## More Information

Further documentation for Mroonga can be found at <http://mroonga.org/docs/>

### 4.3.12.2 Mroonga Overview

#### Contents

1. [Score](#)
2. [Parser](#)
  1. [Examples](#)
    1. [TokenBigram vs TokenBigramSplitSymbol](#)
    2. [TokenBigram vs TokenBigramSplitSymbolAlpha](#)

Once Mroonga has been installed (see [About Mroonga](#)), its basic usage is similar to that of a [regular fulltext index](#).

For example:

```
CREATE TABLE ft_mroonga(copy TEXT,FULLTEXT(copy)) ENGINE=Mroonga;

INSERT INTO ft_mroonga(copy) VALUES ('Once upon a time'),
('There was a wicked witch'), ('Who ate everybody up');

SELECT * FROM ft_mroonga WHERE MATCH(copy) AGAINST('wicked');
+-----+
| copy          |
+-----+
| There was a wicked witch |
+-----+
```

# Score

Mroonga can also order by weighting. For example, first add another record:

```
INSERT INTO ft_mroonga(copy) VALUES ('She met a wicked, wicked witch');
```

Records can be returned by weighting, for example, the newly added record has two occurrences of the word 'wicked' and a higher weighting:

```
SELECT *, MATCH(copy) AGAINST('wicked') AS score FROM ft_mroonga
  WHERE MATCH(copy) AGAINST('wicked') ORDER BY score DESC;
+-----+-----+
| copy           | score |
+-----+-----+
| She met a wicked, wicked witch | 299594 |
| There was a wicked witch      | 149797 |
+-----+-----+
```

# Parser

Mroonga permits you to set a different parser for searching by specifying the parser in the

```
CREATE TABLE
  statement as a comment or, in older versions, changing the value of the mroonga\_default\_parser system variable.
```

For example:

```
CREATE TABLE ft_mroonga(copy TEXT,FULLTEXT(copy) COMMENT 'parser "TokenDelimitNull"'
  ENGINE=Mroonga,;
```

or

```
SET GLOBAL mroonga_default_parser = 'TokenBigramSplitSymbol';
```

The following parser settings are available:

Setting	Description
off	No tokenizing is performed.
TokenBigram	Default value. Continuous alphabetical characters, numbers or symbols are treated as a token.
TokenBigramIgnoreBlank	Same as TokenBigram except that white spaces are ignored.
TokenBigramIgnoreBlankSplitSymbol	Same as TokenBigramSplitSymbol . except that white spaces are ignore.
TokenBigramIgnoreBlankSplitSymbolAlpha	Same as TokenBigramSplitSymbolAlpha except that white spaces are ignored.
TokenBigramIgnoreBlankSplitSymbolAlphaDigit	Same as TokenBigramSplitSymbolAlphaDigit except that white spaces are ignored.
TokenBigramSplitSymbol	Same as TokenBigram except that continuous symbols are not treated as a token, but tokenised in bigram.
TokenBigramSplitSymbolAlpha	Same as TokenBigram except that continuous alphabetical characters are not treated as a token, but tokenised in bigram.
TokenDelimit	Tokenises by splitting on white spaces.
TokenDelimitNull	Tokenises by splitting on null characters (\0).
TokenMecab	Tokenise using MeCab. Required Groonga to be built with MeCab support.
TokenTrigram	Tokenises in trigrams but continuous alphabetical characters, numbers or symbols are treated as a token.

TokenUnigram	Tokenises in unigrams but continuous alphabetical characters, numbers or symbols are treated as a token.
--------------	----------------------------------------------------------------------------------------------------------

## Examples

### TokenBigram vs TokenBigramSplitSymbol

```
TokenBigram
failing to match partial symbols which
TokenBigramSplitSymbol
matches, since
TokenBigramSplitSymbol
does not treat continuous symbols as a token.
```

```
DROP TABLE ft_mroonga;
CREATE TABLE ft_mroonga(copy TEXT,FULLTEXT(copy) COMMENT 'parser "TokenBigram"'
ENGINE=Mroonga;
INSERT INTO ft_mroonga(copy) VALUES ('Once upon a time'),
('There was a wicked witch'),
('Who ate everybody up'),
('She met a wicked, wicked witch'),
('A really wicked, wicked witch!!?!');
SELECT * FROM ft_mroonga WHERE MATCH(copy) AGAINST('!?');
Empty set (0.00 sec)

DROP TABLE ft_mroonga;
CREATE TABLE ft_mroonga(copy TEXT,FULLTEXT(copy) COMMENT 'parser "TokenBigramSplitSymbol"'
ENGINE=Mroonga;
INSERT INTO ft_mroonga(copy) VALUES ('Once upon a time'),
('There was a wicked witch'),
('Who ate everybody up'),
('She met a wicked, wicked witch'),
('A really wicked, wicked witch!!?!');
SELECT * FROM ft_mroonga WHERE MATCH(copy) AGAINST('!?');
+-----+
| copy           |
+-----+
| A really wicked, wicked witch!!?! |
+-----+
```

### TokenBigram vs TokenBigramSplitSymbolAlpha

```
DROP TABLE ft_mroonga;
CREATE TABLE ft_mroonga(copy TEXT,FULLTEXT(copy) COMMENT 'parser "TokenBigram"'
ENGINE=Mroonga;
INSERT INTO ft_mroonga(copy) VALUES ('Once upon a time'),
('There was a wicked witch'),
('Who ate everybody up'),
('She met a wicked, wicked witch'),
('A really wicked, wicked witch!!?!');
SELECT * FROM ft_mroonga WHERE MATCH(copy) AGAINST('ick');
Empty set (0.00 sec)

DROP TABLE ft_mroonga;
CREATE TABLE ft_mroonga(copy TEXT,FULLTEXT(copy) COMMENT 'parser "TokenBigramSplitSymbolAlpha"'
ENGINE=Mroonga;
INSERT INTO ft_mroonga(copy) VALUES ('Once upon a time'),
('There was a wicked witch'),
('Who ate everybody up'),
('She met a wicked, wicked witch'),
('A really wicked, wicked witch!!?!');
SELECT * FROM ft_mroonga WHERE MATCH(copy) AGAINST('ick');
+-----+
| copy           |
+-----+
| There was a wicked witch      |
| She met a wicked, wicked witch |
| A really wicked, wicked witch!!?! |
+-----+
```

## 4.3.12.3 Mroonga Status Variables

### Contents

1. [Mroonga\\_count\\_skip](#)
2. [Mroonga\\_fast\\_order\\_limit](#)

This page documents status variables related to the [Mroonga storage engine](#). See [Server Status Variables](#) for a complete list of status variables that can be viewed with `SHOW STATUS`.

#### Mroonga\_count\_skip

- **Description:** Incremented each time the 'fast line count feature' is used. Can be used to check if the feature is working after enabling it.
- **Data Type:**

numeric

---

#### Mroonga\_fast\_order\_limit

- **Description:** Incremented each time the 'fast ORDER BY LIMIT feature' is used. Can be used to check if the feature is working after enabling it.
- **Data Type:**

numeric

---

## 4.3.12.4 Mroonga System Variables

### Contents

1. [mroonga\\_action\\_on\\_fulltext\\_query\\_error](#)
2. [mroonga\\_boolean\\_mode\\_syntax\\_flags](#)
3. [mroonga\\_database\\_path\\_prefix](#)
4. [mroonga\\_default\\_parser](#)
5. [mroonga\\_default\\_tokenizer](#)
6. [mroonga\\_default\\_wrapper\\_engine](#)
7. [mroonga\\_dry\\_write](#)
8. [mroonga\\_enable\\_operations\\_recording](#)
9. [mroonga\\_enable\\_optimization](#)
10. [mroonga\\_libgroonga\\_embedded](#)
11. [mroonga\\_libgroonga\\_support\\_lz4](#)
12. [mroonga\\_libgroonga\\_support\\_zlib](#)
13. [mroonga\\_libgroonga\\_support\\_zstd](#)
14. [mroonga\\_libgroonga\\_version](#)
15. [mroonga\\_lock\\_timeout](#)
16. [mroonga\\_log\\_file](#)
17. [mroonga\\_log\\_level](#)
18. [mroonga\\_match\\_escalation\\_threshold](#)
19. [mroonga\\_max\\_n\\_records\\_for\\_estimate](#)
20. [mroonga\\_query\\_log\\_file](#)
21. [mroonga\\_vector\\_column\\_delimiter](#)
22. [mroonga\\_version](#)

This page documents system variables related to the [Mroonga storage engine](#). See [Server System Variables](#) for a complete list of system variables and instructions on setting them.

See also the [Full list of MariaDB options, system and status variables](#).

#### mroonga\_action\_on\_fulltext\_query\_error

- **Description:** Action to take when encountering a Mroonga fulltext error.

◦

ERROR

: Report an error without logging.

◦

ERROR\_AND\_LOG

- : Report an error with logging (the default)
- - IGNORE**  
: No logging or reporting - the error is ignored.
  - IGNORE\_AND\_LOG**  
: Log the error without reporting it.

- **Commandline:**

```
--mroonga-action-on-fulltext-query-error=value
```

- **Scope:** Global, Session

- **Dynamic:** Yes

- **Data Type:**

enum

- **Default Value:**

ERROR\_AND\_LOG

---

## mroonga\_boolean\_mode\_syntax\_flags

- **Description:** Flags to customize syntax in BOOLEAN MODE searches. Available flags:

- - DEFAULT**  
:(=SYNTAX\_QUERY,ALLOW.LEADING.NOT)
  - ALLOW\_COLUMN**  
: Allows  
COLUMN:...  
syntax in query syntax, an incompatible change to the regular BOOLEAN MODE syntax. Permits multiple indexes in one MATCH () AGAINST ()  
. Can be used in other operations besides full-text search, such as equal, and prefix search. See [Groonga query syntax](#) for more details.
  - ALLOW.LEADING.NOT**  
Permits using the  
NOTINCLUDED\_KEYWORD  
syntax in the query syntax.
  - ALLOW\_UPDATE**  
: Permits updating values with the  
COLUMN:=NEW\_VALUE  
syntax in the query syntax.
  - SYNTAX\_QUERY**  
: Mroonga will use Groonga's query syntax, compatible with MariaDB's BOOLEAN MODE syntax. Unless  
SYNTAX\_SCRIPT  
is specified, this mode is always in use.
  - SYNTAX\_SCRIPT**  
: Mroonga will use Groonga's script syntax, a JavaScript-like syntax. If both  
SYNTAX\_QUERY  
and  
SYNTAX\_SCRIPT  
are specified,  
SYNTAX\_SCRIPT  
will take precedence..

- **Commandline:**

```
--mroonga-boolean-mode-syntax-flags=value
```

- **Scope:** Global, Session

- **Dynamic:** Yes

- **Data Type:**

enum

- **Default Value:**

DEFAULT

## `mroonga_database_path_prefix`

- **Description:** The database path prefix.
  - **Commandline:**  
`--mroonga-database-path-prefix=value`
  - **Scope:** Global
  - **Dynamic:** Yes
  - **Data Type:**  
`string`
  - **Default Value:** (Empty)
- 

## `mroonga_default_parser`

- **Description:** The fulltext default parser, for example  
`TokenBigramSplitSymbolAlphaDigit`  
or  
`TokenBigram`  
(the default). See the list of options at [Mroonga Overview:Parser](#). Deprecated since Mroonga 5.0.4, use `mroonga_default_tokenizer` instead.
  - **Commandline:**  
`--mroonga-default-parser=value`
  - **Scope:** Global
  - **Dynamic:** Yes
  - **Data Type:**  
`string`
  - **Default Value:**  
`TokenBigram`
  - **Deprecated:** [MariaDB 10.1.6](#), Mroonga 5.0.4
- 

## `mroonga_default_tokenizer`

- **Description:** The fulltext default parser, for example  
`TokenBigramSplitSymbolAlphaDigit`  
or  
`TokenBigram`  
(the default). See the list of options at [Mroonga Overview:Parser](#).
  - **Commandline:**  
`--mroonga-default-tokenizer=value`
  - **Scope:** Global, Session
  - **Dynamic:** Yes
  - **Data Type:**  
`string`
  - **Default Value:**  
`TokenBigram`
  - **Introduced:** [MariaDB 10.1.6](#), Mroonga 5.0.4
- 

## `mroonga_default_wrapper_engine`

- **Description:** The default engine for wrapper mode.
- **Commandline:**  
`--mroonga-default-wrapper-engine=value`
- **Scope:** Global

- **Dynamic:** No
  - **Data Type:**  
string
  - **Default Value:** (Empty)
- 

mroonga\_dry\_write

- **Description:** If set to
    - on
    - , (
    - offis default), data is not actually written to the Groonga database. Only really useful to change for benchmarking.
  - **Commandline:**  
--mroonga-dry-write[={0|1}]
  - **Scope:** Global, Session
  - **Dynamic:** Yes
  - **Data Type:**  
boolean
  - **Default Value:**  
off
- 

mroonga\_enable\_operations\_recording

- **Description:** Whether recording operations for recovery to the Groonga database is enabled (default) or not. Requires reopening the database with [FLUSH TABLES](#) after changing the variable.
  - **Commandline:**  
--mroonga-enable-operations-recording={0|1}
  - **Scope:** Global
  - **Dynamic:** Yes
  - **Data Type:**  
boolean
  - **Default Value:**  
ON
  - **Introduced:** [MariaDB 10.2.11](#) , [MariaDB 10.1.29](#)
- 

mroonga\_enable\_optimization

- **Description:** If set to
    - on
    - (the default), optimization is enabled. Only really useful to change for benchmarking.
  - **Commandline:**  
--mroonga-enable-optimization={0|1}
  - **Scope:** Global, Session
  - **Dynamic:** Yes
  - **Data Type:**  
boolean
  - **Default Value:**  
on
- 

mroonga\_libgroonga\_embedded

- **Description:** Whether libgroonga is embedded or not.

- **Commandline:** None

- **Scope:** Global

- **Dynamic:** No

- **Data Type:**

boolean

- **Default Value:**

ON

- **Introduced:** [MariaDB 10.1.6](#)
- 

#### mroonga\_libgroonga\_support\_lz4

- **Description:** Whether libgroonga supports lz4 or not.

- **Commandline:** None

- **Scope:** Global

- **Dynamic:** No

- **Data Type:**

boolean

- **Default Value:**

OFF

- **Introduced:** [MariaDB 10.0.17](#)
- 

#### mroonga\_libgroonga\_support\_zlib

- **Description:** Whether libgroonga supports zlib or not.

- **Commandline:** None

- **Scope:** Global

- **Dynamic:** No

- **Data Type:**

boolean

- **Default Value:**

ON

---

#### mroonga\_libgroonga\_support\_zstd

- **Description:** Whether libgroonga supports Zstandard or not.

- **Commandline:** None

- **Scope:** Global

- **Dynamic:** No

- **Data Type:**

boolean

- **Default Value:**

OFF

- **Introduced:** [MariaDB 10.2.11](#) , [MariaDB 10.1.29](#)
- 

#### mroonga\_libgroonga\_version

- **Description:** Groonga library version.

- **Commandline:** None

- **Scope:** Global

- **Dynamic:** No

- **Data Type:**

string

---

### mroonga\_lock\_timeout

- **Description:** Lock timeout used in Groonga.

- **Commandline:**

<<

code

>>

--mroonga-lock-timeout=#</code>>

- **Scope:** Global

- **Dynamic:** Yes

- **Data Type:**

numeric

- **Default Value:**

900000

- **Range:**

-1

to

2147483647

---

### mroonga\_log\_file

- **Description:** Name and path of the Mroonga log file.

- **Commandline:**

--mroonga-log-file=value

- **Scope:** Global

- **Dynamic:** Yes

- **Data Type:**

string

- **Default Value:**

groonga.log

---

### mroonga\_log\_level

- **Description:** Mroonga log file output level, which determines what is logged. Valid levels include:

○

NONE

No output.

○

EMERG

: Only emergency error messages, such as database corruption.

○

ALERT

: Alert messages, such as internal errors.

○

CRIT

: Critical error messages, such as deadlocks.

- - ERROR  
: Errors, such as API errors.
  - - WARNING  
: Warnings, such as invalid arguments.
  - - NOTICE  
: Notices, such as a change in configuration or a status change.
  - - INFO  
: Information messages, such as file system operations.
  - - DEBUG  
: Debug messages, suggested for developers or testers.
  - - DUMP  
: Dump messages.

- **Commandline:**

```
--mroonga-log-level=value
```

- **Scope:** Global

- **Dynamic:** Yes

- **Data Type:**

enum

- **Default Value:**

NOTICE

---

## mroonga\_match\_escalation\_threshold

- **Description:** The threshold to determine whether the match method is escalated.

-1  
means never escalate.

- **Commandline:**

```
--mroonga-match-escalation-threshold=#
```

- **Scope:** Global, Session

- **Dynamic:** Yes

- **Data Type:**

numeric

- **Default Value:**

0

- **Range:**

-1  
to  
9223372036854775807

---

## mroonga\_max\_n\_records\_for\_estimate

- **Description:** The max number of records to estimate the number of matched records

- **Commandline:**

```
--mroonga-max-n-records-for-estimate=#
```

- **Scope:** Global, Session

- **Dynamic:** Yes

- **Data Type:**

numeric

- **Default Value:**

1000

- **Range:**

```
-1  
to  
2147483647
```

- **Introduced:** [MariaDB 10.0.18](#) , [Mroonga 5.0.2](#)
- 

### mroonga\_query\_log\_file

- **Description:** Query log file for Mroonga.

- **Commandline:**

```
--mroonga-query-log-file=filename
```

- **Scope:** Global

- **Dynamic:** Yes

- **Data Type:**

```
string
```

- **Default Value:** (Empty string)

- **Introduced:** [MariaDB 10.2.11](#) , [MariaDB 10.1.29](#)
- 

### mroonga\_vector\_column\_delimiter

- **Description:** Delimiter to use when outputting a vector column. The default is a white space.

- **Commandline:**

```
--mroonga-vector-column-delimiter=value
```

- **Scope:** Global

- **Dynamic:** Yes

- **Data Type:**

```
string
```

- **Default Value:**

```
(white space)
```

---

### mroonga\_version

- **Description:** Mroonga version

- **Commandline:** None

- **Scope:** Global

- **Dynamic:** No

- **Data Type:**

```
string
```

---

## 4.3.12.5

### 4.3.12.5.1 Creating Mroonga User-Defined Functions

The [Mroonga storage engine](#) includes a number of [user-defined functions](#) that need to be created before they can be used. If these are not created already during Mroonga setup, you will need to do so yourself. The full list of available functions and the statements to create them are found in

```
share/mroonga/install.sql  
, for example, as of Mroonga 7.07 ( MariaDB 10.2.11 and MariaDB 10.1.29 ) running on Linux:
```

```

DROP FUNCTION IF EXISTS last_insert_grn_id;
CREATE FUNCTION last_insert_grn_id RETURNS INTEGER
  SONAME 'ha_mroonga.so';

DROP FUNCTION IF EXISTS mroonga_snippet;
CREATE FUNCTION mroonga_snippet RETURNS STRING
  SONAME 'ha_mroonga.so';

DROP FUNCTION IF EXISTS mroonga_command;
CREATE FUNCTION mroonga_command RETURNS STRING
  SONAME 'ha_mroonga.so';

DROP FUNCTION IF EXISTS mroonga_escape;
CREATE FUNCTION mroonga_escape RETURNS STRING
  SONAME 'ha_mroonga.so';

DROP FUNCTION IF EXISTS mroonga_snippet_html;
CREATE FUNCTION mroonga_snippet_html RETURNS STRING
  SONAME 'ha_mroonga.so';

DROP FUNCTION IF EXISTS mroonga_normalize;
CREATE FUNCTION mroonga_normalize RETURNS STRING
  SONAME 'ha_mroonga.so';

DROP FUNCTION IF EXISTS mroonga_highlight_html;
CREATE FUNCTION mroonga_highlight_html RETURNS STRING
  SONAME 'ha_mroonga.so';

DROP FUNCTION IF EXISTS mroonga_query_expand;
CREATE FUNCTION mroonga_query_expand RETURNS STRING
  SONAME 'ha_mroonga.so';

```

## 4.3.12.5.2 last\_insert\_grn\_id

### Syntax

```
last_insert_grn_id()
```

### Contents

1. [Syntax](#)
2. [Description](#)
3. [Examples](#)
4. [See Also](#)

### Description

`last_insert_grn_id` is a [user-defined function](#) (UDF) included with the [Mroonga storage engine](#). It returns the unique Groonga id of the last-inserted record. See [Creating Mroonga User-Defined Functions](#) for details on creating this UDF if required.

### Examples

```

SELECT last_insert_grn_id();
+-----+
| last_insert_grn_id() |
+-----+
|            3 |
+-----+

```

### See Also

- [Creating Mroonga User-Defined Functions](#)

## 4.3.12.5.3 mroonga\_command

## Contents

- 1. [Syntax](#)
- 2. [Description](#)
- 3. [Example](#)
- 4. [See Also](#)

## Syntax

```
mroonga_command (command)
```

## Description

`mroonga_command` is a [user-defined function](#) (UDF) included with the [Mroonga storage engine](#). It passes a command to Groonga for execution. See [Creating Mroonga User-Defined Functions](#) for details on creating this UDF if required.

- - command
    - string, required parameter specifying the command to pass that will be executed by Groonga. See [the Groonga reference](#) for a list of commands.

Returns the result of the Groonga command.

## Example

```
SELECT mroonga_command('status');
+-----+
| mroonga_command('status') |
+-----+
| {"alloc_count":593,"starttime":1512022368,"start_time":1512022368,"uptime":13510,"version":"7.0.7","n_queries":0,"cache_hit_ra
|
```

## See Also

- [Creating Mroonga User-Defined Functions](#)

## 4.3.12.5.4 mroonga\_escape

### Contents

- 1. [Syntax](#)
- 2. [Description](#)
- 3. [Example](#)
- 4. [See Also](#)

## Syntax

```
mroonga_escape (string [,special_characters])
```

- - string
    - required parameter specifying the text you want to escape
- - special\_characters
    - optional parameter specifying the characters to escape

## Description

`mroonga_escape` is a [user-defined function](#) (UDF) included with the [Mroonga storage engine](#), used for escaping a string. See [Creating Mroonga User-Defined Functions](#) for details on creating this UDF if required.

If no

    special\_characters  
parameter is provided, by default

+-<>\*():  
are escaped.

Returns the escaped string.

## Example

```
SELECT mroonga_escape("+-<>~*()\"\\:");
'\\+\\-\\<\\>\\~\\*\\(\\)\\\"\\:'
```

## See Also

- [Creating Mroonga User-Defined Functions](#)

### 4.3.12.5.5 mroonga\_highlight\_html

## Syntax

```
mroonga_highlight_html(text[, query AS query])
mroonga_highlight_html(text[, keyword1, ..., keywordN])
```

## Contents

1. [Syntax](#)
2. [Description](#)
3. [Examples](#)
4. [See Also](#)

## Description

`mroonga_highlight_html`

is a [user-defined function](#) (UDF) included with the [Mroonga storage engine](#). It highlights the specified keywords in the target text. See [Creating Mroonga User-Defined Functions](#) for details on creating this UDF if required.

The optional parameter can either be one or more *keywords*, or a Groonga *query*.

The function highlights the specified keywords in the target text by surrounding each keyword with

```
<span class="keyword">...</span>
, and escaping special HTML characters such as
<
and
>
```

Returns highlighted HTML.

## Examples

```
SELECT mroonga_highlight_html('<p>MariaDB includes the Mroonga storage engine</p>.')
 AS highlighted_html;
+-----+
| highlighted_html
+-----+
| &lt;p&gt;MariaDB includes the Mroonga storage engine&lt;/p&gt;.
+-----+
```

Highlighting the words

```
MariaDB
and
Mroonga
in a given text:
```

```
SELECT mroonga_highlight_html('MariaDB includes the Mroonga storage engine.', 'MariaDB', 'Mroonga')
AS highlighted_html;
+-----+
| highlighted_html
+-----+
| <span class="keyword">MariaDB</span> includes the <span class="keyword">Mroonga</span> storage engine. |
+-----+
```

The same outcome, formulated as a Groonga query:

```
SELECT mroonga_highlight_html('MariaDB includes the Mroonga storage engine.', 'MariaDB OR Mroonga'
AS query) AS highlighted_text;
+-----+
| highlighted_text
+-----+
| <span class="keyword">MariaDB</span> includes the <span class="keyword">Mroonga</span> storage engine. |
+-----+
```

## See Also

- [Creating Mroonga User-Defined Functions](#)

### 4.3.12.5.6 mroonga\_normalize

#### Syntax

```
mroonga_normalize(string[, normalizer_name])
```

#### Contents

1. [Syntax](#)
2. [Description](#)
3. [Examples](#)
4. [See Also](#)

#### Description

`mroonga_normalize`

is a [user-defined function \(UDF\)](#) included with the [Mroonga storage engine](#). It uses Groonga's normalizer to normalize text. See [Creating Mroonga User-Defined Functions](#) for details on creating this UDF if required.

Given a string, returns the normalized text.

See the [Groonga Normalizer Reference](#) for details on the Groonga normalizers. The default if no normalizer is provided is

`NormalizerAuto`

#### Examples

```
SELECT mroonga_normalize("ABいり");
+-----+
| mroonga_normalize("ABいり")   |
+-----+
| abiirittorl                  |
+-----+
```

#### See Also

- [Creating Mroonga User-Defined Functions](#)

### 4.3.12.5.7 mroonga\_snippet

#### Syntax

```
mroonga_snippet document,
    max_length,
    max_count,
    encoding,
    skip_leading_spaces,
    html_escape,
    snippet_prefix,
    snippet_suffix,
    word1, word1_prefix, word1_suffix
    ...
    [wordN wordN_prefix wordN_suffix]
```

## Contents

1. [Syntax](#)
2. [Description](#)
3. [Example](#)
4. [See Also](#)

## Description

`mroonga_snippet`

is a [user-defined function](#) (UDF) included with the [Mroonga storage engine](#). It provides a keyword with surrounding text, or the keyword in context. See [Creating Mroonga User-Defined Functions](#) for details on creating this UDF if required.

The required parameters include:

- - document
    - Column name or string value.
  - max\_length
    - Maximum length of the snippet, in bytes.
  - max\_count
    - Maximum snippet elements (N word).
  - encoding
    - Encoding of the document, for example
    - cp932\_japanese\_ci
  - skip\_leading\_spaces
    - 
    - 1
      - to skip leading spaces,
    - 0
      - to not skip.
  - html\_escape
    - =
    - 1
      - to enable HTML escape,
    - 0
      - to disable.
  - prefix
    - Snippet start text.
  - suffix
    - Snippet end text.

The optional parameters include:

- - wordN
    - A word.
  - wordN\_prefix
    - wordN start text.
  - wordN\_suffix
    - wordN end text

It can be used in both storage and wrapper mode.

Returns the snippet string.

## Example

### See Also

- [Creating Mroonga User-Defined Functions](#)

## 4.3.12.5.8 mroonga\_snippet\_html

### Description

`mroonga_snippet_html`

is a [user-defined function](#) (UDF) included with the [Mroonga storage engine](#). It provides a keyword with surrounding text, or the keyword in context. It is still considered experimental. See [Creating Mroonga User-Defined Functions](#) for details on creating this UDF if required.

### See Also

- [Creating Mroonga User-Defined Functions](#)
- [mroonga\\_snippet](#)

## 4.3.12.6 Information Schema MROONGA\_STATS Table

The [Information Schema](#)

MROONGA\_STATS

table only exists if the [Mroonga](#) storage engine is installed, and contains information about its activities.

Column	Description
VERSION	Mroonga version.
rows_written	Number of rows written into Mroonga tables.
rows_read	Number of rows read from all Mroonga tables.

This table always contains 1 row.

## 4.3.13 MyISAM

MyISAM was the default [storage engine](#) from MySQL 3.23 until it was replaced by [InnoDB](#) in MariaDB and MySQL 5.5. It's a light, non-transactional engine with great performance, is easy to copy between systems and has a small data footprint.

You're encouraged to rather use the [Aria](#) storage engine for new applications, which has even better performance and the goal of being crash-safe.

Until [MariaDB 10.4](#), [system tables](#) used the MyISAM storage engine.

### 4.3.13.1 MyISAM Overview

The MyISAM storage engine was the default storage engine from MySQL 3.23 until it was replaced by InnoDB in MariaDB and MySQL 5.5. Historically, MyISAM is a replacement for the older ISAM engine, removed in MySQL 4.1.

It's a light, non-transactional engine with great performance, is easy to copy between systems and has a small data footprint.

You're encouraged to rather use the Aria storage engine for new applications, which has even better performance in most cases and the goal of being crash-safe.

A MyISAM table is stored in three files on disk. There's a table definition file with an extension of

```
.frm  
, a data file with the extension  
.MYD  
, and an index file with the extension  
.MYI  
.
```

### MyISAM features

- Does not support transactions .
- Does not support foreign keys.
- Supports FULLTEXT indexes .
- Supports GIS data types.
- Storage limit of 256TB.
- Maximum of 64 indexes per table.
- Maximum of 32 columns per index.
- Maximum index length of 1000 bytes.
- Limit of  $(2^{32})^2$  (1.844E+19) rows per table.
- Supports large files up to 63-bits in length where the underlying system supports this.
- All data is stored with the low byte first, so all files will still work if copied to other systems or other machines.
- The data file and the index file can be placed on different devices to improve speed.
- Supports table locking, not row locking.
- Supports a key buffer that is segmented in MariaDB.
- Supports concurrent inserts .
- Supports fixed length, dynamic and compressed formats - see MyISAM Storage Formats .
- Numeric index values are stored with the high byte first, which enables more efficient index compression.
- Data values are stored with the low byte first, making it mostly machine and operating system independent. The only exceptions are if a machine doesn't use two's-complement signed integers and the IEEE floating-point format.
- Can be copied between databases or systems with normal system tools, as long as the files are not open on either system. Use FLUSH\_TABLES to ensure files are not in use.
- There are a number of tools for working with MyISAM tables. These include:
  - mysqlcheck for checking or repairing
  - myisamchk for checking or repairing
  - myisampack for compressing
- It is possible to build a MERGE table on the top of one or more MyISAM tables.

### 4.3.13.2 MyISAM System Variables

16. [myisam\\_use\\_mmap](#)

This page documents system variables related to the [MyISAM](#) storage engine. For options, see [MyISAM Options](#).

See [Server System Variables](#) for a complete list of system variables and instructions on setting them.

See also the [Full list of MariaDB options, system and status variables](#).

### key\_buffer\_size

- **Description:** Size of the buffer for the index blocks used by MyISAM tables and shared for all threads. See [Optimizing key\\_buffer\\_size](#) for more on selecting the best value.

- **Commandline:**

```
--key-buffer-size=#
```

- **Scope:** Global

- **Dynamic:** Yes

- **Data Type:**

numeric

- **Default Value:**

134217728

- **Range:**

8

upwards (upper limit determined by operating system per process limit)

### key\_cache\_age\_threshold

- **Description:** The lower the setting, the more quickly buffers move from the hot key cache sublist to the warm sublist.

- **Commandline:**

```
--key-cache-age-threshold=#
```

- **Scope:** Global

- **Dynamic:** Yes

- **Data Type:**

numeric

- **Default Value:**

300

- **Range:**

100

to

4294967295

### key\_cache\_block\_size

- **Description:** MyISAM key cache block size in bytes .

- **Commandline:**

```
--key-cache-block-size=#
```

- **Scope:** Global

- **Dynamic:** Yes

- **Data Type:**

numeric

- **Default Value:**

1024

- **Range:**

512

to

16384

---

## key\_cache\_division\_limit

- **Description:** Percentage to use for the warm key cache buffer list (the remainder is allocated between the hot and cold caches).

- **Commandline:**

```
--key-cache-division-limit=#
```

- **Scope:** Global

- **Dynamic:** Yes

- **Data Type:**

numeric

- **Default Value:**

100

- **Range:**

1

to

100

---

## key\_cache\_file\_hash\_size

- **Description:** Number of hash buckets for open and changed files. If you have many MyISAM files open you should increase this for faster flushing of changes. A good value is probably 1/10th of the number of possible open MyISAM files.

- **Commandline:**

```
--key-cache-file-hash-size=#
```

- **Scope:** Global

- **Dynamic:** Yes

- **Data Type:**

numeric

- **Default Value:**

512

- **Range:**

128

to

16384

- **Introduced:** MariaDB 10.0.13
- 

## key\_cache\_segments

- **Description:** The number of segments in a key cache. See [Segmented Key Cache](#).

- **Commandline:**

```
--key-cache-segments=#
```

- **Scope:** Global

- **Dynamic:** Yes

- **Type:** numeric

- **Default Value:**

0

*(non-segmented)*

- **Range:**

0

to

64

### `myisam_block_size`

- **Description:** Block size to be used for MyISAM index pages.

- **Commandline:**

```
--myisam-block-size=#
```

- **Scope:** Global

- **Dynamic:** No

- **Data Type:**

numeric

- **Default Value:**

1024

### `myisam_data_pointer_size`

- **Description:** Size in bytes of the default pointer, used in a [MyISAM CREATE TABLE](#) with no MAX\_ROWS option.

- **Commandline:**

```
--myisam-data-pointer-size=#
```

- **Scope:** Global

- **Dynamic:** Yes

- **Data Type:**

numeric

- **Default Value:**

6

- **Range:**

2

to

7

### `myisam_max_extra_sort_file_size`

- **Description:** Removed in MySQL 5.0.6, was used as a way to force long character keys in large tables to use the key cache method.

- **Removed:** MySQL 5.0.6

### `myisam_max_sort_file_size`

- **Description:** Maximum size in bytes of the temporary file used while recreating a MyISAM index. If the this size is exceeded, the slower process of

using the key cache is done instead.

- **Commandline:**

```
--myisam-max-sort-file-size=#
```

- **Scope:** Global

- **Dynamic:** Yes

- **Data Type:**

```
    numeric
```

- **Default Value - 32 bit:**

```
    2147483648
```

- **Default Value - 64 bit:**

```
    9223372036854775807
```

---

## myisam\_mmap\_size

- **Description:** Maximum memory in bytes that can be used for memory mapping compressed MyISAM files. Too high a value may result in swapping if there are many compressed MyISAM tables.

- **Commandline:**

```
--myisam-mmap-size=#
```

- **Scope:** Global, Session

- **Dynamic:** Yes

- **Data Type:**

```
    numeric
```

- **Default Value - 32 bit:**

```
    4294967295
```

- **Default Value - 64 bit:**

```
    18446744073709547520
```

- **Range - 32-bit:**

```
    7  
    to  
    4294967295
```

- **Range - 64-bit:**

```
    7  
    to  
    18446744073709547520
```

---

## myisam\_recover\_options

- **Description:** MyISAM recovery mode. Multiple options can be selected, comma-delimited. Using no argument is equivalent to specifying

```
    DEFAULT
```

```
, while specifying "" is equivalent to
```

```
    OFF
```

If enabled each time the server opens a MyISAM table, it checks whether it has been marked as crashed, or wasn't closed properly. If so, mysqld will run a check and then attempt to repair the table, writing to the error log beforehand.

- **OFF** : No recovery.

- **BACKUP** : If the data file is changed while recovering, saves a backup of the .MYD data file. t.MYD will be saved as t.MYD-datetime.BAK.

- **BACKUP\_ALL** : Same as

```
    BACKUP
```

```
        but also backs up the .MYI index file. t.MYI will be saved as t.MYI-datetime.BAK.
```

- **DEFAULT** : Recovers without backing up, forcing, or quick checking.

- **FORCE** : Runs the recovery even if it determines that more than one row from the data file will be lost.

- **QUICK** : Does not check rows in the table if there are no delete blocks.

- **Commandline:**

```
--myisam-recover-options[=name]
```

- **Scope:** Global

- **Dynamic:** No

- **Data Type:**  
enumeration

- **Default Value:**

- BACKUP, QUICK  
( $\geq$  MariaDB 10.2.4 )
- DEFAULT  
( $\leq$  MariaDB 10.2.3 )
- OFF

- **Valid Values:**

- OFF
- ,
- DEFAULT
- ,
- BACKUP
- ,
- BACKUP\_ALL
- ,
- FORCE
- or
- QUICK

---

## myisam\_repair\_threads

- **Description:** If set to more than

- 1 , the default, MyISAM table indexes each have their own thread during repair and sorting. Increasing from the default will usually result in faster repair, but will use more CPU and memory.

- **Commandline:**

- myisam-repair-threads=#

- **Scope:** Global, Session

- **Dynamic:** Yes

- **Data Type:**

- numeric

- **Default Value:**

- 1

- **Range - 32-bit:**

- 1
- to
- 4294967295

- **Range - 64-bit:**

- 1
- to
- 18446744073709547520

---

## myisam\_sort\_buffer\_size

- **Description:** Size in bytes of the buffer allocated when creating or sorting indexes on a MyISAM table.

- **Commandline:**

- myisam-sort-buffer-size=#

- **Scope:** Global, Session

- **Dynamic:** Yes

- **Data Type:**

- numeric

- **Default Value:**

```
134217720  
(128MB),  
8388608  
(8MB - before MariaDB 10.0.3 )
```

- **Range:**

```
4096  
to  
18446744073709547520
```

---

### myisam\_stats\_method

- **Description:** Determines how NULLs are treated for MyISAM index statistics purposes. If set to

```
nulls_equal
```

, the default, all NULL index values are treated as a single group. This is usually fine, but if you have large numbers of NULLs the average group size is slanted higher, and the optimizer may miss using the index for ref accesses when it would be useful. If set to  
`nulls_unequal`

, the opposite approach is taken, with each NULL forming its own group of one. Conversely, the average group size is slanted lower, and the optimizer may use the index for ref accesses when not suitable. Setting to

```
nulls_ignored
```

ignores NULLs altogether from index group calculations. See also [Index Statistics](#) , [aria\\_stats\\_method](#) , [innodb\\_stats\\_method](#) .

- **Commandline:**

```
--myisam-stats-method=name
```

- **Scope:** Global, Session

- **Dynamic:** Yes

- **Data Type:**

```
enumeration
```

- **Default Value:**

```
nulls_equal
```

- **Valid Values:**

```
nulls_equal
```

```
,
```

```
nulls_unequal
```

```
,
```

```
nulls_ignored
```

### myisam\_use\_mmap

- **Description:** If set to

```
1
```

(0 is default), memory mapping will be used to reading and writing MyISAM tables.

- **Commandline:**

```
--myisam-use-mmap
```

- **Scope:** Global

- **Dynamic:** Yes

- **Data Type:**

```
boolean
```

- **Default Value:**

```
OFF
```

## 4.3.13.3 MyISAM Storage Formats

## Contents

1. [Fixed-length](#)
2. [Dynamic](#)
3. [Compressed](#)
4. [See Also](#)

The [MyISAM](#) storage engine supports three different table storage formats.

These are FIXED, DYNAMIC and COMPRESSED. FIXED and DYNAMIC can be set with the ROW FORMAT option in the [CREATE TABLE](#) statement, or will be chosen automatically depending on the columns the table contains. COMPRESSED can only be set via the [myisampack](#) tool.

The [SHOW TABLE STATUS](#) statement can be used to see the storage format used by a table. Note that

COMPRESSED  
tables are reported as  
DYNAMIC  
in that context.

## Fixed-length

Fixed-length (or static) tables contain records of a fixed-length. Each column is the same length for all records, regardless of the actual contents. It is the default format if a table has no [BLOB](#), [TEXT](#), [VARCHAR](#) or [VARBINARY](#) fields, and no ROW FORMAT is provided. You can also specify a fixed table with ROW\_FORMAT=FIXED in the table definition.

Tables containing BLOB or TEXT fields cannot be FIXED, as by design these are both dynamic fields. However, no error or warning will be raised if you specify FIXED.

Fixed-length tables have a number of characteristics

- fast, since MariaDB will always know where a record begins
- easy to repair: [myisamchk](#) is always able to recover all rows, except for the last one if it is not entirely written
- easy to cache
- take up more space than dynamic or compressed tables, as the maximum amount of storage space will be allocated to each record.
- reconstructing after a crash is uncomplicated due to the fixed positions
- no fragmentation or need to re-organize, unless records have been deleted and you want to free the space up.

## Dynamic

Dynamic tables contain records of a variable length. It is the default format if a table has any BLOB, TEXT, VARCHAR or VARBINARY fields, and no ROW FORMAT is provided. You can also specify a DYNAMIC table with ROW\_FORMAT=DYNAMIC in the table definition. If the table contains BLOB or TEXT columns, its format is always DYNAMIC, and the ROW FORMAT option is ignored.

Dynamic tables have a number of characteristics

- Each row contains a header indicating the length of the row.
- Rows tend to become fragmented easily. UPDATING a record to be longer will likely ensure it is stored in different places on the disk. Use [OPTIMIZE TABLE](#) when the fragmentation is too high.
- All string columns with a length of four or more are dynamic.
- They require much less space than fixed-length tables.
- Restoring after a crash is more complicated than with FIXED tables. Some fragments may be lost.

If a DYNAMIC table has some frequently-accessed fixed-length columns, it could be a good idea to move them into a separate FIXED table to avoid fragmentation.

## Compressed

Compressed tables are a read-only format, created with the [myisampack](#) tool. This can be done while the server is running, but external lock must not be disabled. [myisamchk](#) is used to uncompress them.

Compressed tables have a number of characteristics:

- while the data is read-only, DDL statements such as [DROP TABLE](#) and [TRUNCATE TABLE](#) will still function.
- take much less space than fixed or dynamic tables. Each data has usually a 40-70% compression ratio
- rows are compressed separately, reducing access overhead.
- row headers will be from one to three bytes.
- rows can be compressed with different compression types, including
  - prefix space compression
  - suffix space compression
  - columns with small sets of values are converted to ENUM
  - numeric zeros are stored with only one bit
  - integer columns will be reduced to the smallest int type that can hold the contents

## See Also

- [Why we still need MyISAM \(for read-only tables\)](#) describes an important use case for MyISAM compressed tables.

### 4.3.13.4.1 myisamchk

#### Contents

1. [General Options](#)
2. [Checking Tables](#)
3. [Repairing Tables](#)
4. [Other Actions](#)
5. [Examples](#)
6. [See Also](#)

myisamchk is a commandline tool for checking, repairing and optimizing non-partitioned [MyISAM](#) tables.

myisamchk is run from the commandline as follows:

```
myisamchk [OPTIONS] tables[.MYI]
```

The full list of options are listed below. One or more MyISAM tables can be specified. MyISAM tables have an associated .MYI index file, and the table name can either be specified with or without the .MYI extension. Referencing it with the extension allows you to use wildcards, so it's possible to run myisamchk on *all* the MyISAM tables in the database with

\*.MYI

The path to the files must also be specified if they're not in the current directory.

myisamchk should not be run while anyone is accessing any of the affected tables. It is also best to make a backup before running.

With no options, myisamchk simply checks your table as the default operation.

The following options can be set while passed as commandline options to myisamchk, or set with a [myisamchk] section in your [my.cnf](#) file.

#### General Options

Option	Description
-H, --HELP	Display help and exit. Options are presented in a single list.
-?, --help	Display help and exit. Options are grouped by type of operation.
-debug=options, -# options	Write a debugging log. A typical debug_options string is 'd:t:o,file_name'. The default is 'd:t:o,/tmp/myisamchk.trace'. (Available in debug builds only)
-t path, --tmpdir=path	Path for temporary files. Multiple paths can be specified, separated by colon (:) on Unix and semicolon (;) on Windows. They will be used in a round-robin fashion. If not set, the TMPDIR environment variable is used.
-s, --silent	Only print errors. One can use two -s (-ss) to make myisamchk very silent.
-v, --verbose	Print more information. This can be used with --description and --check. Use many -v for more verbosity.
-V, --version	Print version and exit.
-w, --wait	If table is locked, wait instead of returning an error.
--print-defaults	Print the program argument list and exit.
--no-defaults	Don't read default options from any option file.
--defaults-file=filename	Only read default options from the given file <i>filename</i> , which can be the full path, or the path relative to the current directory.
--defaults-extra-file=filename	Read the file <i>filename</i> , which can be the full path, or the path relative to the current directory, after the global files are read.
--defaults-group-suffix=str	Also read groups with a suffix of <i>str</i> . For example, --defaults-group-suffix=x would read the groups [myisamchk] and [myisamchk_x]

The following variables can also be set by using `--var_name=value`, for example `--ft_min_word_len=5`

Variable	Default Value
decode_bits	9

ft_max_word_len	version-dependent
ft_min_word_len	4
ft_stopword_file	built-in list
key_buffer_size	1044480
key_cache_block_size	1024
myisam_block_size	1024
myisam_sort_buffer_size	134216704
myisam_sort_key_blocks	16
read_buffer_size	262136
sort_buffer_size	134216704
sort_key_blocks	16
stats_method	nulls Unequal
write_buffer_size	262136

## Checking Tables

If no option is provided, myisamchk will perform a check table. It is possible to check MyISAM tables without shutting down or restricting access to the server by using [CHECK TABLE](#) instead.

The following check options are available:

Option	Description
-c, --check	Check table for errors. This is the default operation if you specify no option that selects an operation type explicitly.
-e, --extend-check	Check the table VERY thoroughly. Only use this in extreme cases as it may be slow, and myisamchk should normally be able to find out if the table has errors even without this switch. Increasing the key_buffer_size can help speed the process up.
-F, --fast	Check only tables that haven't been closed properly.
-C, --check-only-changed	Check only tables that have changed since last check.
-f, --force	Restart with '-r' (recover) if there are any errors in the table. States will be updated as with '--update-state'.
-i, --information	Print statistics information about the table that is checked.
-m, --medium-check	Faster than extend-check , but only finds 99.99% of all errors. Should be good enough for most cases.
-U --update-state	Mark tables as crashed if you find any errors. This should be used to get the full benefit of the --check-only-changed option, but you shouldn't use this option if the mysqld server is using the table and you are running it with external locking disabled.
-T, --read-only	Don't mark table as checked. This is useful if you use myisamchk to check a table that is in use by some other application that does not use locking, such as mysqld when run with external locking disabled.

## Repairing Tables

It is also possible to repair MyISAM tables by using [REPAIR TABLE](#).

The following repair options are available, and are applicable when using '-r' or '-o':

Option	Description
-B, --backup	Make a backup of the .MYD file as 'filename-time.BAK'.
--correct-checksum	Correct the checksum information for table.
-D len, --data-file-length=#	Max length of data file (when recreating data file when it's full).
-e, --extend-check	Try to recover every possible row from the data file. Normally this will also find a lot of garbage rows; Don't use this option if you are not totally desperate.

-f, --force	Overwrite old temporary files. Add another --force to avoid 'myisam_sort_buffer_size is too small' errors. In this case we will attempt to do the repair with the given myisam_sort_buffer_size and dynamically allocate as many management buffers as needed.
-k val, --keys-used=#	Specify which keys to update. The value is a bit mask of which keys to use. Each binary bit corresponds to a table index, with the first index being bit 0. 0 disables all index updates, useful for faster inserts. Deactivated indexes can be reactivated by using <code>myisamchk -r</code> .
--create-missing-keys	Create missing keys. This assumes that the data file is correct and that the number of rows stored in the index file is correct. Enables --quick
--max-record-length=#	Skip rows larger than this if myisamchk can't allocate memory to hold them.
-r, --recover	Can fix almost anything except unique keys that aren't unique (a rare occurrence). Usually this is the best option to try first. Increase <code>myisam_sort_buffer_size</code> for better performance.
-n, --sort-recover	Forces recovering with sorting even if the temporary file would be very large.
-p, --parallel-recover	Uses the same technique as '-r' and '-n', but creates all the keys in parallel, in different threads.
-o, --safe-recover	Uses old recovery method; Slower than '-r' but uses less disk space and can handle a couple of cases where '-r' reports that it can't fix the data file. Increase <code>key_buffer_size</code> for better performance.
--character-sets-dir=directory_name	Directory where the <a href="#">character sets</a> are installed.
--set-collation=name	Change the collation (and by implication, the <a href="#">character set</a> ) used by the index.
-q, --quick	Faster repair by not modifying the data file. One can give a second '-q' to force myisamchk to modify the original datafile in case of duplicate keys. NOTE: Tables where the data file is corrupted can't be fixed with this option.
-u, --unpack	Unpack file packed with myisampack.

## Other Actions

Option	Description
-a, --analyze	Analyze distribution of keys. Will make some joins faster as the join optimizer can better choose the order in which to join the tables and which indexes to use. You can check the calculated distribution by using '--description --verbose table_name' or <a href="#">SHOW INDEX FROM table_name</a> .
--stats_method=name	Specifies how index statistics collection code should treat NULLs. Possible values of <code>name</code> are "nulls_unequal" (default), "nulls_equal" (emulate MySQL 4.0 behavior), and "nulls_ignored".
-d, --description	Print some descriptive information about the table. Specifying the --verbose option once or twice produces additional information.
-A [value], --set-auto-increment[=value]	Force auto_increment to start at this or higher value. If no value is given, then sets the next auto_increment value to the highest used value for the auto key + 1.
-S, --sort-index	Sort the index tree blocks in high-low order. This optimizes seeks and makes table scans that use indexes faster.
-R index_num, --sort-records=#	Sort records according to the given index (as specified by the index number). This makes your data much more localized and may speed up range-based SELECTs and ORDER BYs using this index. It may be VERY slow to do a sort the first time! To see the index numbers, <a href="#">SHOW INDEX</a> displays table indexes in the same order that myisamchk sees them. The first index is 1.
-b offset, --block-search=offset	Find the record to which a block at the given offset belongs.

For more, see [Memory and Disk Use With myisamchk](#).

## Examples

Check all the MyISAM tables in the current directory:

```
myisamchk *.MYI
```

If you are not in the database directory, you can check all the tables there by specifying the path to the directory:

```
myisamchk /path/to/database_dir/*.MYI
```

Check all tables in all databases by specifying a wildcard with the path to the MariaDB data directory:

```
myisamchk /path/to/datadir/*/*.MYI
```

The recommended way to quickly check all MyISAM tables:

```
myisamchk --silent --fast /path/to/datadir/*/*.MYI
```

Check all MyISAM tables and repair any that are corrupted:

```
myisamchk --silent --force --fast --update-state \  
--key_buffer_size=64M --sort_buffer_size=64M \  
--read_buffer_size=1M --write_buffer_size=1M \  
/path/to/datadir/*/*.MYI
```

## See Also

- [Memory and Disk Use With myisamchk](#)

### 4.3.13.4.2 Memory and Disk Use With myisamchk

myisamchk's performance can be dramatically enhanced for larger tables by making sure that its memory-related variables are set to an optimum level.

By default, myisamchk will use very little memory (about 3MB is allocated), but can temporarily use a lot of disk space. If disk space is a limitation when repairing, the `--safe-recover` option should be used instead of `--recover`. However, if TMPDIR points to a memory file system, an out of memory error can easily be caused, as myisamchk places temporary files in TMPDIR. The `--tmpdir=path` option should be used in this case to specify a directory on disk.

myisamchk has the following requirements for disk space:

- When repairing, space for twice the size of the data file, available in the same directory as the original file. This is for the original file as well as a copy. This space is not required if the `--quick` option is used, in which case only the index file is re-created.
- Disk space in the temporary directory (TMPDIR or the `tmpdir=path` option) is needed for sorting if the `--recover` or `--sort-recover` options are used when not using `--safe-recover`. The space required will be approximately  $(\text{largest\_key} + \text{row\_pointer\_length}) * \text{number\_of\_rows} * 2$ . To get information about the length of the keys as well as the row pointer length, use `myisamchk -dv table_name`.
- Space for a new index file to replace the existing one. The old index is first truncated, so unless the old index file is not present or is smaller for some reason, no significant extra space will be needed.

There are a number of [system variables](#) that are useful to adjust when running myisamchk. They will increase memory usage, and since some are per-session variables, you don't want to increase the general value, but you can either pass an increased value to myisamchk as a commandline option, or with a [myisamchk] section in your [my.cnf](#) file.

- [sort\\_buffer\\_size](#) . By default this is 4M, but it's very useful to increase to make myisamchk sorting much faster. Since the server won't be running when you run myisamchk, you can increase substantially. 16M is usually a minimum, but values such as 256M are not uncommon if memory is available.
- [key\\_buffer\\_size](#) (which particularly helps with the `--extend-check` and `--safe-recover` options).
- [read\\_buffer\\_size](#)
- [write\\_buffer\\_size](#)

For example, if you have more than 512MB available to allocate to the process, the following settings could be used:

```
myisamchk  
--myisam_sort_buffer_size=256M  
--key_buffer_size=512M  
--read_buffer_size=64M  
--write_buffer_size=64M  
...
```

### 4.3.13.4.3 myisamchk Table Information

#### Contents

1. [-dvv output](#)
2. [-eiv output](#)
3. [Examples](#)

[myisamchk](#) can be used to obtain information about MyISAM tables, particularly with the `-d` , `-e` , `-i` and `-v` options.

Common options for gathering information include:

- myisamchk -d
- myisamchk -dv
- myisamchk -dvv
- myisamchk -ei
- myisamchk -eiv

The `-d` option returns a short description of the table and its keys. Running the option while the table is being updated, and with external locking disabled,

may result in an error, but no damage will be done to the table. Each extra *v* adds more output. *-e* checks the table thoroughly (but slowly), and the *-i* options adds statistical information,

## -dvv output

The following table describes the output from the running myisamchk with the *-dvv* option:

Heading	Description
MyISAM file	Name and path of the MyISAM index file (without the extension)
Record format	<a href="#">Storage format</a> . One of <i>packed</i> (dynamic), <i>fixed</i> or <i>compressed</i> .
Character set	Default <a href="#">character set</a> for the table.
File-version	Always 1.
Creation time	Time the data file was created
Recover time	Most recent time the file was reconstructed.
Status	Table status. One or more of <i>analyzed</i> , <i>changed</i> , <i>crashed</i> , <i>open</i> , <i>optimized keys</i> and <i>sorted index pages</i> .
Auto increment key	Index number of the table's <a href="#">auto-increment</a> column. Not shown if no auto-increment column exists.
Last value	Most recently generated auto-increment value. Not shown if no auto-increment column exists.
Data records	Number of records in the table.
Deleted blocks	Number of deleted blocks that are still reserving space. Use <a href="#">OPTIMIZE TABLE</a> to defragment.
Datafile parts	For <a href="#">dynamic tables</a> , the number of data blocks. If the table is optimized, this will match the number of data records.
Deleted data	Number of bytes of unreclaimed deleted data, Use <a href="#">OPTIMIZE TABLE</a> to reclaim the space.
Datafile pointer	Size in bytes of the data file pointer. The size of the data file pointer, in bytes.
Keyfile pointer	Size in bytes of the index file pointer.
Max datafile length	Maximum length, in bytes, that the data file could become.
Max keyfile length	Maximum length, in bytes, that the index file could become.
Recordlength	Space, in bytes, that each row takes.
table description	Description of all indexes in the table, followed by all columns
Key	Index number, starting with one. If not shown, the index is part of a multiple-column index.
Start	Where the index part starts in the row.
Len	Length of the index or index part. The length of a multiple-column index is the sum of the component lengths. Indexes of string columns will be shorter than the full column length if only a string prefix is indexed.
Index	Whether an index value is unique or not. Either <i>multi</i> . or <i>unique</i> .
Type	Data type of the index of index part.
Rec/key	Record of the number of rows per value for the index or index part. Used by the optimizer to calculate query plans. Can be updated with <a href="#">myisamchk-a</a> . If not present, defaults to 30 .
Root	Root index block address.
Blocksize	Index block size, in bytes.
Field	Column number, starting with one. The first line will contain the position and number of bytes used to store NULL flags, if any (see <i>Nullpos</i> and <i>Nullbit</i> , below).
Start	Column's byte position within the table row.
Length	Column length, in bytes.
Nullpos	Byte containing the flag for NULL values. Empty if column cannot be NULL.

Nullbit	Bit containing the flag for NULL values. Empty if column cannot be NULL.
Type	Data type - see the table below for a list of possible values.
Huff tree	Only present for packed tables, contains the Huffman tree number associated with the column.
Bits	Only present for packed tables, contains the number of bits used in the Huffman tree.

Data type	Description
constant	All rows contain the same value.
noendspace	No endspace is stored.
no endspace, not_always	No endspace is stored, and endspace compression is not always performed for all values.
no endspace, no empty	No endspace is stored, no empty values are stored.
table-lookup	Column was converted to an <a href="#">ENUM</a> .
zerofill(N)	Most significant $N$ bytes of the value are not stored, as they are always zero.
no zeros	Zeros are not stored.
always zero	Zero values are stored with one bit.

## -eiv output

The following table describes the output from the running myisamchk with the `-eiv` option:

Heading	Description
Data records	Number of records in the table.
Deleted blocks	Number of deleted blocks that are still reserving space. Use <a href="#">OPTIMIZE TABLE</a> to defragment.
Key	Index number, starting with one.
Keyblocks used	Percentage of the keyblocks that are used. Percentages will be higher for optimized tables.
Packed	Percentage space saved from packing key values with a common suffix.
Max levels	Depth of the <a href="#">b-tree index</a> for the key. Larger tables and longer key values result in higher values.
Records	Number of records in the table.
M.recordlength	Average row length. For fixed rows, will be the actual length of each row.
Packed	Percentage saving from stripping spaces from the end of strings.
Recordspace used	Percentage of the data file used.
Empty space	Percentage of the data file unused.
Blocks/Record	Average number of blocks per record. Values higher than one indicate fragmentation. Use <a href="#">OPTIMIZE TABLE</a> to defragment.
Recordblocks	Number of used blocks. Will match the number of rows for fixed or optimized tables.
Deleteblocks	Number of deleted blocks
Recorddata	Used bytes in the data file.
Deleted data	Unused bytes in the data file.
Lost space	Total bytes lost, such as when a row is updated to a shorter length.
Linkdata	Sum of the bytes used for pointers linking disconnected blocks. Each is four to seven bytes in size.

## Examples

```
myisamchk -d /var/lib/mysql/test/posts

MyISAM file:      /var/lib/mysql/test/posts
Record format:    Compressed
Character set:   utf8mb4_unicode_ci (224)
Data records:     1680 Deleted blocks:          0
Recordlength:    2758
Using only keys '0' of 5 possibly keys
```

table description:				
Key	Start	Len	Index	Type

## 4.3.13.4.4 myisamlog

`myisamlog`  
processes and returns the contents of a [MyISAM log file](#).

Invoke

`myisamlog`  
like this:

```

shell> myisamlog [options] [log_file [tbl_name] ...]
shell> isamlog [options] [log_file [tbl_name] ...]

```

The default operation is update (

- u
- ). If a recovery is done (
- r
- ), all writes and possibly updates and deletes are done and errors are only counted. The default log file name is `myisam.log`
- for
- `myisamlog`
- and
- `isam.log`
- for
- `isamlog`
- if no
- `log_file`

argument is given. If tables are named on the command line, only those tables are updated.

`myisamlog`  
supports the following options:

Option	Description
--------	-------------

-?	Display a help message and exit.
,	
-I	
-c <i>N</i>	Execute only <i>N</i> commands.
-f <i>N</i>	Specify the maximum number of open files.
-i	Display extra information before exiting.
-o <i>offset</i>	Specify the starting offset.
-p <i>N</i>	Remove <i>N</i> components from path.
-r	Perform a recovery operation.
-R <i>record_pos_file</i> <i>record_pos</i>	Specify record position file and record position.
-u	Displays update operations.
-v	Verbose mode. Print more output about what the program does. This option can be given multiple times ( -vv , -vvv ) to produce more and more output.
-w <i>write_file</i>	Specify the write file.
-V	Display version information.

### 4.3.13.4.5 myisampack

## Contents

1. Options
2. Uncompressing
3. Examples
4. See Also

`myisampack`

is a tool for compressing [MyISAM](#) tables. The resulting tables are read-only, and usually about 40% to 70% smaller. It is run as follows:

```
myisampack [options] file_name [file_name2...]
```

The

`file_name`  
is the  
`.MYI`

index file. The extension can be omitted, although keeping it permits wildcards, such as:

```
myisampack *.MYI
```

...to compress all the files.

`myisampack`

compresses each column separately, and, when the resulting data is read, only the individual rows and columns required need to be decompressed, allowing for quicker reading.

Once a table has been packed, use

```
myisamchk -rq
```

(the quick and recover options) to rebuild its indexes.

`myisampack`

does not support partitioned tables.

Do not run `myisampack` if the tables could be updated during the operation, and `skip_external_locking` has been set.

## Options

The following variables can be set while passed as commandline options to

`myisampack`  
, or set with a  
[`myisampack`]  
section in your [my.cnf](#) file.

Option	Description
<code>-b</code> , <code>--backup</code>	Make a backup of the table as <code>table_name.OLD</code> .
<code>--character-sets-dir=name</code>	Directory where character sets are.
<code>-#</code> , <code>--debug[=name]</code>	Output debug log. Often this is <code>'d:t:o,filename'</code> .
<code>-f</code> , <code>--force</code>	Force packing of table even if it gets bigger or if tempfile exists.

-j , --join=name	Join all given tables into 'new_table_name' . All tables <b>must</b> have identical layouts.
-? , --help	Display help and exit.
-s , --silent	Only write output when an error occurs
-T , --tmpdir=name	Use temporary directory to store temporary table.
-t , --test	Don't pack table, only test packing it.
-v , --verbose	Write info about progress and packing result. Use multiple -v flags for more verbosity.
-V , --version	Output version information and exit.
-w , --wait	Wait and retry if table is in use.

## Uncompressing

To uncompress a table compressed with

`myisampack`

, use the

`myisamchk -u`

option.

## Examples

```
> myisampack /var/lib/mysql/test/posts
Compressing /var/lib/mysql/test/posts.MYD: (1680 records)
- Calculating statistics
- Compressing file
37.71%
> myisamchk -rq /var/lib/mysql/test/posts
- check record delete-chain
- recovering (with sort) MyISAM-table '/var/lib/mysql/test/posts'
Data records: 1680
- Fixing index 1
- Fixing index 2
```

## See Also

- [FLUSH TABLES FOR EXPORT](#)
- [myisamchk](#)

### 4.3.13.4.6 myisam\_ftdump

myisam\_ftdump is a utility for displaying information about MyISAM FULLTEXT indexes. It will scan and dump the entire index, and can be a lengthy process.

If the server is running, make sure you run a [FLUSH TABLES](#) statement first.

## Usage

```
myisam_ftdump <table_name> <index_num>
```

The table\_name can be specified with or without the .MYI index extension.

The index number refers to the number of the index when the table was defined, starting at zero. For example, take the following table definition:

```
CREATE TABLE IF NOT EXISTS `employees_example` (
  `id` int(11) NOT NULL AUTO_INCREMENT,
  `first_name` varchar(30) NOT NULL,
  `last_name` varchar(40) NOT NULL,
  `position` varchar(25) NOT NULL,
  `home_address` varchar(50) NOT NULL,
  `home_phone` varchar(12) NOT NULL,
  `employee_code` varchar(25) NOT NULL,
  `bio` text NOT NULL,
  PRIMARY KEY (`id`),
  UNIQUE KEY `employee_code` (`employee_code`),
  FULLTEXT (`bio`)
) ENGINE=MyISAM;
```

The fulltext index will be

```
2
. The primary key is index
0
, and the unique key index
1
.
```

You can use *myisam\_ftdump* to generate a list of index entries in order of frequency of occurrence as follows:

```
myisam_ftdump -c mytexttable 1 | sort -r
```

## Options

Option	Description
-h, --help	Display help and exit.
-?, --help	Synonym for -h.
-c, --count	Calculate per-word stats (counts and global weights).
-d, --dump	Dump index (incl. data offsets and word weights).
-l, --length	Report length distribution.
-s, --stats	Report global stats.
-v, --verbose	Be verbose.

### 4.3.13.5 MyISAM Index Storage Space

Regular MyISAM tables make use of [B-tree indexes](#).

String indexes are space-compressed, which reduces the size of [VARCHARs](#) that don't use the full length, or a string that has trailing spaces. String indexes also make use of prefix-compression, where strings with identical prefixes are compressed.

Numeric indexes can also be prefix-compressed if the [PACK\\_KEYS=1](#) option is used. Regardless, the high byte is always stored first, which allows a reduced index size.

In the worst case, with no strings being space-compressed, the total index storage space will be  $(\text{index\_length}+4)/0.67$  per index.

## 4.3.13.6 MyISAM Log

The MyISAM log records all changes to [MyISAM](#) tables. It is not enabled by default. To enable it, start the server with the `--log-isam` option, for example:

```
--log-isam=myisam.log
```

The *isam* instead of *myisam* above is not a typo - it's a legacy from when the predecessor to the MyISAM format, called ISAM. The option can be used without specifying a filename, in which case the default, *myisam.log* is used.

To process the contents of the log file, use the [myisamlog](#) utility.

## 4.3.13.7 Concurrent Inserts

### Contents

1. [Notes](#)
2. [See Also](#)

The [MyISAM](#) storage engine supports concurrent inserts. This feature allows [SELECT](#) statements to be executed during [INSERT](#) operations, reducing contention.

Whether concurrent inserts can be used or not depends on the value of the [concurrent\\_insert](#) server system variable:

- NEVER  
(0) disables concurrent inserts.
- AUTO  
(1) allows concurrent inserts only when the target table has no free blocks (no data in the middle of the table has been deleted after the last [OPTIMIZE TABLE](#)). This is the default.
- ALWAYS  
(2) always enables concurrent inserts, in which case new rows are added at the end of a table if the table is being used by another thread.

If the [binary log](#) is used, [CREATE TABLE ... SELECT](#) and [INSERT ... SELECT](#) statements cannot use concurrent inserts. These statements acquire a read lock on the table, so concurrent inserts will need to wait. This way the log can be safely used to restore data.

Concurrent inserts are not used by replicas with the row based [replication](#) (see [binary log formats](#) ).

If an [INSERT](#) statement contain the [HIGH\\_PRIORITY](#) clause, concurrent inserts cannot be used. [INSERT ... DELAYED](#) is usually unneeded if concurrent inserts are enabled.

[LOAD DATA INFILE](#) uses concurrent inserts if the

CONCURRENT  
keyword is specified and [concurrent\\_insert](#) is not  
NEVER  
. This makes the statement slower (even if no other sessions access the table) but reduces contention.

[LOCK TABLES](#) allows non-conflicting concurrent inserts if a

READ LOCAL  
lock is used. Concurrent inserts are not allowed if the  
LOCAL  
keyword is omitted.

## Notes

The decision to enable concurrent insert for a table is done when the table is opened. If you change the value of [concurrent\\_insert](#) it will only affect new opened tables. If you want it to work for also for tables in use or cached, you should do [FLUSH TABLES](#) after setting the variable.

## 4.3.13.8 Segmented Key Cache

## Contents

1. About Segmented Key Cache
2. Segmented Key Cache Syntax
3. Segmented Key Cache Statistics
4. See Also

## About Segmented Key Cache

A segmented key cache is a collection of structures for regular [MyISAM](#) key caches called key cache segments. Segmented key caches mitigate one of the major problems of the simple key cache: thread contention for key cache lock (mutex). With regular key caches, every call of a key cache interface function must acquire this lock. So threads compete for this lock even in the case when they have acquired shared locks for the file and the pages they want to read from are in the key cache buffers.

When working with a segmented key cache any key cache interface function that needs only one page has to acquire the key cache lock only for the segment the page is assigned to. This makes the chances for threads not having to compete for the same key cache lock better.

Any page from a file can be placed into a buffer of only one segment. The number of the segment is calculated from the file number and the position of the page in the file, and it's always the same for the page. Pages are evenly distributed among segments.

The idea and the original code of the segmented key cache was provided by Fredrik Nylander from Stardoll.com. The code was extensively reworked, improved, and eventually merged into MariaDB by Igor Babaev from Monty Program (now MariaDB Corporation).

You can find some benchmark results comparing various settings on the [Segmented Key Cache Performance](#) page.

## Segmented Key Cache Syntax

New global variable: `key_cache_segments`. This variable sets the number of segments in a key cache. Valid values for this variable are whole numbers between

0  
and  
64  
. If the number of segments is set to a number greater than  
64  
the number of segments will be truncated to 64 and a warning will be issued.

A value of

0  
means the key cache is a regular (i.e. non-segmented) key cache. This is the default. If  
`key_cache_segments`  
is  
1  
(or higher) then the new key cache segmentation code is used. In practice there is no practical use of a single-segment segmented key cache  
except for testing purposes, and setting  
`key_cache_segments = 1`  
should be slower than any other option and should not be used in production.

Other global variables used when working with regular key caches also apply to segmented key caches: `key_buffer_size`, `key_cache_age_threshold`, `key_cache_block_size`, and `key_cache_division_limit`.

## Segmented Key Cache Statistics

Statistics about the key cache can be found by looking at the `KEY_CACHES` table in the `INFORMATION_SCHEMA` database. Columns in this table are:

Column Name	Description
<code>KEY_CACHE_NAME</code>	The name of the key cache
<code>SEGMENTS</code>	total number of segments (set to NULL for regular key caches)
<code>SEGMENT_NUMBER</code>	segment number (set to NULL for any regular key caches and for rows containing aggregation statistics for segmented key caches)
<code>FULL_SIZE</code>	memory for cache buffers/auxiliary structures
<code>BLOCK_SIZE</code>	size of the blocks

USED_BLOCKS	number of currently used blocks
UNUSED_BLOCKS	number of currently unused blocks
DIRTY_BLOCKS	number of currently dirty blocks
READ_REQUESTS	number of read requests
READS	number of actual reads from files into buffers
WRITE_REQUESTS	number of write requests
WRITES	number of actual writes from buffers into files

1. Greater Space Efficiency
2. Greater Writing Efficiency
3. Faster Data Loading
4. Faster Replication

2. Requirements and Limitations

## About MyRocks for MariaDB

MyRocks is an open source storage engine that was originally developed by Facebook.

MyRocks has been extended by the MariaDB engineering team to be a pluggable storage engine that you use in your MariaDB solutions. It works seamlessly with MariaDB features. This openness in the storage layer allows you to use the right storage engine to optimize your usage requirements, which provides optimum performance. Community contributions are one of MariaDB's greatest advantages over other databases. Under the lead of our developer Sergey Petrunia, MyRocks in MariaDB is occasionally being merged with upstream MyRocks from Facebook.

See more at: <https://mariadb.com/resources/blog/facebook-myrocks-mariadb#sthash.ZIEr7kNq.dpuf>

MyRocks, typically, gives greater performance for web scale type applications. It can be an ideal storage engine solution when you have workloads that require greater compression and IO efficiency. It uses a Log Structured Merge (LSM) architecture, which has advantages over B-Tree algorithms, to provide efficient data ingestion, like read-free replication slaves, or fast bulk data loading. MyRocks distinguishing features include:

- compaction filter
- merge operator
- backup
- column families
- bulk loading
- persistent cache

## Benefits

On production workloads, MyRocks was tested to prove that it provides:

### Greater Space Efficiency

- 2x more compression

MyRocks has 2x better compression compared to compressed InnoDB, 3-4x better compression compared to uncompressed InnoDB, meaning you use less space.

### Greater Writing Efficiency

- 2x lower write rates to storage

MyRocks has a 10x less write amplification compared to InnoDB, giving you better endurance of flash storage and improving overall throughput.

### Faster Data Loading

- faster database loads

MyRocks writes data directly onto the bottommost level, which avoids all compaction overheads when you enable faster data loading for a session.

### Faster Replication

- No random reads for updating secondary keys, except for unique indexes. The Read-Free Replication option does away with random reads when updating primary keys, regardless of uniqueness, with a row-based binary logging format.

<http://myrocks.io> <https://mariadb.com/resources/blog/facebook-myrocks-mariadb>

## Requirements and Limitations

- MyRocks is included from [MariaDB 10.2.5](#).
- MyRocks is available in the MariaDB Server packages for Linux and Windows.
- Maria DB optimistic parallel replication may not be supported.
- MyRocks is not available for 32-bit platforms
- [Galera Cluster](#) is tightly integrated into InnoDB storage engine (it also supports Percona's XtraDB which is a modified version of InnoDB). Galera Cluster does not work with any other storage engines, including MyRocks (or TokuDB for example).

MyRocks builds are available on platforms that support a sufficiently modern compiler, for example:

- Ubuntu Trusty, Xenial, (amd64 and ppc64el)
- Ubuntu Yakkety (amd64)
- Debian Jessie, stable (amd64, ppc64el)
- Debian Stretch, Sid (testing and unstable) (amd64)
- CentOS/RHEL 7 (amd64)
- Centos/RHEL 7.3 (amd64)
- Fedora 24 and 25 (amd64)
- OpenSUSE 42 (amd64)
- Windows 64 (zip and MSI)

### 4.3.14.2 Getting Started with MyRocks

MariaDB starting with [10.2.5](#)

The MyRocks storage engine was first released in [MariaDB 10.2.5](#).

MyRocks is a storage engine that adds the RocksDB database to MariaDB. RocksDB is an LSM database with a great compression ratio that is optimized for flash storage.

The storage engine must be installed before it can be used.

## Contents

1. [Installing the Plugin's Package](#)
  1. [Installing on Linux](#)
    1. [Installing with a Package Manager](#)
      1. [Installing with yum/dnf](#)
      2. [Installing with apt-get](#)
      3. [Installing with zypper](#)
    2. [Installing on Windows](#)
  2. [Installing the Plugin](#)
  3. [Uninstalling the Plugin](#)
  4. [Verifying the Installation](#)
  5. [Compression](#)
  6. [System and Status Variables](#)

## Installing the Plugin's Package

The MyRocks storage engine's shared library is included in MariaDB packages as the

`ha_rocksdb.so`

or

`ha_rocksdb.dll`

shared library on systems where it can be built. The plugin was first included in [MariaDB 10.2.5](#).

## Installing on Linux

The MyRocks storage engine is included in [binary tarballs](#) on Linux.

### Installing with a Package Manager

The MyRocks storage engine can also be installed via a package manager on Linux. In order to do so, your system needs to be configured to install from one of the MariaDB repositories.

You can configure your package manager to install it from MariaDB Corporation's MariaDB Package Repository by using the [MariaDB Package Repository setup script](#).

You can also configure your package manager to install it from MariaDB Foundation's MariaDB Repository by using the [MariaDB Repository Configuration Tool](#).

#### Installing with yum/dnf

On RHEL, CentOS, Fedora, and other similar Linux distributions, it is highly recommended to install the relevant [RPM package](#) from MariaDB's repository using

`yum`

or

`dnf`

. Starting with RHEL 8 and Fedora 22,

`yum`

has been replaced by

`dnf`

, which is the next major version of

`yum`

. However,

`yum`

commands still work on many systems that use

`dnf`

. For example:

```
sudo yum install MariaDB-rocksdb-engine
```

#### Installing with apt-get

On Debian, Ubuntu, and other similar Linux distributions, it is highly recommended to install the relevant [DEB package](#) from MariaDB's repository using

`apt-get`

. For example:

```
sudo apt-get install mariadb-plugin-rocksdb
```

Installing with zypper

On SLES, OpenSUSE, and other similar Linux distributions, it is highly recommended to install the relevant [RPM package](#) from MariaDB's repository using

```
zypper
```

. For example:

```
sudo zypper install MariaDB-rocksdb-engine
```

## Installing on Windows

The MyRocks storage engine is included in [MSI](#) and [ZIP](#) packages on Windows.

## Installing the Plugin

Once the shared library is in place, the plugin is not actually installed by MariaDB by default. There are two methods that can be used to install the plugin with MariaDB.

The first method can be used to install the plugin without restarting the server. You can install the plugin dynamically by executing

```
INSTALL SONAME
```

or

```
INSTALL PLUGIN
```

. For example:

```
INSTALL SONAME 'ha_rocksdb';
```

The second method can be used to tell the server to load the plugin when it starts up. The plugin can be installed this way by providing the

```
--plugin-load
```

or the

```
--plugin-load-add
```

options. This can be specified as a command-line argument to

```
mysqld
```

or it can be specified in a relevant server [option group](#) in an [option file](#) . For example:

```
[mariadb]
...
plugin_load_add = ha_rocksdb
```

Note: When installed with a package manager, an option file that contains the

```
--plugin-load-add
```

option may also be installed. The RPM package installs it as

/etc/my.cnf.d/rocksdb.cnf

, and the DEB package installs it as

/etc/mysql/mariadb.conf.d/rocksdb.cnf

## Uninstalling the Plugin

You can uninstall the plugin dynamically by executing

```
UNINSTALL SONAME
```

or

```
UNINSTALL PLUGIN
```

. For example:

```
UNINSTALL SONAME 'ha_rocksdb';
```

If you installed the plugin by providing the

```
--plugin-load
```

or the

```
--plugin-load-add
```

options in a relevant server [option group](#) in an [option file](#), then those options should be removed to prevent the plugin from being loaded the next time the server is restarted.

## Verifying the Installation

After installing MyRocks you will see RocksDB in the list of plugins:

```
SHOW PLUGINS;
+-----+-----+-----+-----+
| Name           | Status | Type      | Library          | License |
+-----+-----+-----+-----+
...
| ROCKSDB         | ACTIVE | STORAGE ENGINE | ha_rocksdb.so | GPL    |
| ROCKSDB_CFSTATS | ACTIVE | INFORMATION SCHEMA | ha_rocksdb.so | GPL    |
| ROCKSDB_DBSTATS | ACTIVE | INFORMATION SCHEMA | ha_rocksdb.so | GPL    |
| ROCKSDB_PERF_CONTEXT | ACTIVE | INFORMATION SCHEMA | ha_rocksdb.so | GPL    |
| ROCKSDB_PERF_CONTEXT_GLOBAL | ACTIVE | INFORMATION SCHEMA | ha_rocksdb.so | GPL    |
| ROCKSDB_CF_OPTIONS | ACTIVE | INFORMATION SCHEMA | ha_rocksdb.so | GPL    |
| ROCKSDB_COMPACTION_STATS | ACTIVE | INFORMATION SCHEMA | ha_rocksdb.so | GPL    |
| ROCKSDB_GLOBAL_INFO | ACTIVE | INFORMATION SCHEMA | ha_rocksdb.so | GPL    |
| ROCKSDB_DDL     | ACTIVE | INFORMATION SCHEMA | ha_rocksdb.so | GPL    |
| ROCKSDB_INDEX_FILE_MAP | ACTIVE | INFORMATION SCHEMA | ha_rocksdb.so | GPL    |
| ROCKSDB_LOCKS   | ACTIVE | INFORMATION SCHEMA | ha_rocksdb.so | GPL    |
| ROCKSDB_TRX     | ACTIVE | INFORMATION SCHEMA | ha_rocksdb.so | GPL    |
...
+-----+-----+-----+-----+
```

## Compression

Supported compression types are listed in the `rocksdb_supported_compression_types` variable. For example:

```
SHOW VARIABLES LIKE 'rocksdb_supported_compression_types';
+-----+-----+
| Variable_name        | Value   |
+-----+-----+
| rocksdb_supported_compression_types | Snappy,Zlib |
+-----+-----+
```

See [MyRocks and Data Compression](#) for more.

## System and Status Variables

All MyRocks [system variables](#) and [status variables](#) are prefaced with "rocksdb", so you can query them with, for example:

```
SHOW VARIABLES LIKE 'rocksdb%';
SHOW STATUS LIKE 'rocksdb%';
```

## 4.3.14.3 Building MyRocks in MariaDB

## Contents

1. Build Process and Requirements
2. Building on Ubuntu 16.04
3. Starting MyRocks

This page describes how to get [MyRocks in MariaDB](#) when compiling MariaDB from source.

(See <https://github.com/facebook/mysql-5.6/wiki/Build-Steps> for instructions how to build the upstream)

## Build Process and Requirements

MariaDB compile process will compile [MyRocks](#) into

ha\_rocksdb.so  
by default if the platform supports it (That is, no WITH\_ROCKSDB switch is necessary).

Platform requirements:

- A 64-bit platform (due to some 32 bit compilers having difficulties with RocksDB)
- git installed (or git submodules fetched somehow)
- A sufficiently recent compiler:
  - gcc >= 4.8, or
  - clang >= 3.3, or
  - MS Visual Studio 2015 or newer

## Building on Ubuntu 16.04

The steps were checked on a fresh install of Ubuntu 16.04.2 LTS Xenial.

```
sudo apt-get update
sudo apt-get -y install g++ cmake libbz2-dev libaio-dev bison zlib1g-dev libsnapy-dev
sudo apt-get -y install libgflags-dev libreadline6-dev libncurses5-dev libssl-dev liblz4-dev gdb git
;
```

```
git clone https://github.com/MariaDB/server.git mariadb-10.2
cd mariadb-10.2
git checkout 10.2
git submodule init
git submodule update
cmake .
make -j10
```

This should produce

```
storage/rocksdb/ha_rocksdb.so
which is MyRocks storage engine in the loadable form.
```

## Starting MyRocks

MyRocks does not require any special way to initialize the data directory. Minimal my.cnf file:

```
cat > ~/my1.cnf <<EOF
[mysqld]

datadir=../mysql-test/var/install.db
plugin-dir=../storage/rocksdb
language=./share/english
socket=/tmp/mysql.sock
port=3307

plugin-load=ha_rocksdb
default-storage-engine=rocksdb
EOF
```

Run the server like this

```
(cd mysql-test; ./mtr alias)
cp -r mysql-test/var/install.db ~./data1
cd ..sql
./mysqld --defaults-file=~/my1.cnf
```

Compression libraries. Supported compression libraries are listed in [rocksdb\\_supported\\_compression\\_types](#). Compiling like the above, I get:

## 4.3.14.4 Loading Data Into MyRocks

Being a write-optimized storage engine, MyRocks has special ways to load data much faster than normal INSERTs would.

See

- <http://myrocks.io/docs/getting-started/> ; the section about "Migrating from InnoDB to MyRocks in production" has some clues.
- <https://github.com/facebook/mysql-5.6/wiki/Data-Loading> covers the topic in greater detail.

Note When one loads data with `rocksdb_bulk_load=1` and the data conflicts with the data already in the database, one may get non-trivial errors, for example:

```
ERROR 1105 (HY000): [./rocksdb/test.t1_PRIMARY_2_0.bulk_load.tmp] bulk load error:  
Invalid argument: External file requires flush
```

## 4.3.14.5 MyRocks Status Variables

- **Introduced:** [MariaDB 10.2.18](#) , [MariaDB 10.3.10](#)
- 

### Rocksdb\_bloom\_filter\_prefix\_checked

- **Description:** Number of times the Bloom Filter checked before creating an iterator on a file.
- **Scope:** Global, Session
- **Data Type:**

    numeric

---

### Rocksdb\_bloom\_filter\_prefix\_useful

- **Description:** Number of times the Bloom Filter check used to avoid creating an iterator on a file.
  - **Scope:** Global, Session
  - **Data Type:**  
    numeric
- 

### Rocksdb\_bloom\_filter\_useful

- **Description:** Number of times the Bloom Filter used instead of reading from file.
  - **Scope:** Global, Session
  - **Data Type:**  
    numeric
- 

### Rocksdb\_bytes\_read

- **Description:** Total number of uncompressed bytes read from memtables, cache or table files.
  - **Scope:** Global, Session
  - **Data Type:**  
    numeric
- 

### Rocksdb\_bytes\_written

- **Description:** Total number of uncompressed bytes written.
  - **Scope:** Global, Session
  - **Data Type:**  
    numeric
- 

### Rocksdb\_compact\_read\_bytes

- **Description:** Number of bytes read during compaction.
  - **Scope:** Global, Session
  - **Data Type:**  
    numeric
- 

### Rocksdb\_compact\_write\_bytes

- **Description:** Number of bytes written during compaction.
  - **Scope:** Global, Session
  - **Data Type:**  
    numeric
- 

### Rocksdb\_compaction\_key\_drop\_new

- **Description:** Number of keys dropped during compaction due their being overwritten by new values.
- **Scope:** Global, Session

- **Data Type:**

numeric

---

#### Rocksdb\_compaction\_key\_drop\_obsolete

- **Description:** Number of keys dropped during compaction due to their being obsolete.

- **Scope:** Global, Session

- **Data Type:**

numeric

---

#### Rocksdb\_compaction\_key\_drop\_user

- **Description:** Number of keys dropped during compaction due to user compaction.

- **Scope:** Global, Session

- **Data Type:**

numeric

---

#### Rocksdb\_covered\_secondary\_key\_lookups

- **Description:** Incremented when avoiding reading a record via a keyread. This indicates lookups that were performed via a secondary index containing a field that is only a prefix of the **VARCHAR** column, and that could return all requested fields directly from the secondary index.

- **Scope:** Global, Session

- **Data Type:**

numeric

---

#### Rocksdb\_flush\_write\_bytes

- **Description:** Number of bytes written during flush.

- **Scope:** Global, Session

- **Data Type:**

numeric

---

#### Rocksdb\_get\_hit\_l0

- **Description:** Number of times reads got data from the L0 compaction layer.

- **Scope:** Global, Session

- **Data Type:**

numeric

- **Introduced:** [MariaDB 10.2.15](#) , [MariaDB 10.3.7](#)
- 

#### Rocksdb\_get\_hit\_l1

- **Description:** Number of times reads got data from the L1 compaction layer.

- **Scope:** Global, Session

- **Data Type:**

numeric

- **Introduced:** [MariaDB 10.2.15](#) , [MariaDB 10.3.7](#)
- 

`Rocksdb_get_hit_l2_and_up`

- **Description:** Number of times reads got data from the L2 and up compaction layer.
- **Scope:** Global, Session
- **Data Type:**  
    numeric

- **Introduced:** [MariaDB 10.2.15](#) , [MariaDB 10.3.7](#)
- 

`Rocksdb_getupdatessince_calls`

- **Description:** Number of calls to the  
    `GetUpdatesSince`  
    function. You may find this useful when monitoring refreshes of the transaction log.
  - **Scope:** Global, Session
  - **Data Type:**  
    numeric
- 

`Rocksdb_iter_bytes_read`

- **Description:** Total uncompressed bytes read from an iterator, including the size of both key and value.
  - **Scope:** Global, Session
  - **Data Type:**  
    numeric
- **Introduced:** [MariaDB 10.2.15](#) , [MariaDB 10.3.7](#)
- 

`Rocksdb_10_num_files_stall_micros`

- **Description:** Shows how long in microseconds throttled due to too many files in L0.
  - **Scope:** Global, Session
  - **Data Type:**  
    numeric
- **Removed:** [MariaDB 10.3.1](#) , [MariaDB 10.2.8](#)
- 

`Rocksdb_10_slowdown_micros`

- **Description:** Total time spent waiting in microseconds while performing L0-L1 compactions.
  - **Scope:** Global, Session
  - **Data Type:**  
    numeric
- **Removed:** [MariaDB 10.3.1](#) , [MariaDB 10.2.8](#)
- 

`Rocksdb_manual_compactions_processed`

- **Description:**
- **Scope:** Global, Session
- **Data Type:**

numeric

- **Introduced:** [MariaDB 10.2.18](#) , [MariaDB 10.3.10](#)
- 

#### Rocksdb\_manual\_compactions\_running

- **Description:**
- **Scope:** Global, Session
- **Data Type:**

numeric

- **Introduced:** [MariaDB 10.2.18](#) , [MariaDB 10.3.10](#)
- 

#### Rocksdb\_memtable\_compaction\_micros

- **Description:**
- **Scope:** Global, Session
- **Data Type:**

numeric

- **Removed:** [MariaDB 10.3.1](#) , [MariaDB 10.2.8](#)
- 

#### Rocksdb\_memtable\_hit

- **Description:** Number of memtable hits.
- **Scope:** Global, Session
- **Data Type:**

numeric

#### Rocksdb\_memtable\_miss

- **Description:** Number of memtable misses.
- **Scope:** Global, Session
- **Data Type:**

numeric

#### Rocksdb\_memtable\_total

- **Description:** Memory used, in bytes, of all memtables.
- **Scope:** Global, Session
- **Data Type:**

numeric

#### Rocksdb\_memtable\_unflushed

- **Description:** Memory used, in bytes, of all unflushed memtables.
- **Scope:** Global, Session
- **Data Type:**

numeric

---

### Rocksdb\_no\_file\_closes

- **Description:** Number of times files were closed.
- **Scope:** Global, Session
- **Data Type:**

    numeric

---

### Rocksdb\_no\_file\_errors

- **Description:** Number of errors encountered while trying to read data from an SST file.
- **Scope:** Global, Session
- **Data Type:**

    numeric

---

### Rocksdb\_no\_file\_opens

- **Description:** Number of times files were opened.
- **Scope:** Global, Session
- **Data Type:**

    numeric

---

### Rocksdb\_num\_iterators

- **Description:** Number of iterators currently open.
- **Scope:** Global, Session
- **Data Type:**

    numeric

---

### Rocksdb\_number\_block\_not\_compressed

- **Description:** Number of uncompressed blocks.
- **Scope:** Global, Session
- **Data Type:**

    numeric

---

### Rocksdb\_number\_db\_next

- **Description:** Number of next calls.
  - **Scope:** Global, Session
  - **Data Type:**
- numeric
- **Introduced:** [MariaDB 10.2.15](#) , [MariaDB 10.3.7](#)
-

## Rocksdb\_number\_db\_next\_found

- **Description:** Number of next calls that returned data.
  - **Scope:** Global, Session
  - **Data Type:** numeric
- **Introduced:** [MariaDB 10.2.15](#) , [MariaDB 10.3.7](#)
- 

## Rocksdb\_number\_db\_prev

- **Description:** Number of prev calls.
  - **Scope:** Global, Session
  - **Data Type:** numeric
- **Introduced:** [MariaDB 10.2.15](#) , [MariaDB 10.3.7](#)
- 

## Rocksdb\_number\_db\_prev\_found

- **Description:** Number of prev calls that returned data.
  - **Scope:** Global, Session
  - **Data Type:** numeric
- **Introduced:** [MariaDB 10.2.15](#) , [MariaDB 10.3.7](#)
- 

## Rocksdb\_number\_db\_seek

- **Description:** Number of seek calls.
  - **Scope:** Global, Session
  - **Data Type:** numeric
- **Introduced:** [MariaDB 10.2.15](#) , [MariaDB 10.3.7](#)
- 

## Rocksdb\_number\_db\_seek\_found

- **Description:** Number of seek calls that returned data.
  - **Scope:** Global, Session
  - **Data Type:** numeric
- **Introduced:** [MariaDB 10.2.15](#) , [MariaDB 10.3.7](#)
-

### Rocksdb\_number\_deletes\_filtered

- **Description:** Number of deleted records were not written to storage due to a nonexistent key.
  - **Scope:** Global, Session
  - **Data Type:**  
numeric
- 

### Rocksdb\_number\_keys\_read

- **Description:** Number of keys have been read.
  - **Scope:** Global, Session
  - **Data Type:**  
numeric
- 

### Rocksdb\_number\_keys\_updated

- **Description:** Number of keys have been updated.
  - **Scope:** Global, Session
  - **Data Type:**  
numeric
- 

### Rocksdb\_number\_keys\_written

- **Description:** Number of keys have been written.
  - **Scope:** Global, Session
  - **Data Type:**  
numeric
- 

### Rocksdb\_number\_merge\_failures

- **Description:** Number of failures encountered while performing merge operator actions.
  - **Scope:** Global, Session
  - **Data Type:**  
numeric
- 

### Rocksdb\_number\_multiget\_bytes\_read

- **Description:** Number of bytes read during RocksDB MultiGet()  
calls.
  - **Scope:** Global, Session
  - **Data Type:**  
numeric
- 

### Rocksdb\_number\_multiget\_get

- **Description:** Number of RocksDB

```
    MultiGet()  
    requests made.
```

- **Scope:** Global, Session

- **Data Type:**

```
    numeric
```

---

#### Rocksdb\_number\_multiget\_keys\_read

- **Description:** Number of keys read through RocksDB

```
    MultiGet()  
    calls.
```

- **Scope:** Global, Session

- **Data Type:**

```
    numeric
```

---

#### Rocksdb\_number\_reseeks\_iteration

- **Description:** Number of reseeks that have occurred inside an iteration that skipped over a large number of keys with the same user key.

- **Scope:** Global, Session

- **Data Type:**

```
    numeric
```

---

#### Rocksdb\_number\_sst\_entry\_delete

- **Description:** Number of delete markers written.

- **Scope:** Global, Session

- **Data Type:**

```
    numeric
```

---

#### Rocksdb\_number\_sst\_entry\_merge

- **Description:** Number of merge keys written.

- **Scope:** Global, Session

- **Data Type:**

```
    numeric
```

---

#### Rocksdb\_number\_sst\_entry\_other

- **Description:** Number of keys written that are not delete, merge or put keys.

- **Scope:** Global, Session

- **Data Type:**

```
    numeric
```

---

#### Rocksdb\_number\_sst\_entry\_put

- **Description:** Number of put keys written.

- **Scope:** Global, Session

- **Data Type:**

    numeric

---

#### Rocksdb\_number\_sst\_entry\_singledelete

- **Description:** Number of single-delete keys written.

- **Scope:** Global, Session

- **Data Type:**

    numeric

---

#### Rocksdb\_number\_superversion\_acquires

- **Description:** Number of times the superversion structure acquired. This is useful when tracking files for the database.

- **Scope:** Global, Session

- **Data Type:**

    numeric

---

#### Rocksdb\_number\_superversion\_cleanups

- **Description:** Number of times the superversion structure performed cleanups.

- **Scope:** Global, Session

- **Data Type:**

    numeric

---

#### Rocksdb\_number\_superversion\_releases

- **Description:** Number of times the superversion structure released.

- **Scope:** Global, Session

- **Data Type:**

    numeric

---

#### Rocksdb\_queries\_point

- **Description:** Number of single-row queries.

- **Scope:** Global, Session

- **Data Type:**

    numeric

---

#### Rocksdb\_queries\_range

- **Description:** Number of multi-row queries.

- **Scope:** Global, Session

- **Data Type:**

    numeric

---

## Rocksdb\_row\_lock\_deadlocks

- **Description:** Number of deadlocks.
  - **Scope:** Global, Session
  - **Data Type:**  
    numeric
- **Introduced:** [MariaDB 10.2.15](#) , [MariaDB 10.3.7](#)
- 

## Rocksdb\_row\_lock\_wait\_timeouts

- **Description:** Number of row lock wait timeouts.
  - **Scope:** Global, Session
  - **Data Type:**  
    numeric
- **Introduced:** [MariaDB 10.2.15](#) , [MariaDB 10.3.7](#)
- 

## Rocksdb\_rows\_deleted

- **Description:** Number of rows deleted.
- **Scope:** Global, Session
- **Data Type:**  
    numeric

## Rocksdb\_rows\_deleted\_blind

- **Description:**
- **Scope:** Global, Session
- **Data Type:**  
    numeric

## Rocksdb\_rows\_expired

- **Description:** Number of expired rows.
- **Scope:** Global, Session
- **Data Type:**  
    numeric

## Rocksdb\_rows\_filtered

- **Description:** Number of TTL filtered rows.
  - **Scope:** Global, Session
  - **Data Type:**  
    numeric
- **Introduced:** [MariaDB 10.2.15](#) , [MariaDB 10.3.7](#)
- 

## Rocksdb\_rows\_inserted

- **Description:** Number of rows inserted.

- **Scope:** Global, Session

- **Data Type:**

    numeric

---

#### Rocksdb\_rows\_read

- **Description:** Number of rows read.

- **Scope:** Global, Session

- **Data Type:**

    numeric

---

#### Rocksdb\_rows\_updated

- **Description:** Number of rows updated.

- **Scope:** Global, Session

- **Data Type:**

    numeric

---

#### Rocksdb\_snapshot\_conflict\_errors

- **Description:** Number of snapshot conflict errors that have occurred during transactions that forced a rollback.

- **Scope:** Global, Session

- **Data Type:**

    numeric

---

#### Rocksdb\_stall\_l0\_file\_count\_limit\_slowdowns

- **Description:** Write slowdowns due to L0 being near to full.

- **Scope:** Global, Session

- **Data Type:**

    numeric

---

#### Rocksdb\_stall\_l0\_file\_count\_limit\_stops

- **Description:** Write stops due to L0 being full.

- **Scope:** Global, Session

- **Data Type:**

    numeric

---

#### Rocksdb\_stall\_locked\_l0\_file\_count\_limit\_slowdowns

- **Description:** Write slowdowns due to L0 being near to full and L0 compaction in progress.

- **Scope:** Global, Session

- **Data Type:**

numeric

---

#### Rocksdb\_stall\_locked\_l0\_file\_count\_limit\_stops

- **Description:** Write stops due to L0 being full and L0 compaction in progress.
- **Scope:** Global, Session
- **Data Type:**

numeric

---

#### Rocksdb\_stall\_memtable\_limit\_slowdowns

- **Description:** Write slowdowns due to approaching maximum permitted number of memtables.
- **Scope:** Global, Session
- **Data Type:**

numeric

- **Introduced:** [MariaDB 10.2.10](#) , [MariaDB 10.3.3](#)
- 

#### Rocksdb\_stall\_memtable\_limit\_stops

- **Description:** \* **Description:** Write stops due to reaching maximum permitted number of memtables.
- **Scope:** Global, Session
- **Data Type:**

numeric

- **Introduced:** [MariaDB 10.2.10](#) , [MariaDB 10.3.3](#)
- 

#### Rocksdb\_stall\_micros

- **Description:** Time in microseconds that the writer had to wait for the compaction or flush to complete.
- **Scope:** Global, Session
- **Data Type:**

numeric

---

#### Rocksdb\_stall\_pending\_compaction\_limit\_slowdowns

- **Description:** Write slowdowns due to nearing the limit for the maximum number of pending compaction bytes.
- **Scope:** Global, Session
- **Data Type:**

numeric

---

#### Rocksdb\_stall\_pending\_compaction\_limit\_stops

- **Description:** Write stops due to reaching the limit for the maximum number of pending compaction bytes.
- **Scope:** Global, Session
- **Data Type:**

numeric

---

### Rocksdb\_stall\_total\_slowdowns

- **Description:** Total number of write slowdowns.
  - **Scope:** Global, Session
  - **Data Type:**  
    numeric
- 

### Rocksdb\_stall\_total\_stops

- **Description:** Total number of write stops.
  - **Scope:** Global, Session
  - **Data Type:**  
    numeric
- 

### Rocksdb\_system\_rows\_deleted

- **Description:** Number of rows deleted from system tables.
  - **Scope:** Global, Session
  - **Data Type:**  
    numeric
- 

### Rocksdb\_system\_rows\_inserted

- **Description:** Number of rows inserted into system tables.
  - **Scope:** Global, Session
  - **Data Type:**  
    numeric
- 

### Rocksdb\_system\_rows\_read

- **Description:** Number of rows read from system tables.
  - **Scope:** Global, Session
  - **Data Type:**  
    numeric
- 

### Rocksdb\_system\_rows\_updated

- **Description:** Number of rows updated for system tables.
  - **Scope:** Global, Session
  - **Data Type:**  
    numeric
- 

### Rocksdb\_wal\_bytes

- **Description:** Number of bytes written to WAL.

- **Scope:** Global, Session

- **Data Type:**

    numeric

---

#### Rocksdb\_wal\_group\_syncs

- **Description:** Number of group commit WAL file syncs have occurred. This is provided by MyRocks and is not a view of a RocksDB counter.

Increased in

    rocksdb\_flush\_wal()  
    when doing the  
    rdb->FlushWAL()  
    call.

- **Scope:** Global, Session

- **Data Type:**

    numeric

---

#### Rocksdb\_wal\_synced

- **Description:** Number of syncs made on RocksDB WAL file.

- **Scope:** Global, Session

- **Data Type:**

    numeric

---

#### Rocksdb\_write\_other

- **Description:** Number of writes processed by a thread other than the requesting thread.

- **Scope:** Global, Session

- **Data Type:**

    numeric

---

#### Rocksdb\_write\_self

- **Description:** Number of writes processed by requesting thread.

- **Scope:** Global, Session

- **Data Type:**

    numeric

---

#### Rocksdb\_write\_timedout

- **Description:** Number of writes that timed out.

- **Scope:** Global, Session

- **Data Type:**

    numeric

---

#### Rocksdb\_write\_wal

- **Description:** Number of write calls that requested WAL.

- **Scope:** Global, Session

- **Data Type:**

numeric

This page documents system variables related to the [MyRocks](#) storage engine. See [Server System Variables](#) for a complete list of system variables and instructions on setting them.

See also the [Full list of MariaDB options, system and status variables](#).

### `rocksdb_access_hint_on_compaction_start`

- **Description:** DBOptions::access\_hint\_on\_compaction\_start for RocksDB. Specifies the file access pattern, applied to all input files, once a compaction starts.
- **Commandline:**  
`--rocksdb-access-hint-on-compaction-start=`
- **Scope:** Global
- **Dynamic:** No
- **Data Type:**  
numeric
- **Default Value:**  
1
- **Range:**  
0  
to  
3

---

### `rocksdb_advise_random_on_open`

- **Description:** DBOptions::advise\_random\_on\_open for RocksDB.
- **Commandline:**  
`--rocksdb-advise-random-on-open={0|1}`
- **Scope:** Global
- **Dynamic:** No
- **Data Type:**  
boolean
- **Default Value:**  
ON

---

### `rocksdb_allow_concurrent_memtable_write`

- **Description:** DBOptions::allow\_concurrent\_memtable\_write for RocksDB.
- **Commandline:**  
`--rocksdb-allow-concurrent-memtable-write={0|1}`

- **Scope:** Global
- **Dynamic:** No
- **Data Type:**  
boolean

- **Default Value:**  
OFF
- 

rocksdb\_allow\_mmap\_reads

- **Description:** DBOptions::allow\_mmap\_reads for RocksDB
- **Commandline:**

--rocksdb-allow-mmap-reads={0|1}

- **Scope:** Global
- **Dynamic:** No
- **Data Type:**  
boolean

- **Default Value:**  
OFF
- 

rocksdb\_allow\_mmap\_writes

- **Description:** DBOptions::allow\_mmap\_writes for RocksDB
- **Commandline:**

--rocksdb-allow-mmap-writes={0|1}

- **Scope:** Global
- **Dynamic:** No
- **Data Type:**  
boolean

- **Default Value:**  
OFF
- 

rocksdb\_allow\_to\_start\_after\_corruption

- **Description:** Allow server still to start successfully even if RocksDB corruption is detected.
- **Commandline:**

--rocksdb-allow-to-start-after-corruption={0|1}

- **Scope:** Global
- **Dynamic:** No
- **Data Type:**  
boolean

- **Default Value:**  
OFF

- **Introduced:** [MariaDB 10.3.7](#) , [MariaDB 10.2.15](#)
- 

rocksdb\_background\_sync

- **Description:** Turns on background syncs for RocksDB
- **Commandline:**

```
--rocksdb-background-sync={0|1}
```

- **Scope:** Global
  - **Dynamic:** No
  - **Data Type:**  
    boolean
  - **Default Value:**  
    OFF
  - **Removed:** [MariaDB 10.3.1](#) , [MariaDB 10.2.8](#)
- 

### rocksdb\_base\_background\_compactions

- **Description:** DBOptions::base\_background\_compactions for RocksDB
  - **Commandline:**  
    --rocksdb-base-background-compactions=#
  - **Scope:** Global
  - **Dynamic:** No
  - **Data Type:**  
    numeric
  - **Default Value:**  
    1
  - **Range:**  
    -1  
    to  
    64
  - **Removed:** [MariaDB 10.3.1](#) , [MariaDB 10.2.8](#)
- 

### rocksdb\_blind\_delete\_primary\_key

- **Description:** Deleting rows by primary key lookup, without reading rows (Blind Deletes). Blind delete is disabled if the table has secondary key.
  - **Commandline:**  
    --rocksdb-blind-delete-primary-key={0|1}
  - **Scope:** Global, Session
  - **Dynamic:** Yes
  - **Data Type:**  
    boolean
  - **Default Value:**  
    OFF
- 

### rocksdb\_block\_cache\_size

- **Description:** Block\_cache size for RocksDB (block size 1024)
  - **Commandline:**  
    --rocksdb-block-cache-size=#
  - **Scope:** Global
  - **Dynamic:** No
  - **Data Type:**  
    numeric
  - **Default Value:**  
    536870912
-

- **Range:**

```
1024
to
9223372036854775807
```

To see the statistics of block cache usage, check

```
SHOW ENGINE ROCKSDB STATUS
output (search for lines starting with
rocksdb.block.cache
).
```

One can check the size of data of the block cache in

```
DB_BLOCK_CACHE_USAGE
column of the
INFORMATION_SCHEMA.ROCKSDB_DBSTATS
table.
```

---

### rocksdb\_block\_restart\_interval

- **Description:** BlockBasedTableOptions::block\_restart\_interval for RocksDB

- **Commandline:**

```
--rocksdb-block-restart-interval=#
```

- **Scope:** Global

- **Dynamic:** No

- **Data Type:**

```
numeric
```

- **Default Value:**

```
16
```

- **Range:**

```
1
to
2147483647
```

---

### rocksdb\_block\_size

- **Description:** BlockBasedTableOptions::block\_size for RocksDB

- **Commandline:**

```
--rocksdb-block-size=#
```

- **Scope:** Global

- **Dynamic:** No

- **Data Type:**

```
numeric
```

- **Default Value:**

```
4096
```

- **Range:**

```
1
to
18446744073709551615
```

---

### rocksdb\_block\_size\_deviation

- **Description:** BlockBasedTableOptions::block\_size\_deviation for RocksDB

- **Commandline:**

```
--rocksdb-block-size-deviation=#
```

- **Scope:** Global

- **Dynamic:** No

- **Data Type:**

    numeric

- **Default Value:**

    10

- **Range:**

    0

    to

    2147483647

---

### rocksdb\_bulk\_load

- **Description:** Use bulk-load mode for inserts. This disables unique\_checks and enables rocksdb\_commit\_in\_the\_middle.

- **Commandline:**

    --rocksdb-bulk-load={0|1}

- **Scope:** Global, Session

- **Dynamic:** Yes

- **Data Type:**

    boolean

- **Default Value:**

    OFF

---

### rocksdb\_bulk\_load\_allow\_sk

- **Description:** Allow bulk loading of sk keys during bulk-load. Can be changed only when bulk load is disabled.

- **Commandline:**

    --rocksdb-bulk-load\_allow\_sk={0|1}

- **Scope:** Global, Session

- **Dynamic:** Yes

- **Data Type:**

    boolean

- **Default Value:**

    OFF

- **Introduced:** [MariaDB 10.3.10](#) , [MariaDB 10.2.18](#)
- 

### rocksdb\_bulk\_load\_allow\_unsorted

- **Description:** Allow unsorted input during bulk-load. Can be changed only when bulk load is disabled.

- **Commandline:**

    --rocksdb-bulk-load\_allow\_unsorted={0|1}

- **Scope:** Global, Session

- **Dynamic:** Yes

- **Data Type:**

    boolean

- **Default Value:**

    OFF

---

## rocksdb\_bulk\_load\_size

- **Description:** Maximum number of records in a batch for bulk-load mode.

- **Commandline:**

--rocksdb-bulk-load-size=#

- **Scope:** Global, Session

- **Dynamic:** Yes

- **Data Type:**

numeric

- **Default Value:**

1000

- **Range:**

1

to

1073741824

---

## rocksdb\_bytes\_per\_sync

- **Description:** DBOptions::bytes\_per\_sync for RocksDB.

- **Commandline:**

--rocksdb-bytes-per-sync=#

- **Scope:** Global

- **Dynamic:** Yes

- **Data Type:**

numeric

- **Default Value:**

0

- **Range:**

0

to

18446744073709551615

---

## rocksdb\_cache\_dump

- **Description:** Include RocksDB block cache content in core dump.

- **Commandline:**

--rocksdb-cache-dump={0|1}

- **Scope:** Global

- **Dynamic:** Yes

- **Data Type:**

boolean

- **Default Value:**

ON

- **Introduced:** [MariaDB 10.4.7](#) , [MariaDB 10.3.17](#) , [MariaDB 10.2.26](#)
- 

## rocksdb\_cache\_high\_pri\_pool\_ratio

- **Description:** Specify the size of block cache high-pri pool.

- **Commandline:**

```
--rocksdb-cache-high-pri-pool-ratio=#
```

- **Scope:** Global
- **Dynamic:** Yes
- **Data Type:**  
double

- **Default Value:**  
0.000000

- **Range:**  
0  
to  
1

- **Introduced:** [MariaDB 10.4.7](#) , [MariaDB 10.3.17](#) , [MariaDB 10.2.26](#)
- 

### rocksdb\_cache\_index\_and\_filter\_blocks

- **Description:** BlockBasedTableOptions::cache\_index\_and\_filter\_blocks for RocksDB.
- **Commandline:**

```
--rocksdb-cache-index-and-filter-blocks={0|1}
```

- **Scope:** Global
- **Dynamic:** No
- **Data Type:**  
boolean

- **Default Value:**  
ON

### rocksdb\_cache\_index\_and\_filter\_with\_high\_priority

- **Description:** cache\_index\_and\_filter\_blocks\_with\_high\_priority for RocksDB.
- **Commandline:**

```
--rocksdb-cache-index-and-filter-with-high-priority={0|1}
```

- **Scope:** Global
- **Dynamic:** No
- **Data Type:**  
boolean

- **Default Value:**  
ON

- **Introduced:** [MariaDB 10.4.7](#) , [MariaDB 10.3.17](#) , [MariaDB 10.2.26](#)
- 

### rocksdb\_checksums\_pct

- **Description:** Percentage of rows to be checksummed.
- **Commandline:**

```
--rocksdb-checksums-pct=#
```

- **Scope:** Global, Session
- **Dynamic:** Yes
- **Data Type:**  
numeric

- **Default Value:**  
100

- **Range:**

0  
to  
100

---

### rocksdb\_collect\_sst\_properties

- **Description:** Enables collecting SST file properties on each flush.

- **Commandline:**

--rocksdb-collect-sst-properties={0|1}

- **Scope:** Global

- **Dynamic:** No

- **Data Type:**

boolean

- **Default Value:**

ON

---

### rocksdb\_commit\_in\_the\_middle

- **Description:** Commit rows implicitly every rocksdb\_bulk\_load\_size, on bulk load/insert, update and delete.

- **Commandline:**

--rocksdb-commit-in-the-middle={0|1}

- **Scope:** Global, Session

- **Dynamic:** Yes

- **Data Type:**

boolean

- **Default Value:**

OFF

---

### rocksdb\_commit\_time\_batch\_for\_recovery

- **Description:** TransactionOptions::commit\_time\_batch\_for\_recovery for RocksDB.

- **Commandline:**

--rocksdb-commit-time-batch-for-recovery={0|1}

- **Scope:** Global, Session

- **Dynamic:** Yes

- **Data Type:**

boolean

- **Default Value:**

OFF

- **Introduced:** [MariaDB 10.3.10](#) , [MariaDB 10.2.18](#)
- 

### rocksdb\_compact\_cf

- **Description:** Compact column family.

- **Commandline:**

--rocksdb-compact-cf=value

- **Scope:** Global

- **Dynamic:** Yes

- **Data Type:**

string

- **Default Value:** (Empty)
- 

### rocksdb\_compaction\_readahead\_size

- **Description:** DBOptions::compaction\_readahead\_size for RocksDB.

- **Commandline:**

--rocksdb-compaction-readahead-size=#

- **Scope:** Global

- **Dynamic:** Yes

- **Data Type:**

numeric

- **Default Value:**

0

- **Range:**

0

to

18446744073709551615

---

### rocksdb\_compaction\_sequential\_deletes

- **Description:** RocksDB will trigger compaction for the file if it has more than this number sequential deletes per window.

- **Commandline:**

--rocksdb-compaction-sequential-deletes=#

- **Scope:** Global

- **Dynamic:** Yes

- **Data Type:**

numeric

- **Default Value:**

0

- **Range:**

0

to

2000000

---

### rocksdb\_compaction\_sequential\_deletes\_count\_sd

- **Description:** Counting SingleDelete as rocksdb\_compaction\_sequential\_deletes.

- **Commandline:**

--rocksdb-compaction-sequential-deletes-count-sd={0|1}

- **Scope:** Global

- **Dynamic:** Yes

- **Data Type:**

boolean

- **Default Value:**

OFF

---

## `rocksdb_compaction_sequential_deletes_file_size`

- **Description:** Minimum file size required for compaction\_sequential\_deletes.

- **Commandline:**

```
--rocksdb-compaction-sequential-deletes-file-size=#
```

- **Scope:** Global

- **Dynamic:** Yes

- **Data Type:**

    numeric

- **Default Value:**

    0

- **Range:**

    -1

    to

    9223372036854775807

## `rocksdb_compaction_sequential_deletes_window`

- **Description:** Size of the window for counting rocksdb\_compaction\_sequential\_deletes.

- **Commandline:**

```
--rocksdb-compaction-sequential-deletes-window=#
```

- **Scope:** Global

- **Dynamic:** Yes

- **Data Type:**

    numeric

- **Default Value:**

    0

- **Range:**

    0

    to

    2000000

## `rocksdb_concurrent_prepare`

- **Description:** DBOptions::concurrent\_prepare for RocksDB.

- **Commandline:**

```
--rocksdb-coconcurrent-prepare={0|1}
```

- **Scope:** Global

- **Dynamic:** No

- **Data Type:**

    boolean

- **Default Value:**

    1

- **Removed:** [MariaDB 10.3.7](#) , [MariaDB 10.2.15](#)

## `rocksdb_create_checkpoint`

- **Description:** Checkpoint directory.

- **Commandline:**

```
--rocksdb-create-checkpoint=value
```

- **Scope:** Global
  - **Dynamic:** Yes
  - **Data Type:**  
    string
  - **Default Value:** (Empty)
- 

rocksdb\_create\_if\_missing

- **Description:** DBOptions::create\_if\_missing for RocksDB.

- **Commandline:**

```
--rocksdb-create-if-missing={0|1}
```

- **Scope:** Global
- **Dynamic:** No
- **Data Type:**  
    boolean

- **Default Value:**

ON

---

rocksdb\_create\_missing\_column\_families

- **Description:** DBOptions::create\_missing\_column\_families for RocksDB.

- **Commandline:**

```
--rocksdb-create-missing-column-families={0|1}
```

- **Scope:** Global
- **Dynamic:** No
- **Data Type:**  
    boolean

- **Default Value:**

OFF

---

rocksdb\_datadir

- **Description:** RocksDB data directory.

- **Commandline:**

```
--rocksdb-datadir[=value]
```

- **Scope:** Global
- **Dynamic:** No
- **Data Type:**  
    string

- **Default Value:**

./#rocksdb

---

rocksdb\_db\_write\_buffer\_size

- **Description:** DBOptions::db\_write\_buffer\_size for RocksDB.

- **Commandline:**

```
--rocksdb-db-write-buffer-size=
```

- **Scope:** Global
- **Dynamic:** No
- **Data Type:**  
numeric

- **Default Value:**

0

- **Range:**

0

to

18446744073709551615

### rocksdb\_deadlock\_detect

- **Description:** Enables deadlock detection.

- **Commandline:**

--rocksdb-deadlock-detect={0|1}

- **Scope:** Global, Session

- **Dynamic:** Yes

- **Data Type:**

boolean

- **Default Value:**

OFF

### rocksdb\_deadlock\_detect\_depth

- **Description:** Number of transactions deadlock detection will traverse through before assuming deadlock.

- **Commandline:**

--rocksdb-deadlock-detect-depth=#

- **Scope:** Global, Session

- **Dynamic:** Yes

- **Data Type:**

numeric

- **Default Value:**

50

- **Range:**

2

to

18446744073709551615

### rocksdb\_debug\_manual\_compaction\_delay

- **Description:** For debugging purposes only. Sleeping specified seconds for simulating long running compactions.

- **Commandline:**

--rocksdb-debug\_manual\_compaction\_delay=#

- **Scope:** Global

- **Dynamic:** Yes

- **Data Type:**

numeric

- **Default Value:**

0

- **Range:**

0  
to  
4294967295

- **Introduced:** [MariaDB 10.3.10](#) , [MariaDB 10.2.18](#)
- 

### rocksdb\_debug\_optimizer\_no\_zero\_cardinality

- **Description:** If cardinality is zero, override it with some value.

- **Commandline:**

--rocksdb-debug-optimizer-no-zero-cardinality={0|1}

- **Scope:** Global

- **Dynamic:** Yes

- **Data Type:**

boolean

- **Default Value:**

ON

### rocksdb\_debug\_ttl\_ignore\_pk

- **Description:** For debugging purposes only. If true, compaction filtering will not occur on PK TTL data. This variable is a no-op in non-debug builds.
- **Commandline:**

--rocksdb-debug-ttl-ignore-pk={0|1}

- **Scope:** Global

- **Dynamic:** Yes

- **Data Type:**

boolean

- **Default Value:**

OFF

### rocksdb\_debug\_ttl\_read\_filter\_ts

- **Description:** For debugging purposes only. Overrides the TTL read filtering time to time + debug\_ttl\_read\_filter\_ts. A value of 0 denotes that the variable is not set. This variable is a no-op in non-debug builds.

- **Commandline:**

--rocksdb-debug-ttl-read-filter-ts=#

- **Scope:** Global

- **Dynamic:** Yes

- **Data Type:**

numeric

- **Default Value:**

0

- **Range:**

-3600  
to  
3600

- **Introduced:** [MariaDB 10.3.1](#) , [MariaDB 10.2.8](#)
-

## `rocksdb_debug_ttl_rec_ts`

- **Description:** For debugging purposes only. Overrides the TTL of records to now() + debug\_ttl\_rec\_ts. The value can be +/- to simulate a record inserted in the past vs a record inserted in the 'future'. A value of 0 denotes that the variable is not set. This variable is a no-op in non-debug builds.
  - **Commandline:**  
  `--rocksdb-debug-ttl-read-filter-ts=#`
  - **Scope:** Global
  - **Dynamic:** Yes
  - **Data Type:**  
  numeric
  - **Default Value:**  
  0
  - **Range:**  
  -3600  
  to  
  3600
  - **Introduced:** [MariaDB 10.3.1](#) , [MariaDB 10.2.8](#)
- 

## `rocksdb_debug_ttl_snapshot_ts`

- **Description:** For debugging purposes only. Sets the snapshot during compaction to now() + debug\_set\_ttl\_snapshot\_ts. The value can be positive or negative to simulate a snapshot in the past vs a snapshot created in the 'future'. A value of 0 denotes that the variable is not set. This variable is a no-op in non-debug builds.
  - **Commandline:**  
  `--rocksdb-debug-ttl-snapshot-ts=#`
  - **Scope:** Global
  - **Dynamic:** Yes
  - **Data Type:**  
  numeric
  - **Default Value:**  
  0
  - **Range:**  
  -3600  
  to  
  3600
  - **Introduced:** [MariaDB 10.3.1](#) , [MariaDB 10.2.8](#)
- 

## `rocksdb_default_cf_options`

- **Description:** Default cf options for RocksDB.
  - **Commandline:**  
  `--rocksdb-default-cf-options=value`
  - **Scope:** Global
  - **Dynamic:** No
  - **Data Type:**  
  string
  - **Default Value:** (Empty)
- 

## `rocksdb_delayed_write_rate`

- **Description:** DBOptions::delayed\_write\_rate.

- **Commandline:**  
--rocksdb-delayed-write-rate=#

- **Scope:** Global

- **Dynamic:** Yes

- **Data Type:**

    numeric

- **Default Value:**

    0  
    (Previously  
    16777216  
    )  
    )

- **Range:**

    0  
    to  
    18446744073709551615

---

### rocksdb\_delete\_cf

- **Description:** Delete column family.

- **Commandline:**

    --rocksdb-delete-cf=val

- **Scope:** Global

- **Dynamic:** No

- **Data Type:**

    string

- **Default Value:** (Empty string)

- **Introduced:** [MariaDB 10.4.7](#) , [MariaDB 10.3.17](#) , [MariaDB 10.2.26](#)
- 

### rocksdb\_delete\_obsolete\_files\_period\_micros

- **Description:** DBOptions::deleteObsoleteFilesPeriodMicros for RocksDB.

- **Commandline:**

    --rocksdb-delete-obsolete-files-period-micros=#

- **Scope:** Global

- **Dynamic:** No

- **Data Type:**

    numeric

- **Default Value:**

    21600000000

- **Range:**

    0  
    to  
    9223372036854775807

---

### rocksdb\_enable\_2pc

- **Description:** Enable two phase commit for MyRocks. When set, MyRocks will keep its data consistent with the [binary log](#) (in other words, the server will be a crash-safe master). The consistency is achieved by doing two-phase XA commit with the binary log.

- **Commandline:**

    --rocksdb-enable-2pc={0|1}

- **Scope:** Global

- **Dynamic:** Yes

- **Data Type:**

boolean

- **Default Value:**

ON

---

### rocksdb\_enable\_bulk\_load\_api

- **Description:** Enables using SstFileWriter for bulk loading.

- **Commandline:**

--rocksdb-enable-bulk-load-api={0|1}

- **Scope:** Global

- **Dynamic:** No

- **Data Type:**

boolean

- **Default Value:**

ON

---

### rocksdb\_enable\_insert\_with\_update\_caching

- **Description:** Whether to enable optimization where we cache the read from a failed insertion attempt in [INSERT ON DUPLICATE KEY UPDATE](#).

- **Commandline:**

--rocksdb-enable-insert-with-update-caching={0|1}

- **Scope:** Global

- **Dynamic:** Yes

- **Data Type:**

boolean

- **Default Value:**

ON

- **Introduced:** [MariaDB 10.4.7](#) , [MariaDB 10.3.17](#) , [MariaDB 10.2.26](#)

---

### rocksdb\_enable\_thread\_tracking

- **Description:** DBOptions::enable\_thread\_tracking for RocksDB.

- **Commandline:**

--rocksdb-enable-thread-tracking={0|1}

- **Scope:** Global

- **Dynamic:** No

- **Data Type:**

boolean

- **Default Value:**

OFF

---

### rocksdb\_enable\_ttl

- **Description:** Enable expired TTL records to be dropped during compaction.

- **Commandline:**

--rocksdb-enable-ttl={0|1}

- **Scope:** Global
- **Dynamic:** Yes
- **Data Type:**  
boolean

- **Default Value:**  
ON

- **Introduced:** [MariaDB 10.3.1](#) , [MariaDB 10.2.8](#)
- 

#### `rocksdb_enable_ttl_read_filtering`

- **Description:** For tables with TTL, expired records are skipped/filtered out during processing and in query results. Disabling this will allow these records to be seen, but as a result rows may disappear in the middle of transactions as they are dropped during compaction. Use with caution.

- **Commandline:**  
`--rocksdb-enable-ttl-read-filtering={0|1}`

- **Scope:** Global
- **Dynamic:** Yes
- **Data Type:**  
boolean

- **Default Value:**  
ON

- **Introduced:** [MariaDB 10.3.1](#) , [MariaDB 10.2.8](#)
- 

#### `rocksdb_enable_write_thread_adaptive_yield`

- **Description:** DBOptions::enable\_write\_thread\_adaptive\_yield for RocksDB.
- **Commandline:**  
`--rocksdb-enable-write-thread-adaptive-yield={0|1}`

- **Scope:** Global
- **Dynamic:** No
- **Data Type:**  
boolean

- **Default Value:**  
OFF
- 

#### `rocksdb_error_if_exists`

- **Description:** DBOptions::error\_if\_exists for RocksDBB.
- **Commandline:**  
`--rocksdb-error-if-exists={0|1}`

- **Scope:** Global
- **Dynamic:** No
- **Data Type:**  
boolean

- **Default Value:**  
OFF
- 

#### `rocksdb_error_on_suboptimal_collation`

- **Description:** Raise an error instead of warning if a sub-optimal collation is used.

- **Commandline:**

```
--rocksdb-error-on-suboptimal-collation={0|1}
```

- **Scope:** Global

- **Dynamic:** No

- **Data Type:**

boolean

- **Default Value:**

ON

- **Introduced:** [MariaDB 10.3.10](#) , [MariaDB 10.2.18](#)
- 

### rocksdb\_flush\_log\_at\_trx\_commit

- **Description:** Sync on transaction commit. Similar to [innodb\\_flush\\_log\\_at\\_trx\\_commit](#). One can check the flushing by examining the [rocksdb\\_wal\\_synced](#) and [rocksdb\\_wal\\_bytes](#) status variables.

- 1 : Always sync on commit (the default).
- 0 : Never sync.
- 2 : Sync based on a timer controlled via rocksdb-background-sync.

- **Commandline:**

```
--rocksdb-flush-log-at-trx-commit=#
```

- **Scope:** Global

- **Dynamic:** Yes

- **Data Type:**

numeric

- **Default Value:**

1

- **Range:**

0

to

2

---

### rocksdb\_flush\_memtable\_on\_analyze

- **Description:** Forces memtable flush on ANALYZE table to get accurate cardinality.

- **Commandline:**

```
--rocksdb-flush-memtable-on-analyze={0|1}
```

- **Scope:** Global, Session

- **Dynamic:** Yes

- **Data Type:**

boolean

- **Default Value:**

ON

- **Removed:** [MariaDB 10.3.7](#) , [MariaDB 10.2.15](#)
- 

### rocksdb\_force\_compute\_memtable\_stats

- **Description:** Force to always compute memtable stats.

- **Commandline:**

```
--rocksdb-force-compute-memtable-stats={0|1}
```

- **Scope:** Global

- **Dynamic:** Yes

- **Data Type:**

boolean

- **Default Value:**

ON

---

### rocksdb\_force\_compute\_memtable\_stats\_cachetime

- **Description:** Time in usecs to cache memtable estimates.

- **Commandline:**

--rocksdb-force-compute-memtable-stats-cachetime=#

- **Scope:** Global

- **Dynamic:** Yes

- **Data Type:**

numeric

- **Default Value:**

60000000

- **Range:**

0

to

2147483647

---

### rocksdb\_force\_flush\_memtable\_and\_lzero\_now

- **Description:** Acts similar to force\_flush\_memtable\_now, but also compacts all L0 files.

- **Commandline:**

--rocksdb-force-flush-memtable-and-lzero-now={0|1}

- **Scope:** Global

- **Dynamic:** Yes

- **Data Type:**

boolean

- **Default Value:**

OFF

- **Introduced:** [MariaDB 10.3.1](#) , [MariaDB 10.2.8](#)
- 

### rocksdb\_force\_flush\_memtable\_now

- **Description:** Forces memstore flush which may block all write requests so be careful.

- **Commandline:**

--rocksdb-force-flush-memtable-now={0|1}

- **Scope:** Global

- **Dynamic:** Yes

- **Data Type:**

boolean

- **Default Value:**

OFF

---

### rocksdb\_force\_index\_records\_in\_range

- **Description:** Used to override the result of records\_in\_range() when **FORCE INDEX** is used.

- **Commandline:**

```
--rocksdb-force-index-records-in-range=#
```

- **Scope:** Global, Session

- **Dynamic:** Yes

- **Data Type:**

numeric

- **Default Value:**

0

- **Range:**

0

to

2147483647

## rocksdb\_git\_hash

- **Description:** Git revision of the RocksDB library used by MyRocks.

- **Commandline:**

```
--rocksdb-git-hash=value=#
```

- **Scope:** Global

- **Dynamic:** No

- **Data Type:**

string

- **Default Value:** As per git revision.

## rocksdb\_hash\_index\_allow\_collision

- **Description:** BlockBasedTableOptions::hash\_index\_allow\_collision for RocksDB.

- **Commandline:**

```
--rocksdb-hash-index-allow-collision={0|1}
```

- **Scope:** Global

- **Dynamic:** No

- **Data Type:**

boolean

- **Default Value:**

ON

## rocksdb\_ignore\_unknown\_options

- **Description:** Enable ignoring unknown options passed to RocksDB.

- **Commandline:**

```
--rocksdb-ignore-unknown-options={0|1}
```

- **Scope:** Global

- **Dynamic:** No

- **Data Type:**

boolean

- **Default Value:**

ON

- **Introduced:** MariaDB 10.3.7 , MariaDB 10.2.15

## rocksdb\_index\_type

- **Description:** BlockBasedTableOptions::index\_type for RocksDB.

- **Commandline:**

```
--rocksdb-index-type=value
```

- **Scope:** Global

- **Dynamic:** No

- **Data Type:**

enum

- **Default Value:**

```
kBinarySearch
```

- **Valid Values:**

```
kBinarySearch
```

,

```
kHashSearch
```

## rocksdb\_info\_log\_level

- **Description:** Filter level for info logs to be written mysqld error log. Valid values include 'debug\_level', 'info\_level', 'warn\_level', 'error\_level' and 'fatal\_level'.

- **Commandline:**

```
--rocksdb-info-log-level=value
```

- **Scope:** Global

- **Dynamic:** Yes

- **Data Type:**

enum

- **Default Value:**

```
error_level
```

- **Valid Values:**

```
error_level
```

,

```
debug_level
```

,

```
info_level
```

,

```
warn_level
```

,

```
fatal_level
```

## rocksdb\_io\_write\_timeout

- **Description:** Timeout for experimental I/O watchdog.

- **Commandline:**

```
--rocksdb-io-write-timeout=#
```

- **Scope:** Global

- **Dynamic:** Yes

- **Data Type:**

numeric

- **Default Value:**

0

- **Valid Values:**

0

to

- **Introduced:** [MariaDB 10.3.1](#) , [MariaDB 10.2.8](#)
- 

### `rocksdb_is_fd_close_on_exec`

- **Description:** DBOptions::is\_fd\_close\_on\_exec for RocksDB.

- **Commandline:**

```
--rocksdb-is-fd-close-on-exec={0|1}
```

- **Scope:** Global

- **Dynamic:** No

- **Data Type:**

boolean

- **Default Value:**

ON

### `rocksdb_keep_log_file_num`

- **Description:** DBOptions::keep\_log\_file\_num for RocksDB.

- **Commandline:**

```
--rocksdb-keep-log-file-num=
```

- **Scope:** Global

- **Dynamic:** No

- **Data Type:**

numeric

- **Default Value:**

1000

- **Range:**

0

to

18446744073709551615

### `rocksdb_large_prefix`

- **Description:** Support large index prefix length of 3072 bytes. If off, the maximum index prefix length is 767.

- **Commandline:**

```
--rocksdb-large_prefix={0|1}
```

- **Scope:** Global

- **Dynamic:** Yes

- **Data Type:**

boolean

- **Default Value:**

OFF

### `rocksdb_lock_scanned_rows`

- **Description:** Take and hold locks on rows that are scanned but not updated.

- **Commandline:**

```
--rocksdb-lock-scanned-rows={0|1}
```

- **Scope:** Global, Session
- **Dynamic:** Yes
- **Data Type:**  
boolean

- **Default Value:**  
OFF
- 

#### rocksdb\_lock\_wait\_timeout

- **Description:** Number of seconds to wait for lock.
- **Commandline:**  
--rocksdb-lock-wait-timeout=#

- **Scope:** Global, Session
- **Dynamic:** Yes
- **Data Type:**  
numeric

- **Default Value:**  
1

- **Range:**  
1  
to  
1073741824
- 

#### rocksdb\_log\_file\_time\_to\_roll

- **Description:** DBOptions::log\_file\_time\_to\_roll for RocksDB.
- **Commandline:**  
--rocksdb-log-file-time-to\_roll=#

- **Scope:** Global
- **Dynamic:** No
- **Data Type:**  
numeric

- **Default Value:**  
0

- **Range:**  
0  
to  
18446744073709551615
- 

#### rocksdb\_manifest\_preallocation\_size

- **Description:** DBOptions::manifest\_preallocation\_size for RocksDB.

- **Commandline:**  
--rocksdb-manifest-preallocation-size=#

- **Scope:** Global
- **Dynamic:** No
- **Data Type:**  
numeric

- **Default Value:**

- **Range:**

```
0
to
18446744073709551615
```

---

### `rocksdb_manual_compaction_threads`

- **Description:** How many rocksdb threads to run for manual compactions.

- **Commandline:**

```
--rocksdb-manual-compation-threads=#
```

- **Scope:** Global, Session

- **Dynamic:** Yes

- **Data Type:**

```
numeric
```

- **Default Value:**

```
0
```

- **Range:**

```
0
to
128
```

- **Introduced:** [MariaDB 10.3.10](#) , [MariaDB 10.2.18](#)
- 

### `rocksdb_manual_wal_flush`

- **Description:** DBOptions::manual\_wal\_flush for RocksDB.

- **Commandline:**

```
--rocksdb-manual-wal-flush={0|1}
```

- **Scope:** Global

- **Dynamic:** No

- **Data Type:**

```
boolean
```

- **Default Value:**

```
ON
```

---

### `rocksdb_master_skip_tx_api`

- **Description:** Skipping holding any lock on row access. Not effective on slave.

- **Commandline:**

```
--rocksdb-master-skip-tx-api={0|1}
```

- **Scope:** Global, Session

- **Dynamic:** Yes

- **Data Type:**

```
boolean
```

- **Default Value:**

```
OFF
```

---

### `rocksdb_max_background_compactions`

- **Description:** DBOptions::max\_background\_compactions for RocksDB.

- **Commandline:**

```
--rocksdb-max-background-compactions=#
```

- **Scope:** Global

- **Dynamic:** Yes

- **Data Type:**

    numeric

- **Default Value:**

    1

- **Range:**

    1

    to

    64

- **Removed:** [MariaDB 10.3.1](#) , [MariaDB 10.2.8](#)
- 

## rocksdb\_max\_background\_flushes

- **Description:** DBOptions::max\_background\_flushes for RocksDB.

- **Commandline:**

```
--rocksdb-max-background-flushes=#
```

- **Scope:** Global

- **Dynamic:** No

- **Data Type:**

    numeric

- **Default Value:**

    1

- **Range:**

    1

    to

    64

- **Removed:** [MariaDB 10.3.1](#) , [MariaDB 10.2.8](#)
- 

## rocksdb\_max\_background\_jobs

- **Description:** DBOptions::max\_background\_jobs for RocksDB.

- **Commandline:**

```
--rocksdb-max-background-jobs=#
```

- **Scope:** Global

- **Dynamic:** Yes

- **Data Type:**

    numeric

- **Default Value:**

    2

- **Range:**

    -1

    to

    64

- **Introduced:** [MariaDB 10.3.1](#) , [MariaDB 10.2.8](#)
-

## `rocksdb_max_latest_deadlocks`

- **Description:** Maximum number of recent deadlocks to store.

- **Commandline:**

```
--rocksdb-max-latest-deadlocks=#
```

- **Scope:** Global

- **Dynamic:** Yes

- **Data Type:**

    numeric

- **Default Value:**

    5

- **Range:**

    0

    to

    4294967295

## `rocksdb_max_log_file_size`

- **Description:** DBOptions::max\_log\_file\_size for RocksDB.

- **Commandline:**

```
--rocksdb-max-log-file-size=#
```

- **Scope:** Global

- **Dynamic:** No

- **Data Type:**

    numeric

- **Default Value:**

    0

- **Range:**

    0

    to

    18446744073709551615

## `rocksdb_max_manifest_file_size`

- **Description:** DBOptions::max\_manifest\_file\_size for RocksDB.

- **Commandline:**

```
--rocksdb-manifest-log-file-size=#
```

- **Scope:** Global

- **Dynamic:** No

- **Data Type:**

    numeric

- **Default Value:**

    1073741824

- **Range:**

    0

    to

    18446744073709551615

## `rocksdb_max_manual_compactions`

- **Description:** Maximum number of pending + ongoing number of manual compactions..

- **Commandline:**

```
--rocksdb-manual_compactions=#
```

- **Scope:** Global

- **Dynamic:** Yes

- **Data Type:**

    numeric

- **Default Value:**

    10

- **Range:**

    0

    to

    4294967295

- **Introduced:** [MariaDB 10.3.10](#) , [MariaDB 10.2.18](#)
- 

## rocksdb\_max\_open\_files

- **Description:** DBOptions::max\_open\_files for RocksDB.

- **Commandline:**

```
--rocksdb-max-open-files=#
```

- **Scope:** Global

- **Dynamic:** No

- **Data Type:**

    numeric

- **Default Value:**

    -2

- **Range:**

    -2

    to

    2147483647

---

## rocksdb\_max\_row\_locks

- **Description:** Maximum number of locks a transaction can have.

- **Commandline:**

```
--rocksdb-max-row-locks=#
```

- **Scope:** Global, Session

- **Dynamic:** Yes

- **Data Type:**

    numeric

- **Default Value:**

    1048576

- **Range:**

    ◦

        1

        to

        1073741824

        (>= [MariaDB 10.3.10](#) , [MariaDB 10.2.18](#) )

    ◦

        1

        to

        1048576

        (<= [MariaDB 10.3.9](#) , [MariaDB 10.2.17](#) )

---

## rocksdb\_max\_subcompactions

- **Description:** DBOptions::max\_subcompactions for RocksDB.

- **Commandline:**

```
--rocksdb-max-subcompactions=#
```

- **Scope:** Global

- **Dynamic:** No

- **Data Type:**

    numeric

- **Default Value:**

    1

- **Range:**

    1

    to

    64

## rocksdb\_max\_total\_wal\_size

- **Description:** DBOptions::max\_total\_wal\_size for RocksDB. The maximum size limit for write-ahead-log files. Once this limit is reached, RocksDB forces the flushing of memtables.

- **Commandline:**

```
--rocksdb-max-total-wal-size=#
```

- **Scope:** Global

- **Dynamic:** No

- **Data Type:**

    numeric

- **Default Value:**

    0

- **Range:**

    0

    to

    9223372036854775807

## rocksdb\_merge\_buf\_size

- **Description:** Size to allocate for merge sort buffers written out to disk during inplace index creation.

- **Commandline:**

```
--rocksdb-merge-buf-size=#
```

- **Scope:** Global, Session

- **Dynamic:** Yes

- **Data Type:**

    numeric

- **Default Value:**

    67108864

- **Range:**

    100

    to

    18446744073709551615

## `rocksdb_merge_combine_read_size`

- **Description:** Size that we have to work with during combine (reading from disk) phase of external sort during fast index creation.

- **Commandline:**

```
--rocksdb-merge-combine-read-size=#
```

- **Scope:** Global, Session

- **Dynamic:** Yes

- **Data Type:**

    numeric

- **Default Value:**

    1073741824

- **Range:**

    100

    to

    18446744073709551615

## `rocksdb_merge_tmp_file_removal_delay_ms`

- **Description:** Fast index creation creates a large tmp file on disk during index creation. Removing this large file all at once when index creation is complete can cause trim stalls on Flash. This variable specifies a duration to sleep (in milliseconds) between calling chsize() to truncate the file in chunks. The chunk size is the same as merge\_buf\_size.

- **Commandline:**

```
--rocksdb-merge-tmp-file-removal-delay-ms=#
```

- **Scope:** Global, Session

- **Dynamic:** Yes

- **Data Type:**

    numeric

- **Default Value:**

    0

- **Range:**

    0

    to

    18446744073709551615

## `rocksdb_new_table_reader_for_compaction_inputs`

- **Description:** DBOptions::new\_table\_reader\_for\_compaction\_inputs for RocksDB.

- **Commandline:**

```
--rocksdb-new-table-reader-for-compaction-inputs={0|1}
```

- **Scope:** Global

- **Dynamic:** No

- **Data Type:**

    boolean

- **Default Value:**

    OFF

## `rocksdb_no_block_cache`

- **Description:** BlockBasedTableOptions::no\_block\_cache for RocksDB.

- **Commandline:**

```
--rocksdb-no-block-cache={0|1}
```

- **Scope:** Global
  - **Dynamic:** No
  - **Data Type:**  
boolean
  - **Default Value:**  
OFF
- 

### rocksdb\_override\_cf\_options

- **Description:** Option overrides per cf for RocksDB. Note that the

```
rocksdb-override-cf-options
```

syntax is quite strict, and any typos will result in a parse error, and the MyRocks plugin will not be loaded. Depending on your configuration, the server may still start. If it does start, you can use this command to check if the plugin is loaded:

```
select * from information_schema.plugins where plugin_name='ROCKSDB'
```

(note that you need the "ROCKSDB" plugin. Other auxiliary plugins like "ROCKSDB\_TRX" might still get loaded). Another way is to detect the error is check the error log.

- **Commandline:**  
`--rocksdb-override-cf-options=value`

- **Scope:** Global

- **Dynamic:** No

- **Data Type:**

```
string
```

- **Default Value:** (Empty)
- 

### rocksdb\_paranoid\_checks

- **Description:** DBOptions::paranoid\_checks for RocksDB.

- **Commandline:**

```
--rocksdb-paranoid-checks={0|1}
```

- **Scope:** Global

- **Dynamic:** No

- **Data Type:**

```
boolean
```

- **Default Value:**

```
ON
```

---

### rocksdb\_pause\_background\_work

- **Description:** Disable all rocksdb background operations.

- **Commandline:**

```
--rocksdb-pause-background-work={0|1}
```

- **Scope:** Global

- **Dynamic:** Yes

- **Data Type:**

```
boolean
```

- **Default Value:**

```
OFF
```

---

## rocksdb\_perf\_context\_level

- **Description:** Perf Context Level for rocksdb internal timer stat collection.

- **Commandline:**

```
--rocksdb-perf-context-level=#
```

- **Scope:** Global, Session

- **Dynamic:** Yes

- **Data Type:**

```
    numeric
```

- **Default Value:**

```
    0
```

- **Range:**

```
    0
```

```
    to
```

```
    5
```

## rocksdb\_persistent\_cache\_path

- **Description:** Path for BlockBasedTableOptions::persistent\_cache for RocksDB.

- **Commandline:**

```
--rocksdb-persistent-cache-path=value
```

- **Scope:** Global

- **Dynamic:** No

- **Data Type:**

```
    string
```

- **Default Value:** (Empty)

## rocksdb\_persistent\_cache\_size\_mb

- **Description:** Size of cache in MB for BlockBasedTableOptions::persistent\_cache for RocksDB.

- **Commandline:**

```
--rocksdb-persistent-cache-size-mb=#
```

- **Scope:** Global

- **Dynamic:** No

- **Data Type:**

```
    numeric
```

- **Default Value:**

```
    0
```

- **Range:**

```
    0
```

```
    to
```

```
    18446744073709551615
```

## rocksdb\_pin\_10\_filter\_and\_index\_blocks\_in\_cache

- **Description:** pin\_10\_filter\_and\_index\_blocks\_in\_cache for RocksDB.

- **Commandline:**

```
--rocksdb-pin-10-filter-and-index-blocks-in-cache={0|1}
```

- **Scope:** Global

- **Dynamic:** No

- **Data Type:**

boolean

- **Default Value:**

ON

---

### rocksdb\_print\_snapshot\_conflict\_queries

- **Description:** Logging queries that got snapshot conflict errors into \*.err log.

- **Commandline:**

--rocksdb-print-snapshot-conflict-queries={0|1}

- **Scope:** Global

- **Dynamic:** Yes

- **Data Type:**

boolean

- **Default Value:**

OFF

---

### rocksdb\_rate\_limiter\_bytes\_per\_sec

- **Description:** DBOptions::rate\_limiter bytes\_per\_sec for RocksDB.

- **Commandline:**

--rocksdb-rate-limiter-bytes-per-sec=#

- **Scope:** Global

- **Dynamic:** Yes

- **Data Type:**

numeric

- **Default Value:**

0

- **Range:**

0

to

9223372036854775807

---

### rocksdb\_read\_free\_rpl\_tables

- **Description:** List of tables that will use read-free replication on the slave (i.e. not lookup a row during replication).

- **Commandline:**

--rocksdb-read-free-rpl-tables=value

- **Scope:** Global, Session

- **Dynamic:** Yes

- **Data Type:**

string

- **Default Value:** (Empty)

- **Removed:** [MariaDB 10.4.7](#) , [MariaDB 10.3.17](#) , [MariaDB 10.2.26](#)

---

### rocksdb\_records\_in\_range

- **Description:** Used to override the result of records\_in\_range(). Set to a positive number to override.

- **Commandline:**

```
--rocksdb-records-in-range=#
```

- **Scope:** Global, Session

- **Dynamic:** Yes

- **Data Type:**

    numeric

- **Default Value:**

    0

- **Range:**

    0

    to

    2147483647

---

### rocksdb\_remove\_mariabackup\_checkpoint

- **Description:** Remove [mariabackup](#) checkpoint.

- **Commandline:**

```
--rocksdb-remove-mariabackup-checkpoint={0|1}
```

- **Scope:** Global

- **Dynamic:** Yes

- **Data Type:**

    boolean

- **Default Value:**

    OFF

- **Introduced:** [MariaDB 10.3.8](#) , [MariaDB 10.2.16](#)

---

### rocksdb\_reset\_stats

- **Description:** Reset the RocksDB internal statistics without restarting the DB.

- **Commandline:**

```
--rocksdb-reset-stats={0|1}
```

- **Scope:** Global

- **Dynamic:** Yes

- **Data Type:**

    boolean

- **Default Value:**

    OFF

- **Introduced:** [MariaDB 10.3.1](#) , [MariaDB 10.2.8](#)

---

### rocksdb\_rollback\_on\_timeout

- **Description:** Whether to roll back the complete transaction or a single statement on lock wait timeout (a single statement by default).

- **Commandline:**

```
--rocksdb-rollback-on-timeout={0|1}
```

- **Scope:** Global

- **Dynamic:** Yes

- **Data Type:**

    boolean

- **Default Value:**

    OFF

- **Introduced:** MariaDB 10.4.7 , MariaDB 10.3.17 , MariaDB 10.2.26
- 

### rocksdb\_seconds\_between\_stat\_computes

- **Description:** Sets a number of seconds to wait between optimizer stats recomputation. Only changed indexes will be refreshed.
- **Commandline:**

```
--rocksdb-seconds-between-stat-computes=#
```

- **Scope:** Global

- **Dynamic:** Yes

- **Data Type:**

numeric

- **Default Value:**

3600

- **Range:**

0

to

4294967295

---

### rocksdb\_signal\_drop\_index\_thread

- **Description:** Wake up drop index thread.

- **Commandline:**

```
--rocksdb-signal-drop-index-thread={0|1}
```

- **Scope:** Global

- **Dynamic:** Yes

- **Data Type:**

boolean

- **Default Value:**

OFF

---

### rocksdb\_sim\_cache\_size

- **Description:** Simulated cache size for RocksDB.

- **Commandline:**

```
--rocksdb-sim-cache-size=#
```

- **Scope:** Global

- **Dynamic:** No

- **Data Type:**

numeric

- **Default Value:**

0

- **Range:**

0

to

9223372036854775807

---

### rocksdb\_skip\_bloom\_filter\_on\_read

- **Description:** Skip using bloom filter for reads.

- **Commandline:**

```
--rocksdb-skip-bloom-filter-on-read={0|1}
```

- **Scope:** Global, Session

- **Dynamic:** Yes

- **Data Type:**

boolean

- **Default Value:**

OFF

---

### rocksdb\_skip\_fill\_cache

- **Description:** Skip filling block cache on read requests.

- **Commandline:**

```
--rocksdb-skip-fill-cache={0|1}
```

- **Scope:** Global, Session

- **Dynamic:** Yes

- **Data Type:**

boolean

- **Default Value:**

OFF

---

### rocksdb\_skip\_unique\_check\_tables

- **Description:** Skip unique constraint checking for the specified tables.

- **Commandline:**

```
--rocksdb-skip-unique-check-tables=value
```

- **Scope:** Global, Session

- **Dynamic:** Yes

- **Data Type:**

string

- **Default Value:**

.\*

---

### rocksdb\_sst\_mgr\_rate\_bytes\_per\_sec

- **Description:** DBOptions::sst\_file\_manager rate\_bytes\_per\_sec for RocksDB

- **Commandline:**

```
--rocksdb-sst-mgr-rate-bytes-per-sec=#
```

- **Scope:** Global

- **Dynamic:** Yes

- **Data Type:**

numeric

- **Default Value:**

0

- **Range:**

0

to

18446744073709551615

---

## rocksdb\_stats\_dump\_period\_sec

- **Description:** DBOptions::stats\_dump\_period\_sec for RocksDB.

- **Commandline:**

```
--rocksdb-stats-dump-period-sec=#
```

- **Scope:** Global

- **Dynamic:** No

- **Data Type:**

numeric

- **Default Value:**

600

- **Range:**

0

to

2147483647

---

## rocksdb\_stats\_level

- **Description:** Statistics Level for RocksDB. Default is 0 (kExceptHistogramOrTimers).

- **Commandline:**

```
--rocksdb-stats-level=#
```

- **Scope:** Global

- **Dynamic:** Yes

- **Data Type:**

numeric

- **Default Value:**

0

- **Range:**

0

to

4

- **Introduced:** [MariaDB 10.4.7](#) , [MariaDB 10.3.17](#) , [MariaDB 10.2.26](#)
- 

## rocksdb\_stats\_recalc\_rate

- **Description:** The number of indexes per second to recalculate statistics for. 0 to disable background recalculation.

- **Commandline:**

```
--rocksdb-stats-recalc_rate=#
```

- **Scope:** Global

- **Dynamic:** Yes

- **Data Type:**

numeric

- **Default Value:**

0

- **Range:**

0

to

4294967295

- **Introduced:** [MariaDB 10.3.10](#) [MariaDB 10.2.18](#)
-

## `rocksdb_store_row_debug_checksums`

- **Description:** Include checksums when writing index/table records.

- **Commandline:**

```
--rocksdb-store-row-debug-checksums={0|1}
```

- **Scope:** Global, Session

- **Dynamic:** Yes

- **Data Type:**

boolean

- **Default Value:**

OFF

## `rocksdb_strict_collation_check`

- **Description:** Enforce case sensitive collation for MyRocks indexes.

- **Commandline:**

```
--rocksdb-strict-collation-check={0|1}
```

- **Scope:** Global

- **Dynamic:** Yes

- **Data Type:**

boolean

- **Default Value:**

ON

## `rocksdb_strict_collation_exceptions`

- **Description:** List of tables (using regex) that are excluded from the case sensitive collation enforcement.

- **Commandline:**

```
--rocksdb-strict-collation-exceptions=value
```

- **Scope:** Global

- **Dynamic:** Yes

- **Data Type:**

string

- **Default Value:** (Empty)

## `rocksdb_supported_compression_types`

- **Description:** Compression algorithms supported by RocksDB. Note that RocksDB does not make use of [MariaDB 10.7 compression-plugins](#).

- **Commandline:**

```
--rocksdb-supported-compression-types=value
```

- **Scope:** Global

- **Dynamic:** No

- **Data Type:**

string

- **Default Value:**

Snappy,Zlib,ZSTDNotFinal

## rocksdb\_table\_cache\_numshardbits

- **Description:** DBOptions::table\_cache\_numshardbits for RocksDB.

- **Commandline:**

```
--rocksdb-table-cache-numshardbits=#
```

- **Scope:** Global

- **Dynamic:** No

- **Data Type:**

numeric

- **Default Value:**

6

- **Range:**

0

to

19

## rocksdb\_table\_stats\_sampling\_pct

- **Description:** Percentage of entries to sample when collecting statistics about table properties. Specify either 0 to sample everything or percentage [1..100]. By default 10% of entries are sampled.

- **Commandline:**

```
--rocksdb-table-stats-sampling-pct=#
```

- **Scope:** Global

- **Dynamic:** Yes

- **Data Type:**

numeric

- **Default Value:**

10

- **Range:**

0

to

100

## rocksdb\_tmpdir

- **Description:** Directory for temporary files during DDL operations.

- **Commandline:**

```
--rocksdb-tmpdir[=value]
```

- **Scope:** Global, Session

- **Dynamic:** Yes

- **Data Type:**

string

- **Default Value:** (Empty)

## rocksdb\_trace\_sst\_api

- **Description:** Generate trace output in the log for each call to the SSTFileWriter.

- **Commandline:**

```
--rocksdb-trace-sst-api={0|1}
```

- **Scope:** Global, Session

- **Dynamic:** Yes
- **Data Type:**  
boolean

- **Default Value:**  
OFF
- 

### rocksdb\_two\_write\_queues

- **Description:** DBOptions::two\_write\_queues for RocksDB.

- **Commandline:**  
--rocksdb-two-write-queues={0|1}

- **Scope:** Global,

- **Dynamic:** No

- **Data Type:**

boolean

- **Default Value:**

ON

- **Introduced:** [MariaDB 10.3.7](#) , [MariaDB 10.2.15](#)
- 

### rocksdb\_unsafe\_for\_binlog

- **Description:** Allowing statement based binary logging which may break consistency.

- **Commandline:**  
--rocksdb-unsafe-for-binlog={0|1}

- **Scope:** Global, Session

- **Dynamic:** Yes

- **Data Type:**

boolean

- **Default Value:**

OFF

---

### rocksdb\_update\_cf\_options

- **Description:** Option updates per column family for RocksDB.

- **Commandline:**  
--rocksdb-update-cf-options=value

- **Scope:** Global

- **Dynamic:** Yes

- **Data Type:**

varchar

- **Default Value:** (Empty)

- **Introduced:** [MariaDB 10.3.1](#) , [MariaDB 10.2.8](#)
- 

### rocksdb\_use\_adaptive\_mutex

- **Description:** DBOptions::use\_adaptive\_mutex for RocksDB.

- **Commandline:**

--rocksdb-use-adaptive-mutex={0|1}

- **Scope:** Global
  - **Dynamic:** No
  - **Data Type:**  
boolean
- **Default Value:**  
OFF
- 

#### rocksdb\_use\_clock\_cache

- **Description:** Use ClockCache instead of default LRUCache for RocksDB.
- **Commandline:**  
--rocksdb-use-clock-cache={0|1}

- **Scope:** Global
  - **Dynamic:** No
  - **Data Type:**  
boolean
- **Default Value:**  
OFF
- 

#### rocksdb\_use\_direct\_io\_for\_flush\_and\_compaction

- **Description:** DBOptions::use\_direct\_io\_for\_flush\_and\_compaction for RocksDB.
  - **Commandline:**  
--rocksdb-use-direct-io-for-flush-and-compaction={0|1}
- **Scope:** Global
  - **Dynamic:** No
  - **Data Type:**  
boolean
- **Default Value:**  
OFF
- **Introduced:** MariaDB 10.3.1 , MariaDB 10.2.8
- 

#### rocksdb\_use\_direct\_reads

- **Description:** DBOptions::use\_direct\_reads for RocksDB.
  - **Commandline:**  
--rocksdb-use-direct-reads={0|1}
- **Scope:** Global
  - **Dynamic:** No
  - **Data Type:**  
boolean
- **Default Value:**  
OFF
- 

#### rocksdb\_use\_direct\_writes

- **Description:** DBOptions::use\_direct\_writes for RocksDB.
- **Commandline:**

```
--rocksdb-use-direct-reads={0|1}
```

- **Scope:** Global
  - **Dynamic:** No
  - **Data Type:**  
boolean
  - **Default Value:**  
OFF
  - **Removed:** [MariaDB 10.3.1](#) , [MariaDB 10.2.8](#)
- 

### rocksdb\_use\_fsync

- **Description:** DBOptions::use\_fsync for RocksDB.

- **Commandline:**  
`--rocksdb-use-fsync={0|1}`

- **Scope:** Global
- **Dynamic:** No
- **Data Type:**  
boolean

- **Default Value:**  
OFF
- 

### rocksdb\_validate\_tables

- **Description:** Verify all .frm files match all RocksDB tables (0 means no verification, 1 means verify and fail on error, and 2 means verify but continue).

- **Commandline:**  
`--rocksdb-validate-tables=#`

- **Scope:** Global
- **Dynamic:** No
- **Data Type:**  
numeric

- **Default Value:**  
1

- **Range:**  
0  
to  
2
- 

### rocksdb\_verify\_row\_debug\_checksums

- **Description:** Verify checksums when reading index/table records.

- **Commandline:**  
`--rocksdb-verify-row-debug-checksums={0|1}`

- **Scope:** Global, Session
- **Dynamic:** Yes
- **Data Type:**  
boolean

- **Default Value:**  
OFF

---

## rocksdb\_wal\_bytes\_per\_sync

- **Description:** DBOptions::wal\_bytes\_per\_sync for RocksDB.

- **Commandline:**

```
--rocksdb-wal-bytes-per-sync=#
```

- **Scope:** Global

- **Dynamic:** Yes

- **Data Type:**

numeric

- **Default Value:**

0

- **Range:**

0

to

18446744073709551615

---

## rocksdb\_wal\_dir

- **Description:** DBOptions::wal\_dir for RocksDB. Directory where the write-ahead-log files are stored.

- **Commandline:**

```
--rocksdb-wal-dir=value
```

- **Scope:** Global

- **Dynamic:** No

- **Data Type:**

string

- **Default Value:** (Empty)
- 

## rocksdb\_wal\_recovery\_mode

- **Description:** DBOptions::wal\_recovery\_mode for RocksDB. Default is kAbsoluteConsistency. Records that are not yet committed are stored in the Write-Ahead-Log (WAL). If the server is not cleanly shut down, the recovery mode will determine the WAL recovery behavior.

- 1 : kAbsoluteConsistency. Will not start if any corrupted entries (including incomplete writes) are detected (the default).
- 0 : kTolerateCorruptedTailRecords. Ignores any errors found at the end of the WAL
- 2 : kPointInTimeRecovery. Replay of the WAL is halted after finding an error. The system will be recovered to the latest consistent point-in-time. Data from a replica can be used to replay past the point-in-time.
- 3 : kSkipAnyCorruptedRecords. A risky option where any corrupted entries are skipped while subsequent healthy WAL entries are applied.

- **Commandline:**

```
--rocksdb-wal-recovery-mode=#
```

- **Scope:** Global

- **Dynamic:** Yes

- **Data Type:**

numeric

- **Default Value:**

1

- **Range:**

0

to

3

---

## rocksdb\_wal\_size\_limit\_mb

- **Description:** DBOptions::WAL\_size\_limit\_MB for RocksDB. Write-ahead-log files are moved to an archive directory once their memtables are flushed. This variable specifies the largest size, in MB, that the archive can be.

- **Commandline:**

```
--rocksdb-wal-size-limit-mb=#
```

- **Scope:** Global

- **Dynamic:** No

- **Data Type:**

numeric

- **Default Value:**

0

- **Range:**

0

to

9223372036854775807

---

## rocksdb\_wal\_ttl\_seconds

- **Description:** DBOptions::WAL\_ttl\_seconds for RocksDB. Oldest time, in seconds, that a write-ahead-log file should exist.

- **Commandline:**

```
--rocksdb-wal-ttl-seconds=#
```

- **Scope:** Global

- **Dynamic:** No

- **Data Type:**

numeric

- **Default Value:**

0

- **Range:**

0

to

9223372036854775807

---

## rocksdb\_whole\_key\_filtering

- **Description:** BlockBasedTableOptions::whole\_key\_filtering for RocksDB. If set (the default), the bloomfilter to use the whole key (rather than only the prefix) for filtering is enabled. Lookups should use the whole key for matching to make best use of this setting.

- **Commandline:**

```
--rocksdb-whole-key-filtering={0|1}
```

- **Scope:** Global

- **Dynamic:** No

- **Data Type:**

boolean

- **Default Value:**

ON

---

## rocksdb\_write\_batch\_max\_bytes

- **Description:** Maximum size of write batch in bytes. 0 means no limit.

- **Commandline:**

```
--rocksdb-write-batch-max-bytes=#
```

- **Scope:** Global, Session

- **Dynamic:** Yes

- **Data Type:**

    numeric

- **Default Value:**

    0

- **Range:**

    0

    to

    18446744073709551615

---

### rocksdb\_write\_disable\_wal

- **Description:** WriteOptions::disableWAL for RocksDB.

- **Commandline:**

    --rocksdb-write-disable-wal={0|1}

- **Scope:** Global, Session

- **Dynamic:** Yes

- **Data Type:**

    boolean

- **Default Value:**

    OFF

---

### rocksdb\_write\_ignore\_missing\_column\_families

- **Description:** WriteOptions::ignore\_missing\_column\_families for RocksDB.

- **Commandline:**

    --rocksdb-write-ignore-missing-column-families={0|1}

- **Scope:** Global, Session

- **Dynamic:** Yes

- **Data Type:**

    boolean

- **Default Value:**

    OFF

---

### rocksdb\_write\_policy

- **Description:** DBOptions::write\_policy for RocksDB.

- **Commandline:**

    --rocksdb-write-policy=val

- **Scope:** Global

- **Dynamic:** No

- **Data Type:**

    enum

- **Default Value:**

    write\_committed

- **Valid Values:**

    write\_committed

,

```
    write_prepared  
,  
    write_unprepared
```

- **Introduced:** MariaDB 10.3.10 , MariaDB 10.2.18

## 4.3.14.7 MyRocks Transactional Isolation

TODO:

- MyRocks uses snapshot isolation
- Support do READ-COMMITTED and REPEATABLE-READ
- SERIALIZABLE is not supported
  - There is no "Gap Locking" which makes Statement Based Replication unsafe (See MyRocks and Replication).

## 4.3.14.8 MyRocks and Replication

### Contents

1. [MyRocks and Statement-Based Replication](#)
  1. [Can One Still Use SBR with MyRocks?](#)
2. [Read-Free Slave](#)
3. [Differences From Upstream MyRocks](#)

Details about how MyRocks works with [replication](#) .

## MyRocks and Statement-Based Replication

[Statement-based](#) replication (SBR) works as follows: SQL statements are executed on the master (possibly concurrently). They are written into the binlog (this fixes their ordering, "a serialization"). The slave then reads the binlog and executes the statements in their binlog order.

In order to prevent data drift, serial execution of statements on the slave must have the same effect as concurrent execution of these statements on the master. In other words, transaction isolation on the master must be close to

SERIALIZABLE  
transaction isolation level (This is not a strict mathematical proof but shows the idea).

InnoDB achieves this by (almost) supporting

SERIALIZABLE  
transactional isolation level. It does so by supporting "Gap Locks". MyRocks doesn't support  
SERIALIZABLE  
isolation, and it doesn't support gap locks.

Because of that, generally one cannot use MyRocks and statement-based replication.

Updating a MyRocks table while having SBR on, will result in an error as follow:

```
ERROR 4056 (HY000): Can't execute updates on master with binlog_format != ROW.
```

### Can One Still Use SBR with MyRocks?

Yes. In many cases, database applications run a restricted set of SQL statements, and it's possible to prove that lack of Gap Lock support is not a problem and data skew will not occur.

In that case, one can set

```
@@rocksdb_unsafe_for_binlog=1
```

and MyRocks will work with SBR. The user is however responsible for making sure their queries are not causing a data skew.

### Read-Free Slave

TODO

### Differences From Upstream MyRocks

MyRocks upstream (that is, Facebook's MySQL branch) has a number of unique replication enhancements. These are available in upstream's version of MyRocks but not in MariaDB's version of MyRocks.

- Read-Free Replication (see <https://github.com/facebook/mysql-5.6/wiki/Read-Free-Replication> ) TODO
- 

<<

```

unique

_check_lag_threshold

>>
. This is FB/MySQL-5.6 feature where unique checks are disabled if replication lag exceeds a certain threshold.

•
<<

slave

_gtid_info=OPTIMIZED

>>
. This is said to be:

<<quote>>
"Whether SQL threads update mysql.slave_gtid_info table. If this value "
"is OPTIMIZED, updating the table is done inside storage engines to "
"avoid MySQL layer's performance overhead",
<</quote>>

```

## 4.3.14.9 MyRocks and Group Commit with Binary log

### Contents

1. Counter Values to Watch
2. On the Value of `rocksdb_wal_group_syncs`
3. Examples

MyRocks supports group commit with the [binary log](#) ([MDEV-11934](#)).

### Counter Values to Watch

(The following is only necessary if you are studying MyRocks internals)

MariaDB's group commit counters are:

[Binlog\\_commits](#) - how many transactions were written to the binary log

[Binlog\\_group\\_commits](#) - how many group commits happened. (e.g. if each group had two transactions, this will be twice as small as [Binlog\\_commits](#))

On the RocksDB side, there is one relevant counter: [Rocksdb\\_wal\\_synced](#) - How many times RocksDB's WAL file was synced. (TODO: this is after group commit happened, right?)

### On the Value of `rocksdb_wal_group_syncs`

FB/MySQL-5.6 has a [rocksdb\\_wal\\_group\\_syncs](#) counter (The counter is provided by MyRocks, it is not a view of a RocksDB counter). It is increased in `rocksdb_flush_wal()` when doing the `rdb->FlushWAL()` call.

`rocksdb_flush_wal()` is called by MySQL's Group Commit when it wants to make the effect of several `rocksdb_prepare()` calls persistent.

So, the value of [rocksdb\\_wal\\_group\\_syncs](#) in FB/MySQL-5.6 is similar to [Binlog\\_group\\_commits](#) in MariaDB.

MariaDB doesn't have that call, each `rocksdb_prepare()` call takes care of being persistent on its own.

Because of that, [rocksdb\\_wal\\_group\\_syncs](#) is zero for MariaDB. (Currently, it is only incremented when the binlog is rotated).

### Examples

So for a workload with concurrency=50, n\_queries=10K, one gets

- `Binlog_commits`=10K
- `Binlog_group_commits`=794
- `Rocksdb_wal_synced`=8362

This is on a RAM disk

For a workload with concurrency=50, n\_queries=10K, rotating laptop hdd, one gets

- `Binlog_commits`= 10K
- `Binlog_group_commits`=1403

- Rocksdb\_wal\_synced=400

The test took 38 seconds, Number of syncs was 1400+400=1800, which gives 45 syncs/sec which looks normal for this slow rotating desktop hdd.

Note that the WAL was synced fewer times than there were binlog commit groups (?)

## 4.3.14.10 Optimizer Statistics in MyRocks

### Contents

1. [How MyRocks computes statistics](#)
1. [Are index statistics predictable?](#)
2. [Records-in-range estimates](#)
2. [ANALYZE TABLE](#)
3. [Debugging helper variables](#)

This article describes how MyRocks storage engine provides statistics to the query optimizer.

There are three kinds of statistics:

- Table statistics (number of rows in the table, average row size)
- Index cardinality (how distinct values are in the index)
- records-in-range estimates (how many rows are in a certain range "const1 < tbl.key < const2").

### How MyRocks computes statistics

MyRocks (actually RocksDB) uses LSM files which are written once and never updated. When an LSM file is written, MyRocks will compute index cardinalities and number-of-rows for the data in the file. (The file generally has rows, index records and/or tombstones for multiple tables/indexes).

For performance reasons, statistics are computed based on a fraction of rows in the LSM file. The percentage of rows used is controlled by `rocksdb_table_stats_sampling_pct`; the default value is 10%.

Before the data is dumped into LSM file, it is stored in the MemTable. MemTable doesn't allow computing index cardinalities, but it can provide an approximate number of rows in the table. Use of MemTable data for statistics is controlled by `rocksdb_force_compute_memtable_stats`; the default value is

ON

### Are index statistics predictable?

Those who create/run MTR tests, need to know whether EXPLAIN output is deterministic. For MyRocks tables, the answer is NO (just like for InnoDB).

Statistics are computed using sampling and GetApproximateMemTableStats() which means that the #rows column in the EXPLAIN output may vary slightly.

### Records-in-range estimates

MyRocks uses RocksDB's GetApproximateSizes() call to produce an estimate for the number of rows in the certain range. The data in MemTable is also taken into account by issuing a GetApproximateMemTableStats call.

### ANALYZE TABLE

ANALYZE TABLE will possibly flush the MemTable (depending on the `rocksdb_flush_memtable_on_analyze` and `rocksdb_pause_background_work` settings).

After that, it will re-read statistics from the SST files and re-compute the summary numbers (TODO: and if the data was already on disk, the result should not be different from the one we had before ANALYZE?)

### Debugging helper variables

There are a few variables that will cause MyRocks to report certain pre-defined estimate numbers to the optimizer:

- `@@rocksdb_records_in_range` - if not 0, report that any range has this many rows
- `@@rocksdb_force_index_records_in_range` - if not 0, and FORCE INDEX hint is used, report that any range has this many rows.
- `@@rocksdb_debug_optimizer_n_rows` - if not 0, report that any MyRocks table has this many rows.

## 4.3.14.11 Differences Between MyRocks Variants

MyRocks is available in

- Facebook's (FB) MySQL branch (originally based on MySQL 5.6)
- MariaDB (from 10.2 and 10.3)
- Percona Server from 5.7

This page lists differences between these variants.

## Contents

1. RocksDB Data Location
2. Compression Algorithms
3. RocksDB Version Information
4. RocksDB Version
5. Binlog Position in  
information\_schema.rocksdb\_global\_info
6. Gap Lock Detector
7. Generated Columns
8. rpl\_skip\_tx\_api
9. Details

## RocksDB Data Location

FB and Percona store RocksDB files in \$datadir/

```
.rocksdb
. MariaDB puts them in $datadir/
#rocksdb
. This is more friendly for packaging and OS scripts.
```

## Compression Algorithms

- FB's branch doesn't provide binaries. One needs to compile it with appropriate compression libraries.
- In MariaDB, available compression algorithms can be seen in the `rocksdb_supported_compression_types` variable. From [MariaDB 10.7](#), algorithms can be [installed as a plugin](#). In earlier versions, the set of supported compression algorithms depends on the platform.
  - On Ubuntu 16.04 (current LTS) it is  
Snappy, Zlib, LZ4, LZ4HC
  - On CentOS 7.4 it is  
Snappy, Zlib
  - In the bintar tarball it is  
Snappy, Zlib
- Percona Server supports:
  - Zlib, ZSTD, LZ4 (the default), LZ4HC
  - Unsupported algorithms:  
Snappy, BZip2, XPress

## RocksDB Version Information

- FB's branch provides the  
`rocksdb_git_hash`  
\*status\* variable.
- MariaDB provides the  
`@@rocksdb_git_hash`  
\*system\* variable.
- Percona Server doesn't provide either.

## RocksDB Version

- Facebook's branch uses RocksDB 5.10.0 (the version number can be found in  
`include/rocksdb/version.h`  
)

```
commit ba295cda29daee3ffe58549542804efdfd969784
Author: Andrew Kryczka <andrewkr@fb.com>
Date:   Fri Jan 12 11:03:55 2018 -0800
```

- MariaDB currently uses 5.8.0

```
commit 9a970c81af9807071bd690f4c808c5045866291a
Author: Yi Wu <yiwu@fb.com>
Date:   Wed Sep 13 17:21:35 2017 -0700
```

- Percona Server uses 5.8.0

```
commit ab0542f5ec6e7c7e405267eaa2e2a603a77d570b
Author: Maysam Yabandeh <myabandeh@fb.com>
Date:   Fri Sep 29 07:55:22 2017 -0700
```

## Binlog Position in information\_schema.rocksdb\_global\_info

- FB branch provides information\_schema.rocksdb\_global\_info type=BINLOG, NAME=(FILE, POS, GTID).
- Percona Server doesn't provide it.
- MariaDB doesn't provide it.

One use of that information is to take the output of

```
myrocks_hotbackup
```

and make it a new master.

## Gap Lock Detector

- FB branch has a "Gap Lock Detector" feature. It is at the SQL layer. It can be controlled with  
`gap_lock_XXX` variables and is disabled by default (`gap-lock-raise-error=false`, `gap-lock-write-lock=false`).
- Percona Server has gap lock checking ON but doesn't seem to have any way to control it? Queries that use Gap Lock on MyRocks fail with an error like this:

```
mysql> insert into tbl2 select * from tbl1;
ERROR 1105 (HY000): Using Gap Lock without full unique key in multi-table or multi-statement transactions
is not allowed. You need to either rewrite queries to use all unique key columns in WHERE equal conditions,
or rewrite to single-table, single-statement transaction. Query: insert into tbl2 select * from tbl1
```

- MariaDB doesn't include the Gap Lock Detector.

## Generated Columns

- Both MariaDB and Percona Server support [generated columns](#), but neither one supports them for the MyRocks storage engine (attempts to create a table will produce an error).
- [Invisible columns](#) in [MariaDB 10.3](#) are supported (as they are an SQL layer feature).

## rpl\_skip\_tx\_api

Facebook's branch has a performance feature for replication slaves,

```
rpl_skip_tx_api
```

. It is not available in MariaDB or in Percona Server.

## Details

The above comparison was made using

- FB/MySQL 5.6.35
- Percona Server 5.7.20-19-log
- [MariaDB 10.2.13](#) (MyRocks is beta)

## 4.3.14.12 MyRocks and Bloom Filters

### Contents

1. [Bloom Filter Parameters](#)
  1. [Computing Prefix Length](#)
2. [Configuring Bloom Filter](#)
3. [Checking if Bloom Filter is Useful](#)

Bloom filters are used to reduce read amplification. Bloom filters can be set on a per-column family basis (see [myrocks-column-families](#) ).

## Bloom Filter Parameters

- How many bits to use
- whole\_key\_filtering=true/false
- Whether the bloom filter is for the entire key or for the prefix. In case of a prefix, you need to look at the index definition and compute the desired prefix length.

## Computing Prefix Length

- It's 4 bytes for  
index\_nr
- Then, for fixed-size columns (integer, date[time], decimal) it is key\_length as shown by  
EXPLAIN
  - . For VARCHAR columns, determining the length is tricky (It depends on the values stored in the table. Note that MyRocks encodes VARCHARs with "Variable-Length Space-Padded Encoding" format).

## Configuring Bloom Filter

To enable 10-bit bloom filter for 8-byte prefix length for column family "cf1", put this into my.cnf:

```
rocksdb_override_cf_options='cf1={block_based_table_factory={filter_policy=bloomfilter:10:false;whole_key_filtering=0;};prefix_e  
|  
,
```

and restart the server.

Check if the column family actually uses the bloom filter:

```
select *  
from information_schema.rocksdb_cf_options  
where  
cf_name='cf1' and  
option_type IN ('TABLE_FACTORY::FILTER_POLICY','PREFIX_EXTRACTOR');
```

CF_NAME	OPTION_TYPE	VALUE
cf1	PREFIX_EXTRACTOR	rocksdb.CappedPrefix.8
cf1	TABLE_FACTORY::FILTER_POLICY	rocksdb.BuiltinBloomFilter

## Checking if Bloom Filter is Useful

Watch these status variables:

```
show status like '%bloom%';  
+-----+  
| Variable_name | Value |  
+-----+  
| Rocksdb_bloom_filter_prefix_checked | 1 |  
| Rocksdb_bloom_filter_prefix_useful | 0 |  
| Rocksdb_bloom_filter_useful | 0 |  
+-----+
```

Other useful variables are:

- rocksdb\_force\_flush\_memtable\_now
  - bloom filter is only used when reading data from disk. If you are doing testing, flush the data to disk first.
- rocksdb\_skip\_bloom\_filter\_on\_read
  - skip using the bloom filter (default is FALSE).

## 4.3.14.13 MyRocks and CHECK TABLE

MyRocks supports the [CHECK TABLE](#) command.

The command will do a number of checks to verify that the table data is self-consistent.

The details about the errors are printed into the [error log](#). If [log\\_warnings](#) > 2, the error log will also have some informational messages which can help with troubleshooting.

Besides this, RocksDB has its own (low-level) log in

```
#rocksdb/LOG  
file.
```

## 4.3.14.14 MyRocks and Data Compression

### Contents

- 1. [Supported Compression Algorithms](#)
- 2. [Compression Settings](#)
  - 1. [Checking Compression Settings](#)
  - 2. [Modifying Compression Settings](#)
  - 3. [Caveat: Syntax Errors](#)
- 3. [Checking How the Data is Compressed](#)

MyRocks supports several compression algorithms.

## Supported Compression Algorithms

Supported compression algorithms can be checked like so:

```
show variables like 'rocksdb%compress%';
+-----+-----+
| Variable_name | Value |
+-----+-----+
| rocksdb_supported_compression_types | Snappy,Zlib,LZ4,LZ4HC,ZSTDNotFinal |
+-----+-----+
```

Another way to make the check is to look into

```
#rocksdb/LOG  
file in the data directory. It should have lines like:
```

```
2019/04/12-14:08:23.869919 7f839188b540 Compression algorithms supported:  
2019/04/12-14:08:23.869920 7f839188b540 kZSTDNotFinalCompression supported: 1  
2019/04/12-14:08:23.869922 7f839188b540 kZSTD supported: 1  
2019/04/12-14:08:23.869923 7f839188b540 kXpressCompression supported: 0  
2019/04/12-14:08:23.869924 7f839188b540 kLZ4HCCompression supported: 1  
2019/04/12-14:08:23.869924 7f839188b540 kLZ4Compression supported: 1  
2019/04/12-14:08:23.869925 7f839188b540 kBZip2Compression supported: 0  
2019/04/12-14:08:23.869926 7f839188b540 kZlibCompression supported: 1  
2019/04/12-14:08:23.869927 7f839188b540 kSnappyCompression supported: 1
```

## Compression Settings

Compression is set on a per-Column Family basis. See [MyRocks Column Families](#).

### Checking Compression Settings

To check current compression settings for a column family one can use a query like so:

```
select * from information_schema.rocksdb_cf_options
where option_type like '%compression%' and cf_name='default';
```

The output will be like:

```
+-----+-----+
| CF_NAME | OPTION_TYPE | VALUE |
+-----+-----+
| default | COMPRESSION_TYPE | kSnappyCompression |
| default | COMPRESSION_PER_LEVEL | NUL |
| default | COMPRESSION_OPTS | -14:32767:0 |
| default | BOTTOMMOST_COMPRESSION | kDisableCompressionOption |
| default | TABLE_FACTORY::VERIFY_COMPRESSION | 0 |
| default | TABLE_FACTORY::ENABLE_INDEX_COMPRESSION | 1 |
+-----+-----+
```

Current column family settings will be used for the new SST files.

## Modifying Compression Settings

Compression settings are not dynamic parameters, one cannot change them by setting `rocksdb_update_cf_options`.

The procedure to change compression settings is as follows:

- Edit

```
my.cnf  
to set rocksdb_override_cf_options.
```

Example:

```
rocksdb-override-cf-options='cf1={compression=kZSTD;bottommost_compression=kZSTD;}'
```

- Restart the server.

The data will not be re-compressed immediately. However, all new SST files will use the new compression settings, so as data gets inserted/updated the column family will gradually start using the new option.

## Caveat: Syntax Errors

Please note that

```
rocksdb-override-cf-options
```

syntax is quite strict. Any typos will result in the parse error, and MyRocks plugin will not be loaded. Depending on your configuration, the server may still start. If it does start, you can use this command to check if the plugin is loaded:

```
select * from information_schema.plugins where plugin_name='ROCKSDB'
```

(note that you need the "ROCKSDB" plugin. Other auxiliary plugins like "ROCKSDB\_TRX" might still get loaded).

Another way is to detect the error is check the error log. When option parsing fails, it will contain messages like so:

```
2019-04-16 11:07:57 140283675678016 [Warning] Invalid cf config for cf1 in override options (options: cf1={compression=kLZ4Compr  
2019-04-16 11:07:57 140283675678016 [ERROR] RocksDB: Failed to initialize CF options map.  
2019-04-16 11:07:57 140283675678016 [ERROR] Plugin 'ROCKSDB' init function returned error.  
2019-04-16 11:07:57 140283675678016 [ERROR] Plugin 'ROCKSDB' registration as a STORAGE ENGINE failed.
```

## Checking How the Data is Compressed

A query to check what compression is used in the SST files that store the data for a given table (test.t1):

```
select  
SP.sst_name, SP.compression_algo  
from  
information_schema.rocksdb_sst_props SP,  
information_schema.rocksdb_ddl D,  
information_schema.rocksdb_index_file_map IFM  
where  
D.table_schema='test' and D.table_name='t1' and  
D.index_number= IFM.index_number and  
IFM.sst_name=SP.sst_name;
```

Example output:

sst_name	compression_algo
000028.sst	Snappy
000028.sst	Snappy
000026.sst	Snappy
000026.sst	Snappy

## 4.3.14.15 MyRocks and Index-Only Scans

## Contents

1. Secondary Keys Only
2. Background: Mem-Comparable Keys
3. Index-Only Support for Various Datatypes
4. Index-Only Support for Various Collations
  1. Binary (Reversible) Collations
  2. Restorable Collations
  3. All Other Collations
5. Covering Secondary Key Lookups for VARCHARs

This article is about [MyRocks](#) and index-only scans on secondary indexes. It applies to MariaDB's MyRocks, Facebook's MyRocks, and other variants.

## Secondary Keys Only

The primary key in MyRocks is always the clustered key, that is, the index record is THE table record and so it's not possible to do "index only" because there isn't anything that is not in the primary key's (Key,Value) pair.

Secondary keys may or may not support index-only scans, depending on the datatypes of the columns that the query is trying to read.

## Background: Mem-Comparable Keys

MyRocks indexes store "mem-comparable keys" (that is, the key values are compared with

`memcmp`

). For some datatypes, it is easily possible to convert between the column value and its mem-comparable form, while for others the conversion is one-way.

For example, in case-insensitive collations capital and regular letters are considered identical, i.e. '`c`' = '`C`'. For some datatypes, MyRocks stores some extra data which allows it to restore the original value back. (For the

`latin1_general_ci`

`collation` and character '`c`', for example, it will store one bit which says whether the original value was a small '`c`' or a capital letter '`C`'. This doesn't work for all datatypes, though.

## Index-Only Support for Various Datatypes

Index-only scans are supported for numeric and date/time datatypes. For CHAR and VAR[CHAR], it depends on which collation is used, see below for details.

Index-only scans are currently not supported for less frequently used datatypes, like

•

`BIT(n)`

•

`SET(...)`

•

`ENUM(...)`

*It is actually possible to add support for those, feel free to write a patch or at least make a case why a particular datatype is important*

## Index-Only Support for Various Collations

As far as Index-only support is concerned, MyRocks distinguishes three kinds of collations:

### 1. Binary (Reversible) Collations

These are

`binary`

,

`latin1_bin`

, and

`utf8_bin`

For these collations, it is possible to convert a value back from its mem-comparable form. Hence, one can restore the original value back from its index record, and index-only scans are supported.

## 2. Restorable Collations

These are collations where one can store some extra information which helps to restore the original value.

Criteria (from storage/rocksdb/rdb\_datadic.cc, rdb\_is\_collation\_supported()) are:

- The charset should use 1-byte characters (so, unicode-based collations are not included)
- strxfrm(1 byte) = {one 1-byte weight value always}
- no binary sorting
- PAD attribute

The examples are:

```
latin1_general_ci  
,  
latin1_general_cs  
,  
latin1_swedish_ci  
, etc.
```

Index-only scans are supported for these collations.

## 3. All Other Collations

For these collations, there is no known way to restore the value from its mem-comparable form, and so index-only scans are not supported.

MyRocks needs to fetch the clustered PK record to get the field value.

## Covering Secondary Key Lookups for VARCHARs

TODO: there is also this optimization:

<https://github.com/facebook/mysql-5.6/issues/303> <https://github.com/facebook/mysql-5.6/commit/f349c95848e92b5b27b44f0e57194100eb0997e7>

document it.

### 4.3.14.16 MyRocks and START TRANSACTION WITH CONSISTENT SNAPSHOT

FB/MySQL has added new syntax:

```
START TRANSACTION WITH CONSISTENT ROCKSDB|INNODB SNAPSHOT;
```

The statement returns the binlog coordinates pointing at the snapshot.

MariaDB (and Percona Server) support extension to the regular

```
START TRANSACTION WITH CONSISTENT SNAPSHOT;
```

syntax as documented in [Enhancements for START TRANSACTION WITH CONSISTENT SNAPSHOT](#).

After issuing the statement, one can examine the `binlog_snapshot_file` and `binlog_snapshot_position` status variables to see the binlog position that corresponds to the snapshot.

## See Also

- [START TRANSACTION](#)
- [Enhancements for START TRANSACTION WITH CONSISTENT SNAPSHOT](#)

### 4.3.14.17 MyRocks Column Families

MyRocks stores data in column families. These are similar to tablespaces. By default, the data is stored in the default column family.

One can specify which column family the data goes to by using index comments:

```
INDEX index_name(col1, col2, ...) COMMENT 'column_family_name'
```

## Contents

1. Reasons for Column Families
2. Creating a Column Family
3. Dropping a Column Family
4. Setting Column Family Parameters
  1. `rocksdb_override_cf_options`
5. Examining Column Family Parameters

If the column name starts with

`rev:`

, the column family is reverse-ordered.

## Reasons for Column Families

Storage parameters like

- Bloom filter settings
- Compression settings
- Whether the data is stored in reverse order

are specified on a per-column family basis.

## Creating a Column Family

When creating a table or index, you can specify the name of the column family for it. If the column family doesn't exist, it will be automatically created.

## Dropping a Column Family

There is currently no way to drop a column family. RocksDB supports this internally but MyRocks doesn't provide any way to do it.

## Setting Column Family Parameters

Use these variables:

- `rocksdb_default_cf_options` - a my.cnf parameter specifying default options for all column families.
- `rocksdb_override_cf_options` - a my.cnf parameter specifying per-column family option overrides.
- `rocksdb_update_cf_options` - a dynamically-settable variable which allows to change parameters online. Not all parameters can be changed.

### `rocksdb_override_cf_options`

This parameter allows one to override column family options for specific column families. Here is an example of how to set option1=value1 and option2=value for column family cf1, and option3=value3 for column family cf3:

```
rocksdb_override_cf_options='cf1={option1=value1;option2=value2};cf2={option3=value3}'
```

One can check the contents of

```
INFORMATION_SCHEMA.ROCKSDB_CF_OPTIONS
```

to see what options are available.

Options that are frequently configured are:

- Data compression. See [myrocks-and-data-compression](#).
- Bloom Filters. See [myrocks-and-bloom-filters](#).

## Examining Column Family Parameters

See the [INFORMATION\\_SCHEMA.ROCKSDB\\_CF\\_OPTIONS](#) table.

### 4.3.14.18 MyRocks in MariaDB 10.2 vs MariaDB 10.3

MyRocks storage engine itself is identical in [MariaDB 10.2](#) and [MariaDB 10.3](#).

[MariaDB 10.3](#) has a feature that should be interesting for MyRocks users. It is the `gtid_pos_auto_engines` option ([MDEV-12179](#)). This is a performance feature for replication slaves that use multiple transactional storage engines.

For further information, see [mysql.gtid\\_slave\\_pos table](#).

### 4.3.14.19 MyRocks Performance Troubleshooting

## Contents

1. Status Variables
2. SHOW ENGINE ROCKSDB STATUS
3. Performance Context

MyRocks exposes its performance metrics through several interfaces:

- Status variables
- SHOW ENGINE ROCKSDB STATUS
- RocksDB's perf context

the contents slightly overlap, but each source has its own unique information, so be sure to check all three.

## Status Variables

Check the output of

```
SHOW STATUS like 'Rocksdb%'
```

See [MyRocks Status Variables](#) for more information.

## SHOW ENGINE ROCKSDB STATUS

This produces a lot of information.

One particularly interesting part is compaction statistics. It shows the amount of data on each SST level and other details:

```
***** 4. row *****
Type: CF_COMPACTION
Name: default
Status:
** Compaction Stats [default] **
Level    Files     Size      Score Read(GB)  Rn(GB)  Rnp1(GB) Write(GB) Wnew(GB) Moved(GB) W-Amp Rd(MB/s) Wr(MB/s) Comp(sec) Comp(cn)
-----+
L0      3/0      30.16 MB  1.0      0.0      0.0      0.0      11.9      11.9      0.0      1.0      0.0      76.6      159      63
L1      5/0      247.54 MB  1.0      0.7      0.2      0.5      0.5      0.0      11.6      2.6      58.5      44.1      12
L2      112/0     2.41 GB   1.0      0.6      0.0      0.6      0.5      -0.1      11.4      43.4      55.2      45.9      11
L3      466/0     8.91 GB   0.4      0.0      0.0      0.0      0.0      0.0      8.9      0.0      0.0      0.0      0.0
Sum     586/0     11.59 GB  0.0      1.3      0.2      1.0      12.8      11.8      32.0      1.1      7.1      72.6      181      63
Int     0/0       0.00 KB   0.0      0.9      0.1      0.8      0.8      0.0      0.1      20.5      48.4      45.3      19
```

## Performance Context

RocksDB has an internal mechanism called "perf context". The counter values are exposed through two tables:

- [INFORMATION\\_SCHEMA.ROCKSDB\\_PERF\\_CONTEXT\\_GLOBAL](#) - global counters
- [INFORMATION\\_SCHEMA.ROCKSDB\\_PERF\\_CONTEXT](#) - Per-table/partition counters

By default statistics are NOT collected. One needs to set

```
rocksdb_perf_context_level
to some value (e.g. 3) to enable collection.
```

## 4.3.15 OQGRAPH

The Open Query GRAPH computation engine, or OQGRAPH as the engine itself is called, allows you to handle hierarchies (tree structures) and complex graphs (nodes having many connections in several directions).

OQGRAPH Version	Introduced	Maturity
3.0	<a href="#">MariaDB 10.0.25</a>	Gamma
3.0	<a href="#">MariaDB 10.0.7</a>	Beta
2.0	<a href="#">MariaDB 5.2.1</a>	

### Installing OQGRAPH

[Installing OQGRAPH](#).

### OQGRAPH Overview

[Overview of the OQGRAPH storage engine](#).

### OQGRAPH Examples

There are [5 related questions](#).

## 4.3.15.1 Installing OQGRAPH

### Contents

- 1. [Installation](#)
  - 1. [Debian and Ubuntu](#)
  - 2. [Fedora/Red Hat/CentOS](#)
  - 3. [Installing the Plugin](#)
- 2. [See Also](#)

The Open Query GRAPH computation engine, or OQGRAPH as the engine itself is called, allows you to handle hierarchies (tree structures) and complex graphs (nodes having many connections in several directions).

## Installation

The OQGRAPH storage engine exists as a separate package in the repositories for [MariaDB 10.0.7](#) and later. On Ubuntu and Debian the package is called

`mariadb-oqgraph-engine-10.0`

or

`mariadb-plugin-oqgraph`

. On Red Hat, CentOS, and Fedora the package is called

`MariaDB-oqgraph-engine`

. To install the plugin, first install the appropriate package and then install the plugin using the [INSTALL SONAME](#) or [INSTALL PLUGIN](#) commands.

### Debian and Ubuntu

On Debian and Ubuntu, install the package as follows:

```
sudo apt-get install mariadb-plugin-oqgraph
```

or (for [MariaDB 10.0](#))

```
sudo apt-get install mariadb-oqgraph-engine-10.0
```

### Fedora/Red Hat/CentOS

Note that OQGRAPH v3 requires libjudy, which is not in the official Red Hat/Fedora repositories. This needs to be installed first, for example:

```
wget http://dl.fedoraproject.org/pub/epel/6/x86_64/epel-release-6-8.noarch.rpm  
rpm -Uvh epel-release-6-8.noarch.rpm
```

Then install the package, as follows:

```
sudo yum install MariaDB-oqgraph-engine
```

### Installing the Plugin

On either system you can then launch the

`mysql`

command-line client and install the plugin in MariaDB as follows:

```
INSTALL SONAME 'ha_oqgraph';
```

## See Also

More information on this engine is found on the OpenQuery website: <https://openquery.com.au/products/graph-engine>

### 4.3.15.2 OQGRAPH Overview

#### Contents

1. [Installing](#)
2. [Creating a Table](#)
3. [Example with origin and destination nodes only](#)
4. [Manipulating Weight](#)

The Open Query GRAPH computation engine, or OQGRAPH as the engine itself is called, allows you to handle hierarchies (tree structures) and complex graphs (nodes having many connections in several directions).

OQGRAPH is unlike other storage engines, consisting of an entirely different architecture to a regular storage engine such as Aria, MyISAM or InnoDB.

It is intended to be used for retrieving hierarchical information, such as those used for graphs, routes or social relationships, in plain SQL.

## Installing

See [Installing OQGRAPH](#). Note that the [query cache](#) needs to be disabled when using OQGRAPH with [MariaDB 5.5.35](#) and before, or 10.0.8 and before (see [MDEV-5744](#)). With newer versions, the query cache can be enabled and OQGRAPH will not use it.

## Creating a Table

The following documentation is based upon [MariaDB 10.0.7](#) and OQGRAPH v3. Details have changed since older versions.

## Example with origin and destination nodes only

To create an OQGRAPH v3 table, a backing table must first be created. This backing table will store the actual data, and will be used for all INSERTs, UPDATEs and so on. It must be a regular table, not a view. Here's a simple example to start with:

```
CREATE TABLE oq_backing (
    origid INT UNSIGNED NOT NULL,
    destid INT UNSIGNED NOT NULL,
    PRIMARY KEY (origid, destid),
    KEY (destid)
);
```

Some data can be inserted into the backing table to test with later:

```
INSERT INTO oq_backing(origid, destid)
VALUES (1,2), (2,3), (3,4), (4,5), (2,6), (5,6);
```

Now the read-only OQGRAPH table is created. The CREATE statement must match the format below - any difference will result in an error.

```
CREATE TABLE oq_graph (
    latch VARCHAR(32) NULL,
    origid BIGINT UNSIGNED NULL,
    destid BIGINT UNSIGNED NULL,
    weight DOUBLE NULL,
    seq BIGINT UNSIGNED NULL,
    linkid BIGINT UNSIGNED NULL,
    KEY (latch, origid, destid) USING HASH,
    KEY (latch, destid, origid) USING HASH
)
ENGINE=OQGRAPH
data_table='oq_backing' origid='origid' destid='destid';
```

An older format has the latch field as a SMALLINT rather than a VARCHAR. In [MariaDB 10.0.7](#) with OQGRAPH v3, the format is still valid, but gives an error by default:

```

CREATE TABLE oq_old (
    latch SMALLINT UNSIGNED NULL,
    origid BIGINT UNSIGNED NULL,
    destid BIGINT UNSIGNED NULL,
    weight DOUBLE NULL,
    seq BIGINT UNSIGNED NULL,
    linkid BIGINT UNSIGNED NULL,
    KEY (latch, origid, destid) USING HASH,
    KEY (latch, destid, origid) USING HASH
)
ENGINE=OQGRAPH
data_table='oq_backing' origid='origid' destid='destid';

ERROR 1005 (HY000): Can't create table `test`.`oq_old` (errno: 140 "Wrong create options")

```

The old, deprecated format can still be used if the value of the `oqgraph_allow_create_integer_latch` system variable is changed from its default,

```

    FALSE
    , to
    TRUE

```

```

SET GLOBAL oqgraph_allow_create_integer_latch=1;

CREATE TABLE oq_old (
    latch SMALLINT UNSIGNED NULL,
    origid BIGINT UNSIGNED NULL,
    destid BIGINT UNSIGNED NULL,
    weight DOUBLE NULL,
    seq BIGINT UNSIGNED NULL,
    linkid BIGINT UNSIGNED NULL,
    KEY (latch, origid, destid) USING HASH,
    KEY (latch, destid, origid) USING HASH
)
ENGINE=OQGRAPH
data_table='oq_backing' origid='origid' destid='destid';
Query OK, 0 rows affected, 1 warning (0.19 sec)

SHOW WARNINGS;
+-----+-----+
| Level | Code | Message
+-----+-----+
| Warning | 1287 | 'latch SMALLINT UNSIGNED NULL' is deprecated and will be removed in a future release. Please use 'latch VARCHAR'
+-----+-----+

```

Data is only inserted into the backing table, not the OQGRAPH table.

Now, having created the

```

oq_graph
table linked to a backing table, it is now possible to query the
oq_graph
table directly. The
weight
field, since it was not specified in this example, defaults to
1

```

```

SELECT * FROM oq_graph;
+-----+-----+-----+-----+-----+
| latch | origid | destid | weight | seq | linkid |
+-----+-----+-----+-----+-----+
| NULL | 1 | 2 | 1 | NULL | NULL |
| NULL | 2 | 3 | 1 | NULL | NULL |
| NULL | 2 | 6 | 1 | NULL | NULL |
| NULL | 3 | 4 | 1 | NULL | NULL |
| NULL | 4 | 5 | 1 | NULL | NULL |
| NULL | 5 | 6 | 1 | NULL | NULL |
+-----+-----+-----+-----+-----+

```

The data here represents one-directional starting and ending nodes. So node 2 has paths to node 3 and node 6, while node 6 has no paths to any other node.

## Manipulating Weight

There are three fields which can be manipulated:

```
origid  
,  
destid  
(the example above uses these two), as well as  
weight  
. To create a backing table with a  
weight  
field as well, the following syntax can be used:
```

```
CREATE TABLE oq2_backing (  
    origid INT UNSIGNED NOT NULL,  
    destid INT UNSIGNED NOT NULL,  
    weight DOUBLE NOT NULL,  
    PRIMARY KEY (origid, destid),  
    KEY (destid)  
);
```

```
INSERT INTO oq2_backing(origid, destid, weight)  
VALUES (1,2,1), (2,3,1), (3,4,3), (4,5,1), (2,6,10), (5,6,2);
```

```
CREATE TABLE oq2_graph (  
    latch VARCHAR(32) NULL,  
    origid BIGINT UNSIGNED NULL,  
    destid BIGINT UNSIGNED NULL,  
    weight DOUBLE NULL,  
    seq BIGINT UNSIGNED NULL,  
    linkid BIGINT UNSIGNED NULL,  
    KEY (latch, origid, destid) USING HASH,  
    KEY (latch, destid, origid) USING HASH  
)  
ENGINE=QQGRAPH  
data_table='oq2_backing' origid='origid' destid='destid' weight='weight';
```

```
SELECT * FROM oq2_graph;  
+-----+-----+-----+-----+-----+  
| latch | origid | destid | weight | seq | linkid |  
+-----+-----+-----+-----+-----+  
| NULL | 1 | 2 | 1 | NULL | NULL |  
| NULL | 2 | 3 | 1 | NULL | NULL |  
| NULL | 2 | 6 | 10 | NULL | NULL |  
| NULL | 3 | 4 | 3 | NULL | NULL |  
| NULL | 4 | 5 | 1 | NULL | NULL |  
| NULL | 5 | 6 | 2 | NULL | NULL |  
+-----+-----+-----+-----+-----+
```

See [QQGRAPH Examples](#) for QQGRAPH usage examples.

### 4.3.15.3 OQGRAPH Examples

#### Contents

1. [Creating a Table with origid, destid Only](#)
2. [Creating a Table with Weight](#)
3. [Shortest Path](#)
4. [Possible Destinations](#)
5. [Leaf Nodes](#)
6. [Summary of Implemented Latch Commands](#)
7. [See Also](#)

#### Creating a Table with origid, destid Only

```
CREATE TABLE oq_backing (  
    origid INT UNSIGNED NOT NULL,  
    destid INT UNSIGNED NOT NULL,  
    PRIMARY KEY (origid, destid),  
    KEY (destid)  
);
```

Some data can be inserted into the backing table to test with later:

```
INSERT INTO oq_backing(origid, destid)
VALUES (1,2), (2,3), (3,4), (4,5), (2,6), (5,6);
```

Now the read-only **OQGRAPH** table is created.

From [MariaDB 10.1.2](#) onwards you can use the following syntax:

```
CREATE TABLE oq_graph
ENGINE=OQGRAPH
data_table='oq_backing' origid='origid' destid='destid';
```

Prior to [MariaDB 10.1.2](#), the **CREATE** statement must match the format below - any difference will result in an error.

```
CREATE TABLE oq_graph (
    latch VARCHAR(32) NULL,
    origid BIGINT UNSIGNED NULL,
    destid BIGINT UNSIGNED NULL,
    weight DOUBLE NULL,
    seq BIGINT UNSIGNED NULL,
    linkid BIGINT UNSIGNED NULL,
    KEY (latch, origid, destid) USING HASH,
    KEY (latch, destid, origid) USING HASH
)
ENGINE=OQGRAPH
data_table='oq_backing' origid='origid' destid='destid';
```

## Creating a Table with Weight

For the examples on this page, we'll create a second OQGRAPH table and backing table, this time with

weight  
as well.

```
CREATE TABLE oq2_backing (
    origid INT UNSIGNED NOT NULL,
    destid INT UNSIGNED NOT NULL,
    weight DOUBLE NOT NULL,
    PRIMARY KEY (origid, destid),
    KEY (destid)
);
```

```
INSERT INTO oq2_backing(origid, destid, weight)
VALUES (1,2,1), (2,3,1), (3,4,3), (4,5,1), (2,6,10), (5,6,2);
```

```
CREATE TABLE oq2_graph (
    latch VARCHAR(32) NULL,
    origid BIGINT UNSIGNED NULL,
    destid BIGINT UNSIGNED NULL,
    weight DOUBLE NULL,
    seq BIGINT UNSIGNED NULL,
    linkid BIGINT UNSIGNED NULL,
    KEY (latch, origid, destid) USING HASH,
    KEY (latch, destid, origid) USING HASH
)
ENGINE=OQGRAPH
data_table='oq2_backing' origid='origid' destid='destid' weight='weight';
```

## Shortest Path

A

latch  
value of  
'dijkstras'  
and an  
origid  
and  
destid  
is used for finding the shortest path between two nodes, for example:

```

SELECT * FROM oq_graph WHERE latch='breadth_first' AND origid=1 AND destid=6;
+-----+-----+-----+-----+
| latch | origid | destid | weight | seq  | linkid |
+-----+-----+-----+-----+
| dijkstras|    1 |      6 |    NULL |    0 |     1 |
| dijkstras|    1 |      6 |      1 |    1 |     2 |
| dijkstras|    1 |      6 |      1 |    2 |     6 |
+-----+-----+-----+-----+

```

Note that nodes are uni-directional, so there is no path from node 6 to node 1:

```

SELECT * FROM oq_graph WHERE latch='dijkstras' AND origid=6 AND destid=1;
Empty set (0.00 sec)

```

Using the [GROUP\\_CONCAT](#) function can produce more readable results, for example:

```

SELECT GROUP_CONCAT(linkid ORDER BY seq) AS path FROM oq_graph
WHERE latch='dijkstras' AND origid=1 AND destid=6;
+-----+
| path  |
+-----+
| 1,2,6 |
+-----+

```

Using the table

[oq2\\_graph](#), the shortest path is different:

```

SELECT GROUP_CONCAT(linkid ORDER BY seq) AS path FROM oq2_graph
WHERE latch='dijkstras' AND origid=1 AND destid=6;
+-----+
| path   |
+-----+
| 1,2,3,4,5,6 |
+-----+

```

The reason is the weight between nodes 2 and 6 is

10  
in  
[oq\\_graph2](#), so the shortest path taking into account  
weight  
is now across more nodes.

## Possible Destinations

```

SELECT GROUP_CONCAT(linkid) AS dests FROM oq_graph WHERE latch='dijkstras' AND origid=2;
+-----+
| dests   |
+-----+
| 5,4,6,3,2 |
+-----+

```

Note that this returns all possible destinations along the path, not just immediate links.

## Leaf Nodes

MariaDB 10.3.3

Support for the  
leaves  
latch value was introduced in [MariaDB 10.3.3](#).

A

latch  
value of  
'leaves'  
and either

origid  
or  
destid  
is used for finding leaf nodes at the beginning or end of a graph.

```
INSERT INTO oq_backing(origid, destid)
VALUES (1,2), (2,3), (3,5), (4,5), (5,6), (6,7), (6,8), (2,8);
```

For example, to find all reachable nodes from

origid  
that only have incoming edges:

```
SELECT * FROM oq_graph WHERE latch='leaves' AND origid=2;
+-----+-----+-----+-----+
| latch | origid | destid | weight | seq | linkid |
+-----+-----+-----+-----+
| leaves |      2 |    NULL |      4 |     2 |      7 |
| leaves |      2 |    NULL |      1 |     1 |      8 |
+-----+-----+-----+-----+
```

And to find all nodes from which a path can be found to

destid  
that only have outgoing edges:

```
SELECT * FROM oq_graph WHERE latch='leaves' AND destid=5;
+-----+-----+-----+-----+
| latch | origid | destid | weight | seq | linkid |
+-----+-----+-----+-----+
| leaves |    NULL |      5 |      3 |     2 |      1 |
| leaves |    NULL |      5 |      1 |     1 |      4 |
+-----+-----+-----+-----+
```

## Summary of Implemented Latch Commands

Latch	Alternative	additional where clause fields	Graph operation
NULL	(unspecified)	(none)	List original data
(empty string)	0	(none extra)	List all vertices in linkid column
(empty string)	0	origid	List all first hop vertices from origid in linkid column
dijkstras	1	origid, destid	Find shortest path using Dijkstras algorithm between origid and destid, with traversed vertex ids in linkid column
dijkstras	1	origid	Find all vertices reachable from origid, listed in linkid column, and report sum of weights of vertices on path to given vertex in weight
dijkstras	1	destid	Find all vertices from which a path can be found to destid, listed in linkid column, and report sum of weights of vertices on path to given vertex in weight
breadth_first	2	origid	List vertices reachable from origid in linkid column
breadth_first	2	destid	List vertices from which a path can be found to destid in linkid column
breadth_first	2	origid, destid	Find shortest path between origid and destid, report in linkid column
leaves	4	origid	List vertices reachable from origid, that only have incoming edges (from <a href="#">MariaDB 10.3.3</a> )
leaves	4	destid	List vertices from which a path can be found to destid, that only have outgoing edges (from <a href="#">MariaDB 10.3.3</a> )
leaves	4	origid, destid	Not supported, will return an empty result

Note: the use of integer latch commands is deprecated and may be phased out in a future release. Currently, numeric values in the strings are interpreted as aliases, and use of an integer column can be optionally allowed, for the latch commands column.

The use of integer latches is controlled using the [oqgraph\\_allow\\_create\\_integer\\_latch](#) system variable.

## 4.3.15.4 Compiling OQGRAPH

To compile OQGraph v2 you need to have the boost library with the versions not earlier than 1.40 and not later than 1.55 and gcc version not earlier than 4.5.

MariaDB starting with 10.0.7

OQGraph v3 compiles fine with the newer boost libraries, but it additionally needs the Judy library installed.

When all build prerequisites are met, OQGraph is enabled and compiled automatically. To enable or disable OQGRAPH explicitly, see the generic [plugin build instructions](#).

### Finding Out Why OQGRAPH Didn't Compile

If OQGRAPH gets compiled properly, there should be a file like:

```
storage/oqgraph/ha_oqgraph.so
```

If this is not the case, then you can find out if there is any modules missing that are required by OQGRAPH by doing:

```
cmake . -LAH | grep -i oqgraph
```

## 4.3.15.5 Building OQGRAPH Under Windows

OQGRAPH v3 can be built on Windows.

MariaDB starting with 10.0.11

This has been tested using Windows 7, Microsoft Visual Studio Express 2010 (32-bit), Microsoft Windows 64-bit Platform SDK 7.1 (64-bit), the Boost library >= 1.55 and Judy 1.0.5. Probably other recent versions of Boost, Judy or MSVC may work but these combinations have not been tested.

- Download the source package for Boost 1.55 from the Boost project website, <http://www.boost.org>
- Download the source package for Judy 1.05 via <http://judy.sourceforge.net/>
- Follow the documented instructions for building under Windows from the command line: [Building\\_MariaDB\\_on\\_Windows](#)
  - Ensure that the following variable is set to CMAKE:  
`JUDY_ROOT=path\to\judy\unzipped`
  - See also comments in  
`storage/oqgraph/cmake/FindJudy.cmake`

## 4.3.15.6 OQGRAPH System and Status Variables

### Contents

1. [System Variables](#)
  1. [oqgraph\\_allow\\_create\\_integer\\_latch](#)
2. [Status Variables](#)
  1. [Oqgraph\\_boost\\_version](#)
  2. [Oqgraph\\_compat\\_mode](#)
  3. [Oqgraph\\_verbose\\_debug](#)

This page documents system and status variables related to the [OQGRAPH storage engine](#). See [Server Status Variables](#) and [Server System Variables](#) for complete list of all system and status variables.

### System Variables

`oqgraph_allow_create_integer_latch`

- **Description:** Created when the OQGRAPH storage engine is installed, if set to

```
1
(
0
is default), permits the
latch
```

field to be an integer (see [OQGRAPH Overview](#) ).

- **Scope:** Global
- **Dynamic:** Yes
- **Data Type:**  
boolean

- **Default Value:**

0

- **Introduced:** [MariaDB 10.0.7](#)

## Status Variables

### Oqgraph\_boost\_version

- **Description:** OQGRAPH boost version.

- **Scope:** Global, Session

- **Data Type:**

string

- **Introduced:** [MariaDB 10.0.7](#) with the [OQGRAPH](#) storage engine.

### Oqgraph\_compat\_mode

- **Description:** Whether or not legacy tables with integer latches are supported.

- **Scope:** Global, Session

- **Data Type:**

string

- **Introduced:** [MariaDB 10.1.5](#)

### Oqgraph\_verbose\_debug

- **Description:** Whether or not verbose debugging is enabled. If it is, performance may be adversely impacted

- **Scope:** Global, Session

- **Data Type:**

string

- **Introduced:** [MariaDB 10.1.5](#)

## 4.3.16 S3 Storage Engine

MariaDB starting with [10.5](#)

The [S3 storage engine](#) has been available since [MariaDB 10.5.4](#) .

S3 is a read-only storage engine that stores its data in Amazon S3.

### Using the S3 Storage Engine

[Using the S3 storage engine](#).

The [S3 storage engine](#) is read only and allows one to archive MariaDB tables in Amazon S3, or any third-party public or private cloud that implements S3 API (of which there are many), but still have them accessible for reading in MariaDB.

### Installing the Plugin

As of [MariaDB 10.5.7](#), the S3 storage engine is currently [gamma maturity](#), so the following step can be omitted.

On earlier releases, when it was [alpha maturity](#), it will not load by default on a stable release of the server due to the default value of the [plugin\\_maturity](#) variable. Set to

`alpha`

(or below) in your config file to permit installation of the plugin:

```
[mysqld]
plugin-maturity = alpha
```

and restart the server.

Now [install the plugin library](#), for example:

```
INSTALL SONAME 'ha_s3';
```

If the library is not available, for example:

```
INSTALL SONAME 'ha_s3';
ERROR 1126 (HY000): Can't open shared library '/var/lib/mysql/lib64/mysql/plugin/ha_s3.so'
(errno: 13, cannot open shared object file: No such file or directory)
```

you may need to install a separate package for the S3 storage engine, for example:

```
shell> yum install MariaDB-s3-engine
```

## Moving Data to S3

To move data from an existing table to S3, one can run:

```
ALTER TABLE old_table ENGINE=S3
```

To get data back to a 'normal' table one can do:

```
ALTER TABLE s3_table ENGINE=INNODB
```

## New Options for `ALTER TABLE`

- `S3_BLOCK_SIZE`  
: Set to 4M as default. This is the block size for all index and data pages stored in S3.
- `COMPRESSION_ALGORITHM`  
: Set to 'none' as default. Which compression algorithm to use for block stored in S3. Options are:  
none  
or  
zlib

`ALTER TABLE` can be used on S3 tables as normal to add columns or change column definitions.

## mysqld Startup Options for S3

To be able to use S3 for storage one \*must\* define how to access S3 and where data are stored in S3:

- `s3_access_key` : The AWS access key to access your data
- `s3_secret_key` : The AWS secret key to access your data
- `s3_bucket` : The AWS bucket where your data should be stored. All MariaDB table data is stored in this bucket.
- `s3_region` : The AWS region where your data should be stored.

If you are using an S3 service that is using HTTP to connect (like <https://min.io/>) you also need to set the following variables:

- `s3_port` : Port number to connect to (0 means use default)
- `s3_use_http` : If true, force use of HTTP protocol

If you are going to use a primary-replica setup, you should look at the following variables:

- `s3_replicate_alter_as_create_select` : When converting an S3 table to local table, log all rows in binary log. Defaults to  
`TRUE`  
. This allows the replica to replicate  
`CREATE TABLE .. SELECT FROM s3_table`  
even if the replica doesn't have access to the original  
`s3_table`
- `s3_slave_ignore_updates` : Should be set if primary and replica share the same S3 instance. This tells the replica that it can ignore any updates to the S3 tables as they are already applied on the primary. Defaults to  
`FALSE`

The above defaults assume that the primary and replica don't share the same S3 instance.

Other, less critical options, are:

- `s3_host_name` : Hostname for the S3 service. "s3.amazonaws.com", Amazon S3 service, by default.
- `s3_protocol_version` : Protocol used to communicate with S3. One of "Auto", "Amazon" or "Original" where "Auto" is the default. If you get errors like "8 Access Denied" when you are connecting to another service provider, then try to change this option. The reason for this variable is that Amazon has changed some parts of the S3 protocol since they originally introduced it but other service providers are still using the original protocol.
- `s3_block_size` : Set to 4M as default. This is the default block size for a table, if not specified in `CREATE TABLE`.
- `s3_pagecache_buffer_size` : Default 128M. The size of the buffer used for data and index blocks for S3 tables. Increase this to get better index handling (for all reads and multiple writes) to as much as you can afford.

Last some options you probably don't have to ever touch:

- `s3_pagecache_age_threshold` : Default 300: This characterizes the number of hits a hot block has to be untouched until it is considered aged enough to be downgraded to a warm block. This specifies the percentage ratio of that number of hits to the total number of blocks in the page

cache.

- **s3\_pagecache\_division\_limit** : Default 100. The minimum percentage of warm blocks in key cache.
- **s3\_pagecache\_file\_hash\_size** : Default 512. Number of hash buckets for open files. If you have a lot of S3 files open you should increase this for faster flush of changes. A good value is probably 1/10 of number of possible open S3 files.
- **s3\_debug** : Default 0. Generates a trace file from libmarias3 on stderr (mysqld.err) for debugging the S3 protocol.

## Typical my.cnf Entry for connecting to Amazon S3 service

```
[mariadb]
s3=ON
s3-bucket=mariadb
s3-access-key=xxxx
s3-secret-key=xxx
s3-region=eu-north-1
s3-host-name=s3.amazonaws.com
# The following is useful if you want to use minio as a S3 server. (https://min.io/)
#s3-port=9000
#s3-use-htp=ON

# Primary and replica share same S3 tables.
s3-slave-ignore-updates=1

[aria_s3_copy]
s3-bucket=mariadb
s3-access-key=xxxx
s3-secret-key=xxx
s3-region=eu-north-1
s3-host-name=s3.amazonaws.com
# The following is useful if you want to use minio as a S3 server. (https://min.io/)
#s3-port=9000
#s3-use-htp=ON
```

## Typical my.cnf entry for connecting to a [minio](#) S3 server

```
[mariadb]
s3=ON
s3-host-name="127.0.0.1"
s3-bucket=storage-engine
s3-access-key=minio
s3-secret-key=minioadmin
s3-port=9000
s3-use-htp=ON

[aria_s3_copy]
s3=ON
s3-host-name="127.0.0.1"
s3-bucket=storage-engine
s3-access-key=minio
s3-secret-key=minioadmin
s3-port=9000
s3-use-htp=ON
```

## Typical Usage Case for S3 Tables

The typical use case would be that there exists tables that after some time would become fairly inactive, but are still important so that they can not be removed. In that case, an option is to move such a table to an archiving service, which is accessible through an S3 API.

Notice that S3 means the Cloud Object Storage API defined by Amazon AWS. Often the whole of Amazon's Cloud Object Storage is referred to as S3. In the context of the S3 archive storage engine, it refers to the API itself that defines how to store objects in a cloud service, being it Amazon's or someone else's. OpenStack for example provides an S3 API for storing objects.

The main benefit of storing things in an S3 compatible storage is that the cost of storage is much cheaper than many other alternatives. Many S3 implementations also provide reliable long-term storage.

## Operations Allowed on S3 Tables

- [ALTER TABLE](#) S3 supports all types, keys and other options that are supported by the [Aria](#) engine. One can also perform [ALTER TABLE](#) on an S3 table to add or modify columns etc.
- [DROP TABLE](#)
- [SELECT](#) Any SELECT operations you can perform on a normal table should work with an S3 table.
- [SHOW TABLES](#) will show all tables that exist in the current defined S3 location.

- S3 tables can be part of [partitions](#) . See Discovery below.

## Discovery

The S3 storage engine supports full [MariaDB discovery](#) . This means that if you have the S3 storage engine enabled and properly configured, the table stored in S3 will automatically be discovered when it's accessed with `SHOW TABLES` , `SELECT` or any other operation that tries to access it. In the case of `SELECT`, the .frm file from S3 will be copied to the local storage to speed up future accesses.

When an S3 table is opened for the first time (it's not in the table cache) and there is a local .frm file, the S3 engine will check if it's still relevant, and if not, update or delete the .frm file.

This means that if the table definition changes on S3 and it's in the local cache, one has to execute

[FLUSH TABLES](#)

to get MariaDB to notice the change and update the .frm file.

If partitioning S3 tables are used, the partition definitions will also be stored on S3 storage and will be discovered by other servers.

Discovery of S3 tables is not done for tables in the [mysql databases](#) to make mysqld boot faster and more securely.

## Replication

S3 works with [replication](#) . One can use replication in two different scenarios:

- The primary and replica share the same S3 storage. In this case the primary will make all changes to the S3 data and the replica will ignore any changes in the replication stream to S3 data . This scenario is achieved by setting `s3_slave_ignore_updates` to 1.
- The primary and replica don't share the same S3 storage or the replica uses another storage engine for the S3 tables. This scenario is achieved by setting `s3_slave_ignore_updates` to 0.

## aria\_s3\_copy

[aria\\_s3\\_copy](#) is an external tool that one can use to copy [Aria](#) tables to and from S3. Use

```
aria_s3_copy --help
to get the options of how to use it.
```

## mysqldump

- [mysqldump](#) will by default ignore S3 tables. If

```
mysqldump
is run with the
--copy-s3-tables
option, the resulting file will contain a CREATE statement for a similar Aria table, followed by the table data and ending with an
ALTER TABLE xxx ENGINE=S3
```

## ANALYZE TABLE

As of [MariaDB 10.5.14](#) ,

[ANALYZE TABLE](#)

is supported for S3 tables. As the S3 tables are read-only, a normal `ANALYZE TABLE` will not do anything. However using `ANALYZE TABLE table_name PERSISTENT FOR...` will now work.

## CHECK TABLE

As of [MariaDB 10.5.14](#) ,

[CHECK TABLE](#)

will work. As S3 tables are read only it is very unlikely that they can become corrupted. The only known way an S3 table could be corrupted if either the original table copied to S3 was corrupted or the process of copying the original table to S3 was somehow interrupted.

## Current Limitations

- [mysql-test-run](#) doesn't by default test the S3 engine as we can't embed AWS keys into mysql-test-run.
- Replicas should not access S3 tables while they are ALTERed! This is because there is no locking implemented to S3 between servers. However, after a table (either the original S3 table or the partitioned S3 table) is changed on the primary, the replica will notice this on the next access and update its local definition.

## Limitations in [ALTER .. PARTITION](#)

All [ALTER PARTITION](#) operations are supported on S3 partitioning tables except:

- REBUILD PARTITION
- TRUNCATE PARTITION
- REORGANIZE PARTITION

## Performance Considerations

Depending on your connection speed to your S3 provider, there can be some notable slowdowns in some operations.

### Discovery

As S3 is supporting discovery (automatically making tables available that are in S3) this can cause some small performance problems if the S3 engine is enabled. Partitioning S3 tables also support discovery.

- CREATE TABLE is a bit slower as the S3 engine has to check if the to-be-created table is already S3.
- Queries on information\_schema tables are slower as S3 has to check if there is new tables in S3.
- DROP of non existing tables are slower as S3 has to check if the table is in S3.

There are no performance degradation's when accessing existing tables on the server. Accessing the S3 table the first time will copy the .frm file from S3 to the local disk, speeding up future accesses to the table.

### Caching

- Accessing a table on S3 can take some time , especially if you are using big packets ( [s3\\_block\\_size](#) ). However the second access to the same data should be fast as it's then cached in the S3 page cache.

## Things to Try to Increase Performance

If you have performance problems with the S3 engine, here are some things you can try:

- Decreasing [s3\\_block\\_size](#) . This can be done both globally and per table.
- Use COMPRESSION\_ALGORITHM=zlib when creating the table. This will decrease the amount of data transferred from S3 to the local cache.
- Increasing the size of the s3 page cache: [s3\\_pagecache\\_buffer\\_size](#)

Try also to execute the query twice to check if the problem is that the data was not properly cached. When data is cached locally the performance should be excellent.

## Future Development Ideas

- Store aws keys and region in the mysql.servers table (as [Spider](#) and [FederatedX](#) ). This will allow one to have different tables on different S3 servers.
- Store s3 bucket, access\_key and secret key in a cache to better be able to reuse connections. This would save some memory and make some S3 accesses a bit faster as we could reuse old connections.

## Troubleshooting S3 on SELinux

If you get errors such as:

```
ERROR 3 (HY000): Got error from put_object(bubu/produkt/frm): 5 Couldn't connect to server
```

one reason could be that your system doesn't allow MariaDB to connect to ports other than 3306. To procedure to enable other ports is the following:

Search for the ports allowed for MariaDB:

```
$ sudo semanage port -l | grep mysqld_port_t
mysqld_port_t          tcp    1186, 3306, 63132-63164
```

Say you want to allow MariaDB to connect to port 32768:

```
$ sudo semanage port -a -t mysqld_port_t -p tcp 32768
```

You can verify that the new port, 32768, is now allowed for MariaDB:

```
$ sudo semanage port -l | grep mysqld_port_t
mysqld_port_t           tcp    32768,1186, 3306, 63132-63164
```

### 4.3.16.2 Testing the Connections to S3

MariaDB starting with [10.5](#)

The [S3 storage engine](#) has been available since [MariaDB 10.5.4](#).

#### Contents

1. [S3 Connection Variables](#)
  1. [Using aria\\_s3\\_copy to Test the Connection](#)
  2. [Using mysql-test-run to Test the Connection and the S3 Storage Engine](#)
2. [What to Do Next](#)
3. [See Also](#)

If you can't get the S3 storage engine to work, here are some steps to help verify where the problem could be.

## S3 Connection Variables

In most cases the problem is to correctly set the S3 connection variables.

The variables are:

- [s3\\_access\\_key](#) : The AWS access key to access your data
- [s3\\_secret\\_key](#) : The AWS secret key to access your data
- [s3\\_bucket](#) : The AWS bucket where your data should be stored. All MariaDB table data is stored in this bucket.
- [s3\\_region](#) : The AWS region where your data should be stored.
- [s3\\_host\\_name](#) : Hostname for the S3 service.
- [s3\\_protocol\\_version](#) : Protocol used to communicate with S3. One of "Amazon" or "Original"

There are several ways to ensure you get them right:

### Using aria\_s3\_copy to Test the Connection

[aria\\_s3\\_copy](#) is a tool that allows you to copy [aria](#) tables to and from S3. It's useful for testing the connection as it allows you to specify all s3 options on the command line.

Execute the following sql commands to create a trivial sql table:

```
use test;
create table s3_test (a int) engine=aria row_format=page transactional=0;
insert into s3_test values (1),(2);
flush tables s3_test;
```

Now you can use the [aria\\_s3\\_copy](#) tool to copy this to S3 from your shell/the command line:

```
shell> cd mariadb-data-directory/test
shell> aria_s3_copy --op=to --verbose --force --**other*options* s3_test.frm

Copying frm file s3_test.frm
Copying aria table: test.s3_test to s3
Creating aria table information test/s3_test/aria
Copying index information test/s3_test/index
Copying data information test/s3_test/data
```

As you can see from the above, [aria\\_s3\\_copy](#) is using the current directory as the database name.

You can also set the [aria\\_s3\\_copy](#) options in your my.cnf file to avoid some typing.

### Using mysql-test-run to Test the Connection and the S3 Storage Engine

One can use the [MariaDB test system](#) to run all default S3 test against your S3 storage.

To do that you have to locate the

```
mysql-test  
directory in your system and  
cd  
to it.
```

The config file for the S3 test system can be found at

```
suite/s3/my.cnf
```

. To enable testing you have to edit this file and add the s3 connection options to the end of the file. It should look something like this after editing:

```
!include include/default_mysqld.cnf  
!include include/default_client.cnf  
  
[mysqld.1]  
s3=ON  
#s3-host-name=s3.amazonaws.com  
#s3-protocol-version=Amazon  
s3-bucket=MariaDB  
s3-access-key=  
s3-secret-key=  
s3-region=
```

You must give values for

```
s3-access-key  
,  
s3-secret-key  
and  
s3-region  
that reflects your S3 provider. The  
s3-bucket  
name is defined by your administrator.
```

If you are not using Amazon Web Services as your S3 provider you must also specify

```
s3-hostname  
and possibly change  
s3-protocol-version  
to "Original".
```

Now you can test the configuration:

```
shell> cd **mysql-test** directory  
shell> ./mysql-test-run --suite=s3  
...  
s3.no_s3 [ pass ] 5  
s3.alter [ pass ] 11073  
s3.arguments [ pass ] 2667  
s3.basic [ pass ] 2757  
s3.discovery [ pass ] 7851  
s3.select [ pass ] 1325  
s3.unsupported [ pass ] 363
```

Note that there may be more tests in your output as we are constantly adding more tests to S3 when needed.

## What to Do Next

When you got the connection to work, you should add the options to your global my.cnf file. Now you can start testing S3 from your [mysql command client](#) by converting some existing table to S3 with [ALTER TABLE ... ENGINE=S3](#).

- [Using MinIO with mysql-test-run to test the S3 storage engine](#)

### 4.3.16.3 S3 Storage Engine Internals

MariaDB starting with [10.5](#)

The [S3 storage engine](#) has been available since [MariaDB 10.5.4](#).

## Contents

1. [ALTER TABLE](#)
2. [Partitioning Tables](#)
3. [Big Reads](#)
4. [Compression](#)
5. [Structure Stored on S3](#)
6. [Using the awsctl Python Tool to Examine Data](#)
  1. [Installing awsctl on Linux](#)
  2. [Using the awsctl Tool](#)
7. [See Also](#)

The [S3 storage engine](#) is based on the [Aria](#) code. Internally the S3 storage inherits from the Aria code, with hooks that change reads, so that instead of reading data from the local disk it reads things from S3.

The S3 engine uses its own page cache, modified to be able to handle reading blocks from S3 (of size

`s3_block_size`

). Internally the S3 page cache uses pages of [aria-block-size](#) for splitting the blocks read from S3.

## ALTER TABLE

[ALTER TABLE](#) will first create a local table in the normal Aria on disk format and then move both index and data to S3 in buckets of [S3\\_BLOCK\\_SIZE](#). The .frm file is also copied to S3 for discovery to support discovery for other MariaDB servers. One can also use [ALTER TABLE](#) to change the structure of an S3 table.

## Partitioning Tables

Starting from [MariaDB 10.5.3](#), S3 tables can also be used with [Partitioning tables](#). All [ALTER PARTITION](#) operations are supported except:

- REBUILD PARTITION
- TRUNCATE PARTITION
- REORGANIZE PARTITION

## Big Reads

One of the properties of many S3 implementations is that they favor large reads. It's said that 4M gives the best performance, which is why the default value for

`S3_BLOCK_SIZE`  
is 4M.

## Compression

If compression (  
`COMPRESSION_ALGORITHM=zlib`  
) is used, then all index blocks and data blocks are compressed. The  
.frm  
file and Aria definition header (first page/pages in the index file) are not compressed as these are used by discovery/open.

If compression is used, then the local block size is

`S3_BLOCK_SIZE`  
, but the block stored in S3 will be the size of the compressed block.

Typical compression we have seen is in the range of 80% saved space.

## Structure Stored on S3

The table will be copied in S3 into the following locations:

`frm` file (for discovery):  
`s3_bucket/database/table/frm`

First index block (contains description of the Aria file):  
`s3_bucket/database/table/aria`

Rest of the index file:  
`s3_bucket/database/table/index/block_number`

Data file:  
`s3_bucket/database/table/data/block_number`

block\_number is a 6-digit decimal number, prefixed with 0 (Can be larger than 6 numbers, the prefix is just for nice output)

## Using the awsctl Python Tool to Examine Data

### Installing awsctl on Linux

```
# install python-pip (on an OpenSuse distribution)
# use the appropriate command for your distribution
zypper install python-pip
pip install --upgrade pip

# the following installs awscli tools in ~/.local/bin
pip install --upgrade --user awscli
export PATH=~/./local/bin:$PATH

# configure your aws credentials
aws configure
```

### Using the awsctl Tool

One can use the

```
aws
python tool to see how things are stored on S3:
```

```
shell> aws s3 ls --recursive s3://mariadb-bucket/
2019-05-10 17:46:48      8192 foo/test1/aria
2019-05-10 17:46:49    3227648 foo/test1/data/000001
2019-05-10 17:46:48      942 foo/test1/frm
2019-05-10 17:46:48   1015808 foo/test1/index/000001
```

To delete an obsolete table

```
foo.test1
one can do:
```

```
shell> ~/.local/bin/aws s3 rm --recursive s3://mariadb-bucket/foo/test1
delete: s3://mariadb-bucket/foo/test1/aria
delete: s3://mariadb-bucket/foo/test1/data/000001
delete: s3://mariadb-bucket/foo/test1/frm
delete: s3://mariadb-bucket/foo/test1/index/000001
```

## See Also

### 4.3.16.4 aria\_s3\_copy

MariaDB starting with [10.5](#)

The [S3 storage engine](#) has been available since [MariaDB 10.5.4](#).

`aria_s3_copy`  
is a tool for copying an [Aria](#) table to and from [S3](#).

The Aria table must be non transactional and have [ROW\\_FORMAT=PAGE](#).

For

```
aria_s3_copy
to work reliably, the table should not be changed by the MariaDB server during the copy, and one should have first performed FLUSH TABLES to ensure that the table is properly closed.
```

Example of properly created Aria table:

```
create table test1 (a int) transactional=0 row_format=PAGE engine=aria;
```

Note that [ALTER TABLE table\\_name ENGINE=S3](#) will work for any kind of table. This internally converts the table to an Aria table and then moves it to S3 storage.

## Main Arguments

Option	Description
-?, --help	Display this help and exit.
-k, --s3-access-key=name	AWS access key ID
-r, --s3-region=name	AWS region
-K, --s3-secret-key=name	AWS secret access key ID
-b, --s3-bucket=name	AWS prefix for tables
-h, --s3-host-name=name	Host name to S3 provider
-c, --compress	Use compression
-o, --op=name	Operation to execute. One of 'from_s3', 'to_s3' or 'delete_from_s3'
-d, --database=name	Database for copied table (second prefix). If not given, the directory of the table file is used
-B, --s3-block-size=#	Block size for data/index blocks in s3
-L, --s3-protocol-version=name	Protocol used to communication with S3. One of "Amazon" or "Original".
-f, --force	Force copy even if target exists
-v, --verbose	Write more information
-V, --version	Print version and exit.
-#, --debug[=name]	Output debug log. Often this is 'd:t:o,filename'.
--s3-debug	Output debug log from marias3 to stdout

## Typical Configuration in a my.cnf File

```
[aria_s3_copy]
s3-bucket=mariadb
s3-access-key=xxxx
s3-secret-key=xxx
s3-region=eu-north-1
#s3-host-name=s3.amazonaws.com
#s3-protocol-version=Amazon
verbose=1
op=to
```

## Example Usage

The following code will copy an existing Aria table named

```
test1
to S3. If the
--database
option is not given, then the directory name where the table files exist will be used as the database.
```

```
shell> aria_s3_copy --force --op=to --database=foo --compress --verbose --s3_block_size=4M test1
Delete of aria table: foo.test1
Delete of index information foo/test1/index
Delete of data information foo/test1/data
Delete of base information and frm
Copying frm file test1.frm
Copying aria table: foo.test1 to s3
Creating aria table information foo/test1/aria
Copying index information foo/test1/index
.
Copying data information foo/test1/data
.
```

When using

```
--verbose
,
aria_s3_copy
will write a dot for each #/79 part of the file copied.
```

2. [See Also](#)

This page documents system variables related to the [S3 storage engine](#).

See [Server System Variables](#) for a complete list of system variables and instructions on setting system variables.

Also see the [Full list of MariaDB options, system and status variables](#)

## Variables

### s3\_access\_key

- **Description:** The AWS access key to access your data. See [mysqld startup options for S3](#).

- **Commandline:**

```
--s3-access-key=val
```

- **Scope:** Global
- **Dynamic:** No
- **Data Type:** String
- **Default Value:** (Empty)
- **Introduced:** [MariaDB 10.5.4](#)

### s3\_block\_size

- **Description:** The default block size for a table, if not specified in [CREATE TABLE](#). Set to 4M as default. See [mysqld startup options for S3](#).

- **Commandline:**

```
--s3-block-size=#
```

- **Scope:** Global
- **Dynamic:** Yes
- **Data Type:** Numeric
- **Default Value:**

4194304

- **Range:**

4194304

to

16777216

- **Introduced:** [MariaDB 10.5.4](#)

### s3\_bucket

- **Description:** The AWS bucket where your data should be stored. All MariaDB table data is stored in this bucket. See [mysqld startup options for S3](#)

- **Commandline:**

```
--s3-bucket=val
```

- **Scope:** Global

- **Dynamic:** No

- **Data Type:** String

- **Default Value:**

MariaDB

- **Introduced:** MariaDB 10.5.4

---

## s3\_debug

- **Description:** Generates a trace file from libmarias3 on stderr (mysqld.err) for debugging the S3 protocol.

- **Commandline:**

```
--s3-debug{=0|1}
```

- **Scope:** Global

- **Dynamic:** No

- **Data Type:** Boolean

- **Valid Values:** 0 or 1

- **Default Value:**

0

- **Introduced:** MariaDB 10.5.4

---

## s3\_host\_name

- **Description:** Hostname for the S3 service. "s3.amazonaws.com", Amazon S3 service, by default

- **Commandline:**

```
--s3-host-name=val
```

- **Scope:** Global;

- **Dynamic:** No

- **Data Type:** String

- **Default Value:**

s3.amazonaws.com

- **Introduced:** MariaDB 10.5.4

---

## s3\_pagecache\_age\_threshold

- **Description:** This characterizes the number of hits a hot block has to be untouched until it is considered aged enough to be downgraded to a warm block. This specifies the percentage ratio of that number of hits to the total number of blocks in the page cache.

- **Commandline:**

```
--s3-pagecache-age-threshold=val
```

- **Scope:** Global

- **Dynamic:** Yes

- **Data Type:** Numeric

- **Default Value:**

300

- **Range:**

100

to

18446744073709551615

- **Introduced:** MariaDB 10.5.4

---

## s3\_pagecache\_buffer\_size

- **Description:** The size of the buffer used for index blocks for S3 tables. Increase this to get better index handling (for all reads and multiple writes) to as much as you can afford. Size can be adjusted in blocks of 8192

- **Commandline:**

```
--s3-pagecache-buffer-size=val
```

- **Scope:** Global
- **Dynamic:** No
- **Data Type:** Numeric
- **Default Value:**

134217728  
(128M)

- **Range:**

33554432  
to  
18446744073709551615

- **Introduced:** MariaDB 10.5.4
- 

## s3\_pagecache\_division\_limit

- **Description:** The minimum percentage of warm blocks in key cache.

- **Commandline:**

```
--s3-pagecache-division-limit=val
```

- **Scope:** Global
- **Dynamic:** Yes
- **Data Type:** Numeric
- **Default Value:**

100

- **Range:**

1  
to  
100

- **Introduced:** MariaDB 10.5.4
- 

## s3\_pagecache\_file\_hash\_size

- **Description:** Number of hash buckets for open files. Default 512. If you have a lot of S3 files open you should increase this for faster flush of changes. A good value is probably 1/10 of number of possible open S3 files.

- **Commandline:**

```
--s3-pagecache-file-hash-size=#
```

- **Scope:** Global
- **Dynamic:** No
- **Data Type:** Numeric
- **Default Value:**

512

- **Range:**

32  
to  
16384

- **Introduced:** MariaDB 10.5.4
- 

## s3\_port

- **Description:** The TCP port number on the S3 host to connect to. A value of 0 means determine automatically.

- **Commandline:**

```
--s3-port=#
```

- **Scope:** Global

- **Dynamic:** No

- **Data Type:** Numeric

- **Default Value:**

```
0
```

- **Range:**

```
0
```

```
to
```

```
65535
```

- **Introduced:** [MariaDB 10.5.7](#)
- 

## s3\_protocol\_version

- **Description:** Protocol used to communicate with S3. One of "Auto", "Amazon" or "Original" where "Auto" is the default. If you get errors like "8 Access Denied" when you are connecting to another service provider, then try to change this option. The reason for this variable is that Amazon has changed some parts of the S3 protocol since they originally introduced it but other service providers are still using the original protocol.

- **Commandline:**

```
--s3-protocol-version=val
```

- **Scope:** Global

- **Dynamic:** Yes

- **Data Type:** Enum

- **Valid Values:**

```
Auto
```

```
,
```

```
Amazon
```

```
or
```

```
Original
```

- **Default Value:**

```
Auto
```

- **Introduced:** [MariaDB 10.5.4](#)
- 

## s3\_region

- **Description:** The AWS region where your data should be stored. See [mysqld startup options for S3](#).

- **Commandline:**

```
--s3-region=val
```

- **Scope:** Global

- **Dynamic:** No

- **Data Type:** String

- **Default Value:** (Empty)

- **Introduced:** [MariaDB 10.5.4](#)
- 

## s3\_replicate\_alter\_as\_create\_select

- **Description:** When converting S3 table to local table, log all rows in binary log. This allows the slave to replicate

```
CREATE TABLE .. SELECT FROM s3_table  
even if the slave doesn't have access to the original  
s3_table
```

- **Commandline:**

```
--s3-replicate-alter-as-create-select{=0|1}
```

- **Scope:** Global
- **Dynamic:** No
- **Data Type:** Boolean
- **Default Value:**

1

- **Introduced:** [MariaDB 10.5.4](#)
- 

### s3\_secret\_key

- **Description:** The AWS secret key to access your data. See [mysqld startup options for S3](#).
- **Commandline:**

```
--s3-secret-key=val
```

- **Scope:** Global
  - **Dynamic:** No
  - **Data Type:** String
  - **Default Value:** (Empty)
  - **Introduced:** [MariaDB 10.5.4](#)
- 

### s3\_slave\_ignore\_updates

- **Description:** Should be set if master and slave share the same S3 instance. This tells the slave that it can ignore any updates to the S3 tables as they are already applied on the master.

- **Commandline:**

```
--s3-slave-ignore-updates{=0|1}
```

- **Scope:** Global
- **Dynamic:** No
- **Data Type:** Boolean
- **Default Value:**

0

- **Introduced:** [MariaDB 10.5.4](#)
- 

### s3\_use\_http

- **Description:** If enabled, HTTP will be used instead of HTTPS.

- **Commandline:**

```
--s3-use-http{=0|1}
```

- **Scope:** Global
- **Dynamic:** No
- **Data Type:** Boolean
- **Default Value:**

0

- **Introduced:** [MariaDB 10.5.7](#)
- 

## See Also

[Using the S3 Storage Engine](#)

## 4.3.17 Sequence Storage Engine

## Contents

1. [Installing](#)
2. [Usage and Examples](#)
3. [Table Name Conflicts](#)
4. [Resources](#)

This article is about the Sequence storage engine. For details about sequence objects, see [Sequences](#).

A **Sequence** engine allows the creation of ascending or descending sequences of numbers (positive integers) with a given starting value, ending value and increment.

It creates completely virtual, ephemeral tables automatically when you need them. There is no way to create a Sequence table explicitly. Nor are they ever written to disk or create

.frm files. They are read-only, [transactional](#), and [support XA](#).

## Installing

Until [MariaDB 10.0](#), the **Sequence** engine is usually distributed as a dynamic plugin, not part of the server binary. To be able to use it, you need to install it first:

```
INSTALL SONAME "ha_sequence";
```

From [MariaDB 10.1](#), the Sequence engine is installed by default.

If it has been correctly installed, [SHOW ENGINES](#) will list the Sequence storage engine as supported:

```
SHOW ENGINES\G
...
***** 5. row *****
  Engine: MyISAM
  Support: YES
  Comment: MyISAM storage engine
Transactions: NO
      XA: NO
  Savepoints: NO
***** 6. row *****
  Engine: SEQUENCE
  Support: YES
  Comment: Generated tables filled with sequential values
Transactions: YES
      XA: YES
  Savepoints: YES
***** 7. row *****
  Engine: MRG_MyISAM
  Support: YES
  Comment: Collection of identical MyISAM tables
Transactions: NO
      XA: NO
  Savepoints: NO
...
...
```

## Usage and Examples

To use a Sequence table, you simply select from it, as in

```
SELECT * FROM seq_1_to_5;
+-----+
| seq |
+-----+
| 1 |
| 2 |
| 3 |
| 4 |
| 5 |
+-----+
```

To use a sequence in a statement, you select from the table named by a pattern **seq\_** FROM

```
_to_
TO
or seq_
FROM
_to_
TO
_step_
STEP
```

In the case of an odd step, the sequence will commence with the

```
FROM
, and end at the final result before
TO
```

```
SELECT * FROM seq_1_to_15_step_3;
+---+
| seq |
+---+
| 1 |
| 4 |
| 7 |
| 10 |
| 13 |
+---+
```

A sequence can go backwards too. In this case the final value will always be the

```
TO
value, so that a descending sequence has the same values as an ascending sequence:
```

```
SELECT * FROM seq_5_to_1_step_2;
+---+
| seq |
+---+
| 5 |
| 3 |
| 1 |
+---+
```

```
SELECT * FROM seq_15_to_1_step_3;
+---+
| seq |
+---+
| 13 |
| 10 |
| 7 |
| 4 |
| 1 |
+---+
```

```
SELECT * FROM seq_15_to_2_step_3;
+---+
| seq |
+---+
| 14 |
| 11 |
| 8 |
| 5 |
| 2 |
+---+
```

This engine is particularly useful with joins and subqueries. For example, this query finds all prime numbers below 50:

```

SELECT seq FROM seq_2_to_50 s1 WHERE 0 NOT IN
    (SELECT s1.seq % s2.seq FROM seq_2_to_50 s2 WHERE s2.seq <= sqrt(s1.seq));
+----+
| seq |
+----+
| 2 |
| 3 |
| 5 |
| 7 |
| 11 |
| 13 |
| 17 |
| 19 |
| 23 |
| 29 |
| 31 |
| 37 |
| 41 |
| 43 |
| 47 |
+----+

```

And almost (without 2, the only even prime number) the same result with joins:

```

SELECT s1.seq FROM seq_2_to_50 s1 JOIN seq_2_to_50 s2
WHERE s1.seq > s2.seq AND s1.seq % s2.seq <> 0
GROUP BY s1.seq HAVING s1.seq - COUNT(*) = 2;
+----+
| seq |
+----+
| 3 |
| 5 |
| 7 |
| 11 |
| 13 |
| 17 |
| 19 |
| 23 |
| 29 |
| 31 |
| 37 |
| 41 |
| 43 |
| 47 |
+----+

```

Sequence tables can also be useful in date calculations. For example, to find the day of the week that a particular date has fallen on over a 40 year period (perhaps for birthday planning ahead!):

```

SELECT DAYNAME('1980-12-05' + INTERVAL (seq) YEAR) day,
    '1980-12-05' + INTERVAL (seq) YEAR date FROM seq_0_to_40;
+-----+-----+
| day      | date       |
+-----+-----+
| Friday   | 1980-12-05 |
| Saturday | 1981-12-05 |
| Sunday   | 1982-12-05 |
...
| Friday   | 2014-12-05 |
| Saturday | 2015-12-05 |
| Monday   | 2016-12-05 |
| Tuesday  | 2017-12-05 |
| Wednesday| 2018-12-05 |
| Thursday | 2019-12-05 |
| Saturday | 2020-12-05 |
+-----+-----+

```

Although Sequence tables can only directly make use of positive integers, they can indirectly be used to return negative results by making use of the [CAST](#) statement. For example:

```
SELECT CAST(seq AS INT) - 5 x FROM seq_5_to_1;
+----+
| x |
+----+
| 0 |
| -1 |
| -2 |
| -3 |
| -4 |
+----+
```

`CAST` is required to avoid a

```
BIGINT UNSIGNED value is out of range  
error.
```

Sequence tables, while virtual, are still tables, so they must be in a database. This means that a default database must be selected (for example, via the `USE` command) to be able to query a Sequence table. The `information_schema` database cannot be used as the default for a Sequence table.

## Table Name Conflicts

If the SEQUENCE storage engine is installed, it is not possible to create a table with a name which follows the SEQUENCE pattern:

```
CREATE TABLE seq_1_to_100 (col INT) ENGINE = InnoDB;  
ERROR 1050 (42S01): Table 'seq_1_to_100' already exists
```

However, a SEQUENCE table can be converted to another engine and the new table can be referred in any statement:

```
ALTER TABLE seq_1_to_100 ENGINE = BLACKHOLE;  
  
SELECT * FROM seq_1_to_100;  
Empty set (0.00 sec)
```

While a SEQUENCE table cannot be dropped, it is possible to drop the converted table. The SEQUENCE table with the same name will still exist:

```
DROP TABLE seq_1_to_100;  
  
SELECT COUNT(*) FROM seq_1_to_100;  
+----+  
| COUNT(*) |  
+----+  
| 100 |  
+----+  
1 row in set (0.00 sec)
```

A temporary table with a SEQUENCE-like name can always be created and used:

```
CREATE TEMPORARY TABLE seq_1_to_100 (col INT) ENGINE = InnoDB;  
  
SELECT * FROM seq_1_to_100;  
Empty set (0.00 sec)
```

There are [3 related questions](#).

### 4.3.18.1 About SphinxSE

#### Contents

1. [Versions of SphinxSE in MariaDB](#)
2. [Enabling SphinxSE in MariaDB](#)
3. [Using SphinxSE](#)
  1. [Basic Usage](#)
  2. [Search Options](#)
  3. [SHOW ENGINE SPHINX STATUS](#)
  4. [JOINS with SphinxSE](#)
4. [Building snippets \(excerpts\) via MariaDB](#)
5. [More Information](#)

The Sphinx storage engine (SphinxSE) is a storage engine that talks to searchd (the Sphinx daemon) to enable text searching. Sphinx and SphinxSE is used as a faster and more customizable alternative to MariaDB's [built-in full-text search](#).

Sphinx does not depend on MariaDB, and can run independently, but SphinxSE provides a convenient interface to the underlying Sphinx daemon.

#### Versions of SphinxSE in MariaDB

SphinxSE Version	Introduced	Maturity
SphinxSE 2.2.6	<a href="#">MariaDB 10.0.15</a>	Stable
SphinxSE 2.1.9	<a href="#">MariaDB 10.0.14</a>	Stable
SphinxSE 2.0.4	<a href="#">MariaDB 5.5</a>	
SphinxSE 0.99	<a href="#">MariaDB 5.2</a> and <a href="#">MariaDB 5.3</a>	

#### Enabling SphinxSE in MariaDB

The Sphinx storage engine is included in the source, binaries, and packages of MariaDB. SphinxSE is built as a dynamically loadable .so plugin. To use it, you need to perform a one-time install:

```
INSTALL SONAME 'ha_sphinx';
```

MariaDB until 10.0

In Debian/Ubuntu packages SphinxSE is statically compiled into the MariaDB server, there is no need to use the

```
INSTALL SONAME  
statement.
```

Once installed, SphinxSE will show up in the list of installed storage engines:

```
SHOW ENGINES;  
+-----+-----+-----+-----+-----+  
| Engine | Support | Comment | Transactions | XA | Savepoints |  
+-----+-----+-----+-----+-----+  
| SPHINX | YES | Sphinx storage engine 0.9.9 | NO | NO | NO |  
+-----+-----+-----+-----+-----+
```

This is a one-time step and will not need to be performed again.

**Note:** SphinxSE is just the storage engine part of Sphinx. You will have to [install Sphinx](#) itself in order to make use of SphinxSE in MariaDB.

Despite the name, SphinxSE does not actually store any data itself. It is actually a built-in client which allows MariaDB to talk to Sphinx, run search

queries, and obtain search results. All indexing and searching happen outside MariaDB.

Some SphinxSE applications include:

- easier porting of MariaDB/MySQL FTS applications to Sphinx
- allowing Sphinx use with programming languages for which native APIs are not available yet
- optimizations when additional Sphinx result set processing on the MariaDB side is required (eg. JOINs with original document tables, additional MariaDB-side filtering, and etc...)

## Using SphinxSE

### Basic Usage

To search via SphinxSE, you would need to create a special

```
ENGINE=SPHINX  
"search table", and then  
SELECT  
from it with full text query put into the  
WHERE  
clause for query column.
```

Here is an example create statement and search query:

```
CREATE TABLE t1  
(  
    id      BIGINT UNSIGNED NOT NULL,  
    weight  INTEGER NOT NULL,  
    query   VARCHAR(3072) NOT NULL,  
    group_id INTEGER,  
    INDEX(query)  
) ENGINE=SPHINX CONNECTION="sphinx://127.0.0.1:9312/test1";  
  
SELECT * FROM t1 WHERE query='test it;mode=any';
```

The first three columns of the search table must have a type of

```
BIGINT  
for the 1st column (document id),  
INTEGER  
or  
BIGINT  
for the 2nd column (match weight), and  
VARCHAR  
or  
TEXT
```

for the 3rd column (your query), respectively. This mapping is fixed; you cannot omit any of these three required columns, or move them around, or change types. Also, the query column must be indexed; all the others must be kept unindexed. Column names are ignored so you can use arbitrary ones.

Additional columns must be either

```
INTEGER  
,  
TIMESTAMP  
,  
BIGINT  
,  
VARCHAR  
, or  
FLOAT  
. They will be bound to the attributes provided in the Sphinx result set by name, so their names must match the attribute names specified in sphinx.conf  
. If there's no such attribute name in the Sphinx search results, the additional columns will have  
NULL  
values.
```

Special "virtual" attribute names can also be bound to SphinxSE columns.

```
_sph_  
needs to be used instead of  
@  
for that. For instance, to obtain the values of '  
@groupby  
','  
@count
```

```
', or
@distinct
' virtual attributes, use '
_sph_groupby
',
_sph_count
' or '
_sph_distinct
' column names, respectively.
```

The

```
CONNECTION
string parameter is used to specify the default
searchd
host, port, and indexes for queries issued using this table. If no connection string is specified in
CREATE
TABLE
, index name'
*
'(ie. search all indexes) and'
127.0.0.1:9312
' are assumed. The connection string syntax is as follows:
```

```
CONNECTION="sphinx://HOST:PORT/INDEXNAME"
```

You can change the default connection string later like so:

```
ALTER TABLE t1 CONNECTION="sphinx://NEWHOST:NEWPORT/NEWINDEXNAME";
```

You can also override all these parameters per-query.

**Note:** To use Linux sockets you can modify the searchd section of the Sphinx configuration file, setting the listen parameter to a socket file. Instruct SphinxSE about the socket using CONNECTION="unix: /path/to/socket[:index]".

## Search Options

As seen in the example above, both query text and search options should be put into the '

```
WHERE
' clause of the search query column (i.e. the 3rd column); the options are separated by semicolons (';
') and separate names from values using an equals sign ('=
'). Any number of options can be specified. Available options are:
```

- query - query text;
- mode - matching mode. Must be one of "all", "any", "phrase", "boolean", or "extended". Default is "all";
- sort - match sorting mode. Must be one of "relevance", "attr\_desc", "attr\_asc", "time\_segments", or "extended". In all modes besides "relevance" attribute name (or sorting clause for "extended") is also required after a colon:

```
... WHERE query='test;sort=attr_asc:group_id';
... WHERE query='test;sort=extended:@weight desc, group_id asc';
```

- offset - offset into result set, default is 0;
- limit - amount of matches to retrieve from result set, default is 20;
- index - names of the indexes to search:

```
... WHERE query='test;index=test1';
... WHERE query='test;index=test1,test2,test3';
```

- minid, maxid - min and max document ID to match;
- weights - comma-separated list of weights to be assigned to Sphinx full-text fields:

```
... WHERE query='test;weights=1,2,3';
```

- filter, !filter - comma-separated attribute name and a set of values to match:

```
# only include groups 1, 5 and 19
... WHERE query='test;filter=group_id,1,5,19;';

# exclude groups 3 and 11
... WHERE query='test;!filter=group_id,3,11;';
```

- range, !range - comma-separated attribute name, min and max value to match:

```
# include groups from 3 to 7, inclusive
... WHERE query='test;range=group_id,3,7;';

# exclude groups from 5 to 25
... WHERE query='test;!range=group_id,5,25;';
```

- maxmatches - per-query max matches value:

```
... WHERE query='test;maxmatches=2000;';
```

- groupby - group-by function and attribute:

```
... WHERE query='test;groupby=day:published_ts;';
... WHERE query='test;groupby=attr:group_id';
```

- groupsort - group-by sorting clause:

```
... WHERE query='test;groupsort=@count desc;';
```

- indexweights - comma-separated list of index names and weights to use when searching through several indexes:

```
... WHERE query='test;indexweights=idx_exact,2, idx_stemmed,1;';
```

- comment - a string to mark this query in query log (mapping to \$comment parameter in Query() API call):

```
... WHERE query='test;comment=marker001;';
```

- select - a string with expressions to compute (mapping to SetSelect() API call):

```
... WHERE query='test;select=2*a+3*b as myexpr;';
```

**Note:** It is much more efficient to allow Sphinx to perform sorting, filtering, and slicing of the result set than to raise max matches count and use 'WHERE

```
''
ORDER BY
', and'
LIMIT
```

' clauses on the MariaDB side. This is for two reasons:

1. Sphinx does a number of optimizations and performs better than MariaDB/MySQL on these tasks.
2. Less data would need to be packed by

```
searchd
, and transferred and unpacked by SphinxSE.
```

## SHOW ENGINE SPHINX STATUS

Starting with version 0.9.9-rc1, additional query info besides the result set can be retrieved with the 'SHOW ENGINE SPHINX STATUS' statement:

```
SHOW ENGINE SPHINX STATUS;
+-----+-----+
| Type   | Name    | Status          |
+-----+-----+
| SPHINX | stats   | total: 25, total found: 25, time: 126, words: 2 |
| SPHINX | words   | sphinx:591:1256 soft:11076:15945
+-----+-----+
```

This information can also be accessed through status variables. Note that this method does not require super-user privileges.

```
SHOW STATUS LIKE 'sphinx %';
+-----+-----+
| Variable_name | Value |
+-----+-----+
| sphinx_total | 25 |
| sphinx_total_found | 25 |
| sphinx_time | 126 |
| sphinx_word_count | 2 |
| sphinx_words | sphinx:591:1256 soft:11076:15945 |
+-----+-----+
```

## JOINs with SphinxSE

You can perform

`JOIN`

`s` on a SphinxSE search table and tables using other engines. Here's an example with "documents" from example.sql:

```
SELECT content, date_added FROM test.documents docs
  JOIN t1 ON (docs.id=t1.id)
 WHERE query="one document;mode=any";
+-----+-----+
| content | docdate |
+-----+-----+
| this is my test document number two | 2006-06-17 14:04:28 |
| this is my test document number one | 2006-06-17 14:04:28 |
+-----+-----+

SHOW ENGINE SPHINX STATUS;
+-----+-----+
| Type | Name | Status |
+-----+-----+
| SPHINX | stats | total: 2, total found: 2, time: 0, words: 2 |
| SPHINX | words | one:1:2 document:2:2 |
+-----+-----+
```

## Building snippets (excerpts) via MariaDB

Starting with version 0.9.9-rc2, SphinxSE also includes a UDF function that lets you create snippets through MariaDB. The functionality is fully similar to the [BuildExcerpts](#) API call but is accessible through MariaDB+SphinxSE.

### MariaDB until 5.5

The binary that provides the UDF is named `sphinx.so` and is automatically built and installed to the proper location along with SphinxSE itself. Register the UDF using the following statement:

```
CREATE FUNCTION sphinx_snippets RETURNS STRING SONAME 'sphinx.so';
```

### MariaDB until 10.0

The UDF is packed together with the storage engine, in the same binary named `ha_sphinx.so`. Register the UDF using the following statement:

```
CREATE FUNCTION sphinx_snippets RETURNS STRING SONAME 'ha_sphinx.so';
```

The function name must be '

`sphinx_snippets`  
' , you can not use an arbitrary name. Function arguments are as follows:

```
Prototype: function sphinx_snippets ( document, index, words, [options] );
```

Document and words arguments can be either strings or table columns. Options must be specified like this: `<code>'value' AS option_name</code>`. For a list of supported options, refer to the [BuildExcerpts\(\)](#) API call. The only UDF-specific additional option is named 'sphinx' and lets you specify searchd location (host and port).

Usage examples:

```

SELECT sphinx_snippets('hello world doc', 'main', 'world',
    'sphinx://192.168.1.1/' AS sphinx, true AS exact_phrase,
    '[b]' AS before_match, '[/b]' AS after_match)
FROM documents;

SELECT title, sphinx_snippets(text, 'index', 'mysql php') AS text
    FROM sphinx, documents
    WHERE query='mysql php' AND sphinx.id=documents.id;

```

## More Information

More information on Sphinx and SphinxSE is available on the [Sphinx website](#).

### 4.3.18.2 Installing Sphinx

In order to use the [Sphinx Storage Engine](#), it is necessary to install the Sphinx daemon.

Many Linux distributions have Sphinx in their repositories. These can be used to install Sphinx instead of following the instructions below, but these are usually quite old versions and don't all include API's for easy integration. Ubuntu users can use the updated repository at <https://launchpad.net/~builds/+archive/sphinxsearch-rel21> (see instructions below). Alternatively, download from <http://sphinxsearch.com/downloads/release/>

## Debian and Ubuntu

Ubuntu users can make use of the repository, as follows:

```

sudo add-apt-repository ppa:builds/sphinxsearch-rel21
sudo apt-get update
sudo apt-get install sphinxsearch

```

Alternatively, install as follows:

- The Sphinx package and daemon are named sphinxsearch
- sudo apt-get install unixodbc libpq5 mariadb-client
- sudo dpkg -i sphinxsearch\*.deb

- [Configure Sphinx](#) as required
- You may need to check  
`/etc/default/sphinxsearch`  
to see that  
`START=yes`

- Start with  
`sudo service sphinxsearch start`  
(and stop with  
`sudo service sphinxsearch stop`)

## Red Hat and CentOS

- The package name is sphinx and the daemon searchd
- sudo yum install postgresql-libs unixODBC
- sudo rpm -Uhv sphinx\*.rpm
- [Configure Sphinx](#) as required
- service searchd start

# Windows

- Unzip and extract the downloaded zip file
- Move the extracted directory to  
C:\Sphinx
- Configure Sphinx as required
- Install as a service:
  - C:\Sphinx\bin> C:\Sphinx\bin\searchd --install --config C:\Sphinx\sphinx.conf.in --servicename SphinxSearch

Once Sphinx has been installed, it will need to be [configured](#).

Full instructions, including details on compiling Sphinx yourself, are available at <http://sphinxsearch.com/docs/current.html>.

## 4.3.18.3 Configuring Sphinx

Before you can get Sphinx working with the Sphinx Storage Engine on MariaDB, you need to configure it.

- The default configuration file is called

```
sphinx.conf  
, usually located in  
/etc/sphinxsearch  
(Debian/Ubuntu),  
/etc/sphinx/sphinx.conf.  
(Red Hat/CentOS) or  
C:\Sphinx\sphinx.conf  
(Windows).
```

If it doesn't already exist, you can use the sample configuration file,

```
sphinx.conf.dist  
. There is also sample data supplied that we can use for testing. Load the sample data (which creates two tables,  
documents  
and  
tags  
in the  
test  
database), for example:
```

```
mysql -u test < /usr/local/sphinx/etc/example.sql  
(Red Hat, CentOS)  
mysql -u test < /usr/share/doc/sphinxsearch/example-conf/example.sql  
(Debian/Ubuntu)
```

The sample configuration file documents the available options. You will need to make at least a few changes. A MariaDB user with permission to access the database must be created. For example:

```
CREATE USER 'sphinx'@localhost  
IDENTIFIED BY 'sphinx_password';  
GRANT SELECT on test.* to 'sphinx'@localhost;
```

Add these details to the

```
mysql  
section of the config file:
```

```
sql_host = localhost  
sql_user = sphinx  
sql_pass = sphinx_password  
sql_db = test  
sql_port = 3306
```

On Windows, the

```
path  
and  
pid  
lines will need to be changed to reflect a valid path, usually as follows:
```

```
path = C:\Sphinx\docsidx  
...  
pid_file = C:\Sphinx\sphinx.pid
```

The query in the configuration files is the query that will be used for building the index. In the sample data, this is:

```
sql_query = \
    SELECT id, group_id, UNIX_TIMESTAMP(date_added) AS date_added, title, content \
    FROM documents
```

## 4.3.18.4 Installing and Testing SphinxSE with MariaDB

To use SphinxSE with MariaDB you need to first [download and install Sphinx](#).

Complete Sphinx documentation is available on the [Sphinx website](#).

### Tips for Installing Sphinx

#### libexpat

One library we know you will need on Linux before you can install Sphinx is

```
libexpat
. If it is not installed, you will get the warning
checking for libexpat... not found
. On Suse the package is called
libexpat-devel
, on Ubuntu the package is called
libexpat1-dev
.
```

#### MariaDB detection

If you run into problems with MariaDB not being detected, use the following options:

```
--with-mysql      compile with MySQL support (default is enabled)
--with-mysql-includes  path to MySQL header files
--with-mysql-libs    path to MySQL libraries
```

The above will tell the

```
configure
script where your MySQL/MariaDB installation is.
```

### Testing Sphinx

After installing Sphinx, you can check that things are working in MariaDB by doing the following:

```
cd installation-dir/mysql-test
./mysql-test-run --suite=sphinx
```

If the above test doesn't pass, check the logs in the

```
'var'
directory. If there is a problem with the sphinx installation, the reason can probably be found in the log file at:
var/log/sphinx.sphinx/searchd/sphinx.log
.
```

## 4.3.18.5 Sphinx Status Variables

2. Features

## SQL Syntax

- With

SpiderForMySQL  
, the **CREATE TABLE** statement uses  
CONNECTION  
to define spider table variables whereas MariaDB uses  
COMMENT

## Features

- 

**HANDLER**

can not be translated to SQL in MariaDB

- Concurrent background search is not yet implemented in MariaDB
- Vertical partitioning storage engine VP is not implemented in MariaDB

- 

**CREATE TABLE**

can use **table discovery** in MariaDB

- 

**JOIN**

performance improvement using

**join\_cache\_level**

>1

and

**join\_buffer\_size**

in MariaDB

## 4.3.19.15 Spider Case Studies

A list of users or clients that are using Spider and agree to be referenced:

- Tencent Games. They handle 100TB data on 396 Spider nodes and 2800 data nodes. They use this cluster for their online games.
- Kadokawa Corporation

## 4.3.19.16 Spider Benchmarks

This is best run on a cluster of 3 nodes intel NUC servers 12 virtual cores model name : Intel ® Core(TM) i3-3217U CPU @ 1.80GHz

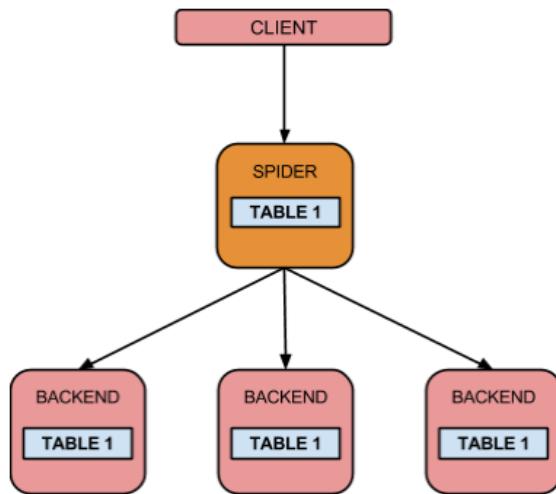

All nodes have been running a mysqlslap client attached to the local spider node in the best run.

```
/usr/local/skysql/mysql-client/bin/mysqlslap --user=skysql --password=skyvodka --host=192.168.0.201 --port=5012 -i1000000 -c32 -
```

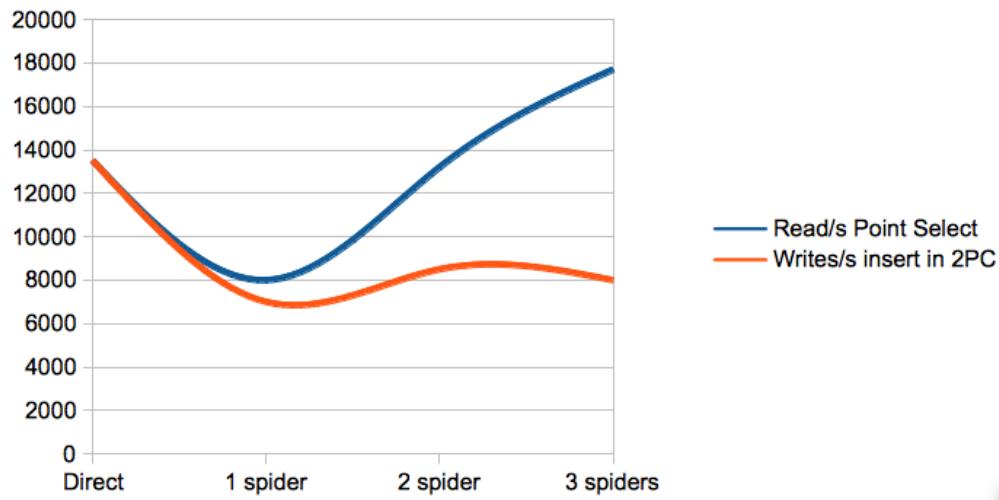

```
spider_conn_recycle_mode=1;
```

The read point select is produce with a 10M rows sysbench table

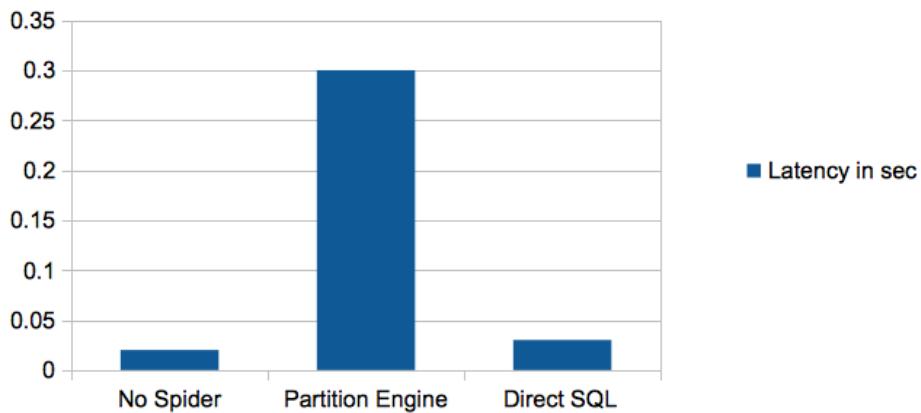

The write insert a single string into a memory table

Before Engine Condition Push Down patch .

## 1000 point select IN(...)

Spider can benefit by 10% additional performance with Independent Storage Engine Statistics.

```
set global use_stat_tables='preferably';
USE backend;
ANALYZE TABLE sbtest;
```

## 4.3.19.17 Spider FAQ

### Contents

1. [What does "\[ERROR\] mysqld: Can't find record in 'spider\\_tables'" mean?](#)
2. [Are there minimum Spider settings?](#)
3. [What does "select spider\\_ping\\_table\(\)" in the general log mean?](#)
4. [Do I need a primary key on physical tables?](#)
5. [Can I use Spider on top of Galera shards?](#)
6. [What are the most used architectures for Spider HA?](#)
7. [What are the most used architectures for Spider Map Reduce?](#)
8. [What about Grants on shards?](#)

### What does "[ERROR] mysqld: Can't find record in 'spider\_tables'" mean?

This happens when you have a Spider table defined that does not point to an existing table on a data node.

### Are there minimum Spider settings?

```
myisam-recover=FORCE,BACKUP
```

MariaDB until 10.1.1

```
optimizer_switch='engine_condition_pushdown=on'
```

MariaDB until 10.3.7

When using spider\_autoincrement\_mode = 0, partitioned Spider tables work as spider\_autoincrement\_mode = 1 see : [MDEV-21404](#)

### What does "select spider\_ping\_table()" in the general log mean?

This is used by Spider monitoring to ask other monitoring nodes the status of a table.

### Do I need a primary key on physical tables?

Not having a primary key will generate errors for resynchronizing tables via spider\_copy\_table().

## Can I use Spider on top of Galera shards?

Yes, XA transactions can be disabled from Spider. Until Galera 4.0 fully supports xa transactions, spider can point to a maxscale proxy that can manage transparent node election in case of failure inside a shard group. Note that disabling XA will break cross shard WRITES in case of transaction ROLLBACK. This architecture need to be used with care if you have a highly transactional workload that can generate cross shard deadlocks.

## What are the most used architectures for Spider HA?

- Delegation of shard node replication using asynchronous replication and slave election with GTID.
- Delegation of shard node replication via active passive HA solutions.
- Shard builds via replication into Spider tables is interesting when you can route READS to a pool of Spider nodes reattaching the shards.

## What are the most used architectures for Spider Map Reduce?

- Map reduce in Spider is limited to a single table. Building spider on top of some views can eliminate the need to use joins.
- Replication to universal tables to every shard is commonly used to enable the views on each shard.

## What about Grants on shards?

- When using MRR and BKA (and you do so with network storage), when Spider needs to create temporary tables on the backends, use the CREATE TEMPORARY TABLES privilege. Spider can still switch to a lower performance solution using `spider_bka_mode=2`, or Query push down or range predicate using `spider_bka_mode=0`

## 4.3.20 Information Schema ENGINES Table

## 4.3.21 PERFORMANCE\_SCHEMA Storage Engine

## 4.3.22 Storage Engine Development

### 4.3.22.1 Storage Engine FAQ

#### Are storage engines designed for MySQL compatible with MariaDB?

In most cases, yes. MariaDB tries to keep API compatibility with MySQL, even across major versions.

#### Will storage engines created for MariaDB work in MySQL?

It will mostly work. It would need #ifdef's to adjust to MySQL-5.6 API, for example, for multi-read-range API, for table discovery API, etc. But most of the code will work as is, without any changes.

#### Do storage engine binaries need to be recompiled for MariaDB?

Yes. You will need to recompile the storage engine against the exact version of MySQL or MariaDB you intend to run it on. This is due to the version of the server being stored in the storage engine binary, and the server will refuse to load it if it was compiled for a different version.

## 4.3.22.2 Engine-defined New Table/Field/Index Attributes

### Contents

1. [API](#)
2. [SQL](#)
3. [See Also](#)

In MariaDB, a storage engine can allow the user to specify additional attributes per index, field, or table. The engine needs to declare what attributes it introduces.

## API

There are three new members in the

`handlerton`

structure, they can be set in the engine's initialization function as follows:

```
example_hton->table_options= example_table_option_array;  
example_hton->field_options= example_field_option_array;  
example_hton->index_options= example_index_option_array;
```

The arrays are declared statically, as in the following example:

```
static MYSQL_THDVAR ULONG(varopt_default, PLUGIN_VAR_RQCMDARG,
    "default value of the VAROPT table option", NULL, NULL, 5, 0, 100, 0);

struct ha_table_option_struct
{
    char *strparam;
    ulonglong ullparam;
    uint enumparam;
    bool boolparam;
    ulonglong varparam;
};

ha_create_table_option example_table_option_list[]=
{
    HA_TOPTION_NUMBER("NUMBER", ullparam, UINT_MAX32, 0, UINT_MAX32, 10),
    HA_TOPTION_STRING("STR", strparam),
    HA_TOPTION_ENUM("ONE_OR_TWO", enumparam, "one,two", 0),
    HA_TOPTION_BOOL("YESNO", boolparam, 1),
    HA_TOPTION_SYSVAR("VAROPT", varopt, varparam),
    HA_TOPTION_END
};
```

The engine declares a structure

```
ha_table_option_struct
```

that will hold values of these new attributes.

And it describes these attributes to MySQL by creating an array of

```
HA_TOPTION_
```

```
*
```

macros. Note a detail: these macros expect a structure called

```
ha_table_option_struct
```

, if the structure is called differently, a

```
#define
```

will be needed.

There are five supported kinds of attributes:

macro name	attribute value type	corresponding C type	additional parameters of a macro
HA_TOPTION_NUMBER	an integer number	unsigned long long	a default value, minimal allowed value, maximal allowed value, a factor, that any allowed should be a multiple of.
HA_TOPTION_STRING	a string	char *	none. The default value is a null pointer.
HA_TOPTION_ENUM	one value from a list of allowed values	int	unsigned a string with a comma-separated list of allowed values, and a default value as a number, starting from 0.
HA_TOPTION_BOOL	a boolean	bool	a default value
HA_TOPTION_SYSVAR	defined by the system variable	defined by the system variable	system variable name

*Do not use*

enum

*for your  
 HA\_OPTION\_ENUM  
 C structure members, the size of the  
 enum  
 depends on the compiler, and even on the compilation options, and the plugin API uses only types with known storage sizes.*

In all macros the first two parameters are name of the attribute as should be used in SQL in the

```
CREATE TABLE
statement, and the name of the corresponding member of the
ha_table_option_struct
structure.
```

The

HA\_TOPTION\_SYSVAR

stands aside a bit. It does not specify the attribute type or the default value, instead it binds the attribute to a system variable. The attribute type and the range of allowed values will be the same as of the corresponding system variable. The attribute **default value** will be the **current value** of its system variable. And unlike other attribute types that are only stored in the

```
.frm
file if explicitly set in the
```

```
CREATE TABLE
statement, the
```

HA\_TOPTION\_SYSVAR

attributes are always stored. If the system variable value is changed, it will not affect existing tables. Note that for this very reason, if a table was created in the old version of a storage engine, and a new version has introduced a

```
HA_TOPTION_SYSVAR
attribute, the attribute value in the old tables will be the default value of the system variable, not its current value.
```

The array ends with a

```
HA_TOPTION_END
macro.
```

Field and index (key) attributes are declared similarly using

```
HA_FOPTION_*
and
HA_IOPTION_*
macros.
```

When in a

```
CREATE TABLE
statement, the
::create()
handler method is called, the table attributes are available in the
table_arg->s->option_struct
, field attributes - in the
option_struct
member of the individual fields (objects of the
Field
class), index attributes - in the
option_struct
member of the individual keys (objects of the
KEY
class).
```

Additionally, they are available in most other handler methods: the attributes are stored in the

```
.frm
file and on every open MySQL makes them available to the engine by filling the corresponding
option_struct
members of the table, fields, and keys.
```

The

ALTER TABLE

needs a special support from the engine. MySQL compares old and new table definitions to decide whether it needs to rebuild the table or not. As the semantics of the engine declared attributes is unknown, MySQL cannot make this decision by analyzing attribute values - this is delegated to the engine. The

```
HA_CREATE_INFO
structure has three new members:
```

```
ha_table_option_struct *option_struct;           /////< structure with parsed table options
ha_field_option_struct **fields_option_struct;  /////< array of field option structures
ha_index_option_struct **indexes_option_struct; /////< array of index option structures
```

The engine (in the

```
::check_if_incompatible_data()
```

method) is responsible for comparing new values of the attributes from the HA\_CREATE\_INFO structure with the old values from the table and returning COMPATIBLE\_DATA\_NO if they were changed in such a way that requires the table to be rebuilt.

The example of declaring the attributes and comparing the values for the

```
ALTER TABLE  
can be found in the EXAMPLE engine.
```

## SQL

The engine declared attributes can be specified per field, index, or table in the

```
CREATE TABLE  
or  
ALTER TABLE  
. The syntax is the conventional:
```

```
CREATE TABLE ... (  
    field ... [attribute=value [attribute=value ...]],  
    ...  
    index ... [attribute=value [attribute=value ...]],  
    ...  
) ... [attribute=value [attribute=value ...]]
```

All values must be specified as literals, not expressions. The value of a boolean option may be specified as one of YES, NO, ON, OFF, 1, or 0. A string value may be specified either quoted or not, as an identifier (if it is a valid identifier, of course). Compare with the old behavior:

```
CREATE TABLE ... ENGINE=FEDERATED CONNECTION='mysql://root@127.0.0.1';
```

where the value of the ENGINE attribute is specified not quoted, while the value of the CONNECTION is quoted.

When an attribute is set, it will be stored with the table definition and shown in the

```
SHOW
```

```
CREATE
```

```
TABLE
```

```
;
```

. To remove an attribute from a table definition use

```
ALTER
```

```
TABLE
```

to set its value to a

```
DEFAULT
```

The values of unknown attributes or attributes with the illegal values cause an error by default. But with [ALTER TABLE](#) one can change the storage engine and some previously valid attributes may become unknown — to the new engine. They are not removed automatically, though, because the table might be altered back to the first engine, and these attributes will be valid again. Still [SHOW CREATE TABLE](#) will comment these unknown attributes out in the output, otherwise they would make a generated [CREATE TABLE](#) statement invalid.

With the

```
IGNORE_BAD_TABLE_OPTIONS
```

[sql mode](#) this behavior changes. Unknown attributes do not cause an error, they only result in a warning. And [SHOW CREATE TABLE](#) will not comment them out. This mode is implicitly enabled in the replication slave thread.

### 4.3.22.3 Table Discovery

In MariaDB it is not always necessary to run an explicit

```
CREATE TABLE
```

statement for a table to appear. Sometimes a table may already exist in the storage engine, but the server does not know about it, because there is no

```
.frm
```

file for this table. This can happen for various reasons; for example, for a cluster engine the table might have been created in the cluster by another MariaDB server node. Or for the engine that supports table shipping a table file might have been simply copied into the MariaDB data directory. But no matter what the reason is, there is a mechanism for an engine to tell the server that the table exists. This mechanism is called **table discovery** and if an engine wants the server to discover its tables, the engine should support the table discovery API.

## Contents

1. [Automatic Discovery](#)
  1. [handlerton::tablefile\\_extensions](#)
  2. [handlerton::discover\\_table\\_names\(\)](#)
  3. [handlerton::discover\\_table\\_existence\(\)](#)
  4. [handlerton::discover\\_table\(\)](#)
  5. [TABLE\\_SHARE::init\\_from\\_binary\\_frm\\_in](#)
  6. [TABLE\\_SHARE::init\\_from\\_sql\\_statemen](#)
  7. [TABLE\\_SHARE::read\\_frm\\_image\(\)](#)
  8. [TABLE\\_SHARE::free\\_frm\\_image\(\)](#)
  9. [HA\\_ERR\\_TABLE\\_DEF\\_CHANGED](#)
  10. [TABLE\\_SHARE::tabledef\\_version](#)
2. [Assisted discovery](#)
  1. [handlerton::discover\\_table\\_structure\(\)](#)
  3. [The role of .frm files](#)

There are two different kinds of table discovery — a fully automatic discovery and a user-assisted one. In the former, the engine can automatically discover the table whenever an SQL statement needs it. In MariaDB, the [Archive](#) and [Sequence](#) engines support this kind of discovery. For example, one can copy a

```
t1.ARZ
```

file into the database directory and immediately start using it — the corresponding

```
.frm
```

file will be created automatically. Or one can select from say, the

```
seq_1_to_10
```

table without any explicit

```
CREATE TABLE
```

```
statement.
```

In the latter, user-assisted, discovery the engine does not have enough information to discover the table all on its own. But it can discover the table structure if the user provides certain additional information. In this case, an explicit

```
CREATE TABLE
```

statement is still necessary, but it should contain no table structure — only the table name and the table attributes. In MariaDB, the [FederatedX](#) storage engine supports this. When creating a table, one only needs to specify the

```
CONNECTION
```

attribute and the table structure — fields and indexes — will be provided automatically by the engine.

## Automatic Discovery

As far as automatic table discovery is concerned, the tables, from the server point of view, may appear, disappear, or change structure anytime. Thus the server needs to be able to ask whether a given table exists and what its structure is. It needs to be notified when a table structure changes outside of the server. And it needs to be able to get a list of all (unknown to the server) tables, for statements like

```
SHOW TABLES
```

. The server does all that by invoking specific methods of the

```
handlerton
```

```
:
```

```
const char **tablefile_extensions;
int (*discover_table_names)(handlerton *hton, LEX_STRING *db, MY_DIR *dir,
                           discovered_list *result);
int (*discover_table_existence)(handlerton *hton, const char *db,
                               const char *table_name);
int (*discover_table)(handlerton *hton, THD* thd, TABLE_SHARE *share);
```

## handlerton::tablefile\_extensions

Engines that store tables in separate files (one table might occupy many files with different extensions, but having the same base file name) should store the list of possible extensions in the **tablefile\_extensions** member of the

```
handlerton
(earlier this list was returned by the
handler::bas_ext()
method). This will significantly simplify the discovery implementation for these engines, as you will see below.
```

## handlerton::discover\_table\_names()

When a user asks for a list of tables in a specific database — for example, by using

```
SHOW TABLES
or by selecting from
INFORMATION_SCHEMA.TABLES
— the server invokes discover_table_names() method of the
handlerton
. For convenience this method, besides the database name in question, gets the list of all files in this database directory, so that the engine can
look for table files without doing any filesystem i/o. All discovered tables should be added to the
result
collector object. It is defined as
```

```
class discovered_list
{
public:
    bool add_table(const char *pname, size_t tlen);
    bool add_file(const char *fname);
};
```

and the engine should call

```
result->add_table()
or
result->add_file()
for every discovered table (use
add_file()
if the name to add is in the MariaDB file name encoding, and
add_table()
if it's a true table name, as shown in
SHOW TABLES
).
```

If the engine is file-based, that is, it has non-empty list in the

```
tablefile_extensions
, this method is optional. For any file-based engine that does not implement
discover_table_names()
, MariaDB will automatically discover the list of all tables of this engine, by looking for files with the extension
tablefile_extensions[0]
```

## handlerton::discover\_table\_existence()

In some rare cases MariaDB needs to know whether a given table exists, but does not particularly care about this table structure (for example, when executing a

```
DROP TABLE
statement). In these cases, the server uses the discover_table_existence() method to find out whether a table with the given name exists in the
engine.
```

This method is optional. For the engine that does not implement it, MariaDB will look for files with the

```
tablefile_extensions[0]
, if possible. But if the engine is not file-based, MariaDB will use the
discover_table()
method to perform a full table discovery. While this will allow determining correctly whether a table exists, a full discovery is usually slower than
the simple existence check. In other words, engines that are not file-based might want to support
discover_table_existence()
method as a useful optimization.
```

## handlerton::discover\_table()

This is the main method of table discovery, the heart of it. The server invokes it when it wants to use the table. The **discover\_table()** method gets the

```
TABLE_SHARE
structure, which is not completely initialized — only the table and the database name (and a path to the table file) are filled in. It should initialize
```

this

```
TABLE_SHARE  
with the desired table structure.
```

MariaDB provides convenient and easy to use helpers that allow the engine to initialize the

```
TABLE_SHARE  
with minimal efforts. They are the  
TABLE_SHARE  
methods  
init_from_binary_frm_image()  
and  
init_from_sql_statement_string()  
.
```

## TABLE\_SHARE::init\_from\_binary\_frm\_image()

This method is used by engines that use "frm shipping" — such as [Archive](#) or NDB Cluster in MySQL. An frm shipping engine reads the frm file for a given table, exactly as it was generated by the server, and stores it internally. Later it can discover the table structure by using this very frm image. In this sense, a separate frm file in the database directory becomes redundant, because a copy of it is stored in the engine.

## TABLE\_SHARE::init\_from\_sql\_statement\_string()

This method allows initializing the

```
TABLE_SHARE  
using a conventional SQL  
CREATE TABLE  
syntax.
```

## TABLE\_SHARE::read\_frm\_image()

Engines that use frm shipping need to get the frm image corresponding to a particular table (typically in the

```
handler::create()  
method). They do it via the read_frm_image() method. It returns an allocated buffer with the binary frm image, that the engine can use the way it needs.
```

## TABLE\_SHARE::free\_frm\_image()

The frm image that was returned by

```
read_frm_image()  
must be freed with the free_frm_image().
```

## HA\_ERR\_TABLE\_DEF\_CHANGED

One of the consequences of automatic discovery is that the table definition might change when the server doesn't expect it to. Between two

```
SELECT  
queries, for example. If this happens, if the engine detects that the server is using an outdated version of the table definition, it should return a  
HA_ERR_TABLE_DEF_CHANGED handler error. Depending on when in the query processing this error has happened, MariaDB will either re-discover  
the table and execute the query with the correct table structure, or abort the query and return an error message to the user.
```

## TABLE\_SHARE::tabledef\_version

The previous paragraph doesn't cover one important question — how can the engine know that the server uses an outdated table definition? The answer is — by checking the **tabledef\_version**, the table definition version. Every table gets a unique

```
tabledef_version  
value. Normally it is generated automatically when a table is created. When a table is discovered the engine can force it to have a specific  
tabledef_version  
value (simply by setting it in the  
TABLE_SHARE  
before calling the  
init_from_binary_frm_image()  
or  
init_from_sql_statement_string()  
methods).
```

Now the engine can compare the table definition version that the server is using (from any handler method it can be accessed as

```
this->table->s->tabledef_version  
) with the version of the actual table definition. If they differ — it is  
HA_ERR_TABLE_DEF_CHANGED  
.
```

Assisted discovery is a lot simpler from the server point of view, a lot more controlled. The table cannot appear or disappear at will, one still needs explicit DDL statements to manipulate it. There is only one new handlerton method that the server uses to discover the table structure when a user has issued an explicit

```
CREATE TABLE  
statement without declaring any columns or indexes.
```

```
int (*discover_table_structure)(handlerton *hton, THD* thd,  
                                TABLE_SHARE *share, HA_CREATE_INFO *info);
```

The assisted discovery API is pretty much independent from the automatic discovery API. An engine can implement either of them or both (or none); there is no requirement to support automatic discovery if only assisted discovery is needed.

### handlerton::discover\_table\_structure()

Much like the

```
discover_table()  
method, the discover_table_structure() handlerton method gets a partially initialized  
TABLE_SHARE  
with the table name, database name, and a path to table files filled in, but without a table structure. Unlike  
discover_table()  
, here the  
TABLE_SHARE  
has all the engine-defined table attributes in the the  
TABLE_SHARE::option_struct  
structure. Based on the values of these attributes the  
discover_table_structure()  
method should initialize the  
TABLE_SHARE  
with the desired set of fields and keys. It can use  
TABLE_SHARE  
helper methods  
init_from_binary_frm_image()  
and  
init_from_sql_statement_string()  
for that.
```

## The role of

### .frm files

Before table discovery was introduced, MariaDB used

```
.frm  
files to store the table definition. But now the engine can store the table definition (if the engine supports automatic discovery, of course), and  
.frm  
files become redundant. Still, the server can use  
.frm  
files for such an engine — but they are no longer the only source of the table definition. Now  
.frm  
files are merely a cache of the table definition, while the original authoritative table definition is stored in the engine. Like any cache, its purpose  
is to reduce discovery attempts for a table. The engine decides whether it makes sense to cache table definition in the  
.frm  
file or not (see the second argument for the  
TABLE_SHARE::init_from_binary_frm_image()  
). For example, the Archive engine uses  
.frm  
cache, while the Sequence engine does not. In other words, MariaDB creates  
.frm  
files for Archive tables, but not for Sequence tables.
```

The cache is completely transparent for a user; MariaDB makes sure that it always stores the actual table definition and invalidates the

```
.frm  
file automatically when it becomes out of date. This can happen, for example, if a user copies a new Archive table into the datadir and forgets to  
delete the  
.frm  
file of the old table with the same name.
```

## 4.3.23 Converting Tables from MyISAM to InnoDB

## Contents

1. [The task](#)
2. [INDEX Issues](#)
3. [Non-INDEX Issues](#)
4. [See Also](#)

## The task

You have decided to change one or more tables from [MyISAM](#) to [InnoDB](#). That should be as simple as

```
ALTER TABLE foo ENGINE=InnoDB
```

- . But you have heard that there might be some subtle issues.

This describes possible issues that may arise and what to do about them.

*Recommendation.* One way to assist in searching for issues in is to do (at least in \*nix)

```
mysqldump --no-data --all-databases >schemas  
egrep 'CREATE|PRIMARY' schemas    # Focusing on PRIMARY KEYS  
egrep 'CREATE|FULLTEXT' schemas   # Looking for FULLTEXT indexes  
egrep 'CREATE|KEY' schemas       # Looking for various combinations of indexes
```

Understanding how the indexes work will help you better understand what might run faster or slower in InnoDB.

## INDEX Issues

(*Most of these Recommendations and some of these Facts have exceptions.*)

*Fact.* Every InnoDB table has a PRIMARY KEY. If you do not provide one, then the first non-NULL UNIQUE key is used. If that can't be done, then a 6-byte, hidden, integer is provided.

*Recommendation.* Look for tables without a PRIMARY KEY. Explicitly specify a PRIMARY KEY, even if it's an artificial AUTO\_INCREMENT. This is not an absolute requirement, but it is a stronger admonishment for InnoDB than for MyISAM. Some day you may need to walk through the table; without an explicit PK, you can't do it.

*Fact.* The fields of the PRIMARY KEY are included in each Secondary key.

- Check for redundant indexes with this in mind.

```
PRIMARY KEY(id),  
INDEX(b), -- effectively the same as INDEX(b, id)  
INDEX(b, id) -- effectively the same as INDEX(b)
```

(Keep one of the INDEXes, not both)

- Note subtle things like

```
PRIMARY KEY(id),  
UNIQUE(b), -- keep for uniqueness constraint  
INDEX(b, id) -- DROP this one
```

- Also, since the PK and the data coexist:

```
PRIMARY KEY(id),  
INDEX(id, b) -- DROP this one; it adds almost nothing
```

*Contrast.* This feature of MyISAM is not available in InnoDB; the value of 'id' will start over at 1 for each different value of 'abc':

```
id INT UNSIGNED NOT NULL AUTO_INCREMENT,  
PRIMARY KEY (abc, id)
```

A way to simulate the MyISAM 'feature' might be something like: What you want is this, but it won't work because it is referencing the table twice:

```
INSERT INTO foo  
(other, id, ...)  
VALUES  
(123, (SELECT MAX(id)+1 FROM foo WHERE other = 123), ...);
```

Instead, you need some variant on this. (You may already have a BEGIN...COMMIT.)

```

BEGIN;
SELECT @id := MAX(id)+1 FROM foo WHERE other = 123 FOR UPDATE;
INSERT INTO foo
    (other, id, ...)
VALUES
    (123, @id, ...);
COMMIT;

```

Having a transaction is mandatory to prevent another thread from grabbing the same id.

*Recommendation.* Look for such PRIMARY KEYS. If you find such, ponder how to change the design. There is no straightforward workaround. However, the following may be ok. (Be sure that the datatype for id is big enough since it won't start over.):

```

id INT UNSIGNED NOT NULL AUTO_INCREMENT,
PRIMARY KEY (abc, id),
UNIQUE(id)

```

*Recommendation.* Keep the PRIMARY KEY short. If you have Secondary keys, remember that they include the fields of the PK. A long PK would make the Secondary keys bulky. Well, maybe not — if there is a lot of overlap in fields. Example:

```

PRIMARY KEY(a,b,c), INDEX(c,b,a)
— no extra bulk.

```

*Recommendation.* Check AUTO\_INCREMENT sizes.

- BIGINT is almost never needed. It wastes at least 4 bytes per row (versus INT).
- Always use UNSIGNED and NOT NULL.
- MEDIUMINT UNSIGNED (16M max) might suffice instead of INT
- Be sure to be pessimistic — it is painful to ALTER.

*Contrast.* "Vertical Partitioning". This is where you artificially split a table to move bulky columns (eg, a BLOB) into another, parallel, table. It is beneficial in MyISAM to avoid stepping over the blob when you don't need to read it. InnoDB stores BLOB and TEXT differently — 767 bytes are in the record, the rest is in some other block. So, it may (or may not) be worth putting the tables back together. Caution: An InnoDB row is limited to 8KB, and the 767 counts against that.

*Fact.* FULLTEXT (prior to MariaDB 10.0.5) and SPATIAL indexes are not available in InnoDB. Note that MyISAM and InnoDB [FULLTEXT indexes](#) use different [stopword](#) lists and different system variables.

*Recommendation.* Search for such indexes. Keep such tables in MyISAM. Better yet, do Vertical Partitioning (see above) to split out the minimum number of columns from InnoDB.

*Fact.* The maximum length of an INDEX is different between the Engines. (This change is not likely to hit you, but watch out.) MyISAM allows 1000 bytes; InnoDB allows 767 bytes, just big enough for a

```

VARCHAR(255) CHARACTER SET utf8.

ERROR 1071 (42000): Specified key was too long; max key length is 767 bytes

```

*Fact.* The PRIMARY KEY is included in the data. Hence, SHOW TABLE STATUS will show and

```

Index_length
of 0 bytes (or 16KB) for a table with no secondary indexes. Otherwise,
Index_length
is the total size for the secondary keys.

```

*Fact.* The PRIMARY KEY is included in the data. Hence, exact match by PK may be a little faster with InnoDB. And, "range" scans by PK are likely to be faster.

*Fact.* A lookup by Secondary Key traverses the secondary key's BTree, grabs the PRIMARY KEY, then traverses the PK's BTree. Hence, secondary key lookups are a little more cumbersome in InnoDB.

*Contrast.* The fields of the PRIMARY KEY are included in each Secondary key. This may lead to "Using index" (in the EXPLAIN plan) for InnoDB for cases where it did not happen in MyISAM. (This is a slight performance boost, and counteracts the double-lookup otherwise needed.) However, when "Using index" would be useful on the PRIMARY KEY, MyISAM would do an "index scan", yet InnoDB effectively has to do a "table scan".

*Same as MyISAM.* Almost always

```

INDEX(a) -- DROP this one because the other one handles it.
INDEX(a,b)

```

*Contrast.* The data is stored in PK order. This means that "recent" records are 'clustered' together at the end. This may give you better 'locality of reference' than in MyISAM.

*Same as MyISAM.* The optimizer almost never uses two indexes in a single SELECT. (5.1 will occasionally do "index merge".) SELECT in subqueries and UNIONs can independently pick indexes.

*Subtle issue.* When you DELETE a row, the AUTO\_INCREMENT id will be burned. Ditto for REPLACE, which is a DELETE plus an INSERT.

*Very subtle issue.* Replication occurs on COMMIT. If you have multiple threads using transactions, the AUTO\_INCREMENTs can arrive at a slave out of

order. One transaction BEGINs, grabs an id. Then another transaction grabs an id but COMMITS before the first finishes.

Same as MyISAM. "Prefix" indexing is usually bad in both InnoDB and MyISAM. Example:

```
INDEX(foo(30))
```

## Non-INDEX Issues

Disk space for InnoDB is likely to be 2-3 times as much as for MyISAM.

MyISAM and InnoDB use RAM radically differently. If you change all your tables, you should make significant adjustments:

- `key_buffer_size` — small but non-zero; say, 10M;
- `innodb_buffer_pool_size` — 70% of available RAM

InnoDB has essentially no need for CHECK, OPTIMIZE, or ANALYZE. Remove them from your maintenance scripts. (No real harm if you keep them.)

Backup scripts may need checking. A MyISAM table can be backed up by copying three files. With InnoDB this is only possible if `innodb_file_per_table` is set to 1. Before MariaDB 10.0, capturing a table or database for copying from production to a development environment was not possible. Change to `mysqldump`. Since MariaDB 10.0 a hot copy can be created - see [Backup and restore overview](#).

Before MariaDB 5.5, the DATA DIRECTORY table option was not supported for InnoDB. Since MariaDB 5.5 it is supported, but only in CREATE TABLE. INDEX DIRECTORY has no effect, since InnoDB does not use separate files for indexes. To better balance the workload through several disks, the paths of some InnoDB log files can also be changed.

Understand autocommit and BEGIN/COMMIT.

- (default) autocommit = 1: In the absence of any BEGIN or COMMIT statements, every statement is a transaction by itself. This is close to the MyISAM behavior, but is not really the best.
- autocommit = 0: COMMIT will close a transaction and start another one. To me, this is kludgy.
- (recommended) BEGIN...COMMIT gives you control over what sequence of operation(s) are to be considered a transaction and "atomic". Include the ROLLBACK statement if you need to undo stuff back to the BEGIN.

Perl's DBIx::DWIW and Java's JDBC have API calls to do BEGIN and COMMIT. These are probably better than 'executing' BEGIN and COMMIT.

Test for errors everywhere! Because InnoDB uses row-level locking, it can stumble into deadlocks that you are not expecting. The engine will automatically ROLLBACK to the BEGIN. The normal recovery is to redo, beginning at the BEGIN. Note that this is a strong reason to have BEGINs.

LOCK/UNLOCK TABLES — remove them. Replace them (sort of) with BEGIN ... COMMIT. (LOCK will work if `innodb_table_locks` is set to 1, but it is less efficient, and may have subtle issues.)

In 5.1, ALTER ONLINE TABLE can speed up some operations significantly. (Normally ALTER TABLE copies the table over and rebuilds the indexes.)

The "limits" on virtually everything are different between MyISAM and InnoDB. Unless you have huge tables, wide rows, lots of indexes, etc, you are unlikely to stumble into a different limit.

Mixture of MyISAM and InnoDB? This is OK. But there are caveats.

- RAM settings should be adjusted to accordingly.
- JOINing tables of different Engines works.
- A transaction that affects tables of both types can ROLLBACK InnoDB changes, but will leave MyISAM changes intact.
- Replication: MyISAM statements are replicated when finished; InnoDB statements are held until the COMMIT.

FIXED (vs DYNAMIC) is meaningless in InnoDB.

PARTITION — You can partition MyISAM and InnoDB tables. Remember the screwball rule: You must either

- have no UNIQUE (or PRIMARY) keys, or
- have the value you are "partitioning on" in every UNIQUE key.

The former is not advised for InnoDB. The latter is messy if you want an AUTO\_INCREMENT.

PRIMARY KEY in PARTITION — Since every key must include the field on which you are PARTITIONing, how can AUTO\_INCREMENT work? Well, there seems to be a convenient special case:

- This works: PRIMARY KEY(autoinc, partition\_key)
- This does not work for InnoDB: PRIMARY KEY(partition\_key, autoinc)

That is, an AUTO\_INCREMENT will correctly increment, and be unique across all PARTITINOs, when it is the first field of the PRIMARY KEY, but not otherwise.

## 4.3.24 Machine Learning with MindsDB

## Contents

- 1. Overview
- 2. Installation
- 3. Usage

## Overview

MindsDB is a third-party application that interfaces with MariaDB Server to provide Machine Learning capabilities through SQL. The interface is done via the [Connect Storage Engine](#).

## Installation

To get a functional MariaDB - MindsDB installation, one needs to install the following components:

- **MindsDB** : follow the instructions in the project's [official documentation](#).
- **Connect Storage Engine** must be enabled for the integration to work. See [installing the connect storage engine](#).

MindsDB connects to MariaDB Server via a regular user to setup a dedicated database called

```
mindsdb
. Which user will be used is specified within MindsDB's configuration file.
```

For example, if MindsDB is installed locally, one can create a user called

```
mindsdb@localhost
. MindsDB only authenticates via the mysql_native_password plugin, hence one must set a password for the user:
```

```
CREATE USER mindsdb@localhost;
SET PASSWORD FOR mindsdb@localhost=PASSWORD("password");
```

The user must be granted the global `FILE` privilege and all privileges on the

```
mindsdb
database.
```

```
GRANT FILE ON *.* TO mindsdb@localhost;
GRANT ALL ON mindsdb.* TO mindsdb@localhost;
```

Assuming MindsDB is in the python path one can start up MindsDB with the following parameters:

```
python -m mindsdb --config=$CONFIG_PATH --api=http,mysql
```

Make sure

```
$CONFIG_PATH
points to the appropriate MindsDB configuration file.
```

## Usage

Always consult the project's [official documentation](#) for up-to-date usage scenarios as MindsDB is an actively developed project.

For a step-by-step example, you can consult the following [blog post](#).

If the connection between MindsDB and MariaDB is successful, you should see the

```
mindsdb
database present and two tables within it:
commands
and
predictors
```

MindsDB, as an AutoML framework does all the work when it comes to training the AI model. What is necessary is to pass it the initial data, which MindsDB retrieves via a SELECT statement. This can be done by inserting into the

```
predictors
table.
```

```
INSERT INTO `predictors`
(`name`, `predict`, `select_data_query`)
VALUES ('bikes_model', 'count', 'SELECT * FROM test.bike_data');
```

The values inserted into predictors act as a command instructing MindsDB to:

1. Train a model called 'bikes\_model'
2. From the input data, learn to predict the 'count' column.
3. The input data is generated via the select statement 'SELECT \* FROM test.bike\_data'. The

`select_data_query`  
should be a valid select that MindsDB can run against MariaDB.

## 4.4 Plugins

MariaDB supports the use of plugins, software components that may be added to the core software without having to rebuild the MariaDB server from source code. Therefore, plugins can be loaded at start-up, or loaded and unloaded while the server is running without interruption. Plugins are commonly used for adding desired storage engines, additional security requirements, and logging special information about the server.

## 4.4.1.3 Information Schema ALL\_PLUGINS Table

## 4.4.2 Plugin SQL Statements

## 4.4.3 Installing, Using, and Creating Plugins

### 4.4.3.1 Specifying Which Plugins to Build

By default all plugins are enabled and built as dynamic

```
.so
(or
.dll
) modules. If a plugin does not support dynamic builds, it is not built at all.
```

#### MariaDB 5.5 - 10.0

To specify that a specific plugin should be enabled and built statically into the server executable, use the

```
-DWITH_xxx=1
cmake option (where
xxx
```

is the plugin name). Of course, static linking only works if the plugin itself supports it — some plugins can only be built as dynamic modules.

A plugin will automatically be skipped by cmake if it cannot be built; for example, if some required libraries are missing or if you want to statically link a plugin that only supports dynamic linking.

If you want to avoid building some specific plugin, specify the

```
-DWITHOUT_xxx=1
cmake option.
```

MariaDB starting with 10.1

Use

```
PLUGIN_xxx  
cmake variables. They can be set on the command line with  
-DPLUGIN_xxx=  
  
value
```

or in the cmake gui. Supported values are

Value	Effect
<b>NO</b>	the plugin will be not compiled at all
<b>STATIC</b>	the plugin will be compiled statically, if supported. Otherwise it will be not compiled.
<b>DYNAMIC</b>	the plugin will be compiled dynamically, if supported. Otherwise it will be not compiled. This is the default behavior.
<b>AUTO</b>	the plugin will be compiled statically, if supported. Otherwise it will be compiled dynamically.
<b>YES</b>	same as <b>AUTO</b> , but if plugin prerequisites (for example, specific libraries) are missing, it will not be skipped, it will abort cmake with an error.

Note that unlike autotools, cmake tries to configure and build incrementally. You can modify one configuration option and cmake will only rebuild the part of the tree affected by it. For example, when you do

```
cmake -DWITH_EMBEDDED_SERVER=1  
in the already-built tree, it will make libmysqld to be built, but no other configuration options will be changed or reset to their default values.
```

In particular this means that if you have run, for example

MariaDB 5.5 - 10.0

```
cmake -DWITHOUT_OQGRAPH=1
```

MariaDB starting with 10.1

```
cmake -DPLUGIN_OQGRAPH=NO
```

and later you want to restore the default behavior (with OQGraph being built) in the same build tree, you would need to run

MariaDB 5.5 - 10.0

```
cmake -UWITHOUT_OQGRAPH
```

MariaDB starting with 10.1

```
cmake -DPLUGIN_OQGRAPH=DYNAMIC
```

Alternatively, you might simply delete the

CMakeCache.txt  
file — this is the file where cmake stores current build configuration — and rebuild everything from scratch.

#### 4.4.3.2 Writing Plugins for MariaDB

##### Contents

1. [About](#)
2. [Authentication Plugins](#)
3. [Storage Engine Plugins](#)
4. [Information Schema Plugins](#)
5. [Encryption Plugins](#)
6. [Plugin Declaration Structure](#)
  1. [Example Plugin Declaration](#)

# About

Generally speaking, writing plugins for MariaDB is very similar to [writing plugins for MySQL](#).

## Authentication Plugins

See [Pluggable Authentication](#).

## Storage Engine Plugins

Storage engines can extend

```
CREATE TABLE  
syntax with optional index, field, and table attribute clauses. See Extending CREATE TABLE for more information.
```

See [Storage Engine Development](#).

## Information Schema Plugins

Information Schema plugins can have their own [FLUSH](#) and [SHOW](#) statements. See [FLUSH and SHOW for Information Schema plugins](#).

## Encryption Plugins

[Encryption plugins](#) in MariaDB are used for the [data at rest encryption](#) feature. They are responsible for both key management and for the actual encryption and decryption of data.

## Plugin Declaration Structure

The MariaDB plugin declaration differs from the MySQL plugin declaration in the following ways:

1. it has no useless 'reserved' field (the very last field in the MySQL plugin declaration)
2. it has a 'maturity' declaration
3. it has a field for a text representation of the version field

MariaDB can load plugins that only have the MySQL plugin declaration but both

```
PLUGIN_MATURITY  
and  
PLUGIN_AUTH_VERSION  
will show up as 'Unknown' in the INFORMATION\_SCHEMA.PLUGINS table.
```

For compiled-in (not dynamically loaded) plugins, the presence of the MariaDB plugin declaration is mandatory.

## Example Plugin Declaration

The MariaDB plugin declaration looks like this:

```
/* MariaDB plugin declaration */  
maria_declare_plugin(example)  
{  
    MYSQL_STORAGE_ENGINE_PLUGIN, /* the plugin type (see include/mysql/plugin.h) */  
    &example_storage_engine_info, /* pointer to type-specific plugin descriptor */  
    "EXAMPLEDB", /* plugin name */  
    "John Smith", /* plugin author */  
    "Example of plugin interface", /* the plugin description */  
    PLUGIN_LICENSE_GPL, /* the plugin license (see include/mysql/plugin.h) */  
    example_init_func, /* Pointer to plugin initialization function */  
    example_deinit_func, /* Pointer to plugin deinitialization function */  
    0x0001 /* Numeric version 0xAABB means AA.BB version */,  
    example_status_variables, /* Status variables */  
    example_system_variables, /* System variables */  
    "0.1 example", /* String version representation */  
    MariaDB_PLUGIN_MATURITY_EXPERIMENTAL /* Maturity (see include/mysql/plugin.h) */  
}  
maria_declare_plugin_end;
```

## 4.4.4 MariaDB Audit Plugin

## Contents

1. [Additional documentation](#)
2. [Tutorials](#)
3. [Web Log Articles](#)
4. [Sub-Documents](#)

MariaDB and MySQL are used in a broad range of environments, but if you needed to record user access to be in compliance with auditing regulations for your organization, you would previously have had to use other database solutions. To meet this need, though, MariaDB has developed the MariaDB Audit Plugin. Although the MariaDB Audit Plugin has some unique features available only for MariaDB, it can be used also with MySQL.

Basically, the purpose of the MariaDB Audit Plugin is to log the server's activity. For each client session, it records who connected to the server (i.e., user name and host), what queries were executed, and which tables were accessed and server variables that were changed. This information is stored in a rotating log file or it may be sent to the local `syslog`.

The MariaDB Audit Plugin works with MariaDB, MySQL (as of, version 5.5.34 and 10.0.7) and Percona Server. MariaDB started including by default the Audit Plugin from versions 10.0.10 and 5.5.37, and it can be installed in any version from [MariaDB 5.5.20](#).

### Additional documentation

### 4.4.4.1 MariaDB Audit Plugin - Installation

The

`server_audit`

plugin logs the server's activity. For each client session, it records who connected to the server (i.e., user name and host), what queries were executed, and which tables were accessed and server variables that were changed. This information is stored in a rotating log file or it may be sent to the local syslogd.

#### Contents

1. [Locating the Plugin](#)
2. [Installing the Plugin](#)
3. [Uninstalling the Plugin](#)
4. [Prohibiting Uninstallation](#)

### Locating the Plugin

The

`server_audit`

plugin's shared library is included in MariaDB packages as the `server_audit.so` or `server_audit.dll` shared library on systems where it can be built.

The plugin must be located in the plugin directory, the directory containing all plugin libraries for MariaDB. The path to this directory is configured by the

`plugin_dir`

system variable. To see the value of this variable and thereby determine the file path of the plugin library, execute the following SQL statement:

```
SHOW GLOBAL VARIABLES LIKE 'plugin_dir';  
  
+-----+  
| Variable_name | Value          |  
+-----+  
| plugin_dir    | /usr/lib64/mysql/plugin/ |  
+-----+
```

Check the directory returned at the filesystem level to make sure that you have a copy of the plugin library,

`server_audit.so`

or

`server_audit.dll`

, depending on your system. It's included in recent installations of MariaDB. If you do not have it, you should upgrade MariaDB.

### Installing the Plugin

Although the plugin's shared library is distributed with MariaDB by default, the plugin is not actually installed by MariaDB by default. There are two methods that can be used to install the plugin with MariaDB.

The first method can be used to install the plugin without restarting the server. You can install the plugin dynamically by executing

`INSTALL SONAME`

or

## INSTALL PLUGIN

. For example:

```
INSTALL SONAME 'server_audit';
```

The second method can be used to tell the server to load the plugin when it starts up. The plugin can be installed this way by providing the

```
--plugin-load
```

or the

```
--plugin-load-add
```

options. This can be specified as a command-line argument to

```
mysqld
```

or it can be specified in a relevant server [option group](#) in an [option file](#). For example:

```
[mariadb]
...
plugin_load_add = server_audit
```

## Uninstalling the Plugin

You can uninstall the plugin dynamically by executing

```
UNINSTALL SONAME
```

or

```
UNINSTALL PLUGIN
```

. For example:

```
UNINSTALL SONAME 'server_audit';
```

If you installed the plugin by providing the

```
--plugin-load
```

or the

```
--plugin-load-add
```

options in a relevant server [option group](#) in an [option file](#), then those options should be removed to prevent the plugin from being loaded the next time the server is restarted.

## Prohibiting Uninstallation

The

```
UNINSTALL SONAME
```

or

```
UNINSTALL PLUGIN
```

statements may be used to uninstall plugins. For the  
server\_audit

plugin, you might want to disable this capability. To prevent the plugin from being uninstalled, you could set the the

```
server_audit
```

option to

```
FORCE_PLUS_PERMANENT
```

in a relevant server [option group](#) in an [option file](#) after the plugin is loaded once:

```
[mariadb]
...
plugin_load_add = server_audit
server_audit=FORCE_PLUS_PERMANENT
```

Once you've added the option to the server's option file and restarted the server, the plugin can't be uninstalled. If someone tries to uninstall the audit plugin, then an error message will be returned. Below is an example of the error message:

```
UNINSTALL PLUGIN server_audit;

ERROR 1702 (HY000):
Plugin 'server_audit' is force_plus_permanent and can not be unloaded
```

For more information on

[FORCE\\_PLUS\\_PERMANENT](#)

and other option values for the

[server\\_audit](#)

option, see [Plugin Overview: Configuring Plugin Activation at Server Startup](#) for more information.

## 4.4.4.2 MariaDB Audit Plugin - Configuration

After the audit plugin has been installed and loaded, there will be some new global variables within MariaDB. These can be used to configure many components, limits, and methods related to auditing the server. You may set these variables related to the logs, such as their location, size limits, rotation parameters, and method of logging information. You may also set what information is logged, such connects, disconnects, and failed attempts to connect. You can also have the audit plugin log queries, read and write access to tables. So as not to overload your logs, the audit plugin can be configured based on lists of users. You can include or exclude the activities of specific users in the logs.

To see a list of [audit plugin-related variables](#) on the server and their values, execute the follow while connected to the server:

```
SHOW GLOBAL VARIABLES LIKE 'server_audit%';

+-----+-----+
| Variable_name      | Value   |
+-----+-----+
| server_audit_events | CONNECT,QUERY,TABLE |
| server_audit_excl_users |          |
| server_audit_file_path | server_audit.log |
| server_audit_file_rotate_now | OFF |
| server_audit_file_rotate_size | 1000000 |
| server_audit_file_rotations | 9 |
| server_audit_incl_users |          |
| server_audit_logging | ON |
| server_audit_mode | 0 |
| server_audit_output_type | file |
| server_audit_query_log_limit | 1024 |
| server_audit_syslog_facility | LOG_USER |
| server_audit_syslog_ident | mysql-server_auditing |
| server_audit_syslog_info |          |
| server_audit_syslog_priority | LOG_INFO |
+-----+-----+
```

The values of these variables can be changed by an administrator with the

[SUPER](#)

privilege, using the

[SET](#)

statement. Below is an example of how to disable audit logging:

```
SET GLOBAL server_audit_logging=OFF;
```

Although it is possible to change all of the variables shown above, some of them may be reset when the server restarts. Therefore, you may want set them in the configuration file (e.g.,

[/etc/my.cnf.d/server.cnf](#)

) to ensure the values are the same after a restart:

```
[server]
...
server_audit_logging=OFF
...
```

For the reason given in the paragraph above, you would not generally set variables related to the auditing plugin using the

SET

statement. However, you might do so to test settings before making them more permanent. Since one cannot always restart the server, you would use the

SET

statement to change immediately the variables and then include the same settings in the configuration file so that the variables are set again as you prefer when the server is restarted.

## Configuring Logs and Setting Other Variables

Of all of the server variables you can set, you may want to set initially the [server\\_audit\\_events](#) variable to tell the Audit Plugin which events to log. The [Log Settings documentation page](#) describes in detail the choices you have and provides examples of log entries related to them.

You can see a detailed list of system variables related to the MariaDB Audit Plugin on the [System Variables documentation page](#). Status variables related to the Audit Plugin are listed and explained on the [Status Variables documentation page](#).

### 4.4.4.3 MariaDB Audit Plugin - Log Settings

Events that are logged by the MariaDB Audit Plugin are grouped generally into different types: connect, query, and table events. To log based on these types of events, set the variable, [server\\_audit\\_events](#) to

CONNECT

,

QUERY

, or

TABLE

. To have the Audit Plugin log more than one type of event, put them in a comma-separated list like so:

```
SET GLOBAL server_audit_events = 'CONNECT,QUERY,TABLE';
```

## Contents

1. [Logging Connect Events](#)
2. [Logging Query Events](#)
  1. [Queries Not Included in Subordinate Query Event Types](#)
  3. [Logging Table Events](#)
  4. [Logging User Activities](#)
  5. [Excluding or Including Users](#)

You can put the equivalent of this in the configuration file like so:

```
[mysqld]
...
server_audit_events=connect,query
```

By default, logging is set to

OFF

. To enable it, set the [server\\_audit\\_logging](#) variable to

ON

. Note that if the [query cache](#) is enabled, and a query is returned from the query cache, no

TABLE

records will appear in the log since the server didn't open or access any tables and instead relied on the cached results. So you may want to disable query caching.

There are actually a few types of events that may be logged, not just the three common ones mentioned above. A full list of related system variables is detailed on the [Server\\_Audit System Variables](#) page, and status variables on the [Server\\_Audit Status Variables](#) page of this documentation. Some of the major ones are highlighted below:

Type	Description
CONNECT	Connects, disconnects and failed connects — including the error code
QUERY	Queries executed and their results in plain text, including failed queries due to syntax or permission errors
TABLE	Tables affected by query execution

---

Similar to

```
QUERY
, but filters only DDL-type queries (
CREATE
,
ALTER
,
DROP
,
RENAME
and
TRUNCATE
). There are some exceptions however.
RENAME USER
is not logged, while
CREATE/DROP [PROCEDURE / FUNCTION / USER]
are only logged from MariaDB 10.2.38 , MariaDB 10.3.29 , MariaDB 10.4.22 , MariaDB 10.5.13 and
MariaDB 10.6.5 . In earlier versions they are not logged. See MDEV-23457 .
```

---

Similar to

```
QUERY
, but filters only DML-type queries (
DO
,
CALL
,
LOAD DATA/XML
,
DELETE
,
INSERT
,
SELECT
,
UPDATE
,
HANDLER
and
REPLACE
statements)
```

---

Similar to

```
QUERY_DML
, but doesn't log SELECT queries. (since version 1.4.4) (
DO
,
CALL
,
LOAD DATA/XML
,
DELETE
,
INSERT
,
UPDATE
,
HANDLER
and
REPLACE
statements)
```

---

---

Similar to	<b>QUERY</b> , but filters only DCL-type queries ( <b>CREATE USER</b> , <b>DROP USER</b> , <b>RENAME USER</b> , <b>GRANT</b> , <b>REVOKE</b> and <b>SET PASSWORD</b> statements)
QUERY_DCL	

Since there are other types of queries besides DDL and DML, using the

```
QUERY_DDL
and
QUERY_DML
options together is not equivalent to using
QUERY
. Starting in version 1.3.0 of the Audit Plugin, there is the
QUERY_DCL
option for logging DCL types of queries (e.g.,
GRANT
and
REVOKE
```

statements). In the same version, the [server\\_audit\\_query\\_log\\_limit](#) variable was added to be able to set the length of a log record. Previously, a log entry would be truncated due to long query strings.

## Logging Connect Events

If the Audit Plugin has been configured to log connect events, it will log connects, disconnects, and failed connects. For a failed connection, the log includes the error code.

It's possible to define a list of users for which events can be excluded or included for tracing their database activities. This list will be ignored, though, for the loggings of connect events. This is because auditing standards distinguish between technical and physical users. Connects need to be logged for all types of users; access to objects need to be logged only for physical users.

## Logging Query Events

If

```
QUERY
,
QUERY_DDL
,
QUERY_DML
,
QUERY_DML_NO_SELECT
, and/or
QUERY_DCL
```

event types are enabled, then the corresponding types of queries that are executed will be logged for defined users. The queries will be logged exactly as they are executed, in plain text. This is a security vulnerability: anyone who has access to the log files will be able to read the queries. So make sure that only trusted users have access to the log files and that the files are in a protected location. An alternative is to use

```
TABLE
event type instead of the query-related event types.
```

Queries are also logged if they cannot be executed, if they're unsuccessful. For example, a query will be logged because of a syntax error or because the user doesn't have the privileges necessary to access an object. These queries can be parsed by the error code that's provided in the log.

You may find failed queries to be more interesting: They can reveal problems with applications (e.g., an SQL statement in an application that doesn't match the current schema). They can also reveal if a malicious user is guessing at the names of tables and columns to try to get access to data.

Below is an example in which a user attempts to execute an

```
UPDATE
statement on a table for which he does not have permission:
```

```
UPDATE employees
SET salary = salary * 1.2
WHERE emp_id = 18236;

ERROR 1142 (42000):
UPDATE command denied to user 'bob'@'localhost' for table 'employees'
```

Looking in the Audit Plugin log (  
server\_audit.log  
) for this entry, you can see the following entry:

```
20170817 11:07:18,ip-172-30-0-38,bob,localhost,15,46,QUERY,company,
'UPDATE employees SET salary = salary * 1.2 WHERE emp_id = 18236',1142
```

This log entry would be on one line, but it's reformatted here for better rendering. Looking at this log entry, you can see the date and time of the query, followed by the server host, the user and host for the account. Next is the connection and query identification numbers (i.e.,

15  
and  
46  
. After the log event type (i.e.,  
QUERY  
, the database name (i.e.,  
company  
, the query, and the error number is recorded.

Notice that the last value in the log entry is

1142  
. That's the error number for the query. To find failed queries, you would look for two elements: the notation indicating that it's a  
QUERY  
entry, and the last value for the entry. If the query is successful, the value will be  
0  
.

## Queries Not Included in Subordinate Query Event Types

Note that the

QUERY  
event type will log queries that are not included in any of the subordinate  
QUERY\_\*  
event types, such as:

- CREATE FUNCTION
- DROP FUNCTION
- CREATE PROCEDURE
- DROP PROCEDURE
- SET
- CHANGE MASTER TO
- FLUSH
- KILL
- CHECK
- OPTIMIZE
- LOCK
- UNLOCK
- ANALYZE
- INSTALL PLUGIN
- UNINSTALL PLUGIN
- INSTALL SONAME
- UNINSTALL SONAME
- EXPLAIN

## Logging Table Events

MariaDB has the ability to record table events in the logs — this is not a feature of MySQL. This feature is the only way to log which tables have been accessed through a view, a stored procedure, a stored function, or a trigger. Without this feature, a log entry for a query shows only the view, stored procedure or function used, not the underlying tables. Of course, you could create a custom application to parse each query executed to find the SQL statements used and the tables accessed, but that would be a drain on system resources. Table event logging is much simpler: it adds a line to the log for each table accessed, without any parsing. It includes notes as to whether it was a read or a write.

If you want to monitor user access to specific databases or tables (e.g.,

mysql.user  
, you can search the log for them. Then if you want to see a query which accessed a certain table, the audit log entry will include the query

identification number. You can use it to search the same log for the query entry. This can be useful when searching a log containing tens of thousands of entries.

Because of the

TABLE

option, you may disable query logging and still know who accessed which tables. You might want to disable

QUERY

event logging to prevent sensitive data from being logged. Since *table* event logging will log who accessed which table, you can still watch for malicious activities with the log. This is often enough to fulfill auditing requirements.

Below is an example with both

TABLE

and

QUERY

events logging. For this scenario, suppose there is a **VIEW** in which columns are selected from a few tables in a company

database. The underlying tables are related to sensitive employee information, in particular salaries. Although we may have taken precautions to ensure that only certain user accounts have access to those tables, we will monitor the Audit Plugin logs for anyone who queries them — directly or indirectly through a view.

```
20170817 16:04:33,ip-172-30-0-38,root,localhost,29,913,READ,company,employees,
20170817 16:04:33,ip-172-30-0-38,root,localhost,29,913,READ,company,employees_salaries,
20170817 16:04:33,ip-172-30-0-38,root,localhost,29,913,READ,company,ref_job_titles,
20170817 16:04:33,ip-172-30-0-38,root,localhost,29,913,READ,company,org_departments,
20170817 16:04:33,ip-172-30-0-38,root,localhost,29,913,QUERY,company,
'SELECT * FROM employee_pay WHERE title LIKE \'%Executive%' OR title LIKE '%Manager%',0
```

Although the user executed only one **SELECT** statement, there are multiple entries to the log: one for each table accessed and one entry for the query on the view, (i.e.,

employee\_pay

). We know primarily this is all for one query because they all have the same connection and query identification numbers (i.e.,

29

and

913

).

## Logging User Activities

The Audit Plugin will log the database activities of all users, or only the users that you specify. A database activity is defined as a *query* event or a *table* event. *Connect* events are logged for all users.

You may specify users to include in the log with the

server\_audit\_incl\_users

variable or exclude users with the

server\_audit\_excl\_users

variable. This can be useful if you would like to log entries, but are not interested in entries from trusted applications and would like to exclude them from the logs.

You would typically use either the

server\_audit\_incl\_users

variable or the

server\_audit\_excl\_users

variable. You may, though, use both variables. If a username is inadvertently listed in both variables, database activities for that user will be logged because

server\_audit\_incl\_users

takes priority.

Although MariaDB considers a user as the combination of the username and hostname, the Audit Plugin logs only based on the username. MariaDB uses both the username and hostname so as to grant privileges relevant to the location of the user. Privileges are not relevant though for tracing the access to database objects. The host name is still recorded in the log, but logging is not determined based on that information.

The following example shows how to add a new username to the

server\_audit\_incl\_users

variable without removing previous usernames:

```
SET GLOBAL server_audit_incl_users = CONCAT(@@global.server_audit_incl_users, ',Maria');
```

Remember to add also any new users to be included in the logs to the same variable in MariaDB configuration file. Otherwise, when the server restarts it will discard the setting.

## Excluding or Including Users

By default events from all users are logged, but certain users can be excluded from logging by using the `server_audit_excl_users` variable. For example, to exclude users `valerianus` and `rocky` from having their events logged:

```
server_audit_excl_users=valerianus,rocky
```

This option is primarily used to exclude the activities of trusted applications.

Alternatively, `server_audit_incl_users` can be used to specifically include users. Both variables can be used, but if a user appears on both lists, `server_audit_incl_users` has a higher priority, and their activities will be logged.

Note that

`CONNECT`

events are always logged for all users, regardless of these two settings. Logging is also based on username only, not the username and hostname combination that MariaDB uses to determine privileges.

## 4.4.4.4 MariaDB Audit Plugin - Location and Rotation of Logs

### Contents

1. Separate log files
2. System logs

Logs can be written to a separate file or to the system logs. If you prefer to have the logging separated from other system information, the value of the variable, `server_audit_output_type` should be set to

```
file  
. Incidentally,  
file  
is the only option on Windows systems.
```

You can force a rotation by enabling the `server_audit_file_rotate_now` variable like so:

```
SET GLOBAL server_audit_file_rotate_now = ON;
```

### Separate log files

In addition to setting `server_audit_output_type`, you will have to provide the file path and name of the audit file. This is set in the variable, `server_audit_file_path`. You can set the file size limit of the log file with the variable, `server_audit_file_rotate_size`.

So, if rotation is on and the log file has reached the size limit you set, a copy is created with a consecutive number as extension, the original file will be truncated to be used for the auditing again. To limit the number of log files created, set the variable, `server_audit_file_rotations`. You can force log file rotation by setting the variable, `server_audit_file_rotate_now` to a value of

`ON`

. When the number of files permitted is reached, the oldest file will be overwritten. Below is an example of how the variables described above might be set in a server's configuration files:

```
[mysqld]  
...  
server_audit_file_rotate_now=ON  
server_audit_file_rotate_size=1000000  
server_audit_file_rotations=5  
...
```

### System logs

For security reasons, it's better sometimes to use the system logs instead of a local file owned by the

```
mysql  
user. To do this, the value of server_audit_output_type needs to be set to  
syslog  
. Advanced configurations, such as using a remote  
syslogd  
service, are part of the  
syslogd  
configuration.
```

The variables, `server_audit_syslog_ident` and `server_audit_syslog_info` can be used to identify a system log entry made by the audit plugin. If a remote syslogd service is used for several MariaDB servers, these same variables are also used to identify the MariaDB server.

Below is an example of a system log entry taken from a server which had `server_audit_syslog_ident` set to the default value of

```
mysql -server_auditing  
, and server_audit_syslog_info set to
```

```
<prod1>
```

```
Aug 7 17:19:58localhostmysql- server_auditing:  
<prod1> localhost.localdomain,root,localhost,1,7,  
QUERY, mysql, 'SELECT * FROM user',0
```

Although the default values for `server_audit_syslog_facility` and `server_audit_syslog_priority` should be sufficient in most cases, they can be changed based on the definition in

```
syslog.h  
for the functions  
openlog()  
and  
syslog()
```

## 4.4.4.5 MariaDB Audit Plugin - Log Format

The audit plugin logs user access to MariaDB and its objects. The audit trail (i.e., audit log) is a set of records, written as a list of fields to a file in a plain-text format. The fields in the log are separated by commas. The format used for the plugin's own log file is slightly different from the format used if it logs to the system log because it has its own standard format. The general format for the logging to the plugin's own file is defined like the following:

```
[timestamp],[serverhost],[username],[host],[connectionid],  
[queryid],[operation],[database],[object],[retcode]
```

If the `server_audit_output_type` variable is set to

```
syslog  
instead of the default,  
file  
, the audit log file format will be as follows:
```

```
[timestamp][syslog_host][syslog_ident]:[syslog_info][serverhost],[username],[host],  
[connectionid],[queryid],[operation],[database],[object],[retcode]
```

Item logged	Description
timestamp	Time at which the event occurred. If syslog is used, the format is defined by syslogs
syslog_host	Host from which the syslog entry was received.
syslog_ident	For identifying a system log entry, including the MariaDB server.
syslog_info	For providing information for identifying a system log entry.
serverhost	The MariaDB server host name.
username	Connected user.
host	Host from which the user connected.
connectionid	Connection ID number for the related operation.
queryid	Query ID number, which can be used for finding the relational table events and related queries. For TABLE events, multiple lines will be added.
operation	Recorded action type: CONNECT, QUERY, READ, WRITE, CREATE, ALTER, RENAME, DROP.
database	Active database (as set by <code>USE</code> ).
object	Executed query for QUERY events, or the table name in the case of TABLE events.
retcode	Return code of the logged operation.

Various events will result in different audit records. Some events will not return a value for some fields (e.g., when the active database is not set when connecting to the server).

Below is a generic example of the output for connect events, with placeholders representing data. These are events in which a user connected, disconnected, or tried unsuccessfully to connect to the server.

```
[timestamp],[serverhost],[username],[host],[connectionid],0,CONNECT,[database],,0  
[timestamp],[serverhost],[username],[host],[connectionid],0,DISCONNECT,,,0  
[timestamp],[serverhost],[username],[host],[connectionid],0,FAILED_CONNECT,,,[retcode]
```

Here is the one audit record generated for each query event:

```
[timestamp],[serverhost],[username],[host],[connectionid],[queryid],QUERY,[database],[object], [retcode]
```

Below are generic examples of records that are entered in the audit log for each type of table event:

```
[timestamp],[serverhost],[username],[host],[connectionid],[queryid],CREATE,[database],[object],  
[timestamp],[serverhost],[username],[host],[connectionid],[queryid],READ,[database],[object],  
[timestamp],[serverhost],[username],[host],[connectionid],[queryid],WRITE,[database],[object],  
[timestamp],[serverhost],[username],[host],[connectionid],[queryid],ALTER,[database],[object],  
[timestamp],[serverhost],[username],[host],[connectionid],[queryid],RENAME,[database],  
[object_old]||[database_new].[object_new],  
[timestamp],[serverhost],[username],[host],[connectionid],[queryid],DROP,[database],[object],
```

Starting in version 1.2.0, passwords are hidden in the log for certain types of queries. They are replaced with asterisks for

```
GRANT  
,  
CREATE USER  
,  
CREATE MASTER  
,  
CREATE SERVER  
, and  
ALTER SERVER  
statements. Passwords, however, are not replaced for the  
PASSWORD()  
and  
OLD_PASSWORD()  
functions when they are used inside other SQL statements (i.e., SET PASSWORD  
).
```

#### 4.4.4.6 MariaDB Audit Plugin - Versions

Below is a list of the releases of the MariaDB Audit Plugin, the most recent version first, and in which versions of MariaDB each plugin version was included.

Version	Introduced
1.4.13	<a href="#">MariaDB 10.2.38</a> , <a href="#">MariaDB 10.3.29</a> , <a href="#">MariaDB 10.4.19</a> , <a href="#">MariaDB 10.5.10</a>
1.4.10	<a href="#">MariaDB 10.2.35</a> , <a href="#">MariaDB 10.3.26</a> , <a href="#">MariaDB 10.5.7</a>
1.4.7	<a href="#">MariaDB 10.1.41</a> , <a href="#">MariaDB 10.2.26</a> , <a href="#">MariaDB 10.3.17</a> , <a href="#">MariaDB 10.4.7</a>
1.4.5	<a href="#">MariaDB 10.2.24</a> , <a href="#">MariaDB 10.3.15</a> , <a href="#">MariaDB 10.4.5</a>
1.4.4	<a href="#">MariaDB 5.5.61</a> , <a href="#">MariaDB 10.0.36</a> , <a href="#">MariaDB 10.1.34</a> , <a href="#">MariaDB 10.2.15</a> , <a href="#">MariaDB 10.3.7</a> , <a href="#">MariaDB 10.4.0</a>
1.4.0	<a href="#">MariaDB 5.5.48</a> , <a href="#">MariaDB 10.0.24</a> , <a href="#">MariaDB 10.1.11</a>
1.3.0	<a href="#">MariaDB 5.5.43</a> , <a href="#">MariaDB 10.0.18</a> , <a href="#">MariaDB 10.1.5</a>
1.2.0	<a href="#">MariaDB 5.5.42</a> , <a href="#">MariaDB 10.0.17</a> , <a href="#">MariaDB 10.1.4</a>
1.1.7	<a href="#">MariaDB 5.5.38</a> , <a href="#">MariaDB 10.0.11</a> , <a href="#">MariaDB 10.1.0</a>
1.1.6	<a href="#">MariaDB 5.5.37</a> , <a href="#">MariaDB 10.0.10</a>
1.1.5	<a href="#">MariaDB 10.0.09</a>
1.1.4	<a href="#">MariaDB 5.5.36</a>
1.1.3	<a href="#">MariaDB 5.5.34</a> , <a href="#">MariaDB 10.0.7</a>

#### 4.4.4.7 MariaDB Audit Plugin Options and System Variables

## Contents

1. System Variables
  1. `server_audit_events`
  2. `server_audit_excl_users`
  3. `server_audit_file_path`
  4. `server_audit_file_rotate_now`
  5. `server_audit_file_rotate_size`
  6. `server_audit_file_rotations`
  7. `server_audit_incl_users`
  8. `server_audit_loc_info`
  9. `server_audit_logging`
  10. `server_audit_mode`
  11. `server_audit_output_type`
  12. `server_audit_query_log_limit`
  13. `server_audit_syslog_facility`
  14. `server_audit_syslog_ident`
  15. `server_audit_syslog_info`
  16. `server_audit_syslog_priority`
2. Options
  1. `server_audit`

There are several options and system variables related to the [MariaDB Audit Plugin](#), once it has been [installed](#). System variables can be displayed using the `SHOW VARIABLES` statement like so:

```
SHOW GLOBAL VARIABLES LIKE '%server_audit%';

+-----+-----+
| Variable_name      | Value   |
+-----+-----+
| server_audit_events | CONNECT,QUERY,TABLE |
| server_audit_excl_users |          |
| server_audit_file_path | server_audit.log |
| server_audit_file_rotate_now | OFF |
| server_audit_file_rotate_size | 1000000 |
| server_audit_file_rotations | 9 |
| server_audit_incl_users |          |
| server_audit_logging | ON |
| server_audit_mode | 0 |
| server_audit_output_type | file |
| server_audit_query_log_limit | 1024 |
| server_audit_syslog_facility | LOG_USER |
| server_audit_syslog_ident | mysql-server_auditing |
| server_audit_syslog_info |          |
| server_audit_syslog_priority | LOG_INFO |
+-----+-----+
```

To change the value of one of these variables, you can use the

`SET`

statement, or set them at the command-line when starting MariaDB. It's recommended that you set them in the MariaDB configuration for the server like so:

```
[mariadb]
...
server_audit_excl_users='bob,ted'
...
```

## System Variables

Below is a list of all system variables related to the Audit Plugin. See [Server System Variables](#) for a complete list of system variables and instructions on setting them. See also the [full list of MariaDB options, system and status variables](#).

`server_audit_events`

- **Description:** If set, then this restricts audit logging to certain event types. If not set, then every event type is logged to the audit log. For example:  
`SET GLOBAL server_audit_events='connect, query'`
- **Commandline:**  
`--server-audit-events=value`
- **Scope:** Global
- **Dynamic:** Yes

- **Data Type:**

string

- **Default Value:** Empty string

- **Valid Values:**

- - CONNECT
  - ,
  - QUERY
  - ,
  - TABLE

(MariaDB Audit Plugin < 1.2.0)
- - CONNECT
  - ,
  - QUERY
  - ,
  - TABLE
  - ,
  - QUERY\_DDL
  - ,
  - QUERY\_DML

(MariaDB Audit Plugin >= 1.2.0)
- - CONNECT
  - ,
  - QUERY
  - ,
  - TABLE
  - ,
  - QUERY\_DDL
  - ,
  - QUERY\_DML
  - ,
  - QUERY\_DCL

(MariaDB Audit Plugin >=1.3.0)
- - CONNECT
  - ,
  - QUERY
  - ,
  - TABLE
  - ,
  - QUERY\_DDL
  - ,
  - QUERY\_DML
  - ,
  - QUERY\_DCL
  - ,
  - QUERY\_DML\_NO\_SELECT

(MariaDB Audit Plugin >= 1.4.4)

◦ See [MariaDB Audit Plugin - Versions](#) to determine which MariaDB releases contain each MariaDB Audit Plugin versions.

---

### server\_audit\_excl\_users

- **Description:** If not empty, it contains the list of users whose activity will NOT be logged. For example:

```
SET GLOBAL server_audit_excl_users='user_foo, user_bar'
```

. CONNECT records aren't affected by this variable - they are always logged. The user is still logged if it's specified in [server\\_audit\\_incl\\_users](#).

- **Commandline:**

```
--server-audit-excl-users=value
```

- **Scope:** Global

- **Dynamic:** Yes

- **Data Type:**

string

- **Default Value:** Empty string

- **Size limit:** 1024 characters

---

## server\_audit\_file\_path

- **Description:** When `server_audit_output_type=file`, sets the path and the filename to the log file. If the specified path exists as a directory, then the log will be created inside that directory with the name 'server\_audit.log'. Otherwise the value is treated as a filename. The default value is 'server\_audit.log', which means this file will be created in the database directory.

- **Commandline:**

```
--server-audit-file-path=value
```

- **Scope:** Global

- **Dynamic:** Yes

- **Data Type:**

string

- **Default Value:**

server\_audit.log

---

## server\_audit\_file\_rotate\_now

- **Description:** When `server_audit_output_type=file`, the user can force the log file rotation by setting this variable to ON or 1.

- **Commandline:**

```
--server-audit-rotate-now[={0|1}]
```

- **Scope:** Global

- **Dynamic:** Yes

- **Data Type:**

boolean

- **Default Value:**

OFF

---

## server\_audit\_file\_rotate\_size

- **Description:** When `server_audit_output_type=file`, it limits the size of the log file to the given amount of bytes. Reaching that limit turns on the rotation - the current log file is renamed as 'file\_path.1'. The empty log file is created as 'file\_path' to log into it. The default value is 1000000.

- **Commandline:**

```
--server-audit-rotate-size=#
```

- **Scope:** Global

- **Dynamic:** Yes

- **Data Type:**

numeric

- **Default Value:**

1000000

- **Range:**

100  
to  
9223372036854775807

---

## server\_audit\_file\_rotations

- **Description:** When `server_audit_output_type=file`', this specifies the number of rotations to save. If set to 0 then the log never rotates. The default value is 9.

- **Commandline:**

```
--server-audit-rotations=#
```

- **Scope:** Global
- **Dynamic:** Yes
- **Data Type:**  
numeric

- **Default Value:**

9

- **Range:**

0  
to  
999

---

### server\_audit\_incl\_users

- **Description:** If not empty, it contains a comma-delimited list of users whose activity will be logged. For example:

```
SET GLOBAL server_audit_incl_users='user_foo, user_bar'  
. CONNECT records aren't affected by this variable - they are always logged. This setting has higher priority than  
server_audit_excl_users . So if the same user is specified both in incl_ and excl_ lists, they will still be logged.
```

- **Commandline:**

--server-audit-incl-users=value

- **Scope:** Global
- **Dynamic:** Yes
- **Data Type:**  
string

- **Default Value:** Empty string
- **Size limit:** 1024 characters

---

### server\_audit\_loc\_info

- **Description:** Used by plugin internals. It has no useful meaning to users.

- In earlier versions, users see it as a read-only variable.
- In later versions, it is hidden from the user.

- **Commandline:** N/A
- **Scope:** Global
- **Dynamic:** No
- **Data Type:**  
string

- **Default Value:** Empty string
- **Introduced:** MariaDB 10.1.12 , MariaDB 10.0.24 , MariaDB 5.5.48
- **Hidden:** MariaDB 10.1.18 , MariaDB 10.0.28 , MariaDB 5.5.53

---

### server\_audit\_logging

- **Description:** Enables/disables the logging. Expected values are ON/OFF. For example:

```
SET GLOBAL server_audit_logging=on
```

If the server\_audit\_output\_type is FILE, this will actually create/open the logfile so the server\_audit\_file\_path should be properly specified beforehand. Same about the SYSLOG-related parameters. The logging is turned off by default.

- **Commandline:**

--server-audit-logging[={0|1}]

- **Scope:** Global
- **Dynamic:** Yes
- **Data Type:**  
boolean

- **Default Value:**

---

## server\_audit\_mode

- **Description:** This variable doesn't have any distinctive meaning for a user. Its value mostly reflects the server version with which the plugin was started and is intended to be used by developers for testing.

- **Commandline:**

```
--server-audit-mode[=#]
```

- **Scope:** Global

- **Dynamic:** Yes

- **Data Type:**

```
numeric
```

- **Default Value:**

```
0
```

- **Range:**

```
0
```

```
to
```

```
1
```

---

## server\_audit\_output\_type

- **Description:** Specifies the desired output type. Can be SYSLOG, FILE or null as no output. For example:

```
SET GLOBAL server_audit_output_type=file
```

file: log records will be saved into the rotating log file. The name of the file set by [server\\_audit\\_file\\_path](#) variable. syslog: log records will be sent to the local syslogd daemon with the standard <syslog.h> API. The default value is 'file'.

- **Commandline:**

```
--server-audit-output-type=value
```

- **Scope:** Global

- **Dynamic:** Yes

- **Data Type:**

```
enum
```

- **Default Value:**

```
file
```

- **Valid Values:**

```
SYSLOG
```

```
,
```

```
FILE
```

---

## server\_audit\_query\_log\_limit

- **Description:** Limit on the length of the query string in a record.

- **Commandline:**

```
--server-audit-query-log-limit=#
```

- **Scope:** Global

- **Dynamic:** Yes

- **Data Type:**

```
numeric
```

- **Default Value:**

```
1024
```

- **Range:**

0  
to  
2147483647

---

### server\_audit\_syslog\_facility

- **Description:** SYSLOG-mode variable. It defines the 'facility' of the records that will be sent to the syslog. Later the log can be filtered by this parameter.

- **Commandline:**

```
--server-audit-syslog-facility=value
```

- **Scope:** Global

- **Dynamic:** Yes

- **Data Type:**

enum

- **Default Value:**

LOG\_USER

- **Valid Values:**

```
LOG_USER
,
LOG_MAIL
,
LOG_DAEMON
,
LOG_AUTH
,
LOG_SYSLOG
,
LOG_LPR
,
LOG_NEWS
,
LOG_UUCP
,
LOG_CRON
,
LOG_AUTHPRIV
,
LOG_FTP
, and
LOG_LOCAL0
-
LOG_LOCAL7
```

---

### server\_audit\_syslog\_ident

- **Description:** SYSLOG-mode variable. String value for the 'ident' part of each syslog record. Default value is 'mysql-server\_auditing'. New value becomes effective only after restarting the logging.

- **Commandline:**

```
--server-audit-syslog-ident=value
```

- **Scope:** Global

- **Dynamic:** Yes

- **Data Type:**

string

- **Default Value:**

mysql-server\_auditing

---

## server\_audit\_syslog\_info

- **Description:** SYSLOG-mode variable. The 'info' string to be added to the syslog records. Can be changed any time.
  - **Commandline:**  
--server-audit-syslog-info=value
  - **Scope:** Global
  - **Dynamic:** Yes
  - **Data Type:**  
string
  - **Default Value:** Empty string
- 

## server\_audit\_syslog\_priority

- **Description:** SYSLOG-mode variable. Defines the priority of the log records for the syslogd.
  - **Commandline:**  
--server-audit-syslog-priority=value
  - **Scope:** Global
  - **Dynamic:** Yes
  - **Data Type:**  
enum
  - **Default Value:**  
LOG\_INFO
  - **Valid Values:**  
LOG\_EMERG  
,  
LOG\_ALERT  
,  
LOG\_CRIT  
,  
LOG\_ERR  
,  
LOG\_WARNING  
,  
LOG\_NOTICE  
,  
LOG\_INFO  
,  
LOG\_DEBUG
- 

## Options

### server\_audit

- **Description:** Controls how the server should treat the plugin when the server starts up.
    - Valid values are:
      - OFF
        - Disables the plugin without removing it from the `mysql.plugins` table.
      - ON
        - Enables the plugin. If the plugin cannot be initialized, then the server will still continue starting up, but the plugin will be disabled.
-

FORCE

- Enables the plugin. If the plugin cannot be initialized, then the server will fail to start with an error.

FORCE\_PLUS\_PERMANENT

- Enables the plugin. If the plugin cannot be initialized, then the server will fail to start with an error. In addition, the plugin cannot be uninstalled with

UNINSTALL SONAME

or

UNINSTALL PLUGIN

while the server is running.

- See [MariaDB Audit Plugin - Installation: Prohibiting Uninstallation](#) for more information on one use case.
- See [Plugin Overview: Configuring Plugin Activation at Server Startup](#) for more information.

- **Commandline:**

--server-audit=val

- **Data Type:**

enumerated

- **Default Value:**

ON

- **Valid Values:**

OFF

,

ON

,

FORCE

,

FORCE\_PLUS\_PERMANENT

## 4.4.4.8 MariaDB Audit Plugin - Status Variables

### Contents

1. Status Variables
  1. [Server\\_audit\\_active](#)
  2. [Server\\_audit\\_current\\_log](#)
  3. [Server\\_audit\\_last\\_error](#)
  4. [Server\\_audit\\_writes\\_failed](#)

There are a few status variables related to the [MariaDB Audit Plugin](#), once it has been [installed](#). These variables can be displayed using the [SHOW STATUS](#) statement like so:

```
SHOW STATUS LIKE 'server_audit%';

+-----+-----+
| Variable_name      | Value   |
+-----+-----+
| Server_audit_active | ON
| Server_audit_current_log | server_audit.log
| Server_audit_last_error | 
| Server_audit_writes_failed | 0
+-----+-----+
```

### Status Variables

Below is a list of all status variables related to the Audit Plugin. These cannot be set: These are not to be confused with system variables, which can be set. See [Server Status Variables](#) for a complete list of status variables that can be viewed with the [SHOW STATUS](#) statement. See also the [Full list of MariaDB options, system and status variables](#).

#### Server\_audit\_active

- **Description:** If the auditing is actually working. It gets the ON value when the logging is successfully started. Then it can get the OFF value if the logging was stopped or log records can't be properly stored due to file or syslog errors.

- **Data Type:**

boolean

---

#### Server\_audit\_current\_log

- **Description:** The name of the logfile or the SYSLOG parameters that are in current use.

- **Data Type:**

string

---

#### Server\_audit\_last\_error

- **Description:** If something went wrong with the logging here you can see the message.

- **Data Type:**

string

---

#### Server\_audit\_writes\_failed

- **Description:** The number of log records since last logging-start that weren't properly stored because of errors of any kind. The global value can be flushed by

[FLUSH STATUS](#)

- **Data Type:**

numeric

- **Default Value:**

0

---

## 4.4.5 Authentication Plugins

When a user attempts to log in, the authentication plugin controls how MariaDB Server determines whether the connection is from a legitimate user.

When creating or altering a user account with the [GRANT](#), [CREATE USER](#) or [ALTER USER](#) statements, you can specify the authentication plugin you want the user account to use by providing the `IDENTIFIED VIA` clause. By default, when you create a user account without specifying an authentication plugin, MariaDB uses the [mysql\\_native\\_password](#) plugin.

MariaDB starting with [10.4](#)

In [MariaDB 10.4](#) and later, there are some notable changes, such as:

- You can specify multiple authentication plugins for each user account.
- The `root@localhost` user created by [mysql\\_install\\_db](#) is created with the ability to use two authentication plugins. First, it is configured to try to use the `unix_socket` authentication plugin. This allows the `root@localhost` user to login without a password via the local Unix socket file defined by the `socket` system variable, as long as the login is attempted from a process owned by the operating system `root` user account. Second, if authentication fails with the `unix_socket` authentication plugin, then it is configured to try to use the [mysql\\_native\\_password](#) authentication plugin. However, an invalid password is initially set, so in order to authenticate this way, a password must be set with [SET PASSWORD](#).

### Pluggable Authentication Overview

*The authentication of users is delegated to plugins.*

### Authentication Plugin - mysql\_native\_password

*Uses the password hashing algorithm introduced in MySQL 4.1.*

### Authentication Plugin - mysql\_old\_password

*The mysql\_old\_password authentication plugin uses the pre-MySQL 4.1 password hashing algorithm.*

### Authentication Plugin - ed25519

Uses the Elliptic Curve Digital Signature Algorithm to securely store users' passwords.

### Authentication Plugin - GSSAPI

The gssapi authentication plugin uses the GSSAPI interface to authenticate with Kerberos or NTLM.

### Authentication with Pluggable Authentication Modules (PAM)

Uses the Pluggable Authentication Module (PAM) framework to authenticate MariaDB users.

### Authentication Plugin - Unix Socket

Uses the user name that owns the process connected to MariaDB's unix socket file.

### Authentication Plugin - Named Pipe

Uses the user name that owns the process connected to MariaDB's named pipe on Windows.

### Authentication Plugin - SHA-256

MySQL supports the sha256\_password and caching\_sha2\_password authentication plugins.

There are 1 related questions .

When a user attempts to log in, the authentication plugin controls how MariaDB Server determines whether the connection is from a legitimate user.

When creating or altering a user account with the GRANT , CREATE USER or ALTER USER statements, you can specify the authentication plugin you want the user account to use by providing the

IDENTIFIED VIA

clause. By default, when you create a user account without specifying an authentication plugin, MariaDB uses the mysql\_native\_password plugin.

In MariaDB 10.4 and later, there are some notable changes, such as:

- You can specify multiple authentication plugins for each user account.

- The

```
root@localhost
```

user created by `mysql_install_db` is created with the ability to use two authentication plugins. First, it is configured to try to use the `unix_socket` authentication plugin. This allows the the

```
root@localhost
```

user to login without a password via the local Unix socket file defined by the `socket` system variable, as long as the login is attempted from a process owned by the operating system

```
root
```

user account. Second, if authentication fails with the `unix_socket` authentication plugin, then it is configured to try to use the `mysql_native_password` authentication plugin. However, an invalid password is initially set, so in order to authenticate this way, a password must be set with `SET PASSWORD`.

## Supported Authentication Plugins

The authentication process is a conversation between the server and a client. MariaDB implements both server-side and client-side authentication plugins.

### Supported Server Authentication Plugins

MariaDB provides seven server-side authentication plugins:

- `mysql_native_password`
- `mysql_old_password`
- `ed25519`
- `gssapi`
- `pam` (Unix only)
- `unix_socket` (Unix only)
- `named_pipe` (Windows only)

### Supported Client Authentication Plugins

MariaDB provides eight client-side authentication plugins:

- `mysql_native_password`
- `mysql_old_password`
- `client_ed25519`
- `auth_gssapi_client`
- `dialog`
- `mysql_clear_password`
- `sha256_password`
- `caching_sha256_password`

## Options Related to Authentication Plugins

### Server Options Related to Authentication Plugins

MariaDB supports the following server options related to authentication plugins:

Server Option	Description
<code>old_passwords={1   0}</code>	If set to 1 ( 0 is default), MariaDB reverts to using the <code>mysql_old_password</code> authentication plugin by default for newly created users and passwords, instead of the <code>mysql_native_password</code> authentication plugin.
<code>plugin_dir=path</code>	Path to the <code>plugin</code> directory. For security reasons, either make sure this directory can only be read by the server, or set <code>secure_file_priv</code> .

<code>plugin_maturity=level</code>	The lowest acceptable <a href="#">plugin</a> maturity. MariaDB will not load plugins less mature than the specified level.
<code>secure_auth</code>	Connections will be blocked if they use the the <a href="#">mysql_old_password</a> authentication plugin. The server will also fail to start if the privilege tables are in the old, pre-MySQL 4.1 format.

## Client Options Related to Authentication Plugins

Most [clients and utilities](#) support some command line arguments related to client authentication plugins:

Client Option	Description
<code>--connect-expired-password</code>	Notify the server that this client is prepared to handle <a href="#">expired password sandbox mode</a> even if <code>--batch</code> was specified. From <a href="#">MariaDB 10.4.3</a> .
<code>--default-auth=name</code>	Default authentication client-side plugin to use.
<code>--plugin-dir=path</code>	Directory for client-side plugins.
<code>--secure-auth</code>	Refuse to connect to the server if the server uses the <a href="#">mysql_old_password</a> authentication plugin. This mode is off by default, which is a difference in behavior compared to MySQL 5.6 and later, where it is on by default.

Developers who are using [MariaDB Connector/C](#) can implement similar functionality in their application by setting the following options with the `mysql_optionsv` function:

- `MYSQL_OPT_CAN_HANDLE_EXPIRED_PASSWORDS`
- `MYSQL_PLUGIN_DIR`
- `MYSQL_DEFAULT_AUTH`
- `MYSQL_SECURE_AUTH`

For example:

```
mysql_optionsv(mysql, MYSQL_OPT_CAN_HANDLE_EXPIRED_PASSWORDS, 1);
mysql_optionsv(mysql, MYSQL_DEFAULT_AUTH, "name");
mysql_optionsv(mysql, MYSQL_PLUGIN_DIR, "path");
mysql_optionsv(mysql, MYSQL_SECURE_AUTH, 1);
```

## Installation Options Related to Authentication Plugins

[mysql\\_install\\_db](#) supports the following installation options related to authentication plugins:

Installation Option	Description
---------------------	-------------

--auth-root- authentication-method={normal   socket}  user=USER --auth-root-socket-	If set to normal , it creates a root@localhost account that authenticates with the <a href="#">mysql_native_password</a> authentication plugin and that has no initial password set, which can be insecure. If set to socket , it creates a root@localhost account that authenticates with the <a href="#">unix_socket</a> authentication plugin. Set to normal by default. Available since <a href="#">MariaDB 10.1</a> .  Used with --auth-root-authentication-method=socket . It specifies the name of the second account to create with <a href="#">SUPER</a> privileges in addition to root , as well as of the system account allowed to access it. Defaults to the value of --user .
-------------------------------------------------------------------------------------------------------	------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------

## Extended SQL Syntax

MariaDB has extended the SQL standard [GRANT](#), [CREATE USER](#), and [ALTER USER](#) statements, so that they support specifying different authentication plugins for specific users. An authentication plugin can be specified with these statements by providing the

IDENTIFIED VIA  
clause.

For example, the [GRANT](#) syntax is:

```
GRANT <privileges> ON <level> TO <user>  
IDENTIFIED VIA <plugin> [ USING <string> ]
```

And the [CREATE USER](#) syntax is:

```
CREATE USER <user>  
IDENTIFIED VIA <plugin> [ USING <string> ]
```

And the [ALTER USER](#) syntax is:

```
ALTER USER <user>  
IDENTIFIED VIA <plugin> [ USING <string> ]
```

The optional

USING  
clause allows users to provide an authentication string to a plugin. The authentication string's format and meaning is completely defined by the plugin.

For example, for the [mysql\\_native\\_password](#) authentication plugin, the authentication string should be a password hash:

```
CREATE USER mysqltest_up1  
IDENTIFIED VIA mysql_native_password USING '*E8D46CE25265E545D225A8A6F1BAF642FEBEE5CB';
```

Since [mysql\\_native\\_password](#) is the default authentication plugin, the above is just another way of saying the following:

```
CREATE USER mysqltest_up1  
IDENTIFIED BY PASSWORD '*E8D46CE25265E545D225A8A6F1BAF642FEBEE5CB';
```

In contrast, for the [pam](#) authentication plugin, the authentication string should refer to a [PAM service name](#):

```
CREATE USER mysqltest_up1  
IDENTIFIED VIA pam USING 'mariadb';
```

MariaDB starting with 10.4

In [MariaDB 10.4](#) and later, a user account can be associated with multiple authentication plugins.

For example, to configure the

root@localhost  
user account to try the [unix\\_socket](#) authentication plugin, followed by the [mysql\\_native\\_password](#) authentication plugin as a backup, you

could execute the following:

```
CREATE USER root@localhost
IDENTIFIED VIA unix_socket
OR mysql_native_password USING PASSWORD("verysecret");
```

See [Authentication from MariaDB 10.4](#) for more information.

## Authentication Plugins Installed by Default

### Server Authentication Plugins Installed by Default

Not all server-side authentication plugins are installed by default. If a specific server-side authentication plugin is not installed by default, then you can find the installation procedure on the documentation page for the specific authentication plugin.

MariaDB starting with [10.4](#)

In [MariaDB 10.4](#) and later, the following server-side authentication plugins are installed by default:

- The `mysql_native_password` and `mysql_old_password` authentication plugins are installed by default in all builds.
- The `unix_socket` authentication plugin is installed by default in all builds on Unix and Linux.
- The `named_pipe` authentication plugin is installed by default in all builds on Windows.

MariaDB until [10.3](#)

In [MariaDB 10.3](#) and below, the following server-side authentication plugins are installed by default:

- The `mysql_native_password` and `mysql_old_password` authentication plugins are installed by default in all builds.
- The `unix_socket` authentication plugin is installed by default in **new installations** that use the `.deb` packages provided by Debian's default repositories in Debian 9 and later and Ubuntu's default repositories in Ubuntu 15.10 and later. See [Differences in MariaDB in Debian \(and Ubuntu\)](#) for more information.
- The `named_pipe` authentication plugin is installed by default in all builds on Windows.

## Client Authentication Plugins Installed by Default

Client-side authentication plugins do not need to be *installed* in the same way that server-side authentication plugins do. If the client uses either the `libmysqlclient` or [MariaDB Connector/C](#) library, then the library automatically loads client-side authentication plugins from the library's plugin directory whenever they are needed.

Most [clients and utilities](#) support the

```
--plugin-dir
```

command line argument that can be used to set the path to the library's plugin directory:

Client Option	Description
<code>--plugin-dir=path</code>	Directory for client-side plugins.

Developers who are using [MariaDB Connector/C](#) can implement similar functionality in their application by setting the `MYSQL_PLUGIN_DIR` option with the `mysql_optionsv` function.

For example:

```
mysql_optionsv(mysql, MYSQL_PLUGIN_DIR, "path");
```

If your client encounters errors similar to the following, then you may need to set the path to the library's plugin directory:

```
ERROR 2059 (HY000): Authentication plugin 'dialog' cannot be loaded: /usr/lib/mysql/plugin/dialog.so: cannot open shared object
```

If the client does **not** use either the

`libmysqlclient` or [MariaDB Connector/C](#) library, then you will have to determine which authentication plugins are supported by the specific client library used by the client.

If the client uses either the `libmysqlclient` or [MariaDB Connector/C](#) library, but the client is not bundled with either library's *optional* client authentication plugins, then you can only use the conventional authentication plugins (like `mysql_native_password` and `mysql_old_password`) and the non-conventional authentication plugins that don't require special client-side authentication plugins (like `unix_socket` and `named_pipe`).

## Default Authentication Plugin

### Default Server Authentication Plugin

The `mysql_native_password` authentication plugin is currently the default authentication plugin in all versions of MariaDB if the `old_passwords` system variable is set to

`0`, which is the default.

On a system with the `old_passwords` system variable set to

`0`, this means that if you create a user account with either the `GRANT` or `CREATE USER` statements, and if you do not specify an authentication plugin with the `IDENTIFIED VIA` clause, then MariaDB will use the

`mysql_native_password`

authentication plugin for the user account.

For example, this user account will use the `mysql_native_password` authentication plugin:

```
CREATE USER username@hostname;
```

And so will this user account:

```
CREATE USER username@hostname IDENTIFIED BY 'notagoodpassword';
```

The `mysql_old_password` authentication plugin becomes the default authentication plugin in all versions of MariaDB if the `old_passwords` system variable is explicitly set to

`1`.

However, the `mysql_old_password` authentication plugin is not considered secure, so it is recommended to avoid using this authentication plugin. To help prevent undesired use of the `mysql_old_password` authentication plugin, the server supports the `secure_auth` system variable that can be used to configured the server to refuse connections that try to use the `mysql_old_password` authentication plugin:

Server Option	Description
<code>old_passwords={1   0}</code>	If set to <code>1</code> <code>(</code> <code>0</code> is default), MariaDB reverts to using the <code>mysql_old_password</code> authentication plugin by default for newly created users and passwords, instead of the <code>mysql_native_password</code> authentication plugin.
<code>secure_auth</code>	Connections will be blocked if they use the the <code>mysql_old_password</code> authentication plugin. The server will also fail to start if the privilege tables are in the old, pre-MySQL 4.1 format.

Most [clients and utilities](#) also support the

`--secure-auth`

command line argument that can also be used to configure the client to refuse to connect to servers that use the `mysql_old_password` authentication plugin:

Client Option	Description
<code>--secure-auth</code>	Refuse to connect to the server if the server uses the <code>mysql_old_password</code> authentication plugin. This mode is off by default, which is a difference in behavior compared to MySQL 5.6 and later, where it is on by default.

Developers who are using [MariaDB Connector/C](#) can implement similar functionality in their application by setting the `MYSQL_SECURE_AUTH` option with the [mysql\\_optionsv](#) function.

For example:

```
mysql_optionsv(mysql, MYSQL_SECURE_AUTH, 1);
```

## Default Client Authentication Plugin

The default client-side authentication plugin depends on a few factors.

If a client doesn't explicitly set the default client-side authentication plugin, then the client will determine which authentication plugin to use by checking the length of the scramble in the server's handshake packet.

If the server's handshake packet contains a 9-byte scramble, then the client will default to the [mysql\\_old\\_password](#) authentication plugin.

If the server's handshake packet contains a 20-byte scramble, then the client will default to the [mysql\\_native\\_password](#) authentication plugin.

### Setting the Default Client Authentication Plugin

Most [clients and utilities](#) support the

```
--default-auth  
command line argument that can be used to set the default client-side authentication plugin:
```

Client Option	Description
<code>--default-auth=name</code>	Default authentication client-side plugin to use.

Developers who are using [MariaDB Connector/C](#) can implement similar functionality in their application by setting the `MYSQL_DEFAULT_AUTH` option with the [mysql\\_optionsv](#) function.

For example:

```
mysql_optionsv(mysql, MYSQL_DEFAULT_AUTH, "name");
```

If you know that your user account is configured to require a client-side authentication plugin that isn't [mysql\\_old\\_password](#) or [mysql\\_native\\_password](#), then it can help speed up your connection process to explicitly set the default client-side authentication plugin.

According to the [client-server protocol](#), the server first sends the handshake packet to the client, then the client replies with a packet containing the user name of the user account that is requesting access. The server handshake packet initially tells the client to use the default server authentication plugin, and the client reply initially tells the server that it will use the default client authentication plugin.

However, the server-side and client-side authentication plugins mentioned in these initial packets may not be the correct ones for this specific user account. The server only knows what authentication plugin to use for this specific user account after reading the user name from the client reply packet and finding the appropriate row for the user account in either the [mysql.user](#) table or the [mysql.global\\_priv](#) table, depending on the MariaDB version.

If the server finds that either the server-side or client-side default authentication plugin does not match the actual authentication plugin that should be used for the given user account, then the server restarts the authentication on either the server side or the client side.

This means that, if you know what client authentication plugin your user account requires, then you can avoid an unnecessary authentication restart and you can save two packets and two round-trips between the client and server by configuring your client to use the correct authentication plugin by default.

## Authentication Plugins

### Server Authentication Plugins

#### `mysql_native_password`

The [mysql\\_native\\_password](#) authentication plugin uses the password hashing algorithm introduced in MySQL 4.1, which is also used by the [PASSWORD\(\)](#) function when

```
old_passwords=0
```

is set. This hashing algorithm is based on

```
SHA-1
```

## `mysql_old_password`

The `mysql_old_password` authentication plugin uses the pre-MySQL 4.1 password hashing algorithm, which is also used by the `OLD_PASSWORD()` function and by the `PASSWORD()` function when `old_passwords=1` is set.

## `ed25519`

The `ed25519` authentication plugin uses [Elliptic Curve Digital Signature Algorithm](#) to securely store users' passwords and to authenticate users. The `ed25519` algorithm is the same one that is [used by OpenSSH](#). It is based on the elliptic curve and code created by [Daniel J. Bernstein](#).

From a user's perspective, the `ed25519` authentication plugin still provides conventional password-based authentication.

## `gssapi`

The `gssapi` authentication plugin allows the user to authenticate with services that use the [Generic Security Services Application Program Interface \(GSSAPI\)](#). Windows has a slightly different but very similar API called [Security Support Provider Interface \(SSPI\)](#).

On Windows, this authentication plugin supports [Kerberos](#) and [NTLM](#) authentication. Windows authentication is supported regardless of whether a [domain](#) is used in the environment.

On Unix systems, the most dominant GSSAPI service is [Kerberos](#). However, it is less commonly used on Unix systems than it is on Windows. Regardless, this authentication plugin also supports Kerberos authentication on Unix.

The `gssapi` authentication plugin is most often used for authenticating with [Microsoft Active Directory](#).

## `pam`

The `pam` authentication plugin allows MariaDB to offload user authentication to the system's [Pluggable Authentication Module \(PAM\)](#) framework. PAM is an authentication framework used by Linux, FreeBSD, Solaris, and other Unix-like operating systems.

## `unix_socket`

The `unix_socket` authentication plugin allows the user to use operating system credentials when connecting to MariaDB via the local Unix socket file. This Unix socket file is defined by the `socket` system variable.

The `unix_socket` authentication plugin works by calling the `getsockopt` system call with the `SO_PEERCRED` socket option, which allows it to retrieve the `uid` of the process that is connected to the socket. It is then able to get the user name associated with that `uid`. Once it has the user name, it will authenticate the connecting user as the MariaDB account that has the same user name.

For example:

```
$ mysql -uroot
MariaDB []> CREATE USER serg IDENTIFIED VIA unix_socket;
MariaDB []> CREATE USER monty IDENTIFIED VIA unix_socket;
MariaDB []> quit
Bye
$ whoami
serg
$ mysql --user=serg
Welcome to the MariaDB monitor. Commands end with ; or \g.
Your MariaDB connection id is 2
Server version: 5.2.0-MariaDB-alpha-debug Source distribution
MariaDB []> quit
Bye
$ mysql --user=monty
ERROR 1045 (28000): Access denied for user 'monty'@'localhost' (using password: NO)
```

In this example, a user

serg

is already logged into the operating system and has full shell access. He has already authenticated with the operating system and his MariaDB account is configured to use the [unix\\_socket](#) authentication plugin, so he does not need to authenticate again for the database. MariaDB accepts his operating system credentials and allows him to connect. However, any attempt to connect to the database as another operating system user will be denied.

### named\_pipe

The [named\\_pipe](#) authentication plugin allows the user to use operating system credentials when connecting to MariaDB via named pipe on Windows. Named pipe connections are enabled by the [named\\_pipe](#) system variable.

The [named\\_pipe](#) authentication plugin works by using [named pipe impersonation](#) and calling

GetUserName()

to retrieve the user name of the process that is connected to the named pipe. Once it has the user name, it authenticates the connecting user as the MariaDB account that has the same user name.

For example:

```
CREATE USER wlad IDENTIFIED VIA named_pipe;
CREATE USER monty IDENTIFIED VIA named_pipe;
quit

C:\>echo %USERNAME%
wlad

C:\> mysql --user=wlad --protocol=PIPE
Welcome to the MariaDB monitor. Commands end with ; or \g.
Your MariaDB connection id is 4
Server version: 10.1.12-MariaDB-debug Source distribution

Copyright (c) 2000, 2015, Oracle, MariaDB Corporation Ab and others.

Type 'help;' or '\h' for help. Type '\c' to clear the current input statement.

MariaDB [(none)]> quit
Bye

C:\> mysql --user=monty --protocol=PIPE
ERROR 1698 (28000): Access denied for user 'monty'@'localhost'
```

## Authentication Plugin API

The authentication plugin API is extensively documented in the [source code](#) in the following files:

- [mysql/plugin\\_auth.h](#)  
(server part)
- [mysql/client\\_plugin.h](#)  
(client part)
- [mysql/plugin\\_auth\\_common.h](#)  
(common parts)

The MariaDB [source code](#) also contains some authentication plugins that are intended explicitly to be examples for developers. They are located in [plugin/auth\\_examples](#)

The definitions of two example authentication plugins called

two\_questions  
and  
three\_attempts  
can be seen in  
[plugin/auth\\_examples/dialog\\_examples.c](#).  
. These authentication plugins demonstrate how to communicate with the user using the [dialog](#) client authentication plugin.

The

two\_questions  
authentication plugin asks the user for a password and a confirmation ("Are you sure?").

The

three\_attempts  
authentication plugin gives the user three attempts to enter a correct password.

The password for both of these plugins should be specified in the plain text in the

USING  
clause:

```
CREATE USER insecure IDENTIFIED VIA two_questions USING 'notverysecret';
```

## Dialog Client Authentication Plugin - Client Library Extension

The [dialog](#) client authentication plugin, strictly speaking, is not part of the client-server or authentication plugin API. But it can be loaded into any client application that uses the

`libmysqlclient`  
or [MariaDB Connector/C](#) libraries. This authentication plugin provides a way for the application to customize the UI of the dialog function.

In order to use the [dialog](#) client authentication plugin to communicate with the user in a customized way, the application will need to implement a function with the following signature:

```
extern "C" char *mysql_authentication_dialog_ask(  
    MYSQL *mysql, int type, const char *prompt, char *buf, int buf_len)
```

The function takes the following arguments:

- The connection handle.
- A question "type", which has one of the following values:
  - 1
    - Normal question
  - 2
    - Password (no echo)
- A prompt.
- A buffer.
- The length of the buffer.

The function returns a pointer to a string of characters, as entered by the user. It may be stored in

`buf`  
or allocated with  
`malloc()`

Using this function a GUI application can pop up a dialog window, a network application can send the question over the network, as required. If no

`mysql_authentication_dialog_ask`  
function is provided by the application, the [dialog](#) client authentication plugin falls back to `fputs()` and `fgets()`.

Providing this callback is particularly important on Windows, because Windows GUI applications have no associated console and the default dialog function will not be able to reach the user. An example of Windows GUI client that does it correctly is [HeidiSQL](#).

## 4.4.5.2 Authentication Plugin - mysql\_native\_password

The

`mysql_native_password`

authentication plugin is the default authentication plugin that will be used for an account created when no authentication plugin is explicitly mentioned and `old_passwords=0` is set. It uses the password hashing algorithm introduced in MySQL 4.1, which is also used by the `PASSWORD()` function when `old_passwords=0` is set. This hashing algorithm is based on `SHA-1`.

It is not recommended to use the

`mysql_native_password`

authentication plugin for new installations that require **high password security**. If someone is able to both listen to the connection protocol and get a copy of the `mysql.user` table, then the person would be able to use this information to connect to the MariaDB server. The [ed25519](#) authentication plugin is a more modern authentication plugin that provides simple password authentication using a more secure algorithm.

## Contents

  1. [mysql\\_native\\_password](#)
5. [Support in Client Libraries](#)
6. [Known Old Issues \(Only Relevant for Old Installations\)](#)
  1. [Mismatches Between Password and authentication\\_string Columns](#)
7. [See Also](#)

## Installing the Plugin

The

```
mysql_native_password
```

authentication plugin is statically linked into the server, so no installation is necessary.

## Creating Users

The easiest way to create a user account with the

```
mysql_native_password
```

authentication plugin is to make sure that `old_passwords=0` is set, and then create a user account via `CREATE USER` that does not specify an authentication plugin, but does specify a password via the `IDENTIFIED BY` clause. For example:

```
SET old_passwords=0;
CREATE USER username@hostname IDENTIFIED BY 'mariadb';
```

If `SQL_MODE` does not have

```
NO_AUTO_CREATE_USER
```

set, then you can also create the user account via `GRANT`. For example:

```
SET old_passwords=0;
GRANT SELECT ON db.* TO username@hostname IDENTIFIED BY 'mariadb';
```

You can also create the user account by providing a password hash via the `IDENTIFIED BY PASSWORD` clause, and MariaDB will validate whether the password hash is one that is compatible with

```
mysql_native_password
```

. For example:

```
SET old_passwords=0;

SELECT PASSWORD('mariadb');
+-----+
| PASSWORD('mariadb')           |
+-----+
| *54958E764CE10E50764C2EECB71D01F08549980 |
+-----+

CREATE USER username@hostname
  IDENTIFIED BY PASSWORD '*54958E764CE10E50764C2EECB71D01F08549980';
```

Similar to all other `authentication plugins`, you could also specify the name of the plugin in the `IDENTIFIED VIA` clause while providing the password hash as the

```
USING
```

clause. For example:

```
CREATE USER username@hostname
  IDENTIFIED VIA mysql_native_password USING '*54958E764CE10E50764C2EECB71D01F08549980';
```

## Changing User Passwords

You can change a user account's password with the `SET PASSWORD` statement while providing the plain-text password as an argument to the `PASSWORD()` function. For example:

```
SET PASSWORD = PASSWORD('new_secret')
```

You can also change the user account's password with the `ALTER USER` statement. You would have to make sure that `old_passwords=0` is set, and then you would have to specify a password via the `IDENTIFIED BY` clause. For example:

```
SET old_passwords=0;
ALTER USER username@hostname IDENTIFIED BY 'new_secret';
```

## Client Authentication Plugins

For clients that use the

`libmysqlclient`  
or [MariaDB Connector/C](#) libraries, MariaDB provides one client authentication plugin that is compatible with the `mysql_native_password` authentication plugin:

- `mysql_native_password`

When connecting with a [client or utility](#) to a server as a user account that authenticates with the

`mysql_native_password` authentication plugin, you may need to tell the client where to find the relevant client authentication plugin by specifying the `--plugin-dir` option. For example:

```
mysql --plugin-dir=/usr/local/mysql/lib64/mysql/plugin --user=alice
```

However, the

`mysql_native_password` client authentication plugin is generally statically linked into client libraries like `libmysqlclient` or [MariaDB Connector/C](#), so this is not usually necessary.

### `mysql_native_password`

The

`mysql_native_password` client authentication plugin hashes the password before sending it to the server.

## Support in Client Libraries

The

`mysql_native_password` authentication plugin is one of the conventional authentication plugins, so all client libraries should support it.

## Known Old Issues (Only Relevant for Old Installations)

### Mismatches Between Password and `authentication_string` Columns

For compatibility reasons, the

`mysql_native_password` authentication plugin tries to read the password hash from both the `Password` and `authentication_string` columns in the `mysql.user` table. This has caused issues in the past if one of the columns had a different value than the other.

Starting with [MariaDB 10.2.19](#) and [MariaDB 10.3.11](#), `CREATE USER`, `ALTER USER`, `GRANT`, and `SET PASSWORD` will set both columns whenever an account's password is changed.

See [MDEV-16774](#) for more information.

## See Also

- [ed25519](#) secure connection plugin
- [History of MySQL and MariaDB authentication protocols](#)

## 4.4.5.3 Authentication Plugin - mysql\_old\_password

The

```
mysql_old_password
```

authentication plugin is the default authentication plugin that will be used for an account created when no authentication plugin is explicitly mentioned and

```
old_passwords=1
```

is set. It uses the pre-MySQL 4.1 password hashing algorithm, which is also used by the

```
OLD_PASSWORD()
```

function and by the

```
PASSWORD()
```

function when

```
old_passwords=1
```

is set.

It is not recommended to use the

```
mysql_old_password
```

authentication plugin for new installations. The password hashing algorithm is no longer as secure as it used to be, and the plugin is primarily provided for backward-compatibility. The

```
ed25519
```

authentication plugin is a more modern authentication plugin that provides simple password authentication.

### Contents

1. [Installing the Plugin](#)
2. [Creating Users](#)
3. [Changing User Passwords](#)
4. [Client Authentication Plugins](#)
  1. [mysql\\_old\\_password](#)
5. [Support in Client Libraries](#)

## Installing the Plugin

The

```
mysql_old_password
```

authentication plugin is statically linked into the server, so no installation is necessary.

## Creating Users

The easiest way to create a user account with the

```
mysql_old_password
```

authentication plugin is to make sure that

```
old_passwords=1
```

is set, and then create a user account via

```
CREATE USER
```

that does not specify an authentication plugin, but does specify a password via the

```
IDENTIFIED BY
```

clause. For example:

```
SET old_passwords=1;
CREATE USER username@hostname IDENTIFIED BY 'mariadb';
```

If

SQL\_MODE

does not have  
NO\_AUTO\_CREATE\_USER  
set, then you can also create the user via

GRANT

. For example:

```
SET old_passwords=1;
GRANT SELECT ON db.* TO username@hostname IDENTIFIED BY 'mariadb';
```

You can also create the user account by providing a password hash via the

IDENTIFIED BY PASSWORD

clause, and MariaDB will validate whether the password hash is one that is compatible with  
mysql\_old\_password

. For example:

```
SET old_passwords=1;
Query OK, 0 rows affected (0.000 sec)

SELECT PASSWORD('mariadb');
+-----+
| PASSWORD('mariadb') |
+-----+
| 021bec665bf663f1 |
+-----+
1 row in set (0.000 sec)

CREATE USER username@hostname IDENTIFIED BY PASSWORD '021bec665bf663f1';
Query OK, 0 rows affected (0.000 sec)
```

Similar to all other [authentication plugins](#), you could also specify the name of the plugin in the

IDENTIFIED VIA

clause while providing the password hash as the  
USING  
clause. For example:

```
CREATE USER username@hostname IDENTIFIED VIA mysql_old_password USING '021bec665bf663f1';
Query OK, 0 rows affected (0.000 sec)
```

## Changing User Passwords

You can change a user account's password with the

SET PASSWORD

statement while providing the plain-text password as an argument to the

PASSWORD()

function. For example:

```
SET PASSWORD = PASSWORD('new_secret')
```

You can also change the user account's password with the

ALTER USER

statement. You would have to make sure that

old\_passwords=1

is set, and then you would have to specify a password via the

`IDENTIFIED BY`

clause. For example:

```
SET old_passwords=1;
ALTER USER username@hostname IDENTIFIED BY 'new_secret';
```

## Client Authentication Plugins

For clients that use the

`libmysqlclient`  
or [MariaDB Connector/C](#) libraries, MariaDB provides one client authentication plugin that is compatible with the `mysql_old_password` authentication plugin:

- `mysql_old_password`

When connecting with a [client or utility](#) to a server as a user account that authenticates with the

`mysql_old_password` authentication plugin, you may need to tell the client where to find the relevant client authentication plugin by specifying the `--plugin-dir` option. For example:

```
mysql --plugin-dir=/usr/local/mysql/lib64/mysql/plugin --user=alice
```

However, the

`mysql_old_password` client authentication plugin is generally statically linked into client libraries like `libmysqlclient` or [MariaDB Connector/C](#), so this is not usually necessary.

### `mysql_old_password`

The

`mysql_old_password` client authentication plugin hashes the password before sending it to the server.

## Support in Client Libraries

The

`mysql_old_password` authentication plugin is one of the conventional authentication plugins, so all client libraries should support it.

### 4.4.5.4 Authentication Plugin - ed25519

MySQL has used SHA-1 based authentication since version 4.1. Since [MariaDB 5.2](#) this authentication plugin has been called

`mysql_native_password`

. Over the years as computers became faster, new attacks on SHA-1 were being developed. Nowadays SHA-1 is no longer considered as secure as it was in 2001. That's why the

`ed25519` authentication plugin was created.

The

`ed25519` authentication plugin uses [Elliptic Curve Digital Signature Algorithm \(ECDSA\)](#) to securely store users' passwords and to authenticate users. The `ed25519` algorithm is the same one that is [used by OpenSSH](#). It is based on the elliptic curve and code created by [Daniel J. Bernstein](#).

From a user's perspective, the

`ed25519` authentication plugin still provides conventional password-based authentication.

2. [Uninstalling the Plugin](#)
3. [Creating Users](#)
4. [Changing User Passwords](#)
5. [Client Authentication Plugins](#)
  1. [client\\_ed25519](#)
6. [Support in Client Libraries](#)
  1. [Using the Plugin with MariaDB Connector/C](#)
  2. [Using the Plugin with MariaDB Connector/ODBC](#)
  3. [Using the Plugin with MariaDB Connector/J](#)
  4. [Using the Plugin with MariaDB Connector/Node.js](#)
  5. [Using the Plugin with MySqlConnector for .NET](#)
7. [Versions](#)
8. [Options](#)
  1. [ed25519](#)

## Installing the Plugin

Although the plugin's shared library is distributed with MariaDB by default as

`auth_ed25519.so`

or

`auth_ed25519.dll`

depending on the operating system, the plugin is not actually installed by MariaDB by default. There are two methods that can be used to install the plugin with MariaDB.

The first method can be used to install the plugin without restarting the server. You can install the plugin dynamically by executing

`INSTALL SONAME`

or

`INSTALL PLUGIN`

. For example:

```
INSTALL SONAME 'auth_ed25519';
```

The second method can be used to tell the server to load the plugin when it starts up. The plugin can be installed this way by providing the

`--plugin-load`

or the

`--plugin-load-add`

options. This can be specified as a command-line argument to

`mysqld`

or it can be specified in a relevant server [option group](#) in an [option file](#). For example:

```
[mariadb]
...
plugin_load_add = auth_ed25519
```

## Uninstalling the Plugin

You can uninstall the plugin dynamically by executing

`UNINSTALL SONAME`

or

## UNINSTALL PLUGIN

. For example:

```
UNINSTALL SONAME 'auth_ed25519';
```

If you installed the plugin by providing the

```
--plugin-load
```

or the

```
--plugin-load-add
```

options in a relevant server [option group](#) in an [option file](#), then those options should be removed to prevent the plugin from being loaded the next time the server is restarted.

## Creating Users

MariaDB starting with [10.4](#)

In [MariaDB 10.4](#) and later, you can create a user account by executing the

```
CREATE USER
```

statement and providing the

```
IDENTIFIED VIA
```

clause followed by the the name of the plugin, which is  
ed25519  
, and providing the the  
USING  
clause followed by the

```
PASSWORD()
```

function with the plain-text password as an argument. For example:

```
CREATE USER username@hostname IDENTIFIED VIA ed25519 USING PASSWORD('secret');
```

If

```
SQL_MODE
```

does not have  
NO\_AUTO\_CREATE\_USER  
set, then you can also create the user account via

```
GRANT
```

. For example:

```
GRANT SELECT ON db.* TO username@hostname IDENTIFIED VIA ed25519 USING PASSWORD('secret');
```

MariaDB until [10.3](#)

In [MariaDB 10.3](#) and before, the

```
PASSWORD()
```

function and

```
SET PASSWORD
```

statement did not work with the  
ed25519  
authentication plugin. Instead, you would have to use the [UDF](#) that comes with the authentication plugin to calculate the password hash. For

example:

```
CREATE FUNCTION ed25519_password RETURNS STRING SONAME "auth_ed25519.so";
```

Now you can calculate a password hash by executing:

```
SELECT ed25519_password("secret");
+-----+
| SELECT ed25519_password("secret")           |
+-----+
| ZIgUREUg5PVgQ6LskhXm0+eZLS0nC8be6HPjYWR4YJY |
+-----+
```

Now you can use it to create the user account using the new password hash.

To create a user account via

[CREATE USER](#)

, specify the name of the plugin in the

[IDENTIFIED VIA](#)

clause while providing the password hash as the  
[USING](#)  
clause. For example:

```
CREATE USER username@hostname IDENTIFIED VIA ed25519 USING 'ZIgUREUg5PVgQ6LskhXm0+eZLS0nC8be6HPjYWR4YJY';
```

If

[SQL\\_MODE](#)

does not have

[NO\\_AUTO\\_CREATE\\_USER](#)

set, then you can also create the user account via

[GRANT](#)

. For example:

```
GRANT SELECT ON db.* TO username@hostname IDENTIFIED VIA ed25519 USING 'ZIgUREUg5PVgQ6LskhXm0+eZLS0nC8be6HPjYWR4YJY';
```

Note that users require a password in order to be able to connect. It is possible to create a user without specifying a password, but they will be unable to connect.

## Changing User Passwords

MariaDB starting with [10.4](#)

In [MariaDB 10.4](#) and later, you can change a user account's password by executing the

[SET PASSWORD](#)

statement followed by the

[PASSWORD\(\)](#)

function and providing the plain-text password as an argument. For example:

```
SET PASSWORD = PASSWORD('new_secret');
```

You can also change the user account's password with the

[ALTER USER](#)

statement. You would have to specify the name of the plugin in the

[IDENTIFIED VIA](#)

clause while providing the plain-text password as an argument to the

`PASSWORD()`

function in the

`USING`

clause. For example:

```
ALTER USER username@hostname IDENTIFIED VIA ed25519 USING PASSWORD('new_secret');
```

MariaDB until 10.3

In MariaDB 10.3 and before, the

`PASSWORD()`

function and

`SET PASSWORD`

statement did not work with the

`ed25519`

authentication plugin. Instead, you would have to use the [UDF](#) that comes with the authentication plugin to calculate the password hash. For example:

```
CREATE FUNCTION ed25519_password RETURNS STRING SONAME "auth_ed25519.so";
```

Now you can calculate a password hash by executing:

```
SELECT ed25519_password("secret");
+-----+
| SELECT ed25519_password("secret");      |
+-----+
| ZIgUREUg5PVgQ6LskhXm0+eZLS0nC8be6HPjYWR4YJY |
+-----+
```

Now you can change the user account's password using the new password hash.

You can change the user account's password with the

`ALTER USER`

statement. You would have to specify the name of the plugin in the

`IDENTIFIED VIA`

clause while providing the password hash as the

`USING`

clause. For example:

```
ALTER USER username@hostname IDENTIFIED VIA ed25519 USING 'ZIgUREUg5PVgQ6LskhXm0+eZLS0nC8be6HPjYWR4YJY';
```

## Client Authentication Plugins

For clients that use the

`libmysqlclient`

or [MariaDB Connector/C](#) libraries, MariaDB provides one client authentication plugin that is compatible with the

`ed25519`

authentication plugin:

- `client_ed25519`

When connecting with a [client or utility](#) to a server as a user account that authenticates with the

`ed25519`

authentication plugin, you may need to tell the client where to find the relevant client authentication plugin by specifying the  
`--plugin-dir`

option. For example:

```
mysql --plugin-dir=/usr/local/mysql/lib64/mysql/plugin --user=alice
```

client\_ed25519

The

client\_ed25519

client authentication plugin hashes and signs the password using the [Elliptic Curve Digital Signature Algorithm \(ECDSA\)](#) before sending it to the server.

## Support in Client Libraries

### Using the Plugin with MariaDB Connector/C

MariaDB Connector/C supports

ed25519

authentication using the [client authentication plugins](#) mentioned in the previous section since MariaDB Connector/C 3.1.0.

### Using the Plugin with MariaDB Connector/ODBC

MariaDB Connector/ODBC supports

ed25519

authentication using the [client authentication plugins](#) mentioned in the previous section since MariaDB Connector/ODBC 3.1.2.

### Using the Plugin with MariaDB Connector/J

MariaDB Connector/J supports

ed25519

authentication since MariaDB Connector/J 2.2.1.

### Using the Plugin with MariaDB Connector/Node.js

MariaDB Connector/Node.js supports

ed25519

authentication since MariaDB Connector/Node.js 2.1.0.

### Using the Plugin with MySqlConnector for .NET

MySqlConnector for ADO.NET supports

ed25519

authentication since MySqlConnector 0.56.0.

The connector implemented support for this authentication plugin in a separate [NuGet](#) package called

[MySqlConnector.Authentication.Ed25519](#)

. After the package is installed, your application must call

`Ed25519AuthenticationPlugin.Install`

to enable it.

## Versions

Version	Status	Introduced
1.1	Stable	MariaDB 10.4.0
1.0	Stable	MariaDB 10.3.8 , MariaDB 10.2.17 , MariaDB 10.1.35
1.0	Beta	MariaDB 10.2.5 , MariaDB 10.1.22

## Options

## ed25519

- **Description:** Controls how the server should treat the plugin when the server starts up.

- Valid values are:

- OFF

- Disables the plugin without removing it from the

- `mysql.plugins`

- table.

- ON

- Enables the plugin. If the plugin cannot be initialized, then the server will still continue starting up, but the plugin will be disabled.

- FORCE

- Enables the plugin. If the plugin cannot be initialized, then the server will fail to start with an error.

- FORCE\_PLUS\_PERMANENT

- Enables the plugin. If the plugin cannot be initialized, then the server will fail to start with an error. In addition, the plugin cannot be uninstalled with

- `UNINSTALL SONAME`

- or

- `UNINSTALL PLUGIN`

- while the server is running.

- See [Plugin Overview: Configuring Plugin Activation at Server Startup](#) for more information.

- **Commandline:**

- `--ed25519=value`

- **Data Type:**

- **Default Value:**

- ON

- **Valid Values:**

- OFF

- ,

- ON

- ,

- FORCE

- ,

- FORCE\_PLUS\_PERMANENT

---

## 4.4.5.5 Authentication Plugin - GSSAPI

The

`gssapi`

authentication plugin allows the user to authenticate with services that use the [Generic Security Services Application Program Interface \(GSSAPI\)](#). Windows has a slightly different but very similar API called [Security Support Provider Interface \(SSPI\)](#). The GSSAPI is a standardized API described in [RFC2743](#) and [RFC2744](#). The client and server negotiate using a standardized protocol described in [RFC7546](#).

On Windows, this authentication plugin supports [Kerberos](#) and [NTLM](#) authentication. Windows authentication is supported regardless of whether a [domain](#) is used in the environment.

On Unix systems, the most dominant GSSAPI service is [Kerberos](#). However, it is less commonly used on Unix systems than it is on Windows. Regardless, this authentication plugin also supports Kerberos authentication on Unix.

The

`gssapi`

authentication plugin is most often used for authenticating with [Microsoft Active Directory](#).

This article gives instructions on configuring the

**gssapi**  
authentication plugin for MariaDB for passwordless login.

    1. [gssapi](#)

## Installing the Plugin's Package

The

**gssapi**  
authentication plugin's shared library is included in MariaDB packages as the  
`auth_gssapi.so`  
or  
`auth_gssapi.dll`  
shared library on systems where it can be built. The plugin was first included in [MariaDB 10.1.11](#).

## Installing on Linux

The

**gssapi**  
authentication plugin is included in [binary tarballs](#) on Linux.

### Installing with a Package Manager

The

**gssapi**  
authentication plugin can also be installed via a package manager on Linux. In order to do so, your system needs to be configured to install from

one of the MariaDB repositories.

You can configure your package manager to install it from MariaDB Corporation's MariaDB Package Repository by using the [MariaDB Package Repository setup script](#).

You can also configure your package manager to install it from MariaDB Foundation's MariaDB Repository by using the [MariaDB Repository Configuration Tool](#).

Installing with yum/dnf

On RHEL, CentOS, Fedora, and other similar Linux distributions, it is highly recommended to install the relevant [RPM package](#) from MariaDB's repository using

`yum`

or

`dnf`

. Starting with RHEL 8 and Fedora 22,

`yum`

has been replaced by

`dnf`

, which is the next major version of

`yum`

. However,

`yum`

commands still work on many systems that use

`dnf`

. For example:

```
sudo yum install MariaDB-gssapi-server
```

Installing with apt-get

On Debian, Ubuntu, and other similar Linux distributions, it is highly recommended to install the relevant [DEB package](#) from MariaDB's repository using

`apt-get`

. For example:

```
sudo apt-get install mariadb-plugin-gssapi-server
```

Installing with zypper

On SLES, OpenSUSE, and other similar Linux distributions, it is highly recommended to install the relevant [RPM package](#) from MariaDB's repository using

`zypper`

. For example:

```
sudo zypper install MariaDB-gssapi-server
```

## Installing on Windows

The

`gssapi`

authentication plugin is included in [MSI](#) and [ZIP](#) packages on Windows.

## Installing the Plugin

Although the plugin's shared library is distributed with MariaDB by default, the plugin is not actually installed by MariaDB by default. There are two methods that can be used to install the plugin with MariaDB.

The first method can be used to install the plugin without restarting the server. You can install the plugin dynamically by executing

`INSTALL SONAME`

or

## INSTALL PLUGIN

. For example:

```
INSTALL SONAME 'auth_gssapi';
```

The second method can be used to tell the server to load the plugin when it starts up. The plugin can be installed this way by providing the

```
--plugin-load
```

or the

```
--plugin-load-add
```

options. This can be specified as a command-line argument to

```
mysqld
```

or it can be specified in a relevant server [option group](#) in an [option file](#). For example:

```
[mariadb]
...
plugin_load_add = auth_gssapi
```

## Uninstalling the Plugin

You can uninstall the plugin dynamically by executing

```
UNINSTALL SONAME
```

or

```
UNINSTALL PLUGIN
```

. For example:

```
UNINSTALL SONAME 'auth_gssapi';
```

If you installed the plugin by providing the

```
--plugin-load
```

or the

```
--plugin-load-add
```

options in a relevant server [option group](#) in an [option file](#), then those options should be removed to prevent the plugin from being loaded the next time the server is restarted.

## Configuring the Plugin

If the MariaDB server is running on Unix, then some additional configuration steps will need to be implemented in order to use the plugin.

If the MariaDB server is running on Windows, then no special configuration steps will need to be implemented in order to use the plugin, as long as the following is true:

- The Windows server is joined to a domain.
- The MariaDB server process is running as either a [NetworkService Account](#) or a [Domain User Account](#).

## Creating a Keytab File on Unix

If the MariaDB server is running on Unix, then the KDC server will need to create a keytab file for the MariaDB server. The keytab file contains the service principal name, which is the identity that the MariaDB server will use to communicate with the KDC server. The keytab will need to be transferred to the MariaDB server, and the

```
mysqld
server process will need read access to this keytab file.
```

How this keytab file is generated depends on whether the KDC server is [Microsoft Active Directory KDC](#) or [MIT Kerberos KDC](#).

## Creating a Keytab File with Microsoft Active Directory

If you are using [Microsoft Active Directory KDC](#), then you may need to create a keytab using the

`ktpass.exe`

utility on a Windows host. The service principal will need to be mapped to an existing domain user. To do so, follow the steps listed below.

Be sure to replace the following items in the step below:

- Replace  
     `${HOST}`  
    with the fully qualified DNS name for the MariaDB server host.
- Replace  
     `${DOMAIN}`  
    with the Active Directory domain.
- Replace  
     `${AD_USER}`  
    with the existing domain user.
- Replace  
     `${PASSWORD}`  
    with the password for the service principal.

To create the service principal, execute the following:

```
ktpass.exe /princ mariadb/${HOST}@${DOMAIN} /mapuser ${AD_USER} /pass ${PASSWORD} /out mariadb.keytab /crypto all /ptype KRB5_NT
```

## Creating a Keytab File with MIT Kerberos

If you are using [MIT Kerberos KDC](#), then you can create a [keytab](#) file using the

`kadmin`

utility. To do so, follow the steps listed below.

In the following steps, be sure to replace

`${HOST}`  
    with the fully qualified DNS name for the MariaDB server host.

First, create the service principal using the

`kadmin`

utility. For example:

```
kadmin -q "addprinc -randkey mariadb/${HOST}"
```

Then, export the newly created user to the keytab file using the

`kadmin`

utility. For example:

```
kadmin -q "ktadd -k /path/to/mariadb.keytab mariadb/${HOST}"
```

More details can be found at the following links:

- [MIT Kerberos Documentation: Database administration](#)
- [MIT Kerberos Documentation: Application servers](#)

## Configuring the Path to the Keytab File on Unix

If the MariaDB server is running on Unix, then the path to the keytab file that was previously created can be set by configuring the

`gssapi_keytab_path`

system variable. This can be specified as a command-line argument to

`mysqld`

or it can be specified in a relevant server [option group](#) in an [option file](#). For example:

```
[mariadb]
...
gssapi_keytab_path=/path/to/mariadb.keytab
```

## Configuring the Service Principal Name

The service principal name can be set by configuring the

`gssapi_principal_name`

system variable. This can be specified as a command-line argument to

`mysqld`

or it can be specified in a relevant server option group in an [option file](#). For example:

```
[mariadb]
...
gssapi_principal_name=service_principal_name/host.domain.com@REALM
```

If a service principal name is not provided, then the plugin will try to use

`mariadb/host.domain.com@REALM`  
by default.

If the MariaDB server is running on Unix, then the plugin needs a service principal name in order to function.

If the MariaDB server is running on Windows, then the plugin does not usually need a service principal in order to function. However, if you want to use one anyway, then one can be created with the

`setspn`

utility.

Different KDC implementations may use different canonical forms to identify principals. See [RFC2744: Section 3.10](#) to learn what the standard says about principal names.

More details can be found at the following links:

- [Active Directory Domain Services: Service Principal Names](#)
- [MIT Kerberos Documentation: Realm configuration decisions](#)
- [MIT Kerberos Documentation: Principal names and DNS](#)

## Creating Users

To create a user account via

`CREATE USER`

, specify the name of the plugin in the

`IDENTIFIED VIA`

clause. For example:

```
CREATE USER username@hostname IDENTIFIED VIA gssapi;
```

If

`SQL_MODE`

does not have  
`NO_AUTO_CREATE_USER`  
set, then you can also create the user account via

`GRANT`

. For example:

```
GRANT SELECT ON db.* TO username@hostname IDENTIFIED VIA gssapi;
```

You can also specify the user's [realm](#) for MariaDB with the  
USING  
clause. For example:

```
CREATE USER username@hostname IDENTIFIED VIA gssapi USING 'username@EXAMPLE.COM';
```

The format of the realm depends on the specific authentication mechanism that is used. For example, the format would need to be  
machine\\username  
for Windows users authenticating with NTLM.

If the realm is not provided in the user account's definition, then the realm is **not** used for comparison. Therefore, 'usr1@EXAMPLE.COM', 'usr1@EXAMPLE.CO.UK' and 'mymachine\usr1' would all identify as the following user account:

```
CREATE USER usr1@hostname IDENTIFIED VIA gssapi;
```

## Creating users identified via group membership or SID (Windows-specific)

Since 10.6.0, on Windows only, it is possible to login using a AD or local group-membership. This is achieved by using GROUP prefix in IDENTIFIED ... AS

```
CREATE USER root IDENTIFIED VIA gssapi AS 'GROUP:Administrators'  
CREATE USER root IDENTIFIED VIA gssapi AS 'GROUP:BUILTIN\\Administrators'
```

Effect of the above definition is that every user that identifies as member of group Administrators can login using user name root, passwordless.

User can also login using own or group [SID](#)

```
CREATE USER root IDENTIFIED VIA gssapi AS 'SID:S-1-5-32-544'
```

Using SIDs will perform slightly faster than using name (since it will spare translation between SID and name which is otherwise done), also SIDs immune against user or group renaming.

## Client Authentication Plugins

For clients that use the

libmysqlclient  
or [MariaDB Connector/C](#) libraries, MariaDB provides one client authentication plugin that is compatible with the  
gssapi  
authentication plugin:

- auth\_gssapi\_client

When connecting with a [client or utility](#) to a server as a user account that authenticates with the

gssapi  
authentication plugin, you may need to tell the client where to find the relevant client authentication plugin by specifying the  
--plugin-dir  
option. For example:

```
mysql --plugin-dir=/usr/local/mysql/lib64/mysql/plugin --user=alice
```

### auth\_gssapi\_client

The

auth\_gssapi\_client

client authentication plugin receives the principal name from the server, and then uses either the

[gss\\_init\\_sec\\_context](#)

function (on Unix) or the

[InitializeSecurityContext](#)

function (on Windows) to establish a security context on the client.

# Support in Client Libraries

## Using the Plugin with MariaDB Connector/C

MariaDB Connector/C supports

gssapi

authentication using the [client authentication plugins](#) mentioned in the previous section since MariaDB Connector/C 3.0.1.

## Using the Plugin with MariaDB Connector/ODBC

MariaDB Connector/ODBC supports

gssapi

authentication using the [client authentication plugins](#) mentioned in the previous section since MariaDB Connector/ODBC 3.0.0.

## Using the Plugin with MariaDB Connector/J

MariaDB Connector/J supports

gssapi

authentication since MariaDB Connector/J 1.4.0. Current documentation can be found [here](#).

## Using the Plugin with MariaDB Connector/Node.js

MariaDB Connector/Node.js does not yet support

gssapi

authentication. See [CONJS-72](#) for more information.

## Using the Plugin with MySqlConnector for .NET

MySqlConnector for ADO.NET supports

gssapi

authentication since MySqlConnector 0.47.0.

The support is transparent. Normally, the connector only needs to be provided the correct user name, and no other parameters are required.

However, this connector also supports the

[ServerSPN](#)

connection string parameter, which can be used for mutual authentication.

### .NET specific problems/workarounds

When connecting from Unix client to Windows server with ADO.NET, in an Active Directory domain environment, be aware that .NET Core on Unix does not support principal names in UPN(User Principal Name) form, which is default on Windows (e.g machine\$@domain.com). Thus, upon encountering an authentication exception with "server not found in Kerberos database", use one of workarounds below

- Force host-based SPN on server side.
  - For example, this can be done by setting the

[gssapi\\_principal\\_name](#)

system variable to  
HOST/machine  
in a server [option group](#) in an [option file](#).

- Pass host-based SPN on client side.
  - For example, this can be done by setting the connector's

[ServerSPN](#)

connection string parameter to  
HOST/machine

## Versions

Version	Status	Introduced
1.0	Stable	<a href="#">MariaDB 10.1.15</a>

## System Variables

### gssapi\_keytab\_path

- **Description:** Defines the path to the server's keytab file.
    - This system variable is only meaningful on [Unix](#) .
    - See [Creating a Keytab File on Unix](#) and [Configuring the Path to the Keytab File on Unix](#) for more information.
  - **Commandline:**

```
--gssapi-keytab-path
```
  - **Scope:** Global
  - **Dynamic:** No
  - **Data Type:**  
string
  - **Default Value:** "
  - **Introduced:** MariaDB 10.1.11
- 

### gssapi\_principal\_name

- **Description:** Name of the service principal.
    - See [Configuring the Service Principal Name](#) for more information.
  - **Commandline:**

```
--gssapi-principal-name
```
  - **Scope:** Global
  - **Dynamic:** No
  - **Data Type:**  
string
  - **Default Value:** "
  - **Introduced:** MariaDB 10.1.11
- 

### gssapi\_mech\_name

- **Description:** Name of the SSPI package used by server. Can be either 'Kerberos' or 'Negotiate'. Set it to 'Kerberos', to prevent less secure NTLM in domain environments, but leave it as default (Negotiate) to allow non-domain environments (e.g if server does not run in a domain environment).
    - This system variable is only meaningful on [Windows](#) .
  - **Commandline:**

```
--gssapi-mech-name
```
  - **Scope:** Global
  - **Dynamic:** No
  - **Data Type:**  
enumerated
  - **Default Value:**  
Negotiate
  - **Valid Values:**  
Kerberos  
,Negotiate
  - **Introduced:** MariaDB 10.1.11
-

## Options

### gssapi

- **Description:** Controls how the server should treat the plugin when the server starts up.

- Valid values are:

- OFF

- Disables the plugin without removing it from the

- `mysql.plugins`

- table.

- ON

- Enables the plugin. If the plugin cannot be initialized, then the server will still continue starting up, but the plugin will be disabled.

- FORCE

- Enables the plugin. If the plugin cannot be initialized, then the server will fail to start with an error.

- FORCE\_PLUS\_PERMANENT

- Enables the plugin. If the plugin cannot be initialized, then the server will fail to start with an error. In addition, the plugin cannot be uninstalled with

- `UNINSTALL SONAME`

- or

- `UNINSTALL PLUGIN`

- while the server is running.

- See [Plugin Overview: Configuring Plugin Activation at Server Startup](#) for more information.

- **Commandline:**

- `--gssapi=value`

- **Data Type:**

- enumerated

- **Default Value:**

- ON

- **Valid Values:**

- OFF

- ,

- ON

- ,

- FORCE

## 4.4.5.6 Authentication with Pluggable Authentication Modules (PAM)

### Authentication Plugin - PAM

Uses the Pluggable Authentication Module (PAM) framework to authenticate MariaDB users.

### User and Group Mapping with PAM

Configure PAM to map a given PAM user or group to a different MariaDB user.

### Configuring PAM Authentication and User Mapping with Unix Authentication

Walkthrough configuration of PAM authentication and user mapping with Unix authentication.

## Configuring PAM Authentication and User Mapping with LDAP Authentication

*Configuring PAM authentication and user mapping with LDAP authentication.*

### 4.4.5.7 Authentication Plugin - Unix Socket

MariaDB starting with 10.4.3

In MariaDB 10.4.3 and later, the

```
unix_socket  
authentication plugin is installed by default, and it is used by the  
'root'@'localhost'  
user account by default. See Authentication from MariaDB 10.4 for more information.
```

The

```
unix_socket
```

authentication plugin allows the user to use operating system credentials when connecting to MariaDB via the local Unix socket file. This Unix socket file is defined by the [socket](#) system variable.

The

```
unix_socket
```

```
authentication plugin works by calling the getsockopt system call with the  
SO_PEERCRED  
socket option, which allows it to retrieve the  
uid  
of the process that is connected to the socket. It is then able to get the user name associated with that  
uid
```

. Once it has the user name, it will authenticate the connecting user as the MariaDB account that has the same user name.

The

```
unix_socket
```

authentication plugin is not suited to multiple Unix users accessing a single MariaDB user account.

## Contents

9. [Example](#)
10. [Versions](#)
11. [Options](#)
  1. [unix\\_socket](#)
12. [See Also](#)

## Security

A

```
unix_socket
```

authentication plugin is a passwordless security mechanism. Its security is in the strength of the access to the Unix user rather than the complexity and the secrecy of the password. As the security is different from passwords, the strengths and weaknesses need to be considered, and these aren't the same in every installation.

## Strengths

- Access is limited to the Unix user so, for example, a  

```
www-data  
user cannot access  
root  
with the  
unix_socket  
authentication plugin.
```
- There is no password to brute force.
- There is no password that can be accidentally exposed by user accident, poor security on backups, or poor security on passwords in configuration files.

- Default Unix user security is usually strong on preventing remote access and password brute force attempts.

## Weaknesses

The strength of a

`unix_socket`

authentication plugin is effectively the strength of the security of the Unix users on the system. The Unix user default installation in most cases is sufficiently secure, however, business requirements or unskilled management may expose risks. The following is a non-exhaustive list of potential Unix user security issues that may arise.

- Common access areas without screen locks, where an unauthorized user accesses the logged in Unix user of an authorized user.
- Extensive sudo access grants that provide users with access to execute commands of a different Unix user.
- Scripts writable by Unix users other than the Unix user that are executed (cron or directly) by the unix user.
- Web pages that are susceptible to command injection, where the Unix user running the web page has elevated privileges in the database that weren't intended to be used.
- Poor Unix user password practices including weak user passwords, password exposure and password reuse accompanied by an access vulnerability/mechanism of an unauthorized user to exploit this weakness.
- Weak remote access mechanisms and network file system privileges.
- Poor user security behavior including running untrusted scripts and software.

In some of these scenarios a database password may prevent these security exploits, however it will remove all the strengths of the

`unix_socket`

authentication plugin previously mentioned.

## Disabling the Plugin

MariaDB starting with [10.4.3](#)

In [MariaDB 10.4.3](#) and later, the

`unix_socket`

authentication plugin is installed by default, so **if you do not want it to be available by default on those versions, then you will need to disable it**.

The

`unix_socket`

authentication plugin is also installed by default in **new installations** that use the

`.deb`

packages provided by Debian's default repositories in Debian 9 and later and Ubuntu's default repositories in Ubuntu 15.10 and later, so **if you do not want it to be available by default on those systems when those packages are used, then you will need to disable it**. See [Differences in MariaDB in Debian \(and Ubuntu\)](#) for more information.

The

`unix_socket`

authentication plugin can be disabled by starting the server with the

`unix_socket`

option set to

`OFF`

. This can be specified as a command-line argument to

`mysqld`

or it can be specified in a relevant server `option group` in an `option file`. For example:

```
[mariadb]
...
unix_socket=OFF
```

As an alternative, the

`unix_socket`

option can also be set to

`OFF`

by pairing the option with the

```
disable  
option prefix . For example:
```

```
[mariadb]  
...  
disable_unix_socket
```

## Installing the Plugin

MariaDB starting with [10.4.3](#)

In [MariaDB 10.4.3](#) and later, the `unix_socket` authentication plugin is installed by default, so **this step can be skipped on those versions**.

The

```
unix_socket  
authentication plugin is also installed by default in new installations that use the  
.deb
```

packages provided by Debian's default repositories in Debian 9 and later and Ubuntu's default repositories in Ubuntu 15.10 and later, so **this step can be skipped on those systems when those packages are used**. See [Differences in MariaDB in Debian \(and Ubuntu\)](#) for more information.

In other systems, although the plugin's shared library is distributed with MariaDB by default as

```
auth_socket.so  
, the plugin is not actually installed by MariaDB by default. There are two methods that can be used to install the plugin with MariaDB.
```

The first method can be used to install the plugin without restarting the server. You can install the plugin dynamically by executing

```
INSTALL SONAME
```

or

```
INSTALL PLUGIN
```

. For example:

```
INSTALL SONAME 'auth_socket';
```

The second method can be used to tell the server to load the plugin when it starts up. The plugin can be installed this way by providing the

```
--plugin-load
```

or the

```
--plugin-load-add
```

options. This can be specified as a command-line argument to

```
mysqld
```

or it can be specified in a relevant server [option group](#) in an [option file](#). For example:

```
[mariadb]  
...  
plugin_load_add = auth_socket
```

## Uninstalling the Plugin

You can uninstall the plugin dynamically by executing

```
UNINSTALL SONAME
```

or

## UNINSTALL PLUGIN

. For example:

```
UNINSTALL SONAME 'auth_socket';
```

If you installed the plugin by providing the

```
--plugin-load
```

or the

```
--plugin-load-add
```

options in a relevant server [option group](#) in an [option file](#), then those options should be removed to prevent the plugin from being loaded the next time the server is restarted.

## Creating Users

To create a user account via

```
CREATE USER
```

, specify the name of the plugin in the

```
IDENTIFIED VIA
```

clause. For example:

```
CREATE USER username@hostname IDENTIFIED VIA unix_socket;
```

If

```
SQL_MODE
```

does not have

```
NO_AUTO_CREATE_USER
```

set, then you can also create the user account via

```
GRANT
```

. For example:

```
GRANT SELECT ON db.* TO username@hostname IDENTIFIED VIA unix_socket;
```

## Switching to Password-based Authentication

Sometimes Unix socket authentication does not meet your needs, so it can be desirable to switch a user account back to password-based authentication. This can easily be done by telling MariaDB to use another [authentication plugin](#) for the account by executing the

```
ALTER USER
```

statement. The specific authentication plugin is specified with the

```
IDENTIFIED VIA
```

clause. For example, if you wanted to switch to the

```
mysql_native_password
```

authentication plugin, then you could execute:

```
ALTER USER root@localhost IDENTIFIED VIA mysql_native_password;
SET PASSWORD = PASSWORD('foo');
```

Note that if your operating system has scripts that require password-less access to MariaDB, then this may break those scripts. You may be able to fix that by setting a password in the

```
[client]
option group in your /root/.my.cnf option file . For example:
```

```
[client]
password=foo
```

## Client Authentication Plugins

The

```
unix_socket
authentication plugin does not require any specific client authentication plugins. It should work with all clients.
```

## Support in Client Libraries

The

```
unix_socket
authentication plugin does not require any special support in client libraries. It should work with all client libraries.
```

## Example

```
$ mysql -uroot
MariaDB []> CREATE USER serg IDENTIFIED VIA unix_socket;
MariaDB []> CREATE USER monty IDENTIFIED VIA unix_socket;
MariaDB []> quit
Bye
$ whoami
serg
$ mysql --user=serg
Welcome to the MariaDB monitor. Commands end with ; or \g.
Your MariaDB connection id is 2
Server version: 5.2.0-MariaDB-alpha-debug Source distribution
MariaDB []> quit
Bye
$ mysql --user=monty
ERROR 1045 (28000): Access denied for user 'monty'@'localhost' (using password: NO)
```

In this example, a user

```
serg
is already logged into the operating system and has full shell access. He has already authenticated with the operating system and his MariaDB account is configured to use the
unix_socket
authentication plugin, so he does not need to authenticate again for the database. MariaDB accepts his operating system credentials and allows him to connect. However, any attempt to connect to the database as another operating system user will be denied.
```

## Versions

Version	Status	Introduced
1.0	Stable	MariaDB 10.0.11
1.0	Beta	MariaDB 5.2.0

## Options

### unix\_socket

- **Description:** Controls how the server should treat the plugin when the server starts up.

- Valid values are:

- 

- OFF  
- Disables the plugin without removing it from the

- [mysql.plugin](#)

table.

ON

- Enables the plugin. If the plugin cannot be initialized, then the server will still continue starting up, but the plugin will be disabled.

FORCE

- Enables the plugin. If the plugin cannot be initialized, then the server will fail to start with an error.

FORCE\_PLUS\_PERMANENT

- Enables the plugin. If the plugin cannot be initialized, then the server will fail to start with an error. In addition, the plugin cannot be uninstalled with

[UNINSTALL SONAME](#)

or

[UNINSTALL PLUGIN](#)

while the server is running.

- See [Plugin Overview: Configuring Plugin Activation at Server Startup](#) for more information.

- **Commandline:**

`--unix-socket=value`

- **Data Type:**

enumerated

- **Default Value:**

ON

- **Valid Values:**

OFF

,

ON

,

FORCE

,

FORCE\_PLUS\_PERMANENT

- [Authentication from MariaDB 10.4 video tutorial](#)

## 4.4.5.8 Authentication Plugin - Named Pipe

The

`named_pipe`

authentication plugin allows the user to use operating system credentials when connecting to MariaDB via named pipe on Windows. Named pipe connections are enabled by the

[named\\_pipe](#)

system variable.

The

`named_pipe`

authentication plugin works by using [named pipe impersonation](#) and calling `GetUserName()`

to retrieve the user name of the process that is connected to the named pipe. Once it has the user name, it authenticates the connecting user as the MariaDB account that has the same user name.

## Contents

1. [Installing the Plugin](#)
2. [Uninstalling the Plugin](#)
3. [Creating Users](#)
4. [Client Authentication Plugins](#)
5. [Support in Client Libraries](#)
6. [Example](#)
7. [Versions](#)
8. [Options](#)
  1. [named\\_pipe](#)

## Installing the Plugin

Although the plugin's shared library is distributed with MariaDB by default, the plugin is not actually installed by MariaDB by default. There are two methods that can be used to install the plugin with MariaDB.

The first method can be used to install the plugin without restarting the server. You can install the plugin dynamically by executing

```
INSTALL SONAME
```

or

```
INSTALL PLUGIN
```

. For example:

```
INSTALL SONAME 'auth_named_pipe';
```

The second method can be used to tell the server to load the plugin when it starts up. The plugin can be installed this way by providing the

```
--plugin-load
```

or the

```
--plugin-load-add
```

options. This can be specified as a command-line argument to

```
mysqld
```

or it can be specified in a relevant server [option group](#) in an [option file](#). For example:

```
[mariadb]
...
plugin_load_add = auth_named_pipe
```

## Uninstalling the Plugin

You can uninstall the plugin dynamically by executing

```
UNINSTALL SONAME
```

or

```
UNINSTALL PLUGIN
```

. For example:

```
UNINSTALL SONAME 'auth_named_pipe';
```

If you installed the plugin by providing the

```
--plugin-load
```

or the

```
--plugin-load-add
```

options in a relevant server [option group](#) in an [option file](#), then those options should be removed to prevent the plugin from being loaded the next time the server is restarted.

## Creating Users

To create a user account via

[CREATE\\_USER](#)

, specify the name of the plugin in the

[IDENTIFIED VIA](#)

clause. For example:

```
CREATE USER username@hostname IDENTIFIED VIA named_pipe;
```

If

[SQL\\_MODE](#)

does not have

[NO\\_AUTO\\_CREATE\\_USER](#)

set, then you can also create the user account via

[GRANT](#)

. For example:

```
GRANT SELECT ON db.* TO username@hostname IDENTIFIED VIA named_pipe;
```

## Client Authentication Plugins

The

[named\\_pipe](#)

authentication plugin does not require any specific client authentication plugins. It should work with all clients.

## Support in Client Libraries

The

[named\\_pipe](#)

authentication plugin does not require any special support in client libraries. It should work with all client libraries.

## Example

```
CREATE USER wlad IDENTIFIED VIA named_pipe;
CREATE USER monty IDENTIFIED VIA named_pipe;
quit

C:\>echo %USERNAME%
wlad

C:\> mysql --user=wlad --protocol=PIPE
Welcome to the MariaDB monitor. Commands end with ; or \g.
Your MariaDB connection id is 4
Server version: 10.1.12-MariaDB-debug Source distribution

Copyright (c) 2000, 2015, Oracle, MariaDB Corporation Ab and others.

Type 'help;' or '\h' for help. Type '\c' to clear the current input statement.

MariaDB [(none)]> quit
Bye

C:\> mysql --user=monty --protocol=PIPE
ERROR 1698 (28000): Access denied for user 'monty'@'localhost'
```

In this example, a user

wlad

is already logged into the system. Because he has identified himself to the operating system, he does not need to do it again for the database — MariaDB trusts the operating system credentials. However, he cannot connect to the database as another user.

## Versions

Version	Status	Introduced
1.0	Stable	MariaDB 10.1.11

## Options

### `named_pipe`

- **Description:** Controls how the server should treat the plugin when the server starts up.

- Valid values are:

- OFF

- Disables the plugin without removing it from the

- `mysql.plugins`

- table.

- ON

- Enables the plugin. If the plugin cannot be initialized, then the server will still continue starting up, but the plugin will be disabled.

- FORCE

- Enables the plugin. If the plugin cannot be initialized, then the server will fail to start with an error.

- FORCE\_PLUS\_PERMANENT

- Enables the plugin. If the plugin cannot be initialized, then the server will fail to start with an error. In addition, the plugin cannot be uninstalled with

- `UNINSTALL SONAME`

- or

- `UNINSTALL PLUGIN`

- while the server is running.

- See [Plugin Overview: Configuring Plugin Activation at Server Startup](#) for more information.
  - There may be ambiguity between this option and the

- `named_pipe`

- system variable. See [MDEV-19625](#) about that.

- **Commandline:**

- `--named-pipe=value`

- **Data Type:**

## 4.4.5.9 Authentication Plugin - SHA-256

### Contents

1. [Support in MariaDB Server](#)
2. [Client Authentication Plugins](#)
  1. [sha256\\_password](#)
  2. [caching\\_sha2\\_password](#)
3. [Support in Client Libraries](#)
  1. [Using the Plugin with MariaDB Connector/C](#)
  2. [Using the Plugin with MariaDB Connector/ODBC](#)
  3. [Using the Plugin with MariaDB Connector/J](#)
  4. [Using the Plugin with MariaDB Connector/Node.js](#)
4. [See Also](#)

MySQL 5.6 added support for the

`sha256_password`

authentication plugin, and MySQL 8.0 also added support for the

`caching_sha2_password`

authentication plugin.

The

`caching_sha2_password`

plugin is now the default authentication plugin in MySQL 8.0.4 and above, based on the value of the

`default_authentication_plugin`

system variable.

## Support in MariaDB Server

MariaDB Server does not currently support either the

`sha256_password`

or the

`caching_sha2_password`

authentication plugins. See [MDEV-9804](#) for more information.

MariaDB Server does not support either of these authentication plugins. This is mainly because:

- To use the protocol, one has to distribute the server's public key to all MariaDB users, which can be cumbersome and impractical.
- The server gets the password in clear text which can cause problems if the user is convinced to connect to a malicious server.

## Client Authentication Plugins

For clients that use the [MariaDB Connector/C](#) library, MariaDB provides two client authentication plugins that are compatible with MySQL's SHA-256 authentication plugins:

- `sha256_password`
- `caching_sha2_password`

When connecting with a [client or utility](#) to a server as a user account that authenticates with the

`sha256_password`

or

caching\_sha256\_password  
authentication plugin, you may need to tell the client where to find the relevant client authentication plugin by specifying the  
--plugin-dir  
option. For example:

```
mysql --plugin-dir=/usr/local/mysql/lib64/mysql/plugin --user=alice
```

For clients that use MariaDB's  
`libmysqlclient` library instead of [MariaDB Connector/C](#), these client authentication plugins are not supported.

## sha256\_password

The

`sha256_password`  
client authentication plugin is compatible with MySQL's

[sha256\\_password](#)

authentication plugin, which was added in MySQL 5.6.

## caching\_sha256\_password

The

`caching_sha256_password`  
client authentication plugin is compatible with MySQL's

[caching\\_sha2\\_password](#)

authentication plugin, which was added in MySQL 8.0.

The

`caching_sha2_password`  
plugin is now the default authentication plugin in MySQL 8.0.4 and above, based on the value of the

[default\\_authentication\\_plugin](#)

system variable.

# Support in Client Libraries

## Using the Plugin with MariaDB Connector/C

[MariaDB Connector/C](#) supports

`sha256_password`  
and  
`caching_sha2_password`  
authentication using the [client authentication plugins](#) mentioned in the previous section.

It has supported the

`sha256_password`  
client authentication plugin since MariaDB Connector/C 3.0.2. See [CONC-229](#) for more information.

It has supported the

`caching_sha256_password`  
client authentication plugin since MariaDB Connector/C 3.0.8 and MariaDB Connector/C 3.1.0. See [CONC-312](#) for more information.

## Using the Plugin with MariaDB Connector/ODBC

[MariaDB Connector/ODBC](#) supports

`sha256_password`  
and  
`caching_sha2_password`  
authentication using the [client authentication plugins](#) mentioned in the previous section.

It has supported  
sha256\_password  
and  
caching\_sha2\_password  
authentication since MariaDB Connector/ODBC 3.1.4. See [ODBC-241](#) for more information.

## Using the Plugin with MariaDB Connector/J

[MariaDB Connector/J](#) supports  
sha256\_password  
and  
caching\_sha2\_password  
authentication since MariaDB Connector/J 2.5.0. See [CONJ-327](#) and [CONJ-663](#) for more information.

## Using the Plugin with MariaDB Connector/Node.js

[MariaDB Connector/Node.js](#) supports  
sha256\_password  
and  
caching\_sha2\_password  
authentication since MariaDB Connector/Node.js 2.5.0. See [CONJS-76](#) and [CONJS-77](#) for more information.

## See Also

- [MDEV-9804](#) contains the plans to use if we ever decide to support these protocols.
- [History of MySQL and MariaDB authentication protocols](#)

## 4.4.6 Password Validation Plugins

### 4.4.6.1 Simple Password Check Plugin

simple\_password\_check

is a [password validation](#) plugin. It can check whether a password contains at least a certain number of characters of a specific type. When first installed, a password is required to be at least eight characters, and requires at least one digit, one uppercase character, one lowercase character, and one character that is neither a digit nor a letter.

Note that passwords can be directly set as a hash, bypassing the password validation, if the [strict\\_password\\_validation](#) variable is

OFF  
(it is  
ON  
by default).

#### Contents

1. [Installing the Plugin](#)
2. [Uninstalling the Plugin](#)
3. [Example](#)
4. [Known Issues](#)
  1. [Issues with PAM Authentication Plugin](#)
5. [Versions](#)
6. [System Variables](#)
  1. [simple\\_password\\_check\\_digits](#)
  2. [simple\\_password\\_check\\_letters\\_same\\_case](#)
  3. [simple\\_password\\_check\\_minimal\\_length](#)
  4. [simple\\_password\\_check\\_other\\_characters](#)
7. [Options](#)
  1. [simple\\_password\\_check](#)
8. [See Also](#)

## Installing the Plugin

Although the plugin's shared library is distributed with MariaDB by default, the plugin is not actually installed by MariaDB by default. There are two methods that can be used to install the plugin with MariaDB.

The first method can be used to install the plugin without restarting the server. You can install the plugin dynamically by executing

`INSTALL SONAME`

or

## INSTALL PLUGIN

. For example:

```
INSTALL SONAME 'simple_password_check';
```

The second method can be used to tell the server to load the plugin when it starts up. The plugin can be installed this way by providing the

```
--plugin-load
```

or the

```
--plugin-load-add
```

options. This can be specified as a command-line argument to

```
mysqld
```

or it can be specified in a relevant server [option group](#) in an [option file](#). For example:

```
[mariadb]
...
plugin_load_add = simple_password_check
```

## Uninstalling the Plugin

You can uninstall the plugin dynamically by executing

```
UNINSTALL SONAME
```

or

```
UNINSTALL PLUGIN
```

. For example:

```
UNINSTALL SONAME 'simple_password_check';
```

If you installed the plugin by providing the

```
--plugin-load
```

or the

```
--plugin-load-add
```

options in a relevant server [option group](#) in an [option file](#), then those options should be removed to prevent the plugin from being loaded the next time the server is restarted.

## Example

When creating a new password, if the criteria are not met, the following error is returned:

```
SET PASSWORD FOR 'bob'@'%.loc.gov' = PASSWORD('abc');
ERROR 1819 (HY000): Your password does not satisfy the current policy requirements
```

## Known Issues

### Issues with PAM Authentication Plugin

Prior to [MariaDB 10.4.0](#), all [password validation plugins](#) are incompatible with the

```
pam
```

authentication plugin. See [Authentication Plugin - PAM: Conflicts with Password Validation](#) for more information.

# Versions

Version	Status	Introduced
1.0	Stable	<a href="#">MariaDB 10.1.18</a>
1.0	Gamma	<a href="#">MariaDB 10.1.13</a>
1.0	Beta	<a href="#">MariaDB 10.1.11</a>
1.0	Alpha	<a href="#">MariaDB 10.1.2</a>

## System Variables

### simple\_password\_check\_digits

- **Description:** A password must contain at least this many digits.

- **Commandline:**

```
--simple-password-check-digits=#
```

- **Scope:** Global

- **Dynamic:** Yes

- **Data Type:**

numeric

- **Default Value:**

1

- **Range:**

0

to

1000

### simple\_password\_check\_letters\_same\_case

- **Description:** A password must contain at least this many upper-case and this many lower-case letters.

- **Commandline:**

```
--simple-password-check-letters-same-case=#
```

- **Scope:** Global

- **Dynamic:** Yes

- **Data Type:**

numeric

- **Default Value:**

1

- **Range:**

0

to

1000

### simple\_password\_check\_minimal\_length

- **Description:** A password must contain at least this many characters.

- **Commandline:**

```
--simple-password-check-minimal-length=#
```

- **Scope:** Global

- **Dynamic:** Yes

- **Data Type:**

numeric

- **Default Value:**

8

- **Range:**

0

to

1000

---

simple\_password\_check\_other\_characters

- **Description:** A password must contain at least this many characters that are neither digits nor letters.

- **Commandline:**

--simple-password-check-other-characters=#

- **Scope:** Global

- **Dynamic:** Yes

- **Data Type:**

numeric

- **Default Value:**

1

- **Range:**

0

to

1000

---

## Options

simple\_password\_check

- **Description:** Controls how the server should treat the plugin when the server starts up.

- Valid values are:

- OFF

- Disables the plugin without removing it from the

- `mysql.plugins`

- table.

- ON

- Enables the plugin. If the plugin cannot be initialized, then the server will still continue starting up, but the plugin will be disabled.

- FORCE

- Enables the plugin. If the plugin cannot be initialized, then the server will fail to start with an error.

- FORCE\_PLUS\_PERMANENT

- Enables the plugin. If the plugin cannot be initialized, then the server will fail to start with an error. In addition, the plugin cannot be uninstalled with

- `UNINSTALL SONAME`

- or

- `UNINSTALL PLUGIN`

- while the server is running.

- See [Plugin Overview: Configuring Plugin Activation at Server Startup](#) for more information.

  8. [System Variables](#)
    1. [cracklib\\_password\\_check\\_dictionary](#)
  9. [Options](#)
    1. [cracklib\\_password\\_check](#)
  10. [See Also](#)

### cracklib\_password\_check

is a [password validation](#) plugin. It uses the [CrackLib](#) library to check the strength of new passwords. CrackLib is installed by default in many Linux distributions, since the system's [Pluggable Authentication Module \(PAM\)](#) authentication framework is usually configured to check the strength of new passwords with the

### pam\_cracklib

PAM module.

Note that passwords can be directly set as a hash, bypassing the password validation, if the [strict\\_password\\_validation](#) variable is

OFF

(it is

ON

by default).

The plugin requires at least cracklib 2.9.0, so it is not available on Debian/Ubuntu builds before Debian 8 Jessie/Ubuntu 14.04 Trusty, RedHat Enterprise Linux / CentOS 6.

## Installing the Plugin's Package

The

### cracklib\_password\_check

plugin's shared library is included in MariaDB packages as the `cracklib_password_check.so` or `cracklib_password_check.dll` shared library on systems where it can be built.

## Installing on Linux

The

`cracklib_password_check` plugin is included in `systemd` [binary tarballs](#) on Linux, but not in the older generic and `glibc_214` tarballs.

### Installing with a Package Manager

The

`cracklib_password_check` plugin can also be installed via a package manager on Linux. In order to do so, your system needs to be configured to install from one of the MariaDB repositories.

You can configure your package manager to install it from MariaDB Corporation's MariaDB Package Repository by using the [MariaDB Package Repository setup script](#).

You can also configure your package manager to install it from MariaDB Foundation's MariaDB Repository by using the [MariaDB Repository Configuration Tool](#).

#### Installing with yum/dnf

On RHEL, CentOS, Fedora, and other similar Linux distributions, it is highly recommended to install the relevant [RPM package](#) from MariaDB's repository using

`yum`

or

`dnf`

. Starting with RHEL 8 and Fedora 22,

`yum`

has been replaced by

`dnf`

, which is the next major version of

`yum`

. However,

`yum`

commands still work on many systems that use

`dnf`

. For example:

```
sudo yum install MariaDB-cracklib-password-check
```

#### Installing with apt-get

On Debian, Ubuntu, and other similar Linux distributions, it is highly recommended to install the relevant [DEB package](#) from MariaDB's repository using

`apt-get`

. For example:

```
sudo apt-get install mariadb-plugin-cracklib-password-check
```

#### Installing with zypper

On SLES, OpenSUSE, and other similar Linux distributions, it is highly recommended to install the relevant [RPM package](#) from MariaDB's repository using

`zypper`

. For example:

```
sudo zypper install MariaDB-cracklib-password-check
```

## Installing the Plugin

Once the shared library is in place, the plugin is not actually installed by MariaDB by default. There are two methods that can be used to install the plugin with MariaDB.

The first method can be used to install the plugin without restarting the server. You can install the plugin dynamically by executing

```
INSTALL SONAME
```

or

```
INSTALL PLUGIN
```

. For example:

```
INSTALL SONAME 'cracklib_password_check';
```

The second method can be used to tell the server to load the plugin when it starts up. The plugin can be installed this way by providing the

```
--plugin-load
```

or the

```
--plugin-load-add
```

options. This can be specified as a command-line argument to

```
mysqld
```

or it can be specified in a relevant server [option group](#) in an [option file](#). For example:

```
[mariadb]
...
plugin_load_add = cracklib_password_check
```

## Uninstalling the Plugin

You can uninstall the plugin dynamically by executing

```
UNINSTALL SONAME
```

or

```
UNINSTALL PLUGIN
```

. For example:

```
UNINSTALL SONAME 'cracklib_password_check';
```

If you installed the plugin by providing the

```
--plugin-load
```

or the

```
--plugin-load-add
```

options in a relevant server [option group](#) in an [option file](#), then those options should be removed to prevent the plugin from being loaded the next time the server is restarted.

## Viewing CrackLib Errors

If password validation fails, then the original CrackLib error message can be viewed by executing

```
SHOW WARNINGS
```

## Example

When creating a new password, if the criteria are not met, the following error is returned:

```
SET PASSWORD FOR 'bob'@'%loc.gov' = PASSWORD('abc');
ERROR 1819 (HY000): Your password does not satisfy the current policy requirements
```

## Known Issues

### Issues with PAM Authentication Plugin

Prior to [MariaDB 10.4.0](#), all [password validation plugins](#) are incompatible with the

pam

authentication plugin. See [Authentication Plugin - PAM: Conflicts with Password Validation](#) for more information.

### SELinux

When using the standard [SELinux](#) policy with the mode set to

```
enforcing
,
mysqld
does not have access to
/usr/share/cracklib
, and you may see the following error when attempting to use the
cracklib_password_check
plugin:
```

```
CREATE USER `user`@`hostname` IDENTIFIED BY 's0mePwd123.';
ERROR 1819 (HY000): Your password does not satisfy the current policy requirements
```

```
SHOW WARNINGS;
+-----+-----+
| Level | Code | Message
+-----+-----+
| Warning | 1819 | cracklib: error loading dictionary
| Error   | 1819 | Your password does not satisfy the current policy requirements |
| Error   | 1396 | Operation CREATE USER failed for 'user'@'hostname'           |
+-----+-----+
```

And the SELinux

```
audit.log
will contain errors like the following:
```

```
type=AVC msg=audit(1548371977.821:66): avc: denied { read } for pid=3537 comm="mysqld" name="pw_dict.pwd" dev="xvda2" ino=564
type=SYSCALL msg=audit(1548371977.821:66): arch=c000003e syscall=2 success=no exit=-13 a0=7fdd2a674580 a1=0 a2=1b6 a3=1b items=0
```

This can be fixed by creating an SELinux policy that allows

```
mysqld
to load the CrackLib dictionary. For example:
```

```

cd /usr/share/mysql/policy/selinux/
tee ./mariadb-plugin-cracklib-password-check.te <<EOF

module mariadb-plugin-cracklib-password-check 1.0;

require {
    type mysqld_t;
    type crack_db_t;
    class file { execute setattr read create getattr execute_no_trans write ioctl open append unlink };
    class dir { write search getattr add_name read remove_name open };
}

allow mysqld_t crack_db_t:dir { search read open };
allow mysqld_t crack_db_t:file { getattr read open };
EOF
sudo yum install selinux-policy-devel
make -f /usr/share/selinux/devel/Makefile mariadb-plugin-cracklib-password-check.pp
sudo semodule -i mariadb-plugin-cracklib-password-check.pp

```

See [MDEV-18374](#) for more information.

## Versions

Version	Status	Introduced
1.0	Stable	<a href="#">MariaDB 10.1.18</a>
1.0	Gamma	<a href="#">MariaDB 10.1.13</a>
1.0	Alpha	<a href="#">MariaDB 10.1.2</a>

## System Variables

### cracklib\_password\_check\_dictionary

- **Description:** Sets the path to the CrackLib dictionary. If not set, the default CrackLib dictionary path is used. The parameter expects the base name of a cracklib dictionary (a set of three files with endings

```

.hwm
,
.pwd
,
.pwi
), not a directory path.

```

- **Commandline:**

```
--cracklib-password-check-dictionary=value
```

- **Scope:** Global

- **Dynamic:** No

- **Data Type:**

```
string
```

- **Default Value:** Depends on the system. Often

```
/usr/share/cracklib/pw_dict
```

## Options

### cracklib\_password\_check

- **Description:** Controls how the server should treat the plugin when the server starts up.

- Valid values are:

- 

- OFF

- Disables the plugin without removing it from the

`mysql.plugins`

table.

- - ON
    - Enables the plugin. If the plugin cannot be initialized, then the server will still continue starting up, but the plugin will be disabled.
  - - FORCE
      - Enables the plugin. If the plugin cannot be initialized, then the server will fail to start with an error.
    - - FORCE\_PLUS\_PERMANENT
        - Enables the plugin. If the plugin cannot be initialized, then the server will fail to start with an error. In addition, the plugin cannot be uninstalled with

`UNINSTALL SONAME`

or

`UNINSTALL PLUGIN`

while the server is running.

- See [Plugin Overview: Configuring Plugin Activation at Server Startup](#) for more information.

- **Commandline:**

`--cracklib-password-check=value`

- **Data Type:**

enumerated

- **Default Value:**

ON

- **Valid Values:**

OFF

,

ON

,

FORCE

,

FORCE\_PLUS\_PERMANENT

## 4.4.6.3 Password Reuse Check Plugin

MariaDB starting with 10.7

`password_reuse_check`  
is a [password validation](#) plugin introduced in [MariaDB 10.7.0](#).

### Contents

1. [Description](#)
  1. [Installing the Plugin](#)
  2. [Uninstalling the Plugin](#)
2. [Example](#)
3. [Versions](#)
4. [See Also](#)

## Description

The plugin is used to prevent a user from reusing a password, which can be a requirement in some security policies. The `password_reuse_check_interval` system variable determines the retention period, in days, for a password. By default this is zero, meaning unlimited retention. Old passwords are stored in the `mysql.password_reuse_check_history` table.

Note that passwords can be directly set as a hash, bypassing the password validation, if the `strict_password_validation` variable is OFF (it is ON by default).

## Installing the Plugin

Although the plugin's shared library is distributed with MariaDB by default, the plugin is not actually installed by MariaDB by default.

You can install the plugin dynamically, without restarting the server, by executing `INSTALL SONAME` or `INSTALL PLUGIN`. For example:

```
INSTALL SONAME 'password_reuse_check';
```

The second method can be used to tell the server to load the plugin when it starts up. The plugin can be installed this way by providing the `--plugin-load` or the `--plugin-load-add` options. This can be specified as a command-line argument to `mysqld` or it can be specified in a relevant server option group in an option file . For example:

```
[mariadb]
...
plugin_load_add = password_reuse_check
```

## Uninstalling the Plugin

You can uninstall the plugin dynamically by executing `UNINSTALL SONAME` or `UNINSTALL PLUGIN`. For example:

```
UNINSTALL SONAME 'password_reuse_check';
```

If you installed the plugin by providing the `--plugin-load` or the `--plugin-load-add` options in a relevant server option group in an option file , then those options should be removed to prevent the plugin from being loaded the next time the server is restarted.

## Example

```
INSTALL SONAME 'password_reuse_check';

GRANT SELECT ON *.* TO user1@localhost identified by 'pwd1';
Query OK, 0 rows affected (0.038 sec)

GRANT SELECT ON *.* TO user1@localhost identified by 'pwd1';
ERROR 1819 (HY000): Your password does not satisfy the current policy requirements

GRANT SELECT ON *.* TO user1@localhost identified by 'pwd2';
Query OK, 0 rows affected (0.003 sec)

GRANT SELECT ON *.* TO user1@localhost identified by 'pwd1';
ERROR 1819 (HY000): Your password does not satisfy the current policy requirements
```

## Versions

Version	Status	Introduced
1.0	Alpha	MariaDB 10.7.0

## 4.4.6.4 Password Validation Plugin API

## Contents

- 1. SQL-Level Extensions
  - 1. Password-Changing Statements
    - 1. With Plain Text Password
    - 2. With Password Hash
  - 2. Examples
  - 3. Plugin API

“Password validation” means ensuring that user passwords meet certain minimal security requirements. A dedicated plugin API allows the creation of password validation plugins that will check user passwords as they are set (in `SET PASSWORD` and `GRANT` statements) and either allow or reject them.

## SQL-Level Extensions

MariaDB comes with three password validation plugins — the `simple_password_check` plugin, the `cracklib_password_check` plugin and the `password_reuse_check` plugin. They are not enabled by default; use `INSTALL SONAME` (or `INSTALL PLUGIN`) statement to install them.

When at least one password plugin is loaded, all new passwords will be validated and password-changing statements will fail if the password will not pass validation checks. Several password validation plugin can be loaded at the same time — in this case a password must pass **all** validation checks by **all** plugins.

### Password-Changing Statements

One can use various SQL statements to change a user password:

#### With Plain Text Password

```
SET PASSWORD = PASSWORD('plain-text password');
SET PASSWORD FOR `user`@`host` = PASSWORD('plain-text password');
SET PASSWORD = OLD_PASSWORD('plain-text password');
SET PASSWORD FOR `user`@`host` = OLD_PASSWORD('plain-text password');
CREATE USER `user`@`host` IDENTIFIED BY 'plain-text password';
GRANT privileges TO `user`@`host` IDENTIFIED BY 'plain-text password';
```

These statements are subject to password validation. If at least one password validation plugin is loaded, plain-text passwords specified in these statements will be validated.

#### With Password Hash

```
SET PASSWORD = 'password hash';
SET PASSWORD FOR `user`@`host` = 'password hash';
CREATE USER `user`@`host` IDENTIFIED BY PASSWORD 'password hash';
CREATE USER `user`@`host` IDENTIFIED VIA mysql_native_password USING 'password hash';
CREATE USER `user`@`host` IDENTIFIED VIA mysql_old_password USING 'password hash';
GRANT privileges TO `user`@`host` IDENTIFIED BY PASSWORD 'password hash';
GRANT privileges TO `user`@`host` IDENTIFIED VIA mysql_native_password USING 'password hash';
GRANT privileges TO `user`@`host` IDENTIFIED VIA mysql_old_password USING 'password hash';
```

These statements can not possibly use password validation — there is nothing to validate, the original plain-text password is not available. MariaDB introduces a **strict password validation** mode — controlled by a `strict_password_validation` global server variable. If the strict password validation is enabled and at least one password validation plugin is loaded then these “unvalidatable” passwords will be rejected. Otherwise they will be accepted. By default a strict password validation is enabled (but note that it has no effect if no password validation plugin is loaded).

## Examples

Failed password validation:

```
GRANT SELECT ON *.* to foobar IDENTIFIED BY 'raboof';
ERROR HY000: Your password does not satisfy the current policy requirements

SHOW WARNINGS;
+-----+-----+
| Level | Code | Message |
+-----+-----+
| Warning | 1819 | cracklib: it is based on your username |
| Error   | 1819 | Your password does not satisfy the current policy requirements |
+-----+-----+
```

Strict password validation:

```
GRANT SELECT ON *.* TO foo IDENTIFIED BY PASSWORD '2222222222222222';
ERROR HY000: The MariaDB server is running with the --strict-password-validation option so it cannot execute this statement
```

## Plugin API

Password validation plugin API is very simple. A plugin must implement only one method —

```
validate_password()
```

. This method takes two arguments — user name and the plain-text password. And it returns 0 when the password has passed the validation and 1 otherwise,

See also

```
mysql/plugin_password_validation.h  
and password validation plugins in  
plugin/simple_password_check/  
and  
plugins/cracklib_password_check/
```

### 4.4.6.5 password\_reuse\_check\_interval

The password\_reuse\_check\_interval system variable is available when the [password\\_reuse\\_check plugin](#) is installed. It determines the retention period for the password history in days. Zero, the default, means passwords are never discarded.

- **Commandline:**

```
--password_reuse_check_interval=#
```

- **Scope:** Global

- **Read-only:** No

- **Data Type:**

```
numeric
```

- **Default Value:**

```
0
```

- **Range:**

```
0
```

```
to
```

```
36500
```

## 4.4.7 Key Management and Encryption Plugin

### 4.4.7.1 Encryption Key Management

#### Contents

1. [Choosing an Encryption Key Management Solution](#)
  1. [File Key Management Plugin](#)
  2. [AWS Key Management Plugin](#)

  1. [Support for Key Rotation in Encryption Plugins](#)
    1. [Encryption Plugins with Key Rotation Support](#)
    2. [Encryption Plugins without Key Rotation Support](#)
4. [Encryption Plugin API](#)

MariaDB's [data-at-rest encryption](#) requires the use of a key management and encryption plugin. These plugins are responsible both for the management of encryption keys and for the actual encryption and decryption of data.

MariaDB supports the use of multiple encryption keys. Each encryption key uses a 32-bit integer as a key identifier. If the specific plugin supports key rotation, then encryption keys can also be rotated, which creates a new version of the encryption key.

## Choosing an Encryption Key Management Solution

How MariaDB manages encryption keys depends on which encryption key management solution you choose. Currently, MariaDB has three options:

## File Key Management Plugin

The File Key Management plugin that ships with MariaDB is a basic key management and encryption plugin that reads keys from a plain-text file. It can also serve as example and as a starting point when developing a key management plugin.

For more information, see [File Key Management Plugin](#).

## AWS Key Management Plugin

The AWS Key Management plugin is a key management and encryption plugin that uses the Amazon Web Services (AWS) Key Management Service (KMS). The AWS Key Management plugin depends on the [AWS SDK for C++](#), which uses the [Apache License, Version 2.0](#). This license is not compatible with MariaDB Server's [GPL 2.0 license](#), so we are not able to distribute packages that contain the AWS Key Management plugin. Therefore, the only way to currently obtain the plugin is to install it from source.

For more information, see [AWS Key Management Plugin](#).

## Eperi Key Management Plugin

The Eperi Key Management plugin is a key management and encryption plugin that uses the [eperi Gateway for Databases](#). The [eperi Gateway for Databases](#) stores encryption keys on the key server outside of the database server itself, which provides an extra level of security. The [eperi Gateway for Databases](#) also supports performing all data encryption operations on the key server as well, but this is optional.

For more information, see [Eperi Key Management Plugin](#).

## Using Multiple Encryption Keys

Key management and encryption plugins support using multiple encryption keys. Each encryption key can be defined with a different 32-bit integer as a key identifier.

The support for multiple keys opens up some potential use cases. For example, let's say that a hypothetical key management and encryption plugin is configured to provide two encryption keys. One encryption key might be intended for "low security" tables. It could use short keys, which might not be rotated, and data could be encrypted with a fast encryption algorithm. Another encryption key might be intended for "high security" tables. It could use long keys, which are rotated often, and data could be encrypted with a slower, but more secure encryption algorithm. The user would specify the identifier of the key that they want to use for different tables, only using high level security where it's needed.

There are two encryption key identifiers that have special meanings in MariaDB. Encryption key

1

is intended for encrypting system data, such as InnoDB redo logs, binary logs, and so on. It must always exist when [data-at-rest encryption](#) is enabled. Encryption key

2

is intended for encrypting temporary data, such as temporary files and temporary tables. It is optional. If it doesn't exist, then MariaDB uses encryption key

1

for these purposes instead.

When [encrypting InnoDB tables](#), the key that is used to encrypt tables [can be changed](#).

When [encrypting Aria tables](#), the key that is used to encrypt tables [cannot currently be changed](#).

## Key Rotation

Encryption key rotation is optional in MariaDB Server. Key rotation is only supported if the backend key management service (KMS) supports key rotation, and if the corresponding key management and encryption plugin for MariaDB also supports key rotation. When a key management and encryption plugin supports key rotation, users can opt to rotate one or more encryption keys, which creates a new version of each rotated encryption key.

Key rotation allows users to improve data security in the following ways:

- If the server is configured to automatically re-encrypt table data with the newer version of the encryption key after the key is rotated, then that prevents an encryption key from being used for long periods of time.
- If the server is configured to simultaneously encrypt table data with multiple versions of the encryption key after the key is rotated, then that prevents all data from being leaked if a single encryption key version is compromised.

The [InnoDB storage engine](#) has [background encryption threads](#) that can [automatically re-encrypt pages when key rotations occur](#).

The [Aria storage engine](#) does [not currently have a similar mechanism to re-encrypt pages in the background when key rotations occur](#).

## Support for Key Rotation in Encryption Plugins

### Encryption Plugins with Key Rotation Support

- The [AWS Key Management Service \(KMS\)](#) supports encryption key rotation, and the corresponding [AWS Key Management Plugin](#) also supports encryption key rotation.

- The [eperi Gateway for Databases](#) supports encryption key rotation, and the corresponding [Eperi Key Management Plugin](#) also supports encryption key rotation.

## Encryption Plugins without Key Rotation Support

- The [File Key Management Plugin](#) does not support encryption key rotation, because it does not use a backend key management service (KMS).

# Encryption Plugin API

New key management and encryption plugins can be developed using the [encryption plugin API](#).

## 4.4.7.2 File Key Management Encryption Plugin

  3. `file_key_management_filename`
13. [Options](#)
  1. `file_key_management`

MariaDB's [data-at-rest encryption](#) requires the use of a [key management and encryption plugin](#). These plugins are responsible both for the management of encryption keys and for the actual encryption and decryption of data.

MariaDB supports the use of [multiple encryption keys](#). Each encryption key uses a 32-bit integer as a key identifier. If the specific plugin supports [key rotation](#), then encryption keys can also be rotated, which creates a new version of the encryption key.

The File Key Management plugin that ships with MariaDB is a [key management and encryption plugin](#) that reads encryption keys from a plain-text file.

## Overview

The File Key Management plugin is the easiest [key management and encryption plugin](#) to set up for users who want to use [data-at-rest encryption](#). Some of the plugin's primary features are:

- It reads encryption keys from a plain-text key file.
- As an extra protection mechanism, the plain-text key file can be encrypted.
- It supports multiple encryption keys.
- It does **not** support key rotation.
- It supports two different algorithms for encrypting data.

It can also serve as an example and as a starting point when developing a key management and encryption plugin with the [encryption plugin API](#).

## Installing the File Key Management Plugin's Package

The File Key Management plugin is included in MariaDB packages as the

`file_key_management.so`

or

`file_key_management.dll`

shared library. The shared library is in the main server package, so no additional package installations are necessary.

## Installing the Plugin

Although the plugin's shared library is distributed with MariaDB by default, the plugin is not actually installed by MariaDB by default. The plugin can be

installed by providing the

```
--plugin-load
```

or the

```
--plugin-load-add
```

options. This can be specified as a command-line argument to

```
mysqld
```

or it can be specified in a relevant server [option group](#) in an [option file](#). For example:

```
[mariadb]
...
plugin_load_add = file_key_management
```

## Uninstalling the Plugin

Before you uninstall the plugin, you should ensure that [data-at-rest encryption](#) is completely disabled, and that MariaDB no longer needs the plugin to decrypt tables or other files.

You can uninstall the plugin dynamically by executing

```
UNINSTALL SONAME
```

or

```
UNINSTALL PLUGIN
```

. For example:

```
UNINSTALL SONAME 'file_key_management';
```

If you installed the plugin by providing the

```
--plugin-load
```

or the

```
--plugin-load-add
```

options in a relevant server [option group](#) in an [option file](#), then those options should be removed to prevent the plugin from being loaded the next time the server is restarted.

## Creating the Key File

In order to encrypt your tables with encryption keys using the File Key Management plugin, you first need to create the file that contains the encryption keys. The file needs to contain two pieces of information for each encryption key. First, each encryption key needs to be identified with a 32-bit integer as the key identifier. Second, the encryption key itself needs to be provided in hex-encoded form. These two pieces of information need to be separated by a semicolon. For example, the file is formatted in the following way:

```
<encryption_key_id1>;<hex-encoded_encryption_key1>
<encryption_key_id2>;<hex-encoded_encryption_key2>
```

You can also optionally encrypt the key file to make it less accessible from the file system. That is explained further in the section below.

The File Key Management plugin uses [Advanced Encryption Standard \(AES\)](#) to encrypt data, which supports 128-bit, 192-bit, and 256-bit encryption keys. Therefore, the plugin also supports 128-bit, 192-bit, and 256-bit encryption keys.

You can generate random encryption keys using the

```
openssl rand
```

command. For example, to create a random 256-bit (32-byte) encryption key, you would run the following command:

```
$ openssl rand -hex 32
a7add9adea9978fda19f21e6be987880e68ac92632ca052e5bb42b1a506939a
```

You can copy this encryption key to the key file using a text editor, or you can append a series of keys to a new key file. For example, to append three new encryption keys to a new key file, you could execute the following:

```
$ sudo openssl rand -hex 32 >> /etc/mysql/encryption/keyfile
$ sudo openssl rand -hex 32 >> /etc/mysql/encryption/keyfile
$ sudo openssl rand -hex 32 >> /etc/mysql/encryption/keyfile
```

The new key file would look something like the following after this step:

```
a7add9adea9978fda19f21e6be987880e68ac92632ca052e5bb42b1a506939a
49c16acc2dffe616710c9ba9a10b94944a737de1beccb52dc1560abfdd67388b
8db1ee74580e7e93ab8cf157f02656d356c2f437d548d5bf16bf2a56932954a3
```

The key file still needs to have a key identifier for each encryption key added to the beginning of each line. Key identifiers do not need to be contiguous. Open the new key file in your preferred text editor and add the key identifiers. For example, the key file would look something like the following after this step:

```
1;a7add9adea9978fda19f21e6be987880e68ac92632ca052e5bb42b1a506939a
2;49c16acc2dffe616710c9ba9a10b94944a737de1beccb52dc1560abfdd67388b
100;8db1ee74580e7e93ab8cf157f02656d356c2f437d548d5bf16bf2a56932954a3
```

The key identifiers give you a way to reference the encryption keys from MariaDB. In the example above, you could reference these encryption keys using the key identifiers

1  
,  
2  
or  
100  
with the

`ENCRYPTION_KEY_ID`

table option or with system variables such as

`innodb_default_encryption_key_id`

. You do not necessarily need multiple encryption keys--the encryption key with the key identifier  
1  
is the only mandatory encryption key.

## Configuring the Path to an Unencrypted Key File

If the key file is unencrypted, then the File Key Management plugin only requires the

`file_key_management_filename`

system variable to be configured.

This system variable can be specified as command-line arguments to

`mysqld`

or it can be specified in a relevant server `option group` in an `option file`. For example:

```
[mariadb]
...
loose_file_key_management_filename = /etc/mysql/encryption/keyfile
```

Note that the

`loose`

option prefix is specified. This option prefix is used in case the plugin hasn't been installed yet.

## Encrypting the Key File

By enabling the File Key Management plugin and setting the appropriate path on the

`file_key_management_filename`

system variable, you can begin using the plugin to manage your encryption keys. But, there is a security risk in doing so, given that the keys are stored in plain text on your system. You can reduce this exposure using file permissions, but it's better to encrypt the whole key file to further restrict access.

There are some important details to keep in mind about encrypting the key file, such as:

- The only algorithm that MariaDB currently supports to encrypt the key file is [Cipher Block Chaining \(CBC\)](#) mode of [Advanced Encryption Standard \(AES\)](#).
- The encryption key size can be 128-bits, 192-bits, or 256-bits.
- The encryption key is created from the [SHA-1](#) hash of the encryption password.
- The encryption password has a max length of 256 characters.

You can generate a random encryption password using the

```
openssl rand
```

command. For example, to create a random 256 character encryption password, you could execute the following:

```
$ sudo openssl rand -hex 128 > /etc/mysql/encryption/keyfile.key
```

You can encrypt the key file using the

```
openssl enc
```

command. For example, to encrypt the key file with the encryption password created in the previous step, you could execute the following:

```
$ sudo openssl enc -aes-256-cbc -md sha1 \  
-pass file:/etc/mysql/encryption/keyfile.key \  
-in /etc/mysql/encryption/keyfile \  
-out /etc/mysql/encryption/keyfile.enc
```

Running this command reads the unencrypted

```
keyfile  
file created above and creates a new encrypted  
keyfile.enc  
file, using the encryption password stored in  
keyfile.key  
. Once you've finished preparing your system, you can delete the unencrypted  
keyfile  
file, as it's no longer necessary.
```

## Configuring the Path to an Encrypted Key File

If the key file is encrypted, then the File Key Management plugin requires both the

```
file_key_management_filename
```

and the

```
file_key_management_filekey
```

system variables to be configured.

The

```
file_key_management_filekey
```

system variable can be provided in two forms:

- It can be the actual plain-text encryption password. This is not recommended, since the plain-text encryption password would be visible in the output of the

```
SHOW VARIABLES
```

statement.

- If it is prefixed with

```
FILE:
```

, then it can be a path to a file that contains the plain-text encryption password.

These system variables can be specified as command-line arguments to

```
mysqld
```

or they can be specified in a relevant server [option group](#) in an [option file](#). For example:

```
[mariadb]
...
loose_file_key_management_filename = /etc/mysql/encryption/keyfile.enc
loose_file_key_management_filekey = FILE:/etc/mysql/encryption/keyfile.key
```

Note that the

`loose`

option prefix is specified. This option prefix is used in case the plugin hasn't been installed yet.

## Choosing an Encryption Algorithm

The File Key Management plugin currently supports two encryption algorithms for encrypting data:

`AES_CBC`

and

`AES_CTR`

. Both of these algorithms use [Advanced Encryption Standard \(AES\)](#) in different modes. AES uses 128-bit blocks, and supports 128-bit, 192-bit, and 256-bit keys. The modes are:

- The

`AES_CBC`

mode uses AES in the [Cipher Block Chaining \(CBC\)](#) mode.

- The

`AES_CTR`

mode uses AES in two slightly different modes in different contexts. When encrypting tablespace pages (such as pages in InnoDB, XtraDB, and Aria tables), it uses AES in the [Counter \(CTR\)](#) mode. When encrypting temporary files (where the cipher text is allowed to be larger than the plain text), it uses AES in the authenticated [Galois/Counter Mode \(GCM\)](#).

The recommended algorithm is

`AES_CTR`

, but this algorithm is only available when MariaDB is built with recent versions of [OpenSSL](#). If the server is built with [wolfSSL](#) or [yaSSL](#), then this algorithm is not available. See [TLS and Cryptography Libraries Used by MariaDB](#) for more information about which libraries are used on which platforms.

## Configuring the Encryption Algorithm

The encryption algorithm can be configured by setting the

`file_key_management_encryption_algorithm`

system variable.

This system variable can be set to one of the following values:

System Variable	Description
<code>AES_CBC</code>	Data is encrypted using AES in the <a href="#">Cipher Block Chaining (CBC)</a> mode. This is the default value.
<code>AES_CTR</code>	Data is encrypted using AES either in the <a href="#">Counter (CTR)</a> mode or in the authenticated <a href="#">Galois/Counter Mode (GCM)</a> mode, depending on context. This is only supported in some builds. See the previous section for more information.

This system variable can be specified as command-line arguments to

`mysqld`

or it can be specified in a relevant server [option group](#) in an [option file](#). For example:

```
[mariadb]
...
loose_file_key_management_encryption_algorithm = AES_CTR
```

Note that the

`loose`

option prefix is specified. This option prefix is used in case the plugin hasn't been installed yet.

Note that this variable does not affect the algorithm that MariaDB uses to decrypt the key file. This variable only affects the encryption algorithm that MariaDB uses to encrypt and decrypt data. The only algorithm that MariaDB currently supports to encrypt the key file is [Cipher Block Chaining \(CBC\)](#) mode of [Advanced Encryption Standard \(AES\)](#).

## Using the File Key Management Plugin

Once the File Key Management Plugin is enabled, you can use it by creating an encrypted table:

```
CREATE TABLE t (i int) ENGINE=InnoDB ENCRYPTED=YES
```

Now, table

`t`  
will be encrypted using the encryption key from the key file.

For more information on how to use encryption, see [Data at Rest Encryption](#).

## Using Multiple Encryption Keys

The File Key Management Plugin supports [using multiple encryption keys](#). Each encryption key can be defined with a different 32-bit integer as a key identifier.

When [encrypting InnoDB tables](#), the key that is used to encrypt tables [can be changed](#).

When [encrypting Aria tables](#), the key that is used to encrypt tables [cannot currently be changed](#).

## Key Rotation

The File Key Management plugin does not currently support [key rotation](#). See [MDEV-20713](#) for more information.

## Versions

Version	Status	Introduced
1.0	Stable	<a href="#">MariaDB 10.1.18</a>
1.0	Gamma	<a href="#">MariaDB 10.1.13</a>
1.0	Alpha	<a href="#">MariaDB 10.1.3</a>

## System Variables

### `file_key_management_encryption_algorithm`

- **Description:** This system variable is used to determine which algorithm the plugin will use to encrypt data.

- The recommended algorithm is

`AES_CTR`

, but this algorithm is only available when MariaDB is built with recent versions of [OpenSSL](#). If the server is built with [wolfSSL](#) or [yaSSL](#), then this algorithm is not available. See [TLS and Cryptography Libraries Used by MariaDB](#) for more information about which libraries are used on which platforms.

- **Commandline:**

`--file-key-management-encryption-algorithm=value`

- **Scope:** Global

- **Dynamic:** No

- **Data Type:**

enumerated

- **Default Value:**

`AES_CBC`

- **Valid Values:**

```
AES_CBC  
,  
AES_CTR
```

---

## file\_key\_management\_filekey

- **Description:** This system variable is used to determine the encryption password that is used to decrypt the key file defined by

```
file_key_management_filename
```

- If this system variable's value is prefixed with

FILE:

, then it is interpreted as a path to a file that contains the plain-text encryption password.

- If this system variable's value is **not** prefixed with

FILE:

, then it is interpreted as the plain-text encryption password. However, this is not recommended.

- The encryption password has a max length of 256 characters.

- The only algorithm that MariaDB currently supports when decrypting the key file is [Cipher Block Chaining \(CBC\)](#) mode of [Advanced Encryption Standard \(AES\)](#). The encryption key size can be 128-bits, 192-bits, or 256-bits. The encryption key is calculated by taking a [SHA-1](#) hash of the encryption password.

- **Commandline:**

```
--file-key-management-filekey=value
```

- **Scope:** Global

- **Dynamic:** No

- **Data Type:**

string

- **Default Value:** (empty)
- 

## file\_key\_management\_filename

- **Description:** This system variable is used to determine the path to the file that contains the encryption keys. If

```
file_key_management_filekey
```

is set, then this file can be encrypted with [Cipher Block Chaining \(CBC\)](#) mode of [Advanced Encryption Standard \(AES\)](#).

- **Commandline:**

```
--file-key-management-filename=value
```

- **Scope:** Global

- **Dynamic:** No

- **Data Type:**

string

- **Default Value:** (empty)
- 

# Options

## file\_key\_management

- **Description:** Controls how the server should treat the plugin when the server starts up.

- Valid values are:

■

OFF  
- Disables the plugin without removing it from the  
`mysql.plugins`  
table.

ON  
- Enables the plugin. If the plugin cannot be initialized, then the server will still continue starting up, but the plugin will be disabled.

FORCE  
- Enables the plugin. If the plugin cannot be initialized, then the server will fail to start with an error.

FORCE\_PLUS\_PERMANENT  
- Enables the plugin. If the plugin cannot be initialized, then the server will fail to start with an error. In addition, the plugin cannot be uninstalled with

`UNINSTALL SONAME`

or

`UNINSTALL PLUGIN`

while the server is running.

◦ See [Plugin Overview: Configuring Plugin Activation at Server Startup](#) for more information.

- **Commandline:**

`--file-key-management=value`

- **Data Type:**

enumerated

- **Default Value:**

ON

- **Valid Values:**

OFF  
,

ON  
,

FORCE  
,

FORCE\_PLUS\_PERMANENT

---

MariaDB's [data-at-rest encryption](#) requires the use of a [key management and encryption plugin](#). These plugins are responsible both for the management of encryption keys and for the actual encryption and decryption of data.

MariaDB supports the use of [multiple encryption keys](#). Each encryption key uses a 32-bit integer as a key identifier. If the specific plugin supports [key rotation](#), then encryption keys can also be rotated, which creates a new version of the encryption key.

The AWS Key Management plugin is a [key management and encryption plugin](#) that uses the [Amazon Web Services \(AWS\) Key Management Service \(KMS\)](#).

## Overview

The AWS Key Management plugin uses the [Amazon Web Services \(AWS\) Key Management Service \(KMS\)](#) to generate and store AES keys on disk, in encrypted form, using the Customer Master Key (CMK) kept in AWS KMS. When MariaDB Server starts, the plugin will decrypt the encrypted keys, using the AWS KMS "Decrypt" API function. MariaDB data will then be encrypted and decrypted using the AES key. It supports multiple encryption keys. It supports key rotation.

## Tutorials

Tutorials related to the AWS Key Management plugin can be found at the following pages:

- [Amazon Web Services \(AWS\) Key Management Service \(KMS\) Encryption Plugin Setup Guide](#)
- [Amazon Web Services \(AWS\) Key Management Service \(KMS\) Encryption Plugin Advanced Usage](#)

## Preparation

- Before you use the plugin, you need to create a Customer Master Key (CMK). Create a key using the AWS Console as described in the [AWS KMS developer guide](#).
- The easiest way to give the AWS key management plugin access to the key is to create an IAM Role with access to the key, and to apply that IAM Role to an EC2 instance where MariaDB Server runs.
- Make sure that MariaDB Server runs under the correct AWS identity that has access to the above key. For example, you can store the AWS credentials in a AWS credentials file for the user who runs

mysql

. More information about the credentials file can be found in the [AWS CLI Getting Started Guide](#).

## Installing the Plugin's Package

The AWS Key Management plugin depends on the [AWS SDK for C++](#), which uses the [Apache License, Version 2.0](#). This license is not compatible with MariaDB Server's [GPL 2.0 license](#), so we are not able to distribute packages that contain the AWS Key Management plugin. Therefore, the only way to currently obtain the plugin is to install it from source.

### Installing from Source

When [compiling MariaDB from source](#), the AWS Key Management plugin is not built by default in [MariaDB 10.1](#), but it is built by default in [MariaDB 10.2](#) and later, on systems that support it.

Compilation is controlled by the

```
-DPLUGIN_AWS_KEY_MANAGEMENT=DYNAMIC -DAWS_SDK_EXTERNAL_PROJECT=1
```

`cmake`

arguments.

The plugin uses [AWS C++ SDK](#), which introduces the following restrictions:

- The plugin can only be built on Windows, Linux and macOS.
- The plugin requires that one of the following compilers is used:

```
gcc  
4.8 or later,  
clang  
3.3 or later, Visual Studio 2013 or later.
```

- On Unix, the

```
libcurl  
development package (e.g.  
libcurl3-dev  
on Debian Jessie),  
uuid  
development package and  
openssl  
need to be installed.
```

- You may need to use a newer version of

`cmake`

than is provided by default in your OS.

## Installing the Plugin

Even after the package that contains the plugin's shared library is installed on the operating system, the plugin is not actually installed by MariaDB by default. There are two methods that can be used to install the plugin with MariaDB.

The first method can be used to install the plugin without restarting the server. You can install the plugin dynamically by executing

```
INSTALL SONAME
```

or

```
INSTALL PLUGIN
```

. For example:

```
INSTALL SONAME 'aws_key_management';
```

The second method can be used to tell the server to load the plugin when it starts up. The plugin can be installed this way by providing the

```
--plugin-load
```

or the

```
--plugin-load-add
```

options. This can be specified as a command-line argument to

```
mysqld
```

or it can be specified in a relevant server [option group](#) in an [option file](#). For example:

```
[mariadb]
...
plugin_load_add = aws_key_management
```

## Uninstalling the Plugin

Before you uninstall the plugin, you should ensure that [data-at-rest encryption](#) is completely disabled, and that MariaDB no longer needs the plugin to decrypt tables or other files.

You can uninstall the plugin dynamically by executing

```
UNINSTALL SONAME
```

or

```
UNINSTALL PLUGIN
```

. For example:

```
UNINSTALL SONAME 'aws_key_management';
```

If you installed the plugin by providing the

```
--plugin-load
```

or the

```
--plugin-load-add
```

options in a relevant server [option group](#) in an [option file](#) , then those options should be removed to prevent the plugin from being loaded the next time the server is restarted.

## Configuring the AWS Key Management Plugin

To enable the AWS Key Management plugin, you also need to set the plugin's system variables. The

```
aws_key_management_master_key_id
```

system variable is the primary one to set. These system variables can be specified as command-line arguments to

```
mysqld
```

or they can be specified in a relevant server [option group](#) in an [option file](#) . For example:

```
[mariadb]
...
aws_key_management_master_key_id=alias/<your key's alias>
```

Once you've updated the configuration file, [restart](#) the MariaDB server to apply the changes and make the key management and encryption plugin available for use.

## Using the AWS Key Management Plugin

Once the AWS Key Management Plugin is enabled, you can use it by creating an encrypted table:

```
CREATE TABLE t (i int) ENGINE=InnoDB ENCRYPTED=YES
```

Now, table

t

will be encrypted using the encryption key generated by AWS.

For more information on how to use encryption, see [Data at Rest Encryption](#) .

## Using Multiple Encryption Keys

The AWS Key Management Plugin supports [using multiple encryption keys](#) . Each encryption key can be defined with a different 32-bit integer as a key identifier. If a previously unused identifier is used, then the plugin will automatically generate a new key.

When [encrypting InnoDB tables](#) , the key that is used to encrypt tables [can be changed](#) .

When [encrypting Aria tables](#) , the key that is used to encrypt tables [cannot currently be changed](#) .

## Key Rotation

The AWS Key Management plugin does support [key rotation](#) . To rotate a key, set the

```
aws_key_management_rotate_key
```

system variable. For example, to rotate key with ID 2:

```
SET GLOBAL aws_key_management_rotate_key=2;
```

Or to rotate all keys, set the value to -1:

```
SET GLOBAL aws_key_management_rotate_key=-1;
```

## Versions

Version	Status	Introduced
1.0	Stable	<a href="#">MariaDB 10.2.6</a> , <a href="#">MariaDB 10.1.24</a>
1.0	Beta	<a href="#">MariaDB 10.1.18</a>
1.0	Experimental	<a href="#">MariaDB 10.1.13</a>

## System Variables

### aws\_key\_management\_key\_spec

- **Description:** Encryption algorithm used to create new keys

- **Commandline:**

```
--aws-key-management-key-spec=value
```

- **Scope:** Global

- **Dynamic:** No

- **Data Type:**

enumerated

- **Default Value:**

AES\_128

- **Valid Values:**

AES\_128

,

AES\_256

---

### aws\_key\_management\_log\_level

- **Description:** Dump log of the AWS SDK to MariaDB error log. Permitted values, in increasing verbosity, are **Off** (default), **Fatal** , **Error** , **Warn** , **Info** , **Debug** , and **Trace** .

- **Commandline:**

```
--aws-key-management-log-level=value
```

- **Scope:** Global

- **Dynamic:** No

- **Data Type:**

enumerated

- **Default Value:**

Off

- **Valid Values:**

Off

,

Fatal

,

Warn

,

Info  
,  
Debug  
and  
Trace

---

## aws\_key\_management\_master\_key\_id

- **Description:** AWS KMS Customer Master Key ID (ARN or alias prefixed by alias/) for the master encryption key. Used to create new data keys. If not set, no new data keys will be created.
  - **Commandline:**  
  --aws-key-management-master-key-id=value
  - **Scope:** Global
  - **Dynamic:** No
  - **Data Type:**  
  string
  - **Default Value:**
- 

## aws\_key\_management\_mock

- **Description:** Mock AWS KMS calls (for testing). Must be enabled at compile-time.
  - **Commandline:**  
  --aws-key-management-mock
  - **Scope:** Global
  - **Dynamic:** No
  - **Data Type:**  
  boolean
  - **Default Value:**  
  OFF
  - **Valid Values:**  
  OFF  
  ,  
  ON
- 

## aws\_key\_management\_region

- **Description:** AWS region name, e.g us-east-1 . Default is SDK default, which is us-east-1.
  - **Commandline:**  
  --aws-key-management-region=value
  - **Scope:** Global
  - **Dynamic:** No
  - **Data Type:**  
  string
  - **Default Value:**  
  'us-east-1'
-

## aws\_key\_management\_request\_timeout

- **Description:** Timeout in milliseconds for create HTTPS connection or execute AWS request. Specify 0 to use SDK default.
  - **Commandline:**  
  --aws-key-management-request-timeout=value
  - **Scope:** Global
  - **Dynamic:** No
  - **Data Type:**  
  integer
  - **Default Value:** 0
- 

## aws\_key\_management\_rotate\_key

- **Description:** Set this variable to a data key ID to perform rotation of the key to the master key given in  
  aws\_key\_management\_master\_key\_id  
  . Specify -1 to rotate all keys.
  - **Commandline:**  
  --aws-key-management-rotate-key=value
  - **Scope:** Global
  - **Dynamic:** Yes
  - **Data Type:**  
  integer
  - **Default Value:**
- 

# Options

## aws\_key\_management

- **Description:** Controls how the server should treat the plugin when the server starts up.
  - Valid values are:
    - OFF
      - Disables the plugin without removing it from the  
`mysql.plugins`  
table.
    - ON
      - Enables the plugin. If the plugin cannot be initialized, then the server will still continue starting up, but the plugin will be disabled.
    - FORCE
      - Enables the plugin. If the plugin cannot be initialized, then the server will fail to start with an error.
    - FORCE\_PLUS\_PERMANENT
      - Enables the plugin. If the plugin cannot be initialized, then the server will fail to start with an error. In addition, the plugin cannot be uninstalled with  
`UNINSTALL SONAME`  
or  
`UNINSTALL PLUGIN`  
while the server is running.
- See [Plugin Overview: Configuring Plugin Activation at Server Startup](#) for more information.

- **Commandline:**  
--aws-key-management=value

- **Data Type:**  
enumerated

- **Default Value:**  
ON

- **Valid Values:**  
OFF  
,  
ON  
,  
FORCE  
,  
FORCE\_PLUS\_PERMANENT

## 4.4.7.4 Amazon Web Services (AWS) Key Management Service (KMS) Encryption Plugin Setup Guide

11. [AWS KMS plugin option reference](#)
12. [Next steps](#)

## Overview

MariaDB Server 10.1 introduces robust, full instance, at-rest encryption. This feature uses a flexible plugin interface to allow actual encryption to be done using a key management approach that meets the customer's needs. MariaDB Server, starting with [MariaDB 10.2](#), includes a plugin that uses the Amazon Web Services (AWS) Key Management Service (KMS) to facilitate separation of responsibilities and remote logging & auditing of key access requests.

Rather than storing the encryption key in a local file, this plugin keeps the master key in AWS KMS. When you first start MariaDB, the AWS KMS plugin will connect to the AWS Key Management Service and ask it to generate a new key. MariaDB will store that key on-disk in an encrypted form. The key stored on-disk cannot be used to decrypt the data; rather, on each startup, MariaDB connects to AWS KMS and has the service decrypt the locally-stored key(s). The decrypted key is stored in-memory as long as the MariaDB server process is running, and that in-memory decrypted key is used to encrypt the local data.

This guide is based on CentOS 7, using systemd with SELinux enabled. Some steps will differ if you use other operating systems or configurations.

## Installing the Plugin's Package

The AWS Key Management plugin depends on the [AWS SDK for C++](#), which uses the [Apache License, Version 2.0](#). This license is not compatible with MariaDB Server's [GPL 2.0 license](#), so we are not able to distribute packages that contain the AWS Key Management plugin. Therefore, the only way to currently obtain the plugin is to install it from source.

## Installing from Source

When [compiling MariaDB from source](#), the AWS Key Management plugin is not built by default in [MariaDB 10.1](#), but it is built by default in [MariaDB 10.2](#) and later, on systems that support it.

Compilation is controlled by the

```
-DPLUGIN_AWS_KEY_MANAGEMENT=DYNAMIC -DAWS_SDK_EXTERNAL_PROJECT=1
```

```
cmake
```

arguments.

The plugin uses [AWS C++ SDK](#), which introduces the following restrictions:

- The plugin can only be built on Windows, Linux and macOS.
- The plugin requires that one of the following compilers is used:

```
gcc  
4.8 or later,  
clang  
3.3 or later, Visual Studio 2013 or later.
```

- On Unix, the

```
libcurl  
development package (e.g.  
libcurl3-dev  
on Debian Jessie),  
uuid  
development package and  
openssl  
need to be installed.
```

- You may need to use a newer version of

```
cmake
```

than is provided by default in your OS.

## Installing the Plugin

Even after the package that contains the plugin's shared library is installed on the operating system, the plugin is not actually installed by MariaDB by default. There are two methods that can be used to install the plugin with MariaDB.

The first method can be used to install the plugin without restarting the server. You can install the plugin dynamically by executing

```
INSTALL SONAME
```

or

```
INSTALL PLUGIN
```

. For example:

```
INSTALL SONAME 'aws_key_management';
```

The second method can be used to tell the server to load the plugin when it starts up. The plugin can be installed this way by providing the

```
--plugin-load
```

or the

```
--plugin-load-add
```

options. This can be specified as a command-line argument to

```
mysqlld
```

or it can be specified in a relevant server [option group](#) in an [option file](#). For example:

```
[mariadb]  
...  
plugin_load_add = aws_key_management
```

## Sign up for Amazon Web Services

If you already have an AWS account, you can skip this section.

1. Load <http://aws.amazon.com/>.
2. Click "Create a Free Account" and complete the steps.
3. You'll need to enter credit card information. Charges related only to your use of the AWS KMS service should be limited to about \$1/month for the

single master key we will create. If you use other services, additional charges may apply. Consult AWS Cloud Pricing Principles <https://aws.amazon.com/pricing/> for more information about pricing of AWS services.

4. You'll need to complete the AWS identity verification process.

## Create an IAM User and/or Role

After creating an account or logging in to an existing account, follow these steps to create an IAM User or Role with restricted privileges that will use (but not administer) your master encryption key.

If you intend to run MariaDB Server on an EC2 instance, you should create a Role (or modify an existing Role already attached to your instance). If you intent to run MariaDB Server outside of AWS, you may want to create a User.

### Creating an IAM Role

1. Load the Identity and Access Management Console at <https://console.aws.amazon.com/iam/> .
2. Click "Roles" in the left-hand sidebar
3. Click "Create new role"
4. Select "AWS Service Role"
5. Click the "Select" button next to "Amazon EC2 / Allows EC2 instances to call AWS services on your behalf."
6. Do not select any policies on the "Attach Policy" screen. Click "Next Step"
7. Click "Next Step"
8. Give your Role a "Role name"
9. Click "Create role"

### Creating an IAM User

1. Load the Identity and Access Management Console at <https://console.aws.amazon.com/iam/> .
2. Click "Users" in the left-hand sidebar.

The screenshot shows the AWS IAM service interface. The top navigation bar includes links for AWS Services and Edit. Below it, there's a search bar and a 'Create New Users' button. The main area has tabs for Details, Groups, and Users (which is selected), Roles, Policies, Identity Providers, Account Settings, and Credential Report. A 'Search IAM' button is also present. On the right, there's a 'User Actions' dropdown with options like 'Create New User', 'Edit User', 'Delete User', and 'View User'. A 'Filter' input field is available. The results table has columns for 'User Name' and 'Groups'. A message at the bottom states 'No records found.'

3. Click the "Create New Users" button
4. Enter a single User Name of your choosing. We'll use "MDBEnc" for this demonstration. Keep the "Generate an access key for each user" box checked.

The screenshot shows the 'Create User' form. The left sidebar has 'Create User' and 'Encryption Keys' options. The main form has a title 'Enter User Names:' followed by a list input field containing '1. MDBEnc'. Below it are four empty input fields labeled 2., 3., 4., and 5. A note says 'Maximum 64 characters each'. At the bottom is a checked checkbox for 'Generate an access key for each user'.

5. Click "Create".
6. Click "Show User Security Credentials".

The screenshot shows a confirmation message: 'Your 1 User(s) have been created successfully. This is the last time these User security credentials will be available for download. You can manage and recreate these credentials any time.' Below this is a link 'Show User Security Credentials'.

7. Copy the Access Key ID and Secret Access Key. Optionally, you can click "Download Credentials". We will need these in order for local programs to interact with AWS using its API.

Your 1 User(s) have been created successfully.  
This is the last time these User security credentials will be available for download.  
You can manage and recreate these credentials any time.  
▼ Hide User Security Credentials

	MDBEnc
Access Key ID:	AKIAIG6IZ6TKF52FVV5A
Secret Access Key:	o7CEf7KhZfsVF9cS0a2roqqZNmuzXtIR869zpSBT

8. Create a file on your computer to hold the credentials for this user. We'll use this file later. It should have this structure:

```
[default]
aws_access_key_id = AKIAIG6IZ6TKF52FVV5A
aws_secret_access_key = o7CEf7KhZfsVF9cS0a2roqqZNmuzXtIR869zpSBT
```

9. Click "Close". If prompted because you did not Download Credentials, ensure that you've saved them somewhere, and click "Close".

## Create a master encryption key

Now, we'll create a master encryption key. This key can *never* be retrieved by *any* application or user. This key is used remotely to encrypt (and decrypt) the actual encryption keys that will be used by MariaDB. If this key is deleted or you lose access to it, you will be unable to use the contents of your MariaDB data directory.

1. Click "Encryption Keys" in the left-hand sidebar.
2. Click the "Get Started Now" button.
3. Use the "Filter" dropdown to choose the region where you'd like to create your master key.
4. Click the "Create Key" button.

Dashboard

Search IAM

Details

Groups

Users

Roles

Policies

Identity Providers

Account Settings

Credential Report

Encryption Keys

Create Key

Key Actions

Filter: US East (N. Virginia)

No records found.

5. Enter an Alias and Description of your choosing.
6. Click "Next Step".
7. Do **not** check the box to make your IAM Role or IAM User user a Key Administrator.
8. Click "Next Step" again.
9. Check the boxes to give your IAM Role and/or IAM User permissions to use this key.

Create Key in US East (N. Virginia)

Step 1: Create Alias and Description

Step 2: Define Key Administrative Permissions

Step 3: Define Key Usage Permissions

Step 4: Preview Key Policy

Define Key Usage Permissions

This Account

Choose the IAM users and roles that can use this key to encrypt and decrypt data

Filter	Name	Path
	<input checked="" type="checkbox"/> MDBEnc	/

10. Click "Next Step".
11. Click "Finish".

You should now see your key listed in the console:

The screenshot shows the AWS IAM console with the URL <https://console.aws.amazon.com/iam/home#encryptionKeys/us-west-2>. A success message at the top says 'Your master key was created successfully. Alias: mariadb-encryption'. Below it, a table lists the key: 'Alias' is 'mariadb-encryption', 'Key ID' is '9da6b21e-e50f-43d4-95d5-a89947c2f7..', and 'Status' is 'Enabled'. The table has columns for Alias, Key ID, and Status.

You'll use the "Alias" you provided when you configure MariaDB later.

We now have a Customer Master Key and an IAM user that has privileges to access it using access credentials. This is enough to begin using the AWS KMS plugin.

## Configure AWS credentials

There are a number of ways to give the IAM credentials to the AWS KMS plugin. The plugin supports reading credentials from all standard locations used across the various AWS API clients.

The easiest approach is to run MariaDB Server in an EC2 instance that has an IAM Role with User access to the CMK you wish to use. You can give key access privileges to a Role already attached to your EC2 instance, or you can create a new IAM Role and attach it to an already-running EC2 instance. If you've done that, no further credentials management is required and you do not need to create a

```
credentials
file.
```

If you're not running MariaDB Server on an EC2 instance, you can also place the credentials in the MariaDB data directory. The AWS API client looks for a

```
credentials
file in the
.aws
subdirectory of the home directory of the user running the client process. In the case of MariaDB, its home directory is its
datadir
```

1. Create a

```
credentials
file that MariaDB can read. Use the region you selected when creating the key. Master keys cannot be used across regions. For example:
```

```
$ cat /var/lib/mysql/.aws/credentials
[default]
aws_access_key_id = AKIAIG6IZ6TKF52FVV5A
aws_secret_access_key = o7CEF7KhZfsVF9cS0a2roqqZNmuzXtIR869zpSBT
region = us-east-1
```

2. Change the permissions of the file so that it is owned by, and can only be read by, the

```
mysql
user:
```

```
chown mysql /var/lib/mysql/.aws/credentials
chmod 600 /var/lib/mysql/.aws/credentials
```

## Configure MariaDB

1. Create a new option file to tell MariaDB to enable encryption functionality and to use the AWS KMS plugin. Create a new file under

```
/etc/my.cnf.d/
(or wherever your OS may have you create such files) with contents like this:
```

```
[mariadb]
plugin_load_add = aws_key_management
aws-key-management = FORCE_PLUS_PERMANENT
aws-key-management-master-key-id = alias/mariadb-encryption
aws-key-management-region = us-east-1
!include /etc/my.cnf.d/enable_encryption.preset
```

1. Append the "Alias" value you copied above to

```
alias/
to use as the value for the
aws-key-management-master-key-id
option.
```

Note that you **must** include

```
aws-key-management-region
```

in your .cnf file if you are not using the us-east-1 region.

Now, you have told MariaDB to use the AWS KMS plugin and you've put credentials for the plugin in a location where the plugin will find them. The /etc/my.cnf.d/enable\_encryption.preset file contains a set of options that enable all available encryption functionality.

When you start MariaDB, the AWS KMS plugin will connect to the AWS Key Management Service and ask it to generate a new key. MariaDB will store that key on-disk in an encrypted form. The key stored on-disk cannot be used to decrypt the data; rather, on each startup, MariaDB must connect to AWS KMS and have the service decrypt the locally-stored key. The decrypted version is stored in-memory as long as the MariaDB server process is running, and that in-memory decrypted key is used to encrypt the local data.

## SELinux and outbound connections from MariaDB

Because MariaDB needs to connect to the AWS KMS service, you must ensure that the host has outbound network connectivity over port 443 to AWS and you must ensure that local policies allow the MariaDB server process to make those outbound connections. By default, SELinux restricts MariaDB from making such connections.

The most simple way to cause SELinux to allow outbound HTTPS connections from MariaDB is to enable to mysql\_connect\_any boolean, like this:

```
setsebool -P mysql_connect_any 1
```

There are more complex alternatives that have a more granular effect, but those are beyond the scope of this document.

## Start MariaDB

Start MariaDB using the

systemctl  
tool:

```
systemctl start mariadb
```

If you do not use systemd, you may have to start MariaDB using some other mechanism.

You should see journal output similar to this:

```
# journalctl --no-pager -o cat -u mariadb.service

[Note] /usr/sbin/mysqld (mysqld 10.1.9-MariaDB-enterprise-log) starting as process 19831 ...
[Note] AWS KMS plugin: generated encrypted datakey for key id=1, version=1
[Note] AWS KMS plugin: loaded key 1, version 1, key length 128 bit
[Note] InnoDB: Using mutexes to ref count buffer pool pages
[Note] InnoDB: The InnoDB memory heap is disabled
[Note] InnoDB: Mutexes and rw_locks use GCC atomic builtins
[Note] InnoDB: Memory barrier is not used
[Note] InnoDB: Compressed tables use zlib 1.2.7
[Note] InnoDB: Using CPU crc32 instructions
[Note] InnoDB: Initializing buffer pool, size = 2.0G
[Note] InnoDB: Completed initialization of buffer pool
[Note] InnoDB: Highest supported file format is Barracuda.
[Note] InnoDB: 128 rollback segment(s) are active.
[Note] InnoDB: Waiting for purge to start
[Note] InnoDB: Percona XtraDB (http://www.percona.com) 5.6.26-74.0 started; log sequence number 1616819
[Note] InnoDB: Dumping buffer pool(s) not yet started
[Note] Plugin 'FEEDBACK' is disabled.
[Note] AWS KMS plugin: generated encrypted datakey for key id=2, version=1
[Note] AWS KMS plugin: loaded key 2, version 1, key length 128 bit
[Note] Using encryption key id 2 for temporary files
[Note] Server socket created on IP: '::'.
[Note] Reading of all Master_info entries succeeded
[Note] Added new Master_info '' to hash table
[Note] /usr/sbin/mysqld: ready for connections.
```

Note the several lines of output that refer explicitly to the "AWS KMS plugin". You can see that the plugin generates a "datakey", loads that data key, and then later generates and loads a second data key. The 2nd data key is used to encrypt temporary files and temporary tables.

You can see the encrypted keys stored on-disk in the datadir:

```
# ls -l /var/lib/mysql/aws*
-rw-rw----. 1 mysql mysql 188 Feb 25 18:55 /var/lib/mysql/aws-kms-key.1.1
-rw-rw----. 1 mysql mysql 188 Feb 25 18:55 /var/lib/mysql/aws-kms-key.2.1
```

Note that those keys are not useful alone. They are encrypted. When MariaDB starts up, the AWS KMS plugin decrypts those keys by interacting with AWS KMS.

For maximum security, you should start from an empty datadir and run

```
mysql_install_db  
after configuring encryption. Then you should re-import your data so that it is fully encrypted. Use  
sudo  
to run  
mysql_install_db  
so that it finds your credentials file:
```

```
# sudo -u mysql mysql_install_db  
Installing MariaDB/MySQL system tables in '/var/lib/mysql' ...  
2016-02-25 23:16:06 139731553998976 [Note] /usr/sbin/mysqld (mysqld 10.1.11-MariaDB-enterprise-log) starting as process 39551 ...  
2016-02-25 23:16:07 139731553998976 [Note] AWS KMS plugin: generated encrypted datakey for key id=1, version=1  
2016-02-25 23:16:07 139731553998976 [Note] AWS KMS plugin: loaded key 1, version 1, key length 128 bit  
...
```

## Create encrypted tables

With

```
innodb-encrypt-tables=ON  
, new InnoDB tables will be encrypted by default, using the key ID set in  
innodb_default_encryption_key_id  
(default 1). With  
innodb-encrypt-tables=FORCE  
enabled, it is not possible to manually bypass encryption when creating a table.
```

You can cause the AWS KMS plugin to create new encryption keys at-will by specifying a new ENCRYPTION\_KEY\_ID when creating a table:

```
MariaDB [test]> create table t1 (id serial, v varchar(32)) ENCRYPTION_KEY_ID=3;  
Query OK, 0 rows affected (0.91 sec)
```

```
[Note] AWS KMS plugin: generated encrypted datakey for key id=3, version=1  
[Note] AWS KMS plugin: loaded key 3, version 1, key length 128 bit
```

```
# ls -l /var/lib/mysql/aws*  
-rw-rw---- 1 mysql mysql 188 Feb 25 18:55 /var/lib/mysql/aws-kms-key.1.1  
-rw-rw---- 1 mysql mysql 188 Feb 25 18:55 /var/lib/mysql/aws-kms-key.2.1  
-rw-rw---- 1 mysql mysql 188 Feb 25 19:10 /var/lib/mysql/aws-kms-key.3.1
```

Read more about encrypting data in the [Data at Rest Encryption](#) section of the MariaDB Documentation.

## AWS KMS plugin option reference

- `aws_key_management_master_key_id`  
: AWS KMS Customer Master Key ID (ARN or alias prefixed by  
alias/  
) for master encryption key. Used to create new data keys. If not set, no new data keys will be created.
- `aws_key_management_rotate_key`  
: Set this variable to a data key ID to perform rotation of the key to the master key given in  
`aws_key_management_master_key_id`  
. Specify -1 to rotate all keys.
- `aws_key_management_key_spec`  
: Encryption algorithm used to create new keys. Allowed values are AES\_128 (default) or AES\_256.
- `aws_key_management_log_level`  
: Logging for AWS API. Allowed values, in increasing verbosity, are "Off" (default), "Fatal", "Error", "Warn", "Info", "Debug", and "Trace".

## Next steps

For more information about advanced usage, including strategies to manage credentials, enforce separation of responsibilities, and even require 2-factor authentication to start your MariaDB server, please review [Amazon Web Services \(AWS\) Key Management Service \(KMS\) Encryption Plugin Advanced Usage](#).

    - 2. [CloudWatch](#)

This document assumes you've already set up an Amazon Web Services (AWS) account, created a master key in the Key Management Service (KMS), and have done the basic work to set up the MariaDB AWS KMS plugin. These steps are all described in [Amazon Web Services \(AWS\) Key Management Service \(KMS\) Encryption Plugin Setup Guide](#).

Ultimately, keeping all the credentials required to read the key on a single host means that a user who has gained access to the host has enough information to read the encrypted files in the datadir, read the encrypted keys from the datadir, interact with AWS KMS to decrypt the encrypted keys, and then used the decrypted keys to decrypt the encrypted data.

Theoretically, a superuser can read the memory of the MariaDB server process to read the decrypted keys or restart MariaDB with password authentication disabled in order to dump data, or add new users to MariaDB in order to allow a user to connect and dump the data. Resolving these issues is beyond the scope of this document. A user who gains root access to your operating system or root access to your MariaDB server will have the ability to decrypt your data. Plan accordingly.

## Managing AWS credentials

Putting the AWS credentials in a file inside the MariaDB home directory is not ideal. By default, any user with the FILE privilege can read any files that the MariaDB server has permission to read, which would include the credentials file. To protect against this, you should set

```
secure_file_priv  
to restrict the location the server will allow a user to read from when executing  
LOAD DATA INFILE  
or the  
LOAD_FILE()  
function.
```

But putting them in other locations requires passing additional data to the server, which in the case of CentOS 7 requires customizing the systemd startup procedure. This is most easily done by creating a "drop-in" file in /etc/systemd/system/mariadb.service.d/. The file should end in ".conf" but can otherwise be named whatever you like. After making any changes to systemd files, execute

```
systemctl daemon-reload  
and then start (or restart) the service as usual.
```

You can place the credentials file in a location of your choosing and then refer to that file by setting the AWS\_CREDENTIAL\_PROFILE\_FILE environment variable in the drop-in file:

```
[Service]  
Environment=AWS_CREDENTIAL_PROFILE_FILE=/etc/aws-kms-credentials
```

The credentials file will need to be readable by the "mysql" user, but it does not need to be readable by any other user.

AWS credentials can also be put directly into a "drop-in" systemd file that will be read when starting the MariaDB service:

```
# cat /etc/systemd/system/mariadb.service.d/aws-kms.conf  
[Service]  
Environment=AWS_ACCESS_KEY_ID=AKIAIRSG2XYZATCJLZ4A  
Environment=AWS_SECRET_ACCESS_KEY=ux91LZIxCp4ZXabcdefgIViQNtTan42QAmJqJVqV
```

However, any OS user can read this information from systemd, which could be considered a security risk. Another solution is to put the credentials in a separate file that is only readable by root and then refer to that file using an

```
EnvironmentFile  
directive in a drop-in systemd file.
```

```
# cat /etc/systemd/system/mariadb.service.d/aws-kms.env
AWS_ACCESS_KEY_ID=AKIAIRSG2XYZATCJLZ4A
AWS_SECRET_ACCESS_KEY=ux91LZIxCp4ZXabcdefgIViQNTan42QAmJqJVqV

# chown root /etc/systemd/system/mariadb.service.d/aws-kms.env
# chmod 600 /etc/systemd/system/mariadb.service.d/aws-kms.env

# cat /etc/systemd/system/mariadb.service.d/aws-kms.conf
[Service]
EnvironmentFile=/etc/systemd/system/mariadb.service.d/aws-kms.env
```

That has the advantage the the credentials can only be read directly by root. systemd adds those variables to the environment of the MariaDB server when starting it, and MariaDB can use the credentials to interact with AWS. Note, though, that any process running as the "mysql" user can still read the credentials from the proc filesystem on Linux.

```
$ whoami
mysql
$ cat /proc/$(pgrep mysqld)/environ | tr '\0' '\n' | grep AWS
AWS_ACCESS_KEY_ID=AKIAIRSG2XYZATCJLZ4A
AWS_SECRET_ACCESS_KEY=ux91LZIxCp4ZXabcdefgIViQNTan42QAmJqJVqV
```

## AWS KMS Key Policy

AWS KMS allows flexible, user-editable key policy. This offers fine-grained control over which users can operate on keys. The possibilities range from simply restricting which IP addresses are allowed to perform operations on the key, to requiring a MFA (Multi-Factor Authentication) device to use the key, to enforcing separation of responsibilities by creating an additional user with limited privileges to enable and disable the key. All 3 of these options will be outlined in this section.

For more details about customizing the Key Policy for your master keys, please consult the [AWS Key Management Service Key Policy](#) documentation.

### Source IP restrictions

A simple, common-sense restriction to put in place is to restrict the range of IP addresses that are allowed to use your master key. This way, even if someone obtains API credentials, they'll be unable to use them to decrypt your encryption keys from a different host.

To restrict API access from only a specific IP address or range of IP addresses, you'll need to manually edit the key policy.

1. Load the IAM console at <https://console.aws.amazon.com/iam/>.
2. Click "Encryption Keys" in the left-hand sidebar.
3. Click the name of your encryption key to view its details.
4. Click the link labeled "Switch to policy view", to the right of the heading of the "Key Policy" section.
5. Locate the section that contains

```
"Sid": "Allow use of the key"
```

6. Add this text below the

```
"Sid"
line:
```

```
"Condition": {
    "IpAddress": {
        "aws:SourceIp": [
            "10.1.2.3/32"
        ]
    }
},
```

... replacing

```
10.1.2.3/32
```

above with an IP address or range of IP addresses in CIDR format. For example, a single address would be

```
192.168.12.34/32
```

, while a range of addresses might be

```
192.168.0.0/24
```

7. Click "Save Changes".
8. Click "Proceed" if prompted with a warning about using the default view in the future.

Access to the API will now be restricted to requests coming from the IP address or range of IP addresses specified in the policy.

## Using a Multi-Factor Authentication (MFA) device

One approach is to modify the key policy for the master key so that MFA (Multi-Factor Authentication) is required in order to use the key. This is achieved with a wrapper that handles prompting the user for an MFA token, acquires temporary, limited-privilege credentials from the AWS Security Token Service

(STS), and puts those credentials into the environment of the MariaDB server process. The credentials can expire after as little as 15 minutes.

To require an MFA token for users of the key, you'll need to manually edit the key policy.

1. Load the IAM console at <https://console.aws.amazon.com/iam/>.
2. Click "Encryption Keys" in the left-hand sidebar.
3. Click the name of your encryption key to view its details.
4. Click the link labeled "Switch to policy view", to the right of the heading of the "Key Policy" section.
5. Locate the section that contains  

```
"Sid": "Allow use of the key"
```

6. Add this text below the

```
"Sid"  
line:
```

```
"Condition": {  
    "Bool": {  
        "aws:MultiFactorAuthPresent": "True"  
    }  
},
```

7. Click "Save Changes".
8. Click "Proceed" if prompted with a warning about using the default view in the future.

Now, add an MFA device for your user. You'll need to have a hardware MFA device or an application such as Google Authenticator installed on your smartphone.

1. Click "Users" in the left-hand sidebar.
2. Click the name of your user.
3. Click the "Security Credentials" tab.
4. In the "Sign-In Credentials" section, click the "Manage MFA Device" button.
5. Complete the steps to activate your MFA device.
6. Copy the ARN for your MFA device. You will need to use this when configuring the wrapper program.

Now, set up the wrapper program.

1. Copy the iam-kms-wrapper file to /usr/local/bin/, and ensure that it is executable.
2. Create a drop-in systemd config file in

```
/etc/systemd/system/mariadb.service.d/  
:  
[Service]  
EnvironmentFile=/etc/systemd/system/mariadb.service.d/aws-kms.env  
ExecStart=  
ExecStart=/usr/local/bin/iam-kms-wrapper --config=/etc/my.cnf.d/iam-kms-wrapper.config /usr/sbin/mysqld $MYSQLD_OPTS
```

3. Execute

```
systemctl daemon-reload
```

4. Create a file at

```
/etc/my.cnf.d/iam-kms-wrapper.config  
with these contents, using the ARN for your MFA device as the value for  
kms_mfa_id  
:
```

```
[kms]  
kms_mfa_id = arn:aws:iam::551888187628:mfa/MDBEnc  
kms_mfa_socket = /tmp/kms_mfa_socket
```

When you start the MariaDB service now, the wrapper will temporarily create a socket file at the location given by the

```
kms_mfa_socket
```

option. The wrapper will read the MFA code from the socket and will use it to authenticate to KMS. To give the MFA code, simply write the digits to the socket file using

```
echo  
:  
echo 111676 > /tmp/kms_mfa_socket
```

The

```
systemctl  
command will block until MariaDB starts, so you will need to write the code to the socket file via a separate terminal.
```

Note that the temporary credentials put into the environment of the MariaDB process will expire after a period of time defined by the request to the AWS Security Token Service (STS). In the example below, they will expire after 900 seconds. After that time, MariaDB may be unable to generate new encrypted data keys, which means that, for example, an attempt to create a table with a previously-unused key ID would fail.

## Wrapper program example

Here's an example wrapper program written in go. Build this into an executable named

iam-kms-wrapper

and use it as instructed above. This could of course be written in any language for which an appropriate AWS SDK exists, but go has the benefit of compiling to a static binary, which means you do not have to worry about interpreter versions or installing complex dependencies on the host that runs your MariaDB server.

```
package main

import (
    "syscall"
    "os"
    "log"
    "flag"
    "github.com/aws/aws-sdk-go/aws"
    "github.com/aws/aws-sdk-go/aws/session"
    "github.com/aws/aws-sdk-go/aws/awser"
    "github.com/aws/aws-sdk-go/service/sts"
    "github.com/robfig/config"
)

func main() {

    config_file_p := flag.String("config", "", "location of the config file")
    flag.Parse()

    if flag.NArg() < 1 {
        log.Fatal("Command to wrap must be given as first command-line argument")
    }

    cmd := flag.Arg(0)
    args := flag.Args()[0:]

    conf, err := config.ReadDefault(*config_file_p)
    if err != nil {
        log.Fatal(err)
    }

    kms_mfa_id, err := conf.String("kms", "kms_mfa_id")
    mfa_socket_file, err := conf.String("kms", "kms_mfa_socket")

    sess := session.New()
    svc := sts.New(sess)

    syscall.Umask(0044)

    log.Printf("Reading MFA token from %s\n", mfa_socket_file)

    if err := syscall.Mknod(mfa_socket_file, syscall.S_IFIFO|uint32(os.FileMode(0622)), 0); err != nil {
        log.Fatal(err)
    }

    file, err := os.Open(mfa_socket_file)
    if err != nil {
        log.Fatal(err)
    }

    token := make([]byte, 6)

    if _, err := file.Read(token); err != nil {
        log.Fatal(err)
    }

    file.Close()

    if err := syscall.Unlink(mfa_socket_file); err != nil {
        log.Fatal(err)
    }

    mfa_token := string(token)

    token_params := &sts.GetSessionTokenInput{
        DurationSeconds: aws.Int64(900),
        SerialNumber:   aws.String(kms_mfa_id),
        TokenCode:      aws.String(mfa_token),
    }
```

```

resp, err := svc.GetSessionToken(token_params)
if err != nil {
    if awsErr, ok := err.(awserr.Error); ok {
        // Prints out full error message, including original error if there was one.
        log.Fatal("Error:", awsErr.Error())
    } else {
        log.Fatal("Error:", err.Error())
    }
}

creds := resp.Credentials

os.Setenv("AWS_ACCESS_KEY_ID", *creds.AccessKeyId)
os.Setenv("AWS_SECRET_ACCESS_KEY", *creds.SecretAccessKey)
os.Setenv("AWS_SESSION_TOKEN", *creds.SessionToken)

execErr := syscall.Exec(cmd, args, os.Environ())
if execErr != nil {
    panic(execErr)
}
}

```

## Disabling keys when not needed

Another possibility is to use the API to disable access to the master key and enable it only when a trusted administrator knows that the MariaDB service needs to be started. A specialized tool on a separate host could be used to enable the key for a very short period of time while the service starts and then quickly disable the key.

To do this, you can create an extra IAM User that can only use the kms:EnableKey and kms:DisableKey API endpoints for your key. This user will not be able to encrypt or decrypt any data using the key.

First, create a new user.

1. Load the IAM console at <https://console.aws.amazon.com/iam/>.
2. Click "Users" in the left-hand sidebar.
3. Click "Create New Users".
4. Enter a new user name. (The examples will use "MDBEncAdmin".)
5. Click "Show User Security Credentials".
6. Copy the credentials and put them in a

credentials  
file with this structure:

```
[MDBEncAdmin]
aws_access_key_id=AKIAJMPN07EBKABCDEF
aws_secret_access_key=pVdGwbuK5/jG64aBK1oEJOXR1kdM0aAylgabCDef
```

7. Click "Close".
8. Click "Close" again if prompted.
9. Click the name of your new user to open the details view.
10. Copy the "User ARN" value for your user (for example "arn:aws:iam::551888181234:user/MDBEncAdmin"). You will need this for the next step.

Now, give the new user permission to perform API operations on your key.

1. Click "Encryption Keys" in the left-hand sidebar.
2. Click the name of your key to open the details view.
3. Click "Switch to policy view" if it is not already open. (The "policy view" is a large text field that contains JSON describing the key policy.)
4. Create a new item in the

Statement  
array with this structure:

```
{
    "Sid": "Allow Enable and Disable of the key",
    "Effect": "Allow",
    "Principal": {
        "AWS": "arn:aws:iam::551888181234:user/MDBEncAdmin"
    },
    "Action": [
        "kms:EnableKey",
        "kms:DisableKey"
    ]
},
```

...so that your Key Policy looks like this:

```
{  
    "Version": "2012-10-17",  
    "Id": "key-consolepolicy-2",  
    "Statement": [  
        {  
            "Sid": "Allow Enable and Disable of the key",  
            "Effect": "Allow",  
            "Principal": {  
                ...  
            }  
        }  
    ]  
}
```

#### 5. Click "Save Changes".

You've now added a new IAM user and you've given that user privileges to enable and disable your key. This user will be able to perform those operations using the AWS CLI or via a script of your own design using the AWS API. For example, using the [AWS CLI](#):

```
$ cat ~/.aws/credentials  
[MDBEncAdmin]  
aws_access_key_id=AKIAJMPN07EBKABCDEF  
aws_secret_access_key=pVdGwbuK5/jG64aBK1oEJOXR1kdM0aAylgabCDef  
  
$ AWS_PROFILE=MDBEncAdmin aws --region us-east-1 kms disable-key --key-id arn:aws:kms:us-east-1:551888181234:key/abcd8f6-084b-4  
...
```

In order for MariaDB to start, this new user will have to enable the master key, then the DBA can start MariaDB, and this user can once again disable the master key after the service has started. Note that in this workflow, MariaDB will be unable to create new encryption keys, such as would be done when a user creates a table that refers to a non-existent key ID. The AWS KMS plugin will encounter an error if it tries to generate a new encryption key while the master key is disabled. In that scenario, the key administrator would have to enable the key before the operation could succeed. Here's what you should expect to see in the journal if MariaDB tries to interact with a disabled master key:

```
[ERROR] AWS KMS plugin : GenerateDataKeyWithoutPlaintext failed : DisabledException - Unable to parse ExceptionName: DisabledExc  
...
```

## Adding MFA

It's also possible to add MFA to this technique so that the user that enables & disables the master key has to authenticate using an MFA device. Adapt the instructions in the MFA section above to add MFA to the policy section for the user with `EnableKey` and `DisableKeys` privileges, add an MFA device for that user, use Security Token Service (STS) to get temporary security credentials, and then use those credentials to make the API calls. Here's an example Python script that follows that workflow:

```

#!/usr/bin/env python

import boto3
import sys

# Command-Line argument processing should be more robust than this...
action= sys.argv[1]
mfa_token= sys.argv[2]

# These should perhaps go into a config file instead of here
mfa_serial= 'arn:aws:iam::551888181234:mfa/MDBEncAdmin'
key_id= 'arn:aws:kms:us-east-1:551888181234:key/abcd8f6-084b-4cff-99ca-abcdef6c7907c'

# Make the connection to the Security Token Service to get temporary credentials
token_client= boto3.client('sts')
token_response= token_client.get_session_token(
    DurationSeconds= 900,
    SerialNumber= mfa_serial,
    TokenCode= mfa_token
)
cred= token_response['Credentials']

# Start new session using temporary, MFA-authenticated credentials
kms_session= boto3.session.Session(
    aws_access_key_id= cred['AccessKeyId'],
    aws_secret_access_key= cred['SecretAccessKey'],
    aws_session_token= cred['SessionToken'],
    region_name= key_id.split(':')[3]
)

# Start KMS client and execute operation against key
kms_client= kms_session.client('kms')
if action == 'enable' or action == 'e':
    action_f= kms_client.enable_key
elif action == 'disable' or action == 'd':
    action_f= kms_client.disable_key
else:
    raise Exception('Action must be either "disable" or "enable"')

action_f(KeyId=key_id)

```

```

$ AWS_PROFILE=MDBEncAdmin python kms-manage-key disable 575290
$ AWS_PROFILE=MDBEncAdmin python kms-manage-key enable 799870

```

## Logging and auditing

### CloudTrail

Amazon's CloudTrail service creates JSON-formatted text log files for every API interaction. Enabling CloudTrail requires S3, which incurs additional fees.

First, enable CloudTrail and add a trail.

1. Load the CloudTrail console at <https://console.aws.amazon.com/cloudtrail/> .
2. If you've never used CloudTrail before, click "Get Started Now".
3. Enter a value for "trail name". This example uses "mariadb-encryption-key".
4. Create a new S3 bucket, using a globally unique name, or use an existing S3 bucket, according to your needs.
5. Click "Turn On".

If you navigate to the S3 bucket you created, you should find log files that contain JSON-formatted descriptions of your API interactions.

### CloudWatch

Amazon's CloudWatch service allows you to create alarms and event rules that monitor log information.

First, send your CloudTrail logs to CloudWatch.

1. Load the CloudTrail console at <https://console.aws.amazon.com/cloudtrail/> .
2. Click "Trails" in the left-hand navigation sidebar.
3. Click the name of your trail to open the Configuration view.
4. In the "CloudWatch Logs" section, click "Configure".
5. Click "Continue".
6. Click "Allow".

Now, set up an SNS topic to facilitate email notifications.

1. Open <https://console.aws.amazon.com/sns/>.
2. Make sure the region in the console (look in the upper-right corner) is the same as the region where you created your key!
3. Click "Get Started" is prompted.
4. Click "Events" in the left-hand sidebar.
5. Click "Create new topic".
6. Enter a *Topic name* of your choosing.
7. Enter a *Display name* of your choosing.
8. Click "Create topic".
9. Click the ARN of your new SNS topic.
10. Click "Create Subscription".
11. Select "Email" from the Protocol dropdown.
12. Enter the desired notification email address in the Endpoint field.
13. Wait for the confirmation email to show up and follow the instructions.

Now, configure CloudWatch and create an Event Rule.

1. Open <https://console.aws.amazon.com/cloudwatch/>.
2. Make sure the region in the console (look in the upper-right corner) is the same as the region where you created your key and your SNS topic!
3. Click "Events" in the left-hand sidebar.
4. Click "Create rule".
5. Choose "AWS API call" from the "Select event source" dropdown.
6. Choose "KMS" from the "Service name" dropdown.
7. Decide which operations should trigger the event. (You can keep "Any operation" selected for simplicity.)
8. Click "Add target".
9. Select "SNS target" from the dropdown.
10. Select the SNS topic you created in the previous steps.
11. Click "Configure details".
12. Enter a *Name* and *Description* of your choosing.
13. Click "Create rule".

You should now get emails any time someone executes API calls on the KMS service in the region where you've created the CloudWatch Event rule. That means you should get email any time the key is enabled or disabled, and any time the AWS KMS plugin generates new keys or decrypts the keys stored on disk on the MariaDB server.

You may also wish to create an event rule (or an additional event) that matches only when an unauthorized user tries to access the key. You might accomplish that by manually editing the Event selector of the rule to look something like this:

```
{  
  "detail-type": [  
    "AWS API Call via CloudTrail"  
>  ],  
  "detail": {  
    "eventSource": [  
      "kms.amazonaws.com"  
>  ],  
    "errorCode": [  
      "AccessDenied",  
      "UnauthorizedOperation"  
>  ]  
>  }  
> }
```

The emails are formatted as JSON. Further customization of the CloudWatch email workflow is beyond the scope of this document.

There are many other workflows available using CloudWatch, including workflows with alarms and dashboards. Those are beyond the scope of this document.

MariaDB's [data-at-rest encryption](#) requires the use of a [key management and encryption plugin](#). These plugins are responsible both for the management of encryption keys and for the actual encryption and decryption of data.

MariaDB supports the use of [multiple encryption keys](#). Each encryption key uses a 32-bit integer as a key identifier. If the specific plugin supports [key rotation](#), then encryption keys can also be rotated, which creates a new version of the encryption key.

The Eperi Key Management plugin is a [key management and encryption plugin](#) that integrates with [eperi Gateway for Databases](#).

## Overview

The Eperi Key Management plugin is one of the [key management and encryption plugins](#) that can be set up for users who want to use [data-at-rest encryption](#). Some of the plugin's primary features are:

- It reads encryption keys from [eperi Gateway for Databases](#).
- It supports multiple encryption keys.
- It supports key rotation.
- It supports two different algorithms for encrypting data.

The [eperi Gateway for Databases](#) stores encryption keys on the key server outside of the database server itself, which provides an extra level of security. The [eperi Gateway for Databases](#) also supports performing all data encryption operations on the key server as well, but this is optional.

It also provides the following benefits:

- Key management outside the database
- No keys on database server hard disk
- Graphical user interface for configuration
- Encryption and decryption outside the database, supporting HSM's for maximum security.

Support for MariaDB is provided in [eperi Gateway for Databases 3.4](#).

## Installing the Eperi Key Management Plugin's Package

For information on how to install the package, see Eperi's documentation at the [Eperi Customer Portal](#).

## Installing the Plugin

Even after the package that contains the plugin's shared library is installed on the operating system, the plugin is not actually installed by MariaDB by default. The plugin can be installed by providing the

```
--plugin-load
```

or the

```
--plugin-load-add
```

options. This can be specified as a command-line argument to

```
mysqld
```

or it can be specified in a relevant server [option group](#) in an [option file](#). For example:

```
[mariadb]
...
plugin_load_add = eperi_key_management_plugin
```

## Uninstalling the Plugin

Before you uninstall the plugin, you should ensure that [data-at-rest encryption](#) is completely disabled, and that MariaDB no longer needs the plugin to decrypt tables or other files.

You can uninstall the plugin dynamically by executing

```
UNINSTALL SONAME
```

or

```
UNINSTALL PLUGIN
```

. For example:

```
UNINSTALL SONAME 'eperi_key_management_plugin';
```

If you installed the plugin by providing the

```
--plugin-load
```

or the

```
--plugin-load-add
```

options in a relevant server [option group](#) in an [option file](#), then those options should be removed to prevent the plugin from being loaded the next time the server is restarted.

## Configuring the Eperi Key Management Plugin

For information on how to configure the plugin, see Eperi's documentation at the [Eperi Customer Portal](#).

## Using the Eperi Key Management Plugin

Once the Eperi Key Management Plugin is enabled, you can use it by creating an encrypted table:

```
CREATE TABLE t (i int) ENGINE=InnoDB ENCRYPTED=YES
```

Now, table

t

will be encrypted using the encryption key from the key server.

For more information on how to use encryption, see [Data at Rest Encryption](#).

## Using Multiple Encryption Keys

The Eperi Key Management Plugin supports [using multiple encryption keys](#). Each encryption key can be defined with a different 32-bit integer as a key identifier.

When [encrypting InnoDB tables](#), the key that is used to encrypt tables [can be changed](#).

When [encrypting Aria tables](#), the key that is used to encrypt tables [cannot currently be changed](#).

## Key Rotation

The Eperi Key Management plugin supports [key rotation](#).

## Versions

Version	Status	Introduced
---------	--------	------------

## System Variables

### eperi\_key\_management\_plugin\_databaseId

- **Description:** Determines the database ID which is processed in the eperi Gateway.

- **Commandline:**

```
--eperi-key-management-plugin-databaseid=value
```

- **Scope:** Global

- **Dynamic:** No

- **Data Type:**

integer

- **Default Value:**

1

### eperi\_key\_management\_plugin\_encryption\_algorithm

- **Description:** This system variable is used to determine which algorithm the plugin will use to encrypt data.

- The recommended algorithm is

AES\_CTR

, but this algorithm is only available when MariaDB is built with recent versions of [OpenSSL](#). If the server is built with [wolfSSL](#) or [yaSSL](#), then this algorithm is not available. See [TLS and Cryptography Libraries Used by MariaDB](#) for more information about which libraries are used on which platforms.

- **Commandline:**

```
--eperi-key-management-plugin-encryption-algorithm=value
```

- **Scope:** Global

- **Dynamic:** No

- **Data Type:**

enumerated

- **Default Value:**

AES\_CBC

- **Valid Values:**

AES\_CBC

,

AES\_CTR

### eperi\_key\_management\_plugin\_encryption\_mode

- **Description:** Encryption mode.

- **Commandline:**

```
--eperi-key-management-plugin-encryption-mode=value
```

- **Scope:** Global

- **Dynamic:** No

- **Data Type:**

enumerated

- **Default Value:**

database

- **Valid Values:**

```
database
,
gateway
```

---

## eperi\_key\_management\_plugin\_oss1mt

- **Description:** Determines, whether the plugin should register callback functions for OpenSSL thread support.

- **Commandline:**

```
--eperi-key-management-plugin-oss1mt=value
```

- **Scope:** Global

- **Dynamic:** No

- **Data Type:**

```
boolean
```

- **Default Value:**

```
0
(Linux),
1
(Windows)
```

---

## eperi\_key\_management\_plugin\_port

- **Description:** Listener port for plugin.

- **Commandline:**

```
--eperi-key-management-plugin-port=value
```

- **Scope:** Global

- **Dynamic:** No

- **Data Type:**

```
integer
```

- **Default Value:**

```
14332
```

---

## eperi\_key\_management\_plugin\_url

- **Description:** URL to key server. The expected format of the URL is <host>:<port>. The port number is optional, and the port number defaults to 14333 if it is not specified.

- **Commandline:**

```
--eperi-key-management-plugin-url=value
```

- **Scope:** Global

- **Dynamic:** No

- **Data Type:**

```
string
```

- **Default Value:**

```
NULL
```

---

## eperi\_key\_management\_plugin\_url\_check\_disabled

- **Description:** Determines, whether the connection between plugin and eperi Gateway is tested at server startup.

- **Commandline:**

```
--eperi-key-management-plugin-url-check-disabled=value
```

- **Scope:** Global

- **Dynamic:** No

- **Data Type:**

boolean

- **Default Value:**

1

---

## Options

### eperi\_key\_management\_plugin

- **Description:** Controls how the server should treat the plugin when the server starts up.

- Valid values are:

- OFF

- Disables the plugin without removing it from the

- `mysql.plugins`

- table.

- ON

- Enables the plugin. If the plugin cannot be initialized, then the server will still continue starting up, but the plugin will be disabled.

- FORCE

- Enables the plugin. If the plugin cannot be initialized, then the server will fail to start with an error.

- FORCE\_PLUS\_PERMANENT

- Enables the plugin. If the plugin cannot be initialized, then the server will fail to start with an error. In addition, the plugin cannot be uninstalled with

- `UNINSTALL SONAME`

- or

- `UNINSTALL PLUGIN`

- while the server is running.

- See [Plugin Overview: Configuring Plugin Activation at Server Startup](#) for more information.

- **Commandline:**

```
--eperi-key-management-plugin=value
```

- **Data Type:**

enumerated

- **Default Value:**

ON

- **Valid Values:**

- OFF

- ,

- ON

- ,

- FORCE

- ,

- FORCE\_PLUS\_PERMANENT

    1. [Versions](#)
3. [Encryption Service](#)

MariaDB's [data-at-rest encryption](#) requires the use of a [key management and encryption plugin](#). These plugins are responsible both for the management of encryption keys and for the actual encryption and decryption of data.

MariaDB supports the use of [multiple encryption keys](#). Each encryption key uses a 32-bit integer as a key identifier. If the specific plugin supports [key rotation](#), then encryption keys can also be rotated, which creates a new version of the encryption key.

See [Data at Rest Encryption](#) and [Encryption Key Management](#) for more information.

## Encryption Plugin API

The Encryption plugin API was created to allow a plugin to:

- implement key management, provide encryption keys to the server on request and change them according to internal policies.
- implement actual data encryption and decryption with the algorithm defined by the plugin.

This is how the API reflects that:

```
/* Returned from get_latest_key_version() */
#define ENCRYPTION_KEY_VERSION_INVALID (~(unsigned int)0)
#define ENCRYPTION_KEY_NOT_ENCRYPTED (0)

#define ENCRYPTION_KEY_SYSTEM_DATA 1
#define ENCRYPTION_KEY_TEMPORARY_DATA 2

/* Returned from get_key() */
#define ENCRYPTION_KEY_BUFFER_TOO_SMALL (100)

#define ENCRYPTION_FLAG_DECRYPT 0
#define ENCRYPTION_FLAG_ENCRYPT 1
#define ENCRYPTION_FLAG_NOPAD 2

struct st_mariadb_encryption {
    int interface_version; /*< version plugin uses */

    /******
     * KEY MANAGEMENT *****/
    /**
     * Function returning Latest key version for a given key id.
     *
     * @return A version or ENCRYPTION_KEY_VERSION_INVALID to indicate an error.
     */
    unsigned int (*get_latest_key_version)(unsigned int key_id);

    /**
     * Function returning a key for a key version
     *
     * @param key_id      The requested key id
     * @param version     The requested key version
     * @param key         The key will be stored there. Can be NULL -
     *                   in which case no key will be returned
     * @param key_Length  in: key buffer size
     *                   out: the actual length of the key
     */
}
```

*This method can be used to query the key Length - the required*

```

buffer size - by passing key==NULL.

If the buffer size is less than the key length the content of the
key buffer is undefined (the plugin is free to partially fill it with
the key data or leave it untouched).

@return 0 on success, or
    ENCRYPTION_KEY_VERSION_INVALID, ENCRYPTION_KEY_BUFFER_TOO_SMALL
    or any other non-zero number for errors
*/
unsigned int (*get_key)(unsigned int key_id, unsigned int version,
                      unsigned char *key, unsigned int *key_length);

/********************* ENCRYPTION *****/
/*
The caller uses encryption as follows:
1. Create the encryption context object of the crypt_ctx_size() bytes.
2. Initialize it with crypt_ctx_init().
3. Repeat crypt_ctx_update() until there are no more data to encrypt.
4. Write the remaining output bytes and destroy the context object
   with crypt_ctx_finish().
*/
/***
    Returns the size of the encryption context object in bytes
*/
unsigned int (*crypt_ctx_size)(unsigned int key_id, unsigned int key_version);
/***
    Initializes the encryption context object.
*/
int (*crypt_ctx_init)(void *ctx, const unsigned char *key, unsigned int klen,
                      const unsigned char *iv, unsigned int ivlen, int flags,
                      unsigned int key_id, unsigned int key_version);
/***
    Processes (encrypts or decrypts) a chunk of data

    Writes the output to the dst buffer. note that it might write
    more bytes that were in the input. or less. or none at all.
*/
int (*crypt_ctx_update)(void *ctx, const unsigned char *src,
                       unsigned int slen, unsigned char *dst,
                       unsigned int *dlen);
/***
    Writes the remaining output bytes and destroys the encryption context

    crypt_ctx_update might've cached part of the output in the context,
    this method will flush these data out.
*/
int (*crypt_ctx_finish)(void *ctx, unsigned char *dst, unsigned int *dlen);
/***
    Returns the Length of the encrypted data

    It returns the exact length, given only the source length.
    Which means, this API only supports encryption algorithms where
    the length of the encrypted data only depends on the length of the
    input (a.k.a. compression is not supported).
*/
unsigned int (*encrypted_length)(unsigned int slen, unsigned int key_id,
                                unsigned int key_version);
};

```

The first method is used for key rotation. A plugin that doesn't support key rotation — for example, **file\_key\_management** — can return a fixed version for any valid key id. Note that it still has to return an error for an invalid key id. The version

ENCRYPTION\_KEY\_NOT\_ENCRYPTED

means that the data should not be encrypted.

The second method is used for key management, the server uses it to retrieve the key corresponding to a specific key identifier and a specific key version.

The last five methods deal with encryption. Note that they take the key to use and key identifier and version. This is needed because the server can derive a session-specific, user-specific, or a tablespace-specific key from the original encryption key as returned by

get\_key()  
, so the  
key

argument doesn't have to match the encryption key as the plugin knows it. On the other hand, the encryption algorithm may depend on the key identifier and version (and in the **example\_key\_management** plugin it does) so the plugin needs to know them to be able to encrypt the data.

Encryption methods are optional — if unset (as in the **debug\_key\_management** plugin), the server will fall back to AES\_CBC.

## Current Encryption Plugins

The MariaDB source tree has four encryption plugins. All these plugins are fairly simple and can serve as good examples of the Encryption plugin API.

### file\_key\_management

It reads encryption keys from a plain-text file. It supports two different encryption algorithms. It supports multiple encryption keys. It does not support key rotation. See the [File Key Management Plugin](#) article for more details.

#### Versions

Version	Status	Introduced
1.0	Stable	MariaDB 10.1.18
1.0	Gamma	MariaDB 10.1.13
1.0	Alpha	MariaDB 10.1.3

### aws\_key\_management

The AWS Key Management plugin uses the [Amazon Web Services \(AWS\) Key Management Service \(KMS\)](#) to generate and store AES keys on disk, in encrypted form, using the Customer Master Key (CMK) kept in AWS KMS. When MariaDB Server starts, the plugin will decrypt the encrypted keys, using the AWS KMS "Decrypt" API function. MariaDB data will then be encrypted and decrypted using the AES key. It supports multiple encryption keys. It supports key rotation.

See the [AWS Key Management Plugin](#) article for more details.

#### Versions

Version	Status	Introduced
1.0	Stable	MariaDB 10.2.6 , MariaDB 10.1.24
1.0	Beta	MariaDB 10.1.18
1.0	Experimental	MariaDB 10.1.13

### example\_key\_management

Uses random time-based generated keys, ignores key identifiers, supports key versions and key rotation. Uses AES\_ECB and AES\_CBC as encryption algorithms and changes them automatically together with key versions.

#### Versions

Version	Status	Introduced
1.0	Experimental	MariaDB 10.1.3

### debug\_key\_management

Key is generated from the version, user manually controls key rotation. Only supports key identifier 1, uses only AES\_CBC.

#### Versions

Version	Status	Introduced
1.0	Experimental	MariaDB 10.1.3

## Encryption Service

Encryption is generally needed on the very low level **inside the storage engine**. That is, the storage engine needs to support encryption and have access to the encryption and key management functionality. The usual way for a plugin to access some functionality in the server is via a service . In this case the server provides the Encryption Service for storage engines (and other interested plugins) to use. These service functions are directly hooked into encryption plugin methods (described above).

Service functions are declared as follows:

```

unsigned int encryption_key_get_latest_version(unsigned int key_id);
unsigned int encryption_key_get(unsigned int key_id, unsigned int key_version,
                               unsigned char *buffer, unsigned int *length);
unsigned int encryption_ctx_size(unsigned int key_id, unsigned int key_version);
int encryption_ctx_init(void *ctx, const unsigned char *key, unsigned int klen,
                       const unsigned char *iv, unsigned int ivlen, int flags,
                       unsigned int key_id, unsigned int key_version);
int encryption_ctx_update(void *ctx, const unsigned char *src,
                          unsigned int slen, unsigned char *dst,
                          unsigned int *dlen);
int encryption_ctx_finish(void *ctx, unsigned char *dst, unsigned int *dlen);
unsigned int encryption_encrypted_length(unsigned int slen, unsigned int key_id,
   unsigned int key_version);

```

There are also convenience helpers to check for a key or key version existence and to encrypt or decrypt a block of data with one function call.

```

unsigned int encryption_key_id_exists(unsigned int id);
unsigned int encryption_key_version_exists(unsigned int id,
   unsigned int version);
int encryption_crypt(const unsigned char *src, unsigned int slen,
                     unsigned char *dst, unsigned int *dlen,
                     const unsigned char *key, unsigned int klen,
                     const unsigned char *iv, unsigned int ivlen, int flags,
                     unsigned int key_id, unsigned int key_version);

```

## 4.4.8

### 4.4.8.1 Semisynchronous Replication

MariaDB starting with [10.3.3](#)

Semisynchronous replication is no longer a plugin in [MariaDB 10.3.3](#) and later. This removes some overhead and improves performance. See [MDEV-13073](#) for more information.

## Description

[Standard MariaDB replication](#) is asynchronous, but MariaDB also provides a semisynchronous replication option.

With regular asynchronous replication, replicas request events from the primary's binary log whenever the replicas are ready. The primary does not wait for a replica to confirm that an event has been received.

With fully synchronous replication, all replicas are required to respond that they have received the events. See [Galera Cluster](#).

Semisynchronous replication waits for just one replica to acknowledge that it has received and logged the events.

Semisynchronous replication therefore comes with some negative performance impact, but increased data integrity. Since the delay is based on the roundtrip time to the replica and back, this delay is minimized for servers in close proximity over fast networks.

In MariaDB 10.3 and later, semisynchronous replication is built into the server, so it can be enabled immediately in those versions.

In MariaDB 10.2 and before, semisynchronous replication requires the user to install a plugin on both the primary and the replica before it can be enabled.

## Installing the Plugin

MariaDB starting with 10.3.3

In MariaDB 10.3.3 and later, the Semisynchronous Replication feature is built into MariaDB server and is no longer provided by a plugin. **This means that installing the plugin is not supported on those versions.** In MariaDB 10.3.3 and later, you can skip right to [Enabling Semisynchronous Replication](#).

The semisynchronous replication plugin is actually two different plugins--one for the primary, and one for the replica. Shared libraries for both plugins are included with MariaDB. Although the plugins' shared libraries distributed with MariaDB by default, the plugin is not actually installed by MariaDB by default prior to MariaDB 10.3.3. There are two methods that can be used to install the plugin with MariaDB.

The first method can be used to install the plugin without restarting the server. You can install the plugin dynamically by executing [INSTALL SONAME](#) or [INSTALL PLUGIN](#).

For example, if it's a primary:

```
INSTALL SONAME 'semisync_master';
```

Or if it's a replica:

```
INSTALL SONAME 'semisync_slave';
```

The second method can be used to tell the server to load the plugin when it starts up. The plugin can be installed this way by providing the [--plugin-load](#) or the [--plugin-load-add](#) options. This can be specified as a command-line argument to [mysqld](#) or it can be specified in a relevant server [option group](#) in an [option file](#).

For example, if it's a primary:

```
[mariadb]
...
plugin_load_add = semisync_master
```

Or if it's a replica:

```
[mariadb]
...
plugin_load_add = semisync_slave
```

## Uninstalling the Plugin

MariaDB starting with 10.3.3

In MariaDB 10.3.3 and later, the Semisynchronous Replication feature is built into MariaDB server and is no longer provided by a plugin. **This means that uninstalling the plugin is not supported on those versions.**

You can uninstall the plugin dynamically by executing [UNINSTALL SONAME](#) or [UNINSTALL PLUGIN](#).

For example, if it's a primary:

```
UNINSTALL SONAME 'semisync_master';
```

Or if it's a replica:

```
UNINSTALL SONAME 'semisync_slave';
```

If you installed the plugin by providing the [--plugin-load](#) or the [--plugin-load-add](#) options in a relevant server [option group](#) in an [option file](#), then those options should be removed to prevent the plugin from being loaded the next time the server is restarted.

## Enabling Semisynchronous Replication

Semisynchronous replication can be enabled by setting the relevant system variables on the primary and the replica.

If a server needs to be able to switch between acting as a primary and a replica, then you can enable both the primary and replica system variables on the server. For example, you might need to do this if [MariaDB MaxScale](#) is being used to enable [auto-failover](#) or [switchover](#) with [MariaDB Monitor](#).

## Enabling Semisynchronous Replication on the Primary

Semisynchronous replication can be enabled on the primary by setting the `rpl_semi_sync_master_enabled` system variable to `ON`. It can be set dynamically with [SET GLOBAL](#). For example:

```
SET GLOBAL rpl_semi_sync_master_enabled=ON;
```

It can also be set in a server [option group](#) in an [option file](#) prior to starting up the server. For example:

```
[mariadb]
...
rpl_semi_sync_master_enabled=ON
```

## Enabling Semisynchronous Replication on the Replica

Semisynchronous replication can be enabled on the replica by setting the `rpl_semi_sync_slave_enabled` system variable to `ON`. It can be set dynamically with [SET GLOBAL](#). For example:

```
SET GLOBAL rpl_semi_sync_slave_enabled=ON;
```

It can also be set in a server [option group](#) in an [option file](#) prior to starting up the server. For example:

```
[mariadb]
...
rpl_semi_sync_slave_enabled=ON
```

If semisynchronous replication is enabled on a server when [replica threads](#) were already running, the replica I/O thread will need to be restarted to enable the replica to register as a semisynchronous replica when it connects to the primary. For example:

```
STOP SLAVE IO_THREAD;
START SLAVE IO_THREAD;
```

If this is not done, and the replica thread is already running, then it will continue to use asynchronous replication.

## Configuring the Primary Timeout

In semisynchronous replication, only after the events have been written to the relay log and flushed does the replica acknowledge receipt of a transaction's events. If the replica does not acknowledge the transaction before a certain amount of time has passed, then a timeout occurs and the primary switches to asynchronous replication. This will be reflected in the primary's [error log](#) with messages like the following:

```
[Warning] Timeout waiting for reply of binlog (file: mariadb-1-bin.000002, pos: 538), semi-sync up to file , position 0.
[Note] Semi-sync replication switched OFF.
```

When this occurs, the `Rpl_semi_sync_master_status` status variable will be switched to `OFF`.

When at least one semisynchronous replica catches up, semisynchronous replication is resumed. This will be reflected in the primary's [error log](#) with messages like the following:

```
[Note] Semi-sync replication switched ON with replica (server_id: 184137206) at (mariadb-1-bin.000002, 215076)
```

When this occurs, the `Rpl_semi_sync_master_status` status variable will be switched to `ON`.

The number of times that semisynchronous replication has been switched off can be checked by looking at the value of the `Rpl_semi_sync_master_no_times` status variable.

If you see a lot of timeouts like this in your environment, then you may want to change the timeout period. The timeout period can be changed by setting the `rpl_semi_sync_master_timeout` system variable. It can be set dynamically with [SET GLOBAL](#). For example:

```
SET GLOBAL rpl_semi_sync_master_timeout=20000;
```

It can also be set in a server [option group](#) in an [option file](#) prior to starting up the server. For example:

```
[mariadb]
...
rpl_semi_sync_master_timeout=20000
```

To determine a good value for the `rpl_semi_sync_master_timeout` system variable, you may want to look at the values of the `Rpl_semi_sync_master_net_avg_wait_time` and `Rpl_semi_sync_master_tx_avg_wait_time` status variables.

## Configuring the Primary Wait Point

In semisynchronous replication, there are two potential points at which the primary can wait for the replica acknowledge the receipt of a transaction's events. These two wait points have different advantages and disadvantages.

The wait point is configured by the `rpl_semi_sync_master_wait_point` system variable. The supported values are:

- AFTER\_SYNC
- AFTER\_COMMIT

It can be set dynamically with `SET GLOBAL`. For example:

```
SET GLOBAL rpl_semi_sync_master_wait_point='AFTER_SYNC';
```

It can also be set in a server [option group](#) in an [option file](#) prior to starting up the server. For example:

```
[mariadb]
...
rpl_semi_sync_master_wait_point=AFTER_SYNC
```

When this variable is set to

AFTER\_SYNC

, the primary performs the following steps:

1. Prepares the transaction in the storage engine.
2. Syncs the transaction to the [binary log](#).
3. Waits for acknowledgement from the replica.
4. Commits the transaction to the storage engine.
5. Returns an acknowledgement to the client.

The effects of the

AFTER\_SYNC

wait point are:

- All clients see the same data on the primary at the same time; after acknowledgement by the replica and after being committed to the storage engine on the primary.
- If the primary crashes, then failover should be lossless, because all transactions committed on the primary would have been replicated to the replica.
- However, if the primary crashes, then its [binary log](#) may also contain events for transactions that were prepared by the storage engine and written to the binary log, but that were never actually committed by the storage engine. As part of the server's [automatic crash recovery](#) process, the server may recover these prepared transactions when the server is restarted. This could cause the "old" crashed primary to become inconsistent with its former replicas when they have been reconfigured to replace the old primary with a new one. The old primary in such a scenario can be re-introduced only as a [semisync slave](#). The server post-crash recovery of the server configured with

```
rpl_semi_sync_slave_enabled = ON
```

ensures through [MDEV-21117](#) that the server will not have extra transactions. The reconfigured as semisync replica server's binlog gets truncated to discard transactions proven not to be committed, in any of their branches if they are multi-engine. Truncation does not occur though when there exists a non-transactional group of events beyond the truncation position in which case recovery reports an error. When the semisync replica recovery can't be carried out, the crashed primary may need to be rebuilt.

When this variable is set to

AFTER\_COMMIT

, the primary performs the following steps:

1. Prepares the transaction in the storage engine.
2. Syncs the transaction to the [binary log](#).
3. Commits the transaction to the storage engine.
4. Waits for acknowledgement from the replica.
5. Returns an acknowledgement to the client.

The effects of the

AFTER\_COMMIT  
wait point are:

- Other clients may see the committed transaction before the committing client.
- If the primary crashes, then failover may involve some data loss, because the primary may have committed transactions that had not yet been acknowledged by the replicas.

## Versions

Version	Status	Introduced
N/A	N/A	MariaDB 10.3.3
1.0	Stable	MariaDB 10.1.13
1.0	Gamma	MariaDB 10.0.13
1.0	Unknown	MariaDB 10.0.11
1.0	N/A	MariaDB 5.5

## System Variables

### rpl\_semi\_sync\_master\_enabled

- **Description:** Set to  
ON  
to enable semi-synchronous replication primary. Disabled by default.
- **Commandline:**  
--rpl-semi-sync-master-enabled[={0|1}]
- **Scope:** Global
- **Dynamic:** Yes
- **Data Type:**  
boolean
- **Default Value:**  
OFF

---

### rpl\_semi\_sync\_master\_timeout

- **Description:** The timeout value, in milliseconds, for semi-synchronous replication in the primary. If this timeout is exceeded in waiting on a commit for acknowledgement from a replica, the primary will revert to asynchronous replication.
  - When a timeout occurs, the [Rpl\\_semi\\_sync\\_master\\_status](#) status variable will also be switched to  
OFF
  - See [Configuring the Primary Timeout](#) for more information.
- **Commandline:**  
--rpl-semi-sync-master-timeout[=#]
- **Scope:** Global
- **Dynamic:** Yes
- **Data Type:**  
numeric
- **Default Value:**  
10000  
(10 seconds)
- **Range:**  
0  
to  
18446744073709551615

## rpl\_semi\_sync\_master\_trace\_level

- **Description:** The tracing level for semi-sync replication. Four levels are defined:

- 1 : General level, including for example time function failures.
- 16 : More detailed level, with more verbose information.
- 32 : Net wait level, including more information about network waits.
- 64 : Function level, including information about function entries and exits.

- **Commandline:**

```
--rpl-semi-sync-master-trace-level[=#]
```

- **Scope:** Global

- **Dynamic:** Yes

- **Data Type:**

numeric

- **Default Value:**

32

- **Range:**

0  
to  
18446744073709551615

## rpl\_semi\_sync\_master\_wait\_no\_slave

- **Description:** If set to

ON

, the default, the replica count (recorded by [Rpl\\_semi\\_sync\\_master\\_clients](#)) may drop to zero, and the primary will still wait for the timeout period. If set to

OFF

, the primary will revert to asynchronous replication as soon as the replica count drops to zero.

- **Commandline:**

```
--rpl-semi-sync-master-wait-no-slave[={0|1}]
```

- **Scope:** Global

- **Dynamic:** Yes

- **Data Type:**

boolean

- **Default Value:**

ON

## rpl\_semi\_sync\_master\_wait\_point

- **Description:** Whether the transaction should wait for semi-sync acknowledgement after having synced the binlog (

AFTER\_SYNC

), or after having committed in storage engine (

AFTER\_COMMIT

, the default).

- When this variable is set to

AFTER\_SYNC

, the primary performs the following steps:

1. Prepares the transaction in the storage engine.

2. Syncs the transaction to the [binary log](#).

3. Waits for acknowledgement from the replica.
  4. Commits the transaction to the storage engine.
  5. Returns an acknowledgement to the client.
- When this variable is set to  
AFTER\_COMMIT  
, the primary performs the following steps:
    1. Prepares the transaction in the storage engine.
    2. Syncs the transaction to the [binary log](#).
    3. Commits the transaction to the storage engine.
    4. Waits for acknowledgement from the replica.
    5. Returns an acknowledgement to the client.
  - In [MariaDB 10.1.2](#) and before, this system variable does not exist. However, in those versions, the primary waits for the acknowledgement from replicas at a point that is equivalent to  
AFTER\_COMMIT  
    - See [Configuring the Primary Wait Point](#) for more information.
- **Commandline:**  
--rpl-semi-sync-master-wait-point=value
  - **Scope:** Global
  - **Dynamic:** Yes
  - **Data Type:**  
enum
  - **Default Value:**  
AFTER\_COMMIT
  - **Valid Values:**  
AFTER\_SYNC  
,  
AFTER\_COMMIT
  - **Introduced:** [MariaDB 10.1.3](#)
- 

### rpl\_semi\_sync\_slave\_delay\_master

- **Description:** Only write primary info file when ack is needed.
  - **Commandline:**  
--rpl-semi-sync-slave-delay-master[={0|1}]
  - **Scope:** Global
  - **Dynamic:** Yes
  - **Data Type:**  
boolean
  - **Default Value:**  
OFF
  - **Introduced:** [MariaDB 10.3.3](#)
- 

### rpl\_semi\_sync\_slave\_enabled

- **Description:** Set to  
ON  
to enable semi-synchronous replication replica. Disabled by default.
- **Commandline:**  
--rpl-semi-sync-slave-enabled[={0|1}]
- **Scope:** Global
- **Dynamic:** Yes
- **Data Type:**  
boolean
- **Default Value:**  
OFF

## rpl\_semi\_sync\_slave\_kill\_conn\_timeout

- **Description:** Timeout for the mysql connection used to kill the replica io\_thread's connection on primary. This timeout comes into play when stop slave is executed.
- **Commandline:**  
--rpl-semi-sync-slave-kill-conn-timeout[={0|1}]
- **Scope:** Global
- **Dynamic:** Yes
- **Data Type:**  
numeric
- **Default Value:**  
5
- **Range:**  
0  
to  
4294967295
- **Introduced:** MariaDB 10.3.3

## rpl\_semi\_sync\_slave\_trace\_level

- **Description:** The tracing level for semi-sync replication. The levels are the same as for [rpl\\_semi\\_sync\\_master\\_trace\\_level](#).
- **Commandline:**  
--rpl-semi-sync-slave-trace\_level[=#]
- **Scope:** Global
- **Dynamic:** Yes
- **Data Type:**  
numeric
- **Default Value:**  
32
- **Range:**  
0  
to  
18446744073709551615

# Options

## rpl\_semi\_sync\_master

- **Description:** Controls how the server should treat the plugin when the server starts up.
  - Valid values are:
    - OFF
      - Disables the plugin without removing it from the [mysql.plugins](#) table.
    - ON
      - Enables the plugin. If the plugin cannot be initialized, then the server will still continue starting up, but the plugin will be disabled.
    - FORCE
      - Enables the plugin. If the plugin cannot be initialized, then the server will fail to start with an error.

- - FORCE\_PLUS\_PERMANENT
      - Enables the plugin. If the plugin cannot be initialized, then the server will fail to start with an error. In addition, the plugin cannot be uninstalled with [UNINSTALL SONAME](#) or [UNINSTALL PLUGIN](#) while the server is running.
    - See [Plugin Overview: Configuring Plugin Activation at Server Startup](#) for more information.
  - **Commandline:**

```
--rpl-semi-sync-master=value
```
  - **Data Type:**

enumerated
  - **Default Value:**

ON
  - **Valid Values:**

OFF  
,  
ON  
,  
FORCE  
,  
FORCE\_PLUS\_PERMANENT
  - **Removed:** [MariaDB 10.3.3](#)
- 

## rpl\_semi\_sync\_slave

- **Description:** Controls how the server should treat the plugin when the server starts up.
    - Valid values are:
      - OFF
        - Disables the plugin without removing it from the [mysql.plugins](#) table.
      - ON
        - Enables the plugin. If the plugin cannot be initialized, then the server will still continue starting up, but the plugin will be disabled.
      - FORCE
        - Enables the plugin. If the plugin cannot be initialized, then the server will fail to start with an error.
      - FORCE\_PLUS\_PERMANENT
        - Enables the plugin. If the plugin cannot be initialized, then the server will fail to start with an error. In addition, the plugin cannot be uninstalled with [UNINSTALL SONAME](#) or [UNINSTALL PLUGIN](#) while the server is running.
    - See [Plugin Overview: Configuring Plugin Activation at Server Startup](#) for more information.
  - **Commandline:**

```
--rpl-semi-sync-slave=value
```
  - **Data Type:**

enumerated
  - **Default Value:**

ON
  - **Valid Values:**

OFF  
,  
ON  
,  
FORCE  
,  
FORCE\_PLUS\_PERMANENT
  - **Removed:** [MariaDB 10.3.3](#)
- 

## Status Variables

For a list of status variables added when the plugin is installed, see [Semisynchronous Replication Plugin Status Variables](#).

## 4.4.8.2 WSREP\_INFO Plugin

The

WSREP\_INFO  
plugin library contains the following plugins:

- WSREP\_MEMBERSHIP
- WSREP\_STATUS

The

WSREP\_MEMBERSHIP  
plugin creates the `WSREP_MEMBERSHIP` table in the `INFORMATION_SCHEMA` database. The plugin also adds the `SHOW WSREP_MEMBERSHIP` statement.

The

WSREP\_STATUS  
plugin creates the `WSREP_STATUS` table in the `INFORMATION_SCHEMA` database. The plugin also adds the `SHOW WSREP_STATUS` statement.

These tables and statements provide information about `Galera`. Only users with the `SUPER` privilege can access this information.

### Contents

1. [Installing the Plugin](#)
2. [Uninstalling the Plugin](#)
3. [Example](#)
4. [Versions](#)
5. [Options](#)
  1. [wsrep\\_membership](#)
  2. [wsrep\\_status](#)

## Installing the Plugin

Although the plugin's shared library is distributed with MariaDB by default, the plugin is not actually installed by MariaDB by default. There are two methods that can be used to install the plugin with MariaDB.

The first method can be used to install the plugin without restarting the server. You can install the plugin dynamically by executing `INSTALL SONAME` or `INSTALL PLUGIN`. For example:

```
INSTALL SONAME 'wsrep_info';
```

The second method can be used to tell the server to load the plugin when it starts up. The plugin can be installed this way by providing the `--plugin-load` or the `--plugin-load-add` options. This can be specified as a command-line argument to `mysql` or it can be specified in a relevant server [option group](#) in an [option file](#). For example:

```
[mariadb]
...
plugin_load_add = wsrep_info
```

## Uninstalling the Plugin

You can uninstall the plugin dynamically by executing `UNINSTALL SONAME` or `UNINSTALL PLUGIN`. For example:

```
UNINSTALL SONAME 'wsrep_info';
```

If you installed the plugin by providing the `--plugin-load` or the `--plugin-load-add` options in a relevant server [option group](#) in an [option file](#), then those options should be removed to prevent the plugin from being loaded the next time the server is restarted.

## Example

```
SHOW TABLES FROM information_schema LIKE 'WSREP%';
+-----+
| Tables_in_information_schema (WSREP%) |
+-----+
| WSREP_STATUS                         |
| WSREP_MEMBERSHIP                      |
+-----+
```

## Versions

Version	Status	Introduced
1.0	Stable	MariaDB 10.1.18
1.0	Gamma	MariaDB 10.1.13
1.0	Alpha	MariaDB 10.1.2

## Options

### wsrep\_membership

- **Description:** Controls how the server should treat the plugin when the server starts up.

- Valid values are:

- OFF
  - Disables the plugin without removing it from the `mysql.plugins` table.
- ON
  - Enables the plugin. If the plugin cannot be initialized, then the server will still continue starting up, but the plugin will be disabled.
- FORCE
  - Enables the plugin. If the plugin cannot be initialized, then the server will fail to start with an error.
- FORCE\_PLUS\_PERMANENT
  - Enables the plugin. If the plugin cannot be initialized, then the server will fail to start with an error. In addition, the plugin cannot be uninstalled with `UNINSTALL SONAME` or `UNINSTALL PLUGIN` while the server is running.

- See [Plugin Overview: Configuring Plugin Activation at Server Startup](#) for more information.

- **Commandline:**

`--wsrep-membership=value`

- **Data Type:**

enumerated

- **Default Value:**

ON

- **Valid Values:**

OFF  
,  
ON  
,  
FORCE  
,  
FORCE\_PLUS\_PERMANENT

### wsrep\_status

- **Description:** Controls how the server should treat the plugin when the server starts up.

- Valid values are:

-

- OFF
  - Disables the plugin without removing it from the `mysql.plugins` table.
- ON
  - Enables the plugin. If the plugin cannot be initialized, then the server will still continue starting up, but the plugin will be disabled.
- FORCE
  - Enables the plugin. If the plugin cannot be initialized, then the server will fail to start with an error.
- FORCE\_PLUS\_PERMANENT
  - Enables the plugin. If the plugin cannot be initialized, then the server will fail to start with an error. In addition, the plugin cannot be uninstalled with `UNINSTALL SONAME` or `UNINSTALL PLUGIN` while the server is running.

◦ See [Plugin Overview: Configuring Plugin Activation at Server Startup](#) for more information.

- **Commandline:**

FORCE\_PLUS\_PERMANENT

## 4.4.9 Storage Engines

### 4.4.10

#### 4.4.10.1 Feedback Plugin

The `feedback` plugin is designed to collect and, optionally, upload configuration and usage information to [MariaDB.org](#) or to any other configured URL.

See the [MariaDB User Feedback](#) page on MariaDB.org to see collected MariaDB usage statistics.

The `feedback` plugin exists in all MariaDB versions.

MariaDB is distributed with this plugin included, but it is not enabled by default. On Windows, this plugin is part of the server and has a special checkbox in the installer window. Either way, you need to explicitly install and enable it in order for feedback data to be sent.

# Installing the Plugin

Although the plugin's shared library is distributed with MariaDB by default, the plugin is not actually installed by MariaDB by default. There are two methods that can be used to install the plugin with MariaDB.

The first method can be used to install the plugin without restarting the server. You can install the plugin dynamically by executing

```
INSTALL SONAME
```

or

```
INSTALL PLUGIN
```

. For example:

```
INSTALL SONAME 'feedback';
```

The second method can be used to tell the server to load the plugin when it starts up. The plugin can be installed this way by providing the

```
--plugin-load
```

or the

```
--plugin-load-add
```

options. This can be specified as a command-line argument to

```
mysqld
```

or it can be specified in a relevant server [option group](#) in an [option file](#) . For example:

```
[mariadb]
...
plugin_load_add = feedback
```

# Uninstalling the Plugin

You can uninstall the plugin dynamically by executing

```
UNINSTALL SONAME
```

or

```
UNINSTALL PLUGIN
```

. For example:

```
UNINSTALL SONAME 'feedback';
```

If you installed the plugin by providing the

```
--plugin-load
```

or the

```
--plugin-load-add
```

options in a relevant server [option group](#) in an [option file](#) , then those options should be removed to prevent the plugin from being loaded the next time the server is restarted.

# Enabling the Plugin

You can enable the plugin by setting the

```
feedback
```

option to  
ON

in a relevant server [option group](#) in an [option file](#). For example:

```
[mariadb]
...
feedback=ON
```

In Windows, the plugin can also be enabled during a new [MSI](#) installation. The MSI GUI installation provides the "Enable feedback plugin" checkbox to enable the plugin. The MSI command-line installation provides the FEEDBACK=1 command-line option to enable the plugin.

See the next section for how to verify the plugin is installed and active and (if needed) install the plugin.

## Verifying the Plugin's Status

To verify whether the

```
feedback
plugin is installed and enabled, execute the
```

[SHOW PLUGINS](#)

statement or query the

[information\\_schema.plugins](#)

table. For example:

```
SELECT plugin_status FROM information_schema.plugins
WHERE plugin_name = 'feedback';
```

If that

```
SELECT
returns no rows, then you still need to install the plugin.
```

When the plugin is installed and enabled, you will see:

```
SELECT plugin_status FROM information_schema.plugins
WHERE plugin_name = 'feedback';
+-----+
| plugin_status |
+-----+
| ACTIVE        |
+-----+
```

If you see

```
DISABLED
instead of
ACTIVE
, then you still need to enable the plugin.
```

## Collecting Data

The

```
feedback
plugin will collect:
```

- Certain rows from [SHOW STATUS](#) and [SHOW VARIABLES](#).
- All installed [plugins](#) and their versions.
- System information such as CPU count, memory, architecture, and OS/linux distribution.
- The [feedback\\_server\\_uid](#), which is a SHA1 hash of the MAC address of the first network interface and the TCP port that the server listens on.

The

```
feedback
plugin creates the FEEDBACK table in the INFORMATION\_SCHEMA database. To see the data that has been collected by the plugin, you can execute:
```

```
SELECT * FROM information_schema.feedback;
```

Only the contents of this table are sent to the [feedback\\_url](#).

MariaDB stores collation usage statistics. Each collation that has been used by the server will have a record in "SELECT \* FROM [information\\_schema.feedback](#)" output, for example:

VARIABLE_NAME	VARIABLE_VALUE
Collation used utf8_unicode_ci	10
Collation used latin1_general_ci	20

Collations that have not been used will not be included into the result.

## Sending Data

The

feedback  
plugin sends the data using a  
POST

request to any URL or a list of URLs that you specify by setting the [feedback\\_url](#) system variable. By default, this is set to the following URL:

- [https://mariadb.org/feedback\\_plugin/post](https://mariadb.org/feedback_plugin/post)

Both HTTP and HTTPS protocols are supported.

If HTTP traffic requires a proxy in your environment, then you can specify the proxy by setting the [feedback\\_http\\_proxy](#) system variable.

If the [feedback\\_url](#) system variable is not set to an empty string, then the plugin will automatically send a report to all URLs in the list a few minutes after the server starts up and then once a week after that.

If the [feedback\\_url](#) system variable is set to an empty string, then the plugin will **not** automatically send any data. This may be necessary if outbound HTTP communication from your database server is not permitted. In this case, you can still upload the data manually, if you'd like.

First, generate the report file with the MariaDB command-line [mysql](#) client:

```
$ mysql -e 'select * from information_schema.feedback' > report.txt
```

Then you can upload the generated

report.txt  
[here](#) using your web browser.

Or you can do it from the command line with tools such as [curl](#). For example:

```
$ curl -F data=@report.txt https://mariadb.org/feedback_plugin/post
```

Manual uploading allows you to be absolutely sure that we receive only the data shown in the [INFORMATION\\_SCHEMA.FEEDBACK](#) table and that no private or sensitive information is being sent.

## Versions

Version	Status	Introduced
1.1	Stable	<a href="#">MariaDB 10.0.10</a>
1.1	Beta	<a href="#">MariaDB 5.5.20</a> , <a href="#">MariaDB 5.3.3</a>

## System Variables

### [feedback\\_http\\_proxy](#)

- **Description:** Proxy server for use when http calls cannot be made, such as in a firewall environment. The format is host:port
- **Commandline:**  
--feedback-http=proxy=value
- **Read-only:** Yes
- **Data Type:** string
- **Default Value:**  
''  
(empty)

## `feedback_send_retry_wait`

- **Description:** Time in seconds before retrying if the plugin failed to send the data for any reason.
- **Commandline:**

```
--feedback-send-retry-wait=#
```

- **Scope:** Global
- **Dynamic:** Yes
- **Data Type:** numeric
- **Default Value:**

60

- **Valid Values:**

```
1  
to  
86400
```

---

## `feedback_send_timeout`

- **Description:** An attempt to send the data times out and fails after this many seconds.
- **Commandline:**

```
--feedback-send-timeout=#
```

- **Scope:** Global
- **Dynamic:** Yes
- **Data Type:** numeric
- **Default Value:**

60

- **Valid Values:**

```
1  
to  
86400
```

---

## `feedback_server_uid`

- **Description:** Automatically calculated server unique id hash.
- **Scope:** Global
- **Dynamic:** No
- **Data Type:** string

## `feedback_url`

- **Description:** URL to which the data is sent. More than one URL, separated by spaces, can be specified. Set it to an empty string to disable data sending.
- **Commandline:**

```
--feedback-url=url
```

- **Scope:** Global
- **Dynamic:** No
- **Data Type:** string
- **Default Value:**

[https://mariadb.org/feedback\\_plugin/post](https://mariadb.org/feedback_plugin/post)

## `feedback_user_info`

- **Description:** The value of this option is not used by the plugin, but it is included in the feedback data. It can be used to add any user-specified string to the report. This could be used to help to identify it. For example, a support contract number, or a computer name (if you collect reports internally by specifying your own

```
    feedback-url  
).
```

- **Commandline:**

```
--feedback-user-info=string
```

- **Scope:** Global
- **Dynamic:** No
- **Data Type:** string
- **Default Value:** Empty string

# Options

## `feedback`

- **Description:** Controls how the server should treat the plugin when the server starts up.

- Valid values are:

- OFF
  - Disables the plugin without removing it from the `mysql.plugins` table.
- ON
  - Enables the plugin. If the plugin cannot be initialized, then the server will still continue starting up, but the plugin will be disabled.
- FORCE
  - Enables the plugin. If the plugin cannot be initialized, then the server will fail to start with an error.
- FORCE\_PLUS\_PERMANENT
  - Enables the plugin. If the plugin cannot be initialized, then the server will fail to start with an error. In addition, the plugin cannot be uninstalled with

`UNINSTALL SONAME`

or

`UNINSTALL PLUGIN`

while the server is running.

- See [Plugin Overview: Configuring Plugin Activation at Server Startup](#) for more information.

- **Commandline:**

```
--feedback=value
```

- **Data Type:**

enumerated

- **Default Value:**

ON

- **Valid Values:**

OFF

,

```
ON
,
FORCE
,
FORCE_PLUS_PERMANENT
```

## 4.4.10.2 Locales Plugin

The

### LOCALES

plugin creates the `LOCALES` table in the `INFORMATION_SCHEMA` database. The plugin also adds the `SHOW LOCALES` statement. The table and statement can be queried to see all `locales` that are compiled into the server.

### Contents

1. [Installing the Plugin](#)
2. [Uninstalling the Plugin](#)
3. [Example](#)
4. [Versions](#)
5. [Options](#)
  1. [locales](#)

## Installing the Plugin

Although the plugin's shared library is distributed with MariaDB by default, the plugin is not actually installed by MariaDB by default. There are two methods that can be used to install the plugin with MariaDB.

The first method can be used to install the plugin without restarting the server. You can install the plugin dynamically by executing `INSTALL SONAME` or `INSTALL PLUGIN`. For example:

```
INSTALL SONAME 'locales';
```

The second method can be used to tell the server to load the plugin when it starts up. The plugin can be installed this way by providing the `--plugin-load` or the `--plugin-load-add` options. This can be specified as a command-line argument to `mysql` or it can be specified in a relevant server [option group](#) in an [option file](#). For example:

```
[mariadb]
...
plugin_load_add = locales
```

## Uninstalling the Plugin

You can uninstall the plugin dynamically by executing `UNINSTALL SONAME` or `UNINSTALL PLUGIN`. For example:

```
UNINSTALL SONAME 'locales';
```

If you installed the plugin by providing the `--plugin-load` or the `--plugin-load-add` options in a relevant server [option group](#) in an [option file](#), then those options should be removed to prevent the plugin from being loaded the next time the server is restarted.

## Example

ID	NAME	DESCRIPTION	MAX_MONTH_NAME_LENGTH	MAX_DAY_NAME_LENGTH	DECIMAL_POINT	THOUSAND_SEP
0	en_US	English - United States	9	9	.	,
1	en_GB	English - United Kingdom	9	9	.	,
2	ja_JP	Japanese - Japan	3	3	.	,
3	sv_SE	Swedish - Sweden	9	7	,	
4	de_DE	German - Germany	9	10	,	.
5	fr_FR	French - France	9	8	,	
6	ar_AE	Arabic - United Arab Emirates	6	8	.	,
7	ar_BH	Arabic - Bahrain	6	8	.	,
8	ar_JO	Arabic - Jordan	12	8	.	,
...						
106	no_NO	Norwegian - Norway	9	7	,	.
107	sv_FI	Swedish - Finland	9	7	,	
108	zh_HK	Chinese - Hong Kong SAR	3	3	.	,
109	el_GR	Greek - Greece	11	9	,	.
110	rm_CH	Romanish - Switzerland	9	9	,	.

## Versions

Version	Status	Introduced
1.0	Stable	MariaDB 10.1.13
1.0	Gamma	MariaDB 10.0.10
1.0	Alpha	MariaDB 10.0.4

## Options

### locales

- **Description:** Controls how the server should treat the plugin when the server starts up.

◦ Valid values are:

- OFF
  - Disables the plugin without removing it from the `mysql.plugins` table.
- ON
  - Enables the plugin. If the plugin cannot be initialized, then the server will still continue starting up, but the plugin will be disabled.
- FORCE
  - Enables the plugin. If the plugin cannot be initialized, then the server will fail to start with an error.
- FORCE\_PLUS\_PERMANENT
  - Enables the plugin. If the plugin cannot be initialized, then the server will fail to start with an error. In addition, the plugin cannot be uninstalled with `UNINSTALL SONAME` or `UNINSTALL PLUGIN` while the server is running.

## 4.4.10.3 METADATA\_LOCK\_INFO Plugin

The

### METADATA\_LOCK\_INFO

plugin creates the `METADATA_LOCK_INFO` table in the `INFORMATION_SCHEMA` database. This table shows active `metadata locks`. The table will be empty if there are no active metadata locks.

### Contents

1. [Installing the Plugin](#)
2. [Uninstalling the Plugin](#)
3. [Examples](#)
  1. [Viewing all Metadata Locks](#)
  2. [Matching Metadata Locks with Threads and Queries](#)
4. [Versions](#)
5. [Options](#)
  1. [metadata\\_lock\\_info](#)

## Installing the Plugin

Although the plugin's shared library is distributed with MariaDB by default, the plugin is not actually installed by MariaDB by default. There are two methods that can be used to install the plugin with MariaDB.

The first method can be used to install the plugin without restarting the server. You can install the plugin dynamically by executing `INSTALL SONAME` or `INSTALL PLUGIN`. For example:

```
INSTALL SONAME 'metadata_lock_info';
```

The second method can be used to tell the server to load the plugin when it starts up. The plugin can be installed this way by providing the `--plugin-load` or the `--plugin-load-add` options. This can be specified as a command-line argument to `mysql` or it can be specified in a relevant server `option group` in an `option file`. For example:

```
[mariadb]
...
plugin_load_add = metadata_lock_info
```

## Uninstalling the Plugin

You can uninstall the plugin dynamically by executing `UNINSTALL SONAME` or `UNINSTALL PLUGIN`. For example:

```
UNINSTALL SONAME 'metadata_lock_info';
```

If you installed the plugin by providing the `--plugin-load` or the `--plugin-load-add` options in a relevant server `option group` in an `option file`, then those options should be removed to prevent the plugin from being loaded the next time the server is restarted.

## Examples

### Viewing all Metadata Locks

```
SELECT * FROM information_schema.metadata_lock_info;
+-----+-----+-----+-----+-----+
| THREAD_ID | LOCK_MODE          | LOCK_DURATION | LOCK_TYPE        | TABLE_SCHEMA | TABLE_NAME |
+-----+-----+-----+-----+-----+
| 31       | MDL_INTENTION_EXCLUSIVE | MDL_EXPLICIT   | Global read lock |            |            |
| 31       | MDL_INTENTION_EXCLUSIVE | MDL_EXPLICIT   | Commit lock      |            |            |
| 31       | MDL_INTENTION_EXCLUSIVE | MDL_EXPLICIT   | Schema metadata lock | dbname     |            |
| 31       | MDL_SHARED_NO_READ_WRITE | MDL_EXPLICIT   | Table metadata lock | dbname     | exotics    |
+-----+-----+-----+-----+-----+
4 rows in set (0.00 sec)
```

### Matching Metadata Locks with Threads and Queries

```

SELECT
CONCAT('Thread ',P.ID,' executing ''',P.INFO,'" IS LOCKED BY Thread ',
M.THREAD_ID) WhoLocksWho
FROM INFORMATION_SCHEMA.PROCESSLIST P,
INFORMATION_SCHEMA.METADATA_LOCK_INFO M
WHERE LOCATE(lower(lock_type), lower(state))>0;
+-----+
| WhoLocksWho |
+-----+
| Thread 3 executing "INSERT INTO foo ( b ) VALUES ( 'FOO' )" IS LOCKED BY Thread 2 |
+-----+
1 row in set (0.00 sec)

SHOW PROCESSLIST;
+-----+-----+-----+-----+-----+-----+-----+-----+
| Id | User | Host      | db   | Command | Time | State          | Info           | Prog
+-----+-----+-----+-----+-----+-----+-----+-----+
| 2 | root | localhost | test | Sleep   | 123 | NULL            |                | 0.0
| 3 | root | localhost | test | Query   | 103 | Waiting for global read lock | INSERT INTO foo ( b ) VALUES ( 'FOO' ) | 0.0
| 4 | root | localhost | test | Query   | 0    | init            | SHOW PROCESSLIST | 0.0
+-----+-----+-----+-----+-----+-----+-----+-----+
3 rows in set (0.00 sec)

```

## Versions

Version	Status	Introduced
0.1	Stable	MariaDB 10.1.13
0.1	Beta	MariaDB 10.0.10
0.1	Alpha	MariaDB 10.0.7

## Options

### metadata\_lock\_info

- **Description:** Controls how the server should treat the plugin when the server starts up.

- Valid values are:

- OFF
  - Disables the plugin without removing it from the `mysql.plugins` table.
- ON
  - Enables the plugin. If the plugin cannot be initialized, then the server will still continue starting up, but the plugin will be disabled.
- FORCE
  - Enables the plugin. If the plugin cannot be initialized, then the server will fail to start with an error.
- FORCE\_PLUS\_PERMANENT
  - Enables the plugin. If the plugin cannot be initialized, then the server will fail to start with an error. In addition, the plugin cannot be uninstalled with `UNINSTALL SONAME` or `UNINSTALL PLUGIN` while the server is running.

- See [Plugin Overview: Configuring Plugin Activation at Server Startup](#) for more information.

- **Commandline:**

--metadata-lock-info=value

enumerated

- **Default Value:**

ON

- **Valid Values:**

OFF

,

ON

,

```
FORCE
,
FORCE_PLUS_PERMANENT
```

## 4.4.10.4 Query Cache Information Plugin

The

`QUERY_CACHE_INFO`

plugin creates the `QUERY_CACHE_INFO` table in the `INFORMATION_SCHEMA` database. This table shows all queries in the query cache.

Querying this table acquires the query cache lock and will result in lock waits for queries that are using or expiring from the query cache. You must have the `PROCESS` privilege to query this table.

### Contents

1. [Installing the Plugin](#)
2. [Uninstalling the Plugin](#)
3. [Example](#)
4. [Versions](#)
5. [Options](#)
  1. [query\\_cache\\_info](#)

## Installing the Plugin

Although the plugin's shared library is distributed with MariaDB by default, the plugin is not actually installed by MariaDB by default. There are two methods that can be used to install the plugin with MariaDB.

The first method can be used to install the plugin without restarting the server. You can install the plugin dynamically by executing `INSTALL SONAME` or `INSTALL PLUGIN`. For example:

```
INSTALL SONAME 'query_cache_info';
```

The second method can be used to tell the server to load the plugin when it starts up. The plugin can be installed this way by providing the `--plugin-load` or the `--plugin-load-add` options. This can be specified as a command-line argument to `mysql` or it can be specified in a relevant server `option group` in an `option file`. For example:

```
[mariadb]
...
plugin_load_add = query_cache_info
```

## Uninstalling the Plugin

You can uninstall the plugin dynamically by executing `UNINSTALL SONAME` or `UNINSTALL PLUGIN`. For example:

```
UNINSTALL SONAME 'query_cache_info';
```

If you installed the plugin by providing the `--plugin-load` or the `--plugin-load-add` options in a relevant server `option group` in an `option file`, then those options should be removed to prevent the plugin from being loaded the next time the server is restarted.

## Example

```
select statement_schema, statement_text, result_blocks_count,
       result_blocks_size from information_schema.query_cache_info;
+-----+-----+-----+
| statement_schema | statement_text    | result_blocks_count | result_blocks_size |
+-----+-----+-----+
| test           | select * from t1 |          1 |            512 |
+-----+-----+-----+
```

## Versions

Version	Status	Introduced
1.1	Stable	<a href="#">MariaDB 10.1.13</a>
1.1	Gamma	<a href="#">MariaDB 10.1.8</a>
1.0	Gamma	<a href="#">MariaDB 10.0.10</a>

## Options

### query\_cache\_info

- **Description:** Controls how the server should treat the plugin when the server starts up.

- Valid values are:

- OFF
    - Disables the plugin without removing it from the `mysql.plugins` table.
  - ON
    - Enables the plugin. If the plugin cannot be initialized, then the server will still continue starting up, but the plugin will be disabled.
  - FORCE
    - Enables the plugin. If the plugin cannot be initialized, then the server will fail to start with an error.
  - FORCE\_PLUS\_PERMANENT
    - Enables the plugin. If the plugin cannot be initialized, then the server will fail to start with an error. In addition, the plugin cannot be uninstalled with `UNINSTALL SONAME` or `UNINSTALL PLUGIN` while the server is running.

- See [Plugin Overview: Configuring Plugin Activation at Server Startup](#) for more information.

- **Commandline:**

```

```

- **Data Type:**

enumerated

- **Default Value:**

ON

- **Valid Values:**

OFF  
,  
ON  
,  
FORCE  
,  
FORCE\_PLUS\_PERMANENT

---

## 4.4.10.5 Query Response Time Plugin

The

```
query_response_time
```

plugin creates the `QUERY_RESPONSE_TIME` table in the `INFORMATION_SCHEMA` database. The plugin also adds the `SHOW QUERY_RESPONSE_TIME` and `FLUSH QUERY_RESPONSE_TIME` statements.

The `slow query log` provides exact information about queries that take a long time to execute. However, sometimes there are a large number of queries that each take a very short amount of time to execute. This feature provides a tool for analyzing that information by counting and displaying the number of queries according to the the length of time they took to execute.

This feature is based on Percona's [Response Time Distribution](#).

## Contents

- 1. [Installing the Plugin](#)
- 2. [Uninstalling the Plugin](#)
- 3. [Response Time Distribution](#)
- 4. [Using the Plugin](#)
  - 1. [Using the Information Schema Table](#)
  - 2. [Using the SHOW Statement](#)
  - 3. [Flushing Plugin Data](#)
- 5. [Versions](#)
- 6. [System Variables](#)
  - 1. [query\\_response\\_time\\_flush](#)
  - 2. [query\\_response\\_time\\_range\\_base](#)
  - 3. [query\\_response\\_time\\_exec\\_time\\_debug](#)
  - 4. [query\\_response\\_time\\_stats](#)
- 7. [Options](#)
  - 1. [query\\_response\\_time](#)
  - 2. [query\\_response\\_time\\_audit](#)

## Installing the Plugin

This shared library actually consists of two different plugins:

- - QUERY\_RESPONSE\_TIME
    - An INFORMATION\_SCHEMA plugin that exposes statistics.
- - QUERY\_RESPONSE\_TIME\_AUDIT
    - audit plugin, collects statistics.

Both plugins need to be installed to get meaningful statistics.

Although the plugin's shared library is distributed with MariaDB by default, the plugin is not actually installed by MariaDB by default. There are two methods that can be used to install the plugin with MariaDB.

The first method can be used to install the plugin without restarting the server. You can install the plugin dynamically by executing [INSTALL SONAME](#) or [INSTALL PLUGIN](#). For example:

```
INSTALL SONAME 'query_response_time';
```

The second method can be used to tell the server to load the plugin when it starts up. The plugin can be installed this way by providing the [--plugin-load](#) or the [--plugin-load-add](#) options. This can be specified as a command-line argument to [mysqld](#) or it can be specified in a relevant server [option group](#) in an [option file](#). For example:

```
[mariadb]
...
plugin_load_add = query_response_time
```

## Uninstalling the Plugin

You can uninstall the plugin dynamically by executing [UNINSTALL SONAME](#) or [UNINSTALL PLUGIN](#). For example:

```
UNINSTALL SONAME 'query_response_time';
```

If you installed the plugin by providing the [--plugin-load](#) or the [--plugin-load-add](#) options in a relevant server [option group](#) in an [option file](#), then those options should be removed to prevent the plugin from being loaded the next time the server is restarted.

## Response Time Distribution

The user can define time intervals that divide the range 0 to positive infinity into smaller intervals and then collect the number of commands whose execution times fall into each of those intervals.

Each interval is described as:

```
(range_base ^ n; range_base ^ (n+1)]
```

The range\_base is some positive number (see Limitations). The interval is defined as the difference between two nearby powers of the range base.

For example, if the range base=10, we have the following intervals:

```
(0; 10 ^ -6], (10 ^ -6; 10 ^ -5], (10 ^ -5; 10 ^ -4], ...,
 (10 ^ -1; 10 ^1], (10^1; 10^2]...(10^7; positive infinity]
```

or

```
(0; 0.000001], (0.000001; 0.000010], (0.000010; 0.000100], ...,
 (0.100000; 1.0]; (1.0; 10.0]...(100000; positive infinity]
```

For each interval, a count is made of the queries with execution times that fell into that interval.

You can select the range of the intervals by changing the range base. For example, for base range=2 we have the following intervals:

```
(0; 2 ^ -19], (2 ^ -19; 2 ^ -18], (2 ^ -18; 2 ^ -17], ...,
 (2 ^ -1; 2 ^1], (2 ^ 1; 2 ^ 2]...(2 ^ 25; positive infinity]
```

or

```
(0; 0.000001], (0.000001, 0.000003], ...,
 (0.25; 0.5], (0.5; 2], (2; 4]...(8388608; positive infinity]
```

Small numbers look strange (i.e., don't look like powers of 2), because we lose precision on division when the ranges are calculated at runtime. In the resulting table, you look at the high boundary of the range.

For example, you may see:

```
SELECT * FROM INFORMATION_SCHEMA.QUERY_RESPONSE_TIME;
+-----+-----+
| TIME      | COUNT | TOTAL      |
+-----+-----+
| 0.000001 |     0 | 0.000000 |
| 0.000010 |    17 | 0.000094 |
| 0.000100 |   4301 | 0.236555 |
| 0.001000 |  1499 | 0.824450 |
| 0.010000 | 14851 | 81.680502 |
| 0.100000 |  8066 | 443.635693 |
| 1.000000 |     0 | 0.000000 |
| 10.000000 |     0 | 0.000000 |
| 100.000000 |    1 | 55.937094 |
| 1000.000000 |   0 | 0.000000 |
| 10000.000000 |   0 | 0.000000 |
| 100000.000000 |   0 | 0.000000 |
| 1000000.000000 |   0 | 0.000000 |
| TOO LONG |     0 | TOO LONG  |
+-----+-----+
```

This means there were:

```
* 17 queries with 0.000001 < query execution time < = 0.000010 seconds; total execution time of the 17 queries = 0.000094 seconds

* 4301 queries with 0.000010 < query execution time < = 0.000100 seconds; total execution time of the 4301 queries = 0.236555 seconds

* 1499 queries with 0.000100 < query execution time < = 0.001000 seconds; total execution time of the 1499 queries = 0.824450 seconds

* 14851 queries with 0.001000 < query execution time < = 0.010000 seconds; total execution time of the 14851 queries = 81.680502 seconds

* 8066 queries with 0.010000 < query execution time < = 0.100000 seconds; total execution time of the 8066 queries = 443.635693 seconds

* 1 query with 10.000000 < query execution time < = 100.0000 seconds; total execution time of the 1 query = 55.937094 seconds
```

## Using the Plugin

### Using the Information Schema Table

You can get the distribution by querying the the `QUERY_RESPONSE_TIME` table in the `INFORMATION_SCHEMA` database. For example:

```
SELECT * FROM INFORMATION_SCHEMA.QUERY_RESPONSE_TIME;
```

You can also write more complex queries. For example:

```
SELECT c.count, c.time,
(SELECT SUM(a.count) FROM INFORMATION_SCHEMA.QUERY_RESPONSE_TIME AS a
 WHERE a.count != 0) AS query_count,
(SELECT COUNT(*)      FROM INFORMATION_SCHEMA.QUERY_RESPONSE_TIME AS b
 WHERE b.count != 0) AS not_zero_region_count,
(SELECT COUNT(*)      FROM INFORMATION_SCHEMA.QUERY_RESPONSE_TIME) AS region_count
FROM INFORMATION_SCHEMA.QUERY_RESPONSE_TIME AS c
WHERE c.count > 0;
```

Note: If `query_response_time_stats` is set to

ON

, then the execution times for these two SELECT queries will also be collected.

## Using the SHOW Statement

As an alternative to the `QUERY_RESPONSE_TIME` table in the `INFORMATION_SCHEMA` database, you can also use the `SHOW QUERY_RESPONSE_TIME` statement. For example:

```
SHOW QUERY_RESPONSE_TIME;
```

## Flushing Plugin Data

Flushing the plugin data does two things:

- Clears the collected times from the `QUERY_RESPONSE_TIME` table in the `INFORMATION_SCHEMA` database.
- Reads the value of `query_response_time_range_base` and uses it to set the range base for the table.

Plugin data can be flushed with the `FLUSH QUERY_RESPONSE_TIME` statement. For example:

```
FLUSH QUERY_RESPONSE_TIME;
```

Setting the `query_response_time_flush` system variable has the same effect. For example:

```
SET GLOBAL query_response_time_flush=1;
```

## Versions

Version	Status	Introduced
1.0	Stable	MariaDB 10.1.13
1.0	Gamma	MariaDB 10.0.10
1.0	Alpha	MariaDB 10.0.4

## System Variables

### query\_response\_time\_flush

- **Description:** Updating this variable flushes the statistics and re-reads `query_response_time_range_base`.
- **Commandline:** None
- **Scope:** Global
- **Dynamic:** Yes
- **Data Type:**  
boolean
- **Default Value:**  
OFF

### query\_response\_time\_range\_base

- **Description:** Select base of log for  
    QUERY\_RESPONSE\_TIME  
    ranges. WARNING: variable change takes affect only after flush.
  - **Commandline:**  
    --query-response-time-range-base=#
  - **Scope:** Global
  - **Dynamic:** Yes
  - **Data Type:**  
    numeric
  - **Default Value:**  
    10
  - **Range:**  
    2  
    to  
    1000
- 

## query\_response\_time\_exec\_time\_debug

- **Description:** Pretend queries take this many microseconds. When 0 (the default) use the actual execution time.
    - This system variable is only available when the plugin is a [debug build](#).
  - **Scope:** Global
  - **Dynamic:** Yes
  - **Data Type:**  
    numeric
  - **Default Value:**  
    0
  - **Range:**  
    0  
    to  
    31536000
- 

## query\_response\_time\_stats

- **Description:** Enable or disable query response time statistics collecting
  - **Commandline:**  
    query-response-time-stats[={0|1}]
  - **Scope:** Global
  - **Dynamic:** Yes
  - **Data Type:**  
    boolean
  - **Default Value:**  
    OFF
- 

# Options

## query\_response\_time

- **Description:** Controls how the server should treat the plugin when the server starts up.

- Valid values are:

- OFF
  - Disables the plugin without removing it from the [mysql.plugins](#) table.
- ON
  - Enables the plugin. If the plugin cannot be initialized, then the server will still continue starting up, but the plugin will be disabled.
- FORCE
  - Enables the plugin. If the plugin cannot be initialized, then the server will fail to start with an error.
- FORCE\_PLUS\_PERMANENT
  - Enables the plugin. If the plugin cannot be initialized, then the server will fail to start with an error. In addition, the plugin cannot be uninstalled with [UNINSTALL SONAME](#) or [UNINSTALL PLUGIN](#) while the server is running.

- See [Plugin Overview: Configuring Plugin Activation at Server Startup](#) for more information.

- **Commandline:**

- `--query-response-time=value`

- **Data Type:**

- enumerated

- **Default Value:**

- ON

- **Valid Values:**

- OFF
- ,
- ON
- ,
- FORCE
- ,
- FORCE\_PLUS\_PERMANENT

## query\_response\_time\_audit

- **Description:** Controls how the server should treat the plugin when the server starts up.

- Valid values are:

- OFF
  - Disables the plugin without removing it from the [mysql.plugins](#) table.
- ON
  - Enables the plugin. If the plugin cannot be initialized, then the server will still continue starting up, but the plugin will be disabled.
- FORCE
  - Enables the plugin. If the plugin cannot be initialized, then the server will fail to start with an error.
- FORCE\_PLUS\_PERMANENT
  - Enables the plugin. If the plugin cannot be initialized, then the server will fail to start with an error. In addition, the plugin cannot be uninstalled with [UNINSTALL SONAME](#) or [UNINSTALL PLUGIN](#) while the server is running.

- See [Plugin Overview: Configuring Plugin Activation at Server Startup](#) for more information.

- **Commandline:**

- `--query-response-time-audit=value`

- **Data Type:**

- enumerated

- **Default Value:**

- ON

- **Valid Values:**

- OFF
- ,
- ON

```
,  
FORCE  
,
```

## 4.4.10.6 SQL Error Log Plugin

### Contents

1. [Installing the Plugin](#)
2. [Uninstalling the Plugin](#)
3. [Example](#)
4. [Versions](#)
5. [System Variables](#)
  1. [sql\\_error\\_log\\_filename](#)
  2. [sql\\_error\\_log\\_rate](#)
  3. [sql\\_error\\_log\\_rotate](#)
  4. [sql\\_error\\_log\\_rotations](#)
  5. [sql\\_error\\_log\\_size\\_limit](#)
6. [Options](#)
  1. [sql\\_error\\_log](#)

The

```
SQL_ERROR_LOG
```

plugin collects errors sent to clients in a log file defined by [sql\\_error\\_log\\_filename](#) , so that they can later be analyzed. The log file can be rotated if [sql\\_error\\_log\\_rotate](#) is set.

Errors are logged as they happen and an error will be logged even if it was handled by a [condition handler](#) and was never technically *sent* to the client.

Comments are also logged, which can make the log easier to search. But this is only possible if the client does not strip the comments away. For example, [mysql](#) command-line client only leaves comments when started with the [--comments](#) option.

## Installing the Plugin

Although the plugin's shared library is distributed with MariaDB by default, the plugin is not actually installed by MariaDB by default. There are two methods that can be used to install the plugin with MariaDB.

The first method can be used to install the plugin without restarting the server. You can install the plugin dynamically by executing [INSTALL SONAME](#) or [INSTALL PLUGIN](#) . For example:

```
INSTALL SONAME 'sql_errlog';
```

The second method can be used to tell the server to load the plugin when it starts up. The plugin can be installed this way by providing the [--plugin-load](#) or the [--plugin-load-add](#) options. This can be specified as a command-line argument to [mysqld](#) or it can be specified in a relevant server [option group](#) in an [option file](#) . For example:

```
[mariadb]  
...  
plugin_load_add = sql_errlog
```

## Uninstalling the Plugin

You can uninstall the plugin dynamically by executing [UNINSTALL SONAME](#) or [UNINSTALL PLUGIN](#) . For example:

```
UNINSTALL SONAME 'sql_errlog';
```

If you installed the plugin by providing the [--plugin-load](#) or the [--plugin-load-add](#) options in a relevant server [option group](#) in an [option file](#) , then those options should be removed to prevent the plugin from being loaded the next time the server is restarted.

## Example

```

install plugin SQL_ERROR_LOG soname 'sql_errlog';
Query OK, 0 rows affected (0.00 sec)

use test;
Database changed

set sql_mode='STRICT_ALL_TABLES,NO_ENGINE_SUBSTITUTION';
Query OK, 0 rows affected (0.00 sec)

CREATE TABLE foo2 (id int) ENGINE=WHOOPSIE;
ERROR 1286 (42000): Unknown storage engine 'WHOOPSIE'
\! cat data/sql_errors.log
2013-03-19  9:38:40 msandbox[msandbox] @ localhost [] ERROR 1286: Unknown storage engine 'WHOOPSIE' : CREATE TABLE foo2 (id int)

```

## Versions

Version	Status	Introduced
1.0	Stable	MariaDB 10.1.13
1.0	Gamma	MariaDB 10.0.10
1.0	Alpha	MariaDB 5.5.22

## System Variables

### sql\_error\_log\_filename

- **Description:** The name of the logfile. Rotation of it will be named like

*sql\_error\_log\_filename*

.001

- **Commandline:**

--sql-error-log-filename=value

- **Scope:** Global

- **Dynamic:** No

- **Data Type:**

string

- **Default Value:**

sql\_errors.log

### sql\_error\_log\_rate

- **Description:** The rate of logging.

SET sql\_error\_log\_rate=300;

means that one of 300 errors will be written to the log.

If

sql\_error\_log\_rate

is

0

the logging is disabled.

The default rate is

1

(every error is logged).

- **Commandline:**

--sql-error-log-rate=#

- **Scope:** Global

- **Dynamic:** Yes
- **Data Type:**  
    numeric

- **Default Value:**  
    1
- 

## sql\_error\_log\_rotate

- **Description:** This is the 'write-only' variable. Assigning TRUE to this variable forces the log rotation.
- **Commandline:**

```
--sql-error-log-rotate={0|1}
```

- **Scope:** Global
- **Dynamic:** Yes
- **Data Type:**  
    boolean

- **Default Value:**  
    OFF
- 

## sql\_error\_log\_rotations

- **Description:** The number of rotations. When rotated, the current log file is stored and the new empty one created.  
The sql\_error\_log\_rotations logs are stored, older are removed.
- **Default Value:**  
    9

- **Commandline:**  
    --sql-error-log-rotations

- **Scope:** Global
- **Dynamic:** No
- **Data Type:**  
    numeric

- **Default Value:**  
    9

- **Range:**  
    1  
    to  
    999
- 

## sql\_error\_log\_size\_limit

- **Description:** The limitation for the size of the log file. After reaching the specified limit, the log file is rotated.  
1M limit set by default.

- **Commandline:**  
    --sql-error-log-size-limit=#

- **Scope:** Global
- **Dynamic:** No
- **Data Type:**  
    numeric

- **Default Value:**  
1000000

- **Range:**  
100  
to  
9223372036854775807

---

## Options

### sql\_error\_log

- **Description:** Controls how the server should treat the plugin when the server starts up.

- Valid values are:

- OFF
  - Disables the plugin without removing it from the `mysql.plugins` table.
- ON
  - Enables the plugin. If the plugin cannot be initialized, then the server will still continue starting up, but the plugin will be disabled.
- FORCE
  - Enables the plugin. If the plugin cannot be initialized, then the server will fail to start with an error.
- FORCE\_PLUS\_PERMANENT
  - Enables the plugin. If the plugin cannot be initialized, then the server will fail to start with an error. In addition, the plugin cannot be uninstalled with `UNINSTALL SONAME` or `UNINSTALL PLUGIN` while the server is running.

- See [Plugin Overview: Configuring Plugin Activation at Server Startup](#) for more information.

- **Commandline:**

```
--sql-error-log=value
```

- **Data Type:**

enumerated

- **Default Value:**

ON

- **Valid Values:**

OFF  
,  
ON  
,  
FORCE  
,  
FORCE\_PLUS\_PERMANENT

---

## 4.4.10.7 User Statistics

The User Statistics feature was first released in [MariaDB 5.2.0](#), and moved to the

`userstat`  
plugin in [MariaDB 10.1.1](#).

The

`userstat`  
plugin creates the `USER_STATISTICS`, `CLIENT_STATISTICS`, the `INDEX_STATISTICS`, and the `TABLE_STATISTICS` tables in the `INFORMATION_SCHEMA` database. As an alternative to these tables, the plugin also adds the `SHOW USER_STATISTICS`, the `SHOW CLIENT_STATISTICS`, the `SHOW INDEX_STATISTICS`, and the `SHOW TABLE_STATISTICS` statements.

These tables and commands can be used to understand the server activity better and to identify the sources of your database's load.

The plugin also adds the `FLUSH USER_STATISTICS`, `FLUSH CLIENT_STATISTICS`, `FLUSH INDEX_STATISTICS`, and `FLUSH TABLE_STATISTICS` statements.

The MariaDB implementation of this plugin is based on the [userstatv2 patch](#) from Percona and OurDelta. The original code comes from Google (Mark

Callaghan's team) with additional work from Percona, Ourdelta, and Weldon Whipple. The MariaDB implementation provides the same functionality as the userstatv2 patch but a lot of changes have been made to make it faster and to better fit the MariaDB infrastructure.

## Contents

- 1. [How it Works](#)
- 2. [Enabling the Plugin](#)
- 3. [Using the Plugin](#)
  - 1. [Using the Information Schema Table](#)
  - 2. [Using the SHOW Statements](#)
  - 3. [Flushing Plugin Data](#)
- 4. [Versions](#)
  - 1. [USER\\_STATISTICS](#)
  - 2. [CLIENT\\_STATISTICS](#)
  - 3. [INDEX\\_STATISTICS](#)
  - 4. [TABLE\\_STATISTICS](#)
- 5. [System Variables](#)
  - 1. [userstat](#)

## How it Works

The

```
userstat
```

plugin works by keeping several hash tables in memory. All variables are incremented while the query is running. At the end of each statement the global values are updated.

## Enabling the Plugin

By default statistics are not collected. This is to ensure that statistics collection does not cause any extra load on the server unless desired.

Set the `userstat=ON` system variable in a relevant server [option group](#) in an [option file](#) to enable the plugin. For example:

```
[mariadb]
...
userstat = 1
```

The value can also be changed dynamically. For example:

```
SET GLOBAL userstat=1;
```

## Using the Plugin

### Using the Information Schema Table

The

```
userstat
```

plugin creates the `USER_STATISTICS`, `CLIENT_STATISTICS`, the `INDEX_STATISTICS`, and the `TABLE_STATISTICS` tables in the `INFORMATION_SCHEMA` database.

```

SELECT * FROM INFORMATION_SCHEMA.USER_STATISTICS\G
*****
***** 1. row *****
    USER: root
    TOTAL_CONNECTIONS: 1
    CONCURRENT_CONNECTIONS: 0
    CONNECTED_TIME: 297
        BUSY_TIME: 0.001725
        CPU_TIME: 0.001982
    BYTES RECEIVED: 388
    BYTES SENT: 2327
    BINLOG_BYTES_WRITTEN: 0
        ROWS_READ: 0
        ROWS_SENT: 12
        ROWS_DELETED: 0
    ROWS_INSERTED: 13
        ROWS_UPDATED: 0
    SELECT_COMMANDS: 4
    UPDATE_COMMANDS: 0
    OTHER_COMMANDS: 3
    COMMIT_TRANSACTIONS: 0
    ROLLBACK_TRANSACTIONS: 0
    DENIED_CONNECTIONS: 0
    LOST_CONNECTIONS: 0
    ACCESS_DENIED: 0
    EMPTY_QUERIES: 1

```

```

SELECT * FROM INFORMATION_SCHEMA.CLIENT_STATISTICS\G
*****
***** 1. row *****
    CLIENT: localhost
    TOTAL_CONNECTIONS: 3
    CONCURRENT_CONNECTIONS: 0
    CONNECTED_TIME: 4883
        BUSY_TIME: 0.009722
        CPU_TIME: 0.0102131
    BYTES RECEIVED: 841
    BYTES SENT: 13897
    BINLOG_BYTES_WRITTEN: 0
        ROWS_READ: 0
        ROWS_SENT: 214
        ROWS_DELETED: 0
    ROWS_INSERTED: 207
        ROWS_UPDATED: 0
    SELECT_COMMANDS: 10
    UPDATE_COMMANDS: 0
    OTHER_COMMANDS: 13
    COMMIT_TRANSACTIONS: 0
    ROLLBACK_TRANSACTIONS: 0
    DENIED_CONNECTIONS: 0
    LOST_CONNECTIONS: 0
    ACCESS_DENIED: 0
    EMPTY_QUERIES: 1
1 row in set (0.00 sec)

```

```

SELECT * FROM INFORMATION_SCHEMA.INDEX_STATISTICS WHERE TABLE_NAME = "author";
+-----+-----+-----+-----+
| TABLE_SCHEMA | TABLE_NAME | INDEX_NAME | ROWS_READ |
+-----+-----+-----+-----+
| books       | author      | by_name     |      15 |
+-----+-----+-----+-----+

```

```

SELECT * FROM INFORMATION_SCHEMA.TABLE_STATISTICS WHERE TABLE_NAME='user';
+-----+-----+-----+-----+-----+
| TABLE_SCHEMA | TABLE_NAME | ROWS_READ | ROWS_CHANGED | ROWS_CHANGED_X_INDEXES |
+-----+-----+-----+-----+
| mysql       | user        |      5 |          2 |                  2 |
+-----+-----+-----+-----+

```

## Using the SHOW Statements

As an alternative to the [INFORMATION\\_SCHEMA](#) tables, the

`userstat`

plugin also adds the [SHOW USER\\_STATISTICS](#), the [SHOW CLIENT\\_STATISTICS](#), the [SHOW INDEX\\_STATISTICS](#), and the [SHOW](#)

[TABLE\\_STATISTICS](#) statements.

These commands are another way to display the information stored in the information schema tables. WHERE clauses are accepted. LIKE clauses are accepted but ignored.

```
SHOW USER_STATISTICS  
SHOW CLIENT_STATISTICS  
SHOW INDEX_STATISTICS  
SHOW TABLE_STATISTICS
```

## Flushing Plugin Data

The `userstat` plugin also adds the [FLUSH USER\\_STATISTICS](#), [FLUSH CLIENT\\_STATISTICS](#), [FLUSH INDEX\\_STATISTICS](#), and [FLUSH TABLE\\_STATISTICS](#) statements, which discard the information stored in the specified information schema table.

```
FLUSH USER_STATISTICS  
FLUSH CLIENT_STATISTICS  
FLUSH INDEX_STATISTICS  
FLUSH TABLE_STATISTICS
```

## Versions

### USER\_STATISTICS

Version	Status	Introduced
2.0	Stable	MariaDB 10.1.18
2.0	Gamma	MariaDB 10.1.1

## 4.4.10.8 User Variables Plugin

MariaDB starting with [10.2.0](#)

The

`user_variables`  
plugin was first released in MariaDB [10.2.0](#).

The

`user_variables`  
plugin creates the

[USER\\_VARIABLES](#)

table in the

[INFORMATION\\_SCHEMA](#)

database. This table contains information about [user-defined variables](#).

### Contents

1. [Installing the Plugin](#)
2. [Uninstalling the Plugin](#)
3. [Example](#)
4. [Versions](#)
5. [Options](#)
  1. [user\\_variables](#)

## Installing the Plugin

MariaDB starting with [10.2.6](#)

In [MariaDB 10.2.6](#) and later, the

`user_variables`  
plugin is statically linked into the server by default, so it does not need to be installed.

Although the plugin's shared library is distributed with MariaDB by default, the plugin is not actually installed by MariaDB by default prior to [MariaDB 10.2.6](#). There are two methods that can be used to install the plugin with MariaDB.

The first method can be used to install the plugin without restarting the server. You can install the plugin dynamically by executing

[INSTALL SONAME](#)

or

[INSTALL PLUGIN](#)

. For example:

```
INSTALL SONAME 'user_variables';
```

The second method can be used to tell the server to load the plugin when it starts up. The plugin can be installed this way by providing the

[--plugin-load](#)

or the

[--plugin-load-add](#)

options. This can be specified as a command-line argument to

```
mysql
```

or it can be specified in a relevant server [option group](#) in an [option file](#). For example:

```
[mariadb]
...
plugin_load_add = user_variables
```

## Uninstalling the Plugin

You can uninstall the plugin dynamically by executing

```
UNINSTALL SONAME
```

or

```
UNINSTALL PLUGIN
```

. For example:

```
UNINSTALL SONAME 'user_variables';
```

If you installed the plugin by providing the

```
--plugin-load
```

or the

```
--plugin-load-add
```

options in a relevant server [option group](#) in an [option file](#), then those options should be removed to prevent the plugin from being loaded the next time the server is restarted.

## Example

```
SELECT * FROM information_schema.USER_VARIABLES ORDER BY VARIABLE_NAME;
+-----+-----+-----+
| VARIABLE_NAME | VARIABLE_VALUE | VARIABLE_TYPE | CHARACTER_SET_NAME |
+-----+-----+-----+
| var          | 0           | INT          | utf8            |
| var2         | abc         | VARCHAR      | utf8            |
+-----+-----+-----+
```

## Versions

Version	Status	Introduced
1.0	Stable	MariaDB 10.3.13
1.0	Gamma	MariaDB 10.2.6
1.0	Alpha	MariaDB 10.2.0

## Options

### user\_variables

- **Description:** Controls how the server should treat the plugin when the server starts up.

- Valid values are:

- 

OFF

- Disables the plugin without removing it from the `mysql.plugins` table.
- - `ON`
    - Enables the plugin. If the plugin cannot be initialized, then the server will still continue starting up, but the plugin will be disabled.
  - - `FORCE`
      - Enables the plugin. If the plugin cannot be initialized, then the server will fail to start with an error.
    - - `FORCE_PLUS_PERMANENT`
        - Enables the plugin. If the plugin cannot be initialized, then the server will fail to start with an error. In addition, the plugin cannot be uninstalled with

`UNINSTALL SONAME`

or

`UNINSTALL PLUGIN`

while the server is running.

  - See [Plugin Overview: Configuring Plugin Activation at Server Startup](#) for more information.
  - **Commandline:**
  - `--user-variables=value`
  - **Data Type:**
  - enumerated
  - **Default Value:**
  - `ON`
  - **Valid Values:**
  - `OFF`
  - `,`
  - `ON`
  - `,`
  - `FORCE`
  - `,`
  - `FORCE_PLUS_PERMANENT`

## 4.4.10.9 Disks Plugin

MariaDB starting with [10.1.32](#)

The `DISKS` plugin was first released in [MariaDB 10.3.6](#) , [MariaDB 10.2.14](#) and [MariaDB 10.1.32](#) .

The `DISKS` plugin creates the

`DISKS`

table in the

`INFORMATION_SCHEMA`

database. This table shows metadata about disks on the system.

Before [MariaDB 10.4.7](#) , [MariaDB 10.3.17](#) , [MariaDB 10.2.26](#) and [MariaDB 10.1.41](#) , this plugin did **not** check `user privileges` . When it is enabled, **any** user can query the

`INFORMATION_SCHEMA.DISKS` table and see all the information it provides.

Since [MariaDB 10.4.7](#) , [MariaDB 10.3.17](#) , [MariaDB 10.2.26](#) and [MariaDB 10.1.41](#) , it requires the `FILE privilege` .

The plugin only works on Linux.

## Contents

1. [Installing the Plugin](#)
2. [Uninstalling the Plugin](#)
3. [Example](#)
4. [Versions](#)
5. [Options](#)
  1. [disks](#)

## Installing the Plugin

Although the plugin's shared library is distributed with MariaDB by default, the plugin is not actually installed by MariaDB by default. There are two methods that can be used to install the plugin with MariaDB.

The first method can be used to install the plugin without restarting the server. You can install the plugin dynamically by executing

```
INSTALL SONAME
```

or

```
INSTALL PLUGIN
```

. For example:

```
INSTALL SONAME 'disks';
```

The second method can be used to tell the server to load the plugin when it starts up. The plugin can be installed this way by providing the

```
--plugin-load
```

or the

```
--plugin-load-add
```

options. This can be specified as a command-line argument to

```
mysqld
```

or it can be specified in a relevant server [option group](#) in an [option file](#). For example:

```
[mariadb]
...
plugin_load_add = disks
```

## Uninstalling the Plugin

You can uninstall the plugin dynamically by executing

```
UNINSTALL SONAME
```

or

```
UNINSTALL PLUGIN
```

. For example:

```
UNINSTALL SONAME 'disks';
```

If you installed the plugin by providing the

```
--plugin-load
```

or the

```
--plugin-load-add
```

options in a relevant server [option group](#) in an [option file](#), then those options should be removed to prevent the plugin from being loaded the next time the server is restarted.

# Example

```
SELECT * FROM information_schema.DISKS;
```

Disk	Path	Total	Used	Available
/dev/vda1	/	26203116	2178424	24024692
/dev/vda1	/boot	26203116	2178424	24024692
/dev/vda1	/etc	26203116	2178424	24024692

## Versions

Version	Status	Introduced
1.1	Stable	MariaDB 10.4.7 , MariaDB 10.3.17 , MariaDB 10.2.26 , MariaDB 10.1.41
1.0	Beta	MariaDB 10.3.6 , MariaDB 10.2.14 , MariaDB 10.1.32

## Options

### disks

- **Description:** Controls how the server should treat the plugin when the server starts up.

- Valid values are:

- OFF

- Disables the plugin without removing it from the

- `mysql.plugins`

- table.

- ON

- Enables the plugin. If the plugin cannot be initialized, then the server will still continue starting up, but the plugin will be disabled.

- FORCE

- Enables the plugin. If the plugin cannot be initialized, then the server will fail to start with an error.

- FORCE\_PLUS\_PERMANENT

- Enables the plugin. If the plugin cannot be initialized, then the server will fail to start with an error. In addition, the plugin cannot be uninstalled with

- `UNINSTALL SONAME`

- or

- `UNINSTALL PLUGIN`

- while the server is running.

- See [Plugin Overview: Configuring Plugin Activation at Server Startup](#) for more information.

- **Commandline:**

- `--disks=value`

- **Data Type:**

- enumerated

- **Default Value:**

- ON

- **Valid Values:**

- OFF

- ,

- ON

```
,  
FORCE  
,
```

## 4.4.10.10 Compression Plugins

MariaDB starting with [10.7.0](#)

Compressions plugins were added in a [MariaDB 10.7.0](#) preview release.

### Contents

1. [Installing](#)
2. [Upgrading](#)
3. [See Also](#)

The various MariaDB storage engines, such as [InnoDB](#) , [RocksDB](#) , [Mroonga](#) , can use different compression libraries.

Before [MariaDB 10.7.0](#) , each separate library would have to be compiled in in order to be available for use, resulting in numerous runtime/rpm/deb dependencies, most of which would never be used by users.

From [MariaDB 10.7.0](#) , five additional MariaDB compression libraries (besides the default zlib) are available as plugins (note that these affect InnoDB and Mroonga only; RocksDB still uses the compression algorithms from its own library):

- bzip2
- lzma
- lz4
- lzo
- snappy

## Installing

To use, these simply need to be [installed as a plugin](#) :

```
INSTALL SONAME 'provider_lz4';
```

The compression algorithm can then be used, for example, in [InnoDB compression](#) :

```
SET GLOBAL innodb_compression_algorithm = lz4;
```

## Upgrading

When upgrading from a release without compression plugins, if a non-zlib compression algorithm was used, those tables will be unreadable until the appropriate compression library is installed. [mariadb-upgrade](#) should be run. The

```
--force  
option (to run mariadb-check ) or  
mariadb-check  
itself will indicate any problems with compression, for example:
```

```
Warning : MariaDB tried to use the LZMA compression, but its provider plugin is not loaded  
  
Error   : Table 'test.t' doesn't exist in engine  
  
status  : Operation failed
```

or

```
Error   : Table test/t is compressed with lzma, which is not currently loaded.  
Please load the lzma provider plugin to open the table  
  
error   : Corrupt
```

In this case, the appropriate compression plugin should be installed, and the server restarted.

3. Collecting Additional Information for a Bug Report
  1. Getting a Stack Trace with Details
  2. Extracting a Portion of a Binary Log
4. Getting Help with your Servers

MariaDB's bug and feature tracker is found at <https://jira.mariadb.org>.

This page contains general guidelines for the community for reporting bugs in MariaDB products. If you want to discuss a problem or a new feature with other MariaDB developers, you can find the email lists and forums [here](#).

## Known Bugs

First, check that the bug isn't already filed in the [MariaDB bugs database](#).

For the MariaDB bugs database, use JIRA search to check if a report you are going to submit already exists. You are not expected to be a JIRA search guru, but please at least make some effort.

- Choose
  - Issues => Search for issues
  - ;
- If the form opens for you with a long blank line at top, press
  - Basic
  - on the right to switch to a simpler mode;
- In the
  - Project
  - field, choose the related project, (
  - MDEV
  - for generic MariaDB server and clients);
- In the
  - Contains text
  - text field, enter the most significant key words from your future report;
- Press
  - Enter
  - or the magnifying glass icon to search.

If you see bug reports which are already closed, pay attention to the 'Fix version/s' field -- it is possible that they were fixed in the *upcoming* release. If they are said to be fixed in the release that you are currently using or earlier, you can ignore them and file a new one (although please mention in your bug report that you found them, it might be useful).

If you find an open bug report, please vote/add a comment that the bug also affects you along with any additional information you have that may help us to find and fix the bug.

If the bug is not in the MariaDB bugs database yet, then it's time to file a bug report. If you're filing a bug report about a bug that's already in the [MySQL bugs database](#), please indicate so at the start of the report. Filing bug reports from MySQL in the MariaDB bugs database makes sense, because:

- It shows the MariaDB team that there is interest in having this bug fixed in MariaDB.
- It allows work to start on fixing the bug in MariaDB - assigning versions, assigning MariaDB developers to the bug, etc.

## Reporting a Bug

## JIRA Privacy

Please note that our JIRA entries are public, and JIRA is very good at keeping a record of everything that has been done. What this means is that if you ever include confidential information in the description there will be a log containing it, even after you've deleted it. The only way to get rid of it will be removing the JIRA entry completely.

Attachments in JIRA are also public.

Access to a comment can be restricted to a certain group (e.g. Developers only), but the existing groups are rather wide, so you should not rely on it either.

If you have private information -- SQL fragments, logs, database dumps, etc. -- that you are willing to share with MariaDB team, but not with the entire world, put it into a file, compress if necessary, upload to the [mariadb-ftp-server](#), and just mention it in the JIRA description. This way only the MariaDB team will have access to it.

## Reporting Security Vulnerabilities

As explained above, all JIRA issues are public. If you believe you have found a security vulnerability, send an email to [security@mariadb.org](mailto:security@mariadb.org), please, do not use JIRA for that. We will enter it in JIRA ourselves, following the [responsible disclosure](#) practices.

## Contents of a Good Bug Report

Below is the information we need to be able to fix bugs. The more information we get and the easier we can repeat the bug, the faster it will be fixed.

A good bug report consists of:

- a. The environment (Operating system, hardware and MariaDB version) where the bug happened.

- b. Any related errors or warnings from the server error log file. Normally it is

```
hostname.err  
file in your database directory, but it can be different depending on the distribution and version; if you cannot find it, run
```

```
SELECT @@log_error
```

on the running server. If either the variable or the file it points at is empty, the error log most likely goes to your system log. If this is  
systemd you can get the last 50 lines of the MariaDB log with

```
journalctl -n 50 -u mariadb.service
```

. If possible, attach the full unabridged error log at least from the last server restart and till the end of the log.,

- c. If the problem is related to MariaDB updates, or otherwise changing the version of the server, recovery from a previous crash, and such, then  
include the previous versions used, and the error log from previous server sessions.

- d. The content of your my.cnf file or alternatively the output from

```
mysqld --print-defaults
```

or

```
SHOW VARIABLES
```

- e. Any background information you can provide ( [stack trace](#) , tables, table definitions (

```
show-create-table SHOW CREATE TABLE {tablename}
```

), data dumps, query logs).

- f. If the bug is about server producing wrong query results: the actual result (what you are getting), the expected result (what you think should be produced instead), and, unless it is obvious, the reason why you think the current result is wrong.

- g. If the bug about a performance problem, e.g. a certain query is slower on one version than on another, output of

```
EXPLAIN EXTENDED <query>
```

on both servers. If its a

```
SELECT
```

```
query use analyze-format-json ANALYZE FORMAT=JSON .
```

- h. A test case or some other way to repeat the bug. This should preferably be in plain SQL or in mysqltest format. See [mysqltest/README](#) for  
information about this.

- i. If it's impossible to do a test case, then providing us with a [core dump + the corresponding binary](#) would be of great help.

## JIRA Fields

The section below describes which JIRA fields need to be populated while filing reports, and what should be put there. Apart from what's mentioned below, you don't have to fill or change any fields while creating a new bug report.

### Project

If you are filing a report for MariaDB server, client programs, or MariaDB Galera cluster, the target project is

```
MDEV
```

. Connectors and MaxScale have separate projects with corresponding names. If you choose a wrong project, bug processing can be delayed,  
but there is no reason to panic -- we'll correct it. If you inform us about the mistake, we'll change it faster.

Some project names include:

- CONC - MariaDB Connector/C
- CONJ - MariaDB Connector/J
- CONJS - MariaDB Connector/node.js
- CONPY - MariaDB Connector/Python
- MCOL - ColumnStore
- MDEV - MariaDB server, client programs, or MariaDB Galera Cluster
- MXS - MaxScale
- ODBC - MariaDB Connector/ODBC

## Type

Feature requests are not the same as bug reports. Specify a

Task

type for feature requests in [Jira](#), and a

Bug

type for bug reports. Like with the project field, choosing a wrong type will put the request to the wrong queue and can delay its processing, but eventually it will be noticed and amended.

See also [plans for next release](#) for things that we are considering to have in the next MariaDB release.

## Summary

Please make sure the summary line is informative and distinctive. It should always be easy to recognize your report among other similar ones, otherwise a reasonable question arises -- why are they not duplicates?

Examples:

- good summary: *Server crash with insert statement containing DEFAULT into view*
- not a good summary: *mysqld crash*

Generally, we try not to change the original summary without a good reason to do it, so that you can always recognize your own reports easily.

## Priority

We do not have separate Severity/Priority fields in JIRA, so this Priority field serves a double purpose. For original reports, it indicates the importance of the problem from the reporter's point of view. The default is 'Major'; there are two lower and two higher values. Please set the value accurately. While we do take it into account during initial processing, increasing the value above reasonable won't do any good, the only effect will be the waste of time while somebody will be trying to understand why a trivial problem got such a high priority. After that, the value will be changed, and the report will be processed in its due time anyway.

## Affected Versions

Put everything you know about which versions are affected. There are both major versions (10.6, 10.5 etc.) and minor versions (10.5.9, 10.4.12, etc.) available for choosing. Please always specify there the exact version(s) (X.Y.Z) which you are working with, and where you experience the problem.

Additionally, If you know the exact version where the problem appeared, please put it as well. If the problem has been present, as far as you know, in all previous releases, you can also put there the major version, e.g. 10.0. Alternatively, you can mention all of it in the description or comments.

Please also note in the description or comments which versions you know as *not* affected. This information will help to shorten further processing.

## Environment

Put here environment-related information that might be important for reproducing or analyzing the problem: operating system, hardware, related 3rd-party applications, compilers, etc.

## Description

The most important part of the description are steps to reproduce the problem. See more details about bug report contents above in the section [Contents of a good bug report](#).

If in the process of reproducing, you executed some SQL, don't describe it in words such as "I created a table with text columns and date columns and populated it with some rows" -- instead, whenever possible, put the exact SQL queries that you ran. The same goes for problems that you encountered: instead of saying "it did not work, the query failed, I got an error", always paste the exact output that you received.

*Use {noformat}...{noformat} and {code}...{code} blocks for code and console output in the description.*

## Attachments

If you have SQL code, a database dump, a log etc. of a reasonable size, attach them to the report (archive them first if necessary). If they are too big, you can upload them to [ftp.askmonty.org/private](http://ftp.askmonty.org/private). It is always a good idea to attach your cnf file(s), unless it is absolutely clear from the nature of the report that configuration is irrelevant.

## Links

If you found or filed a bug report either in MariaDB or MySQL or Percona bug base which you think is related to yours, you can put them in the

## Links

section; same for any external links to 3rd-party resources which you find important to mention. Alternatively, you can just mention them in the description or comments.

## Tags

You don't have to set any tags, but if you want to use any for your convenience, feel free to do so. However, please don't put too generic values -- for example, the tag

```
mariadb  
is meaningless, because everything there is  
mariadb  
. Don't be surprised if some tags are removed later during report processing.
```

## Bugs that also Affect MySQL or XtraDB/TokuDB in Percona

Our normal practice is to report a bug upstream if it's applicable to their version. While we can do it on your behalf, it is always better if you do it yourself - it will be easier for you to track it further.

If the bug affects MySQL, it should also be reported at [MySQL bugs database](#). If the bug affects XtraDB or TokuDB and reproducible with Percona server, it should go to [Percona Launchpad](#).

## Collecting Additional Information for a Bug Report

### Getting a Stack Trace with Details

See the article [How to produce a stack trace from a core file](#).

### Extracting a Portion of a Binary Log

See the article [here](#).

## Getting Help with your Servers

If you require personalized assistance, want to ensure that the bug is fixed with high priority, or want someone to login to your server to find out what's wrong, you can always purchase a [Support](#) contract from MariaDB Corporation or use their consulting services.
