CREATE TABLE gis_line (g LINESTRING);
INSERT INTO gis_line VALUES
(LineFromText('LINESTRING(0 0,0 10,10 0)'), 
(LineStringFromText('LINESTRING(10 10,20 10,20 20,10 20,10 10)'), 
(LineStringFromWKB(AsWKB(LineString(Point(10, 10), Point(40, 10)))));
```

### 1.1.12.9.3.1.5 MULTILINESTRING

#### Syntax

```
MultiLineString(ls1,ls2,...)
```

#### Description

Constructs a WKB MultiLineString value using [WKB LineString](#) arguments. If any argument is not a WKB LineString, the return value is  
NULL

#### Example

```

CREATE TABLE gis_multi_line (g MULTILINESTRING);
INSERT INTO gis_multi_line VALUES
(MultiLineStringFromText('MULTILINESTRING((10 48,10 21,10 0),(16 0,16 23,16 48))')),
(MLineFromText('MULTILINESTRING((10 48,10 21,10 0))')),
(MLineFromWKB(AsWKB(MultiLineString(LineString(Point(1, 2), Point(3, 5)), LineString(Point(2, 5),Point(5, 8),Point(21, 7))))));

```

## 1.1.12.9.3.1.6 MULTIPOINT

### Syntax

```
MultiPoint(pt1,pt2,...)
```

### Description

Constructs a [WKB](#) MultiPoint value using WKB [Point](#) arguments. If any argument is not a WKB Point, the return value is `NULL`.

### Examples

```

SET @g = ST_GEOMFROMTEXT('MultiPoint( 1 1, 2 2, 5 3, 7 2, 9 3, 8 4, 6 6, 6 9, 4 9, 1 5 )');

CREATE TABLE gis_multi_point (g MULTIPOINT);
INSERT INTO gis_multi_point VALUES
(MultiPointFromText('MULTIPOINT(0 0,10 10,10 20,20 20)'),,
(MPointFromText('MULTIPOINT(1 1,11 11,11 21,21 21)'),,
(MPointFromWKB(AsWKB(MultiPoint(Point(3, 6), Point(4, 10))))));

```

## 1.1.12.9.3.1.7 MULTIPOLYGON

### Syntax

```
MultiPolygon(poly1,poly2,...)
```

### Description

Constructs a [WKB](#) MultiPolygon value from a set of WKB [Polygon](#) arguments. If any argument is not a WKB Polygon, the return value is `NULL`.

### Example

```

CREATE TABLE gis_multi_polygon (g MULTIPOLYGON);
INSERT INTO gis_multi_polygon VALUES
(MultiPolygonFromText('MULTIPOLYGON(((28 26,28 0,84 0,84 42,28 26),(52 18,66 23,73 9,48 6,52 18)),((59 18,67 18,67 13,59 13,
(MPolyFromText('MULTIPOLYGON(((28 26,28 0,84 0,84 42,28 26),(52 18,66 23,73 9,48 6,52 18)),((59 18,67 18,67 13,59 13,59 18))
(MPolyFromWKB(AsWKB(MultiPolygon(Polygon(LineString(Point(0, 3), Point(3, 3), Point(3, 0), Point(0, 3))))));

```

## 1.1.12.9.3.1.8 POINT

### Syntax

```
Point(x,y)
```

### Description

Constructs a [WKB](#) Point using the given coordinates.

## Examples

```
SET @g = ST_GeomFromText('Point(1 1)';

CREATE TABLE gis_point  (g POINT);
INSERT INTO gis_point VALUES
  (PointFromText('POINT(10 10'))),
  (PointFromText('POINT(20 10'))),
  (PointFromText('POINT(20 20'))),
  (PointFromWKB(AsWKB(PointFromText('POINT(10 20')))));
```

### 1.1.12.9.3.1.9 PointOnSurface

A synonym for [ST\\_PointOnSurface](#).

### 1.1.12.9.3.1.10 POLYGON

#### Syntax

```
Polygon(ls1,ls2,...)
```

#### Description

Constructs a WKB Polygon value from a number of [WKB LineString](#) arguments. If any argument does not represent the WKB of a LinearRing (that is, not a closed and simple LineString) the return value is

NULL

Note that according to the OpenGIS standard, a POLYGON should have exactly one ExteriorRing and all other rings should lie within that ExteriorRing and thus be the InteriorRings. Practically, however, some systems, including MariaDB's, permit polygons to have several 'ExteriorRings'. In the case of there being multiple, non-overlapping exterior rings [ST\\_NUMINTERIORRINGS\(\)](#) will return 1.

## Examples

```
SET @g = ST_GeomFromText('POLYGON((1 1,1 5,4 9,6 9,9 3,7 2,1 1))';

CREATE TABLE gis_polygon  (g POLYGON);
INSERT INTO gis_polygon VALUES
  (PolygonFromText('POLYGON((10 10,20 10,20 20,10 20,10 10))')),
  (PolyFromText('POLYGON((0 0,50 0,50 50,0 50,0 0), (10 10,20 10,20 20,10 20,10 10))'),
  (PolyFromWKB(AsWKB(Polygon(LineString(Point(0, 0), Point(30, 0), Point(30, 30), Point(0, 0))))));
```

Non-overlapping 'polygon':

```
SELECT ST_NumInteriorRings(ST_PolyFromText('POLYGON((0 0,10 0,10 10,0 10,0 0),
  (-1 -1,-5 -5,-1 -5,-1 -1))') AS NumInteriorRings;
+-----+
| NumInteriorRings |
+-----+
|          1 |
+-----+
```

### 1.1.12.9.3.1.11 ST\_BUFFER

#### Syntax

```
ST_BUFFER(g1,r)
BUFFER(g1,r)
```

#### Description

Returns a geometry that represents all points whose distance from geometry

*g1*

is less than or equal to distance, or radius,

$r$

.

Uses for this function could include creating for example a new geometry representing a buffer zone around an island.

BUFFER() is a synonym.

## Examples

Determining whether a point is within a buffer zone:

```
SET @g1 = ST_GEOFROMTEXT('POLYGON((10 10, 10 20, 20 20, 20 10, 10 10))');

SET @g2 = ST_GEOFROMTEXT('POINT(8 8)');

SELECT ST_WITHIN(@g2,ST_BUFFER(@g1,5));
+-----+
| ST_WITHIN(@g2,ST_BUFFER(@g1,5)) |
+-----+
| 1 |
+-----+

SELECT ST_WITHIN(@g2,ST_BUFFER(@g1,1));
+-----+
| ST_WITHIN(@g2,ST_BUFFER(@g1,1)) |
+-----+
| 0 |
+-----+
```

## 1.1.12.9.3.1.12 ST\_CONVEXHULL

MariaDB starting with 10.1.2

ST\_ConvexHull() was introduced in MariaDB 10.1.2

## Syntax

```
ST_ConvexHull(g)
ConvexHull(g)
```

## Description

Given a geometry, returns a geometry that is the minimum convex geometry enclosing all geometries within the set. Returns NULL if the geometry value is NULL or an empty value.

ST\_ConvexHull() and ConvexHull() are synonyms.

## Examples

The ConvexHull of a single point is simply the single point:

```
SET @g = ST_GEOFROMTEXT('Point(0 0)');

SELECT ST_ASTEXT(ST_CONVEXHULL(@g));
+-----+
| ST_ASTEXT(ST_CONVEXHULL(@g)) |
+-----+
| POINT(0 0) |
+-----+
```

```

SET @g = ST_GEOFROMTEXT('MultiPoint(0 0, 1 2, 2 3)');

SELECT ST_ASTEXT(ST_CONVEXHULL(@g));
+-----+
| ST_ASTEXT(ST_CONVEXHULL(@g)) |
+-----+
| POLYGON((0 0,1 2,2 3,0 0)) |
+-----+

```

```

SET @g = ST_GEOFROMTEXT('MultiPoint( 1 1, 2 2, 5 3, 7 2, 9 3, 8 4, 6 6, 6 9, 4 9, 1 5 )');

SELECT ST_ASTEXT(ST_CONVEXHULL(@g));
+-----+
| ST_ASTEXT(ST_CONVEXHULL(@g)) |
+-----+
| POLYGON((1 1,1 5,4 9,6 9,9 3,7 2,1 1)) |
+-----+

```

## 1.1.12.9.3.1.13 ST\_INTERSECTION

### Syntax

```
ST_INTERSECTION(g1,g2)
```

### Description

Returns a geometry that is the intersection, or shared portion, of geometry

*g1*  
and geometry  
*g2*

### Examples

```

SET @g1 = ST_GEOFROMTEXT('POINT(2 1)');

SET @g2 = ST_GEOFROMTEXT('LINESTRING(2 1, 0 2)');

SELECT ASTEXT(ST_INTERSECTION(@g1,@g2));
+-----+
| ASTEXT(ST_INTERSECTION(@g1,@g2)) |
+-----+
| POINT(2 1) |
+-----+

```

## 1.1.12.9.3.1.14 ST\_POINTONSURFACE

MariaDB starting with [10.1.2](#)

ST\_POINTONSURFACE() was introduced in [MariaDB 10.1.2](#).

### Syntax

```
ST_PointOnSurface(g)
PointOnSurface(g)
```

### Description

Given a geometry, returns a [POINT](#) guaranteed to intersect a surface. However, see [MDEV-7514](#).

ST\_PointOnSurface() and PointOnSurface() are synonyms.

## 1.1.12.9.3.1.15 ST\_SYMDIFFERENCE

### Syntax

```
ST_SYMDIFFERENCE(g1,g2)
```

### Description

Returns a geometry that represents the portions of geometry

*g1*  
and geometry  
*g2*  
that don't intersect.

### Examples

```
SET @g1 = ST_GeomFromText('LINESTRING(10 20, 10 40)');

SET @g2 = ST_GeomFromText('LINESTRING(10 15, 10 25)');

SELECT ASTEXT(ST_SYMDIFFERENCE(@g1,@g2));
+-----+
| ASTEXT(ST_SYMDIFFERENCE(@g1,@g2)) |
+-----+
| MULTILINESTRING((10 15,10 20),(10 25,10 40)) |
+-----+

SET @g2 = ST_GeomFromText('LINESTRING(10 20, 10 41)';

SELECT ASTEXT(ST_SYMDIFFERENCE(@g1,@g2));
+-----+
| ASTEXT(ST_SYMDIFFERENCE(@g1,@g2)) |
+-----+
| LINESTRING(10 40,10 41) |
+-----+
```

## 1.1.12.9.3.1.16 ST\_UNION

### Syntax

```
ST_UNION(g1,g2)
```

### Description

Returns a geometry that is the union of the geometry

*g1*  
and geometry  
*g2*

### Examples

```
SET @g1 = GEOMFROMTEXT('POINT (0 2)');

SET @g2 = GEOMFROMTEXT('POINT (2 0)');

SELECT ASTEXT(ST_UNION(@g1,@g2));
+-----+
| ASTEXT(ST_UNION(@g1,@g2)) |
+-----+
| MULTIPOINT(2 0,0 2) |
+-----+
```

```
SET @g1 = GEOMFROMTEXT('POLYGON((0 0,0 3,3 3,3 0,0 0))');
SET @g2 = GEOMFROMTEXT('POLYGON((2 2,4 2,4 4,2 4,2 2))');
SELECT ASTEXT(ST_UNION(@g1,@g2));
+-----+
| ASTEXT(ST_UNION(@g1,@g2)) |
+-----+
| POLYGON((0 0,0 3,2 3,2 4,4 4,4 2,3 2,3 0,0 0)) |
+-----+
```

## 1.1.12.9.3.2 Geometry Properties

### 1.1.12.9.3.2.1 BOUNDARY

A synonym for [ST\\_BOUNDARY](#).

### 1.1.12.9.3.2.2 DIMENSION

A synonym for [ST\\_DIMENSION](#).

### 1.1.12.9.3.2.3 ENVELOPE

A synonym for [ST\\_ENVELOPE](#).

### 1.1.12.9.3.2.4 GeometryN

A synonym for [ST\\_GeometryN](#).

### 1.1.12.9.3.2.5 GeometryType

A synonym for [ST\\_GeometryType](#).

### 1.1.12.9.3.2.6 IsClosed

A synonym for [ST\\_IsClosed](#).

### 1.1.12.9.3.2.7 IsEmpty

A synonym for [ST\\_IsEmpty](#).

### 1.1.12.9.3.2.8 IsRing

A synonym for [ST\\_IsRing](#).

### 1.1.12.9.3.2.9 IsSimple

A synonym for [ST\\_IsSimple](#).

### 1.1.12.9.3.2.10 NumGeometries

A synonym for [ST\\_NumGeometries](#).

### 1.1.12.9.3.2.11 SRID

A synonym for [ST\\_SRID](#).

### 1.1.12.9.3.2.12 ST\_BOUNDARY

MariaDB starting with [10.1.2](#)

The `ST_BOUNDARY` function was introduced in [MariaDB 10.1.2](#)

## Syntax

```
ST_BOUNDARY(g)
BOUNDARY(g)
```

## Description

Returns a geometry that is the closure of the combinatorial boundary of the geometry value

*g*

.  
BOUNDARY() is a synonym.

## Examples

```
SELECT ST_AsText(ST_Boundary(ST_GeomFromText('LINESTRING(3 3,0 0, -3 3)')));  
+-----+  
| ST_AsText(ST_Boundary(ST_GeomFromText('LINESTRING(3 3,0 0, -3 3)'))) |  
+-----+  
| MULTIPOINT(3 3,-3 3) |  
+-----+  
  
SELECT ST_AsText(ST_Boundary(ST_GeomFromText('POLYGON((3 3,0 0, -3 3, 3 3))')));  
+-----+  
| ST_AsText(ST_Boundary(ST_GeomFromText('POLYGON((3 3,0 0, -3 3, 3 3))'))) |  
+-----+  
| LINESTRING(3 3,0 0,-3 3,3 3) |  
+-----+
```

## 1.1.12.9.3.2.13 ST\_DIMENSION

### Syntax

```
ST_Dimension(g)  
Dimension(g)
```

## Description

Returns the inherent dimension of the geometry value

*g*

. The result can be

Dimension	Definition
-1	empty geometry
0	geometry with no length or area
1	geometry with no area but nonzero length
2	geometry with nonzero area

ST\_Dimension()  
and  
Dimension()  
are synonyms.

## Examples

```
SELECT Dimension(GeomFromText('LineString(1 1,2 2)'));
+-----+
| Dimension(GeomFromText('LineString(1 1,2 2)')) |
+-----+
| 1 |
+-----+
```

## 1.1.12.9.3.2.14 ST\_ENVELOPE

### Syntax

```
ST_ENVELOPE(g)
ENVELOPE(g)
```

### Description

Returns the Minimum Bounding Rectangle (MBR) for the geometry value

g  
. The result is returned as a Polygon value.

The polygon is defined by the corner points of the bounding box:

```
POLYGON((MINX MINY, MAXX MINY, MAXX MAXY, MINX MAXY, MINX MINY))
```

ST\_ENVELOPE()  
and  
ENVELOPE()  
are synonyms.

### Examples

```
SELECT AsText(ST_ENVELOPE(GeomFromText('LineString(1 1,4 4)')));
+-----+
| AsText(ST_ENVELOPE(GeomFromText('LineString(1 1,4 4)'))) |
+-----+
| POLYGON((1 1,4 1,4 4,1 4,1 1)) |
+-----+
```

## 1.1.12.9.3.2.15 ST\_GEOEMTRYN

### Syntax

```
ST_GeometryN(gc,N)
GeometryN(gc,N)
```

### Description

Returns the N-th geometry in the GeometryCollection

gc  
. Geometries are numbered beginning with 1.

ST\_GeometryN()  
and  
GeometryN()  
are synonyms.

### Example

```
SET @gc = 'GeometryCollection(Point(1 1),LineString(12 14, 9 11))';

SELECT AsText(GeometryN(GeomFromText(@gc),1));
+-----+
| AsText(GeometryN(GeomFromText(@gc),1)) |
+-----+
| POINT(1 1)                                |
+-----+
```

## 1.1.12.9.3.2.16 ST\_GEOMETRYTYPE

### Syntax

```
ST_GeometryType(g)
GeometryType(g)
```

### Description

Returns as a string the name of the geometry type of which the geometry instance

g

is a member. The name corresponds to one of the instantiable Geometry subclasses.

ST\_GeometryType()  
and  
GeometryType()  
are synonyms.

### Examples

```
SELECT GeometryType(GeomFromText('POINT(1 1)'));

+-----+
| GeometryType(GeomFromText('POINT(1 1)')) |
+-----+
| POINT                                         |
+-----+
```

## 1.1.12.9.3.2.17 ST\_ISCLOSED

### Syntax

```
ST_IsClosed(g)
IsClosed(g)
```

### Description

Returns 1 if a given LINESTRING's start and end points are the same, or 0 if they are not the same. Before MariaDB 10.1.5 , returns NULL if not given a LINESTRING. After MariaDB 10.1.5 , returns -1.

ST\_IsClosed()  
and  
IsClosed()  
are synonyms.

### Examples

```

SET @ls = 'LineString(0 0, 0 4, 4 4, 0 0)';
SELECT ST_ISCLOSED(GEOMFROMTEXT(@ls));
+-----+
| ST_ISCLOSED(GEOMFROMTEXT(@ls)) |
+-----+
| 1 |
+-----+

SET @ls = 'LineString(0 0, 0 4, 4 4, 0 1)';
SELECT ST_ISCLOSED(GEOMFROMTEXT(@ls));
+-----+
| ST_ISCLOSED(GEOMFROMTEXT(@ls)) |
+-----+
| 0 |
+-----+

```

## 1.1.12.9.3.2.18 ST\_ISEMPTY

### Syntax

```
ST_IsEmpty(g)
IsEmpty(g)
```

### Description

`IsEmpty` is a function defined by the OpenGIS specification, but is not fully implemented by MariaDB or MySQL.

Since MariaDB and MySQL do not support GIS EMPTY values such as POINT EMPTY, as implemented it simply returns

```

1
if the geometry value
g
is invalid,
0
if it is valid, and
NULL
if the argument is
NULL
.
```

`ST_IsEmpty()`  
and  
`IsEmpty()`  
are synonyms.

## 1.1.12.9.3.2.19 ST\_IsRing

MariaDB starting with [10.1.2](#)

The `ST_IsRing` function was introduced in [MariaDB 10.1.2](#).

### Syntax

```
ST_IsRing(g)
IsRing(g)
```

### Description

Returns true if a given `LINESTRING` is a ring, that is, both `ST_IsClosed` and `ST_IsSimple`. A simple curve does not pass through the same point more than once. However, see [MDEV-7510](#).

`St_IsRing()`  
and  
`IsRing()`  
are synonyms.

## 1.1.12.9.3.2.20 ST\_IsSimple

### Syntax

```
ST_IsSimple(g)
IsSimple(g)
```

### Description

Returns true if the given Geometry has no anomalous geometric points, false if it does, or NULL if given a NULL value.

ST\_IsSimple() and IsSimple() are synonyms.

### Examples

A POINT is always simple.

```
SET @g = 'Point(1 2)';

SELECT ST_ISSIMPLE(GEOMFROMTEXT(@g));
+-----+
| ST_ISSIMPLE(GEOMFROMTEXT(@g)) |
+-----+
|                         1 |
+-----+
```

## 1.1.12.9.3.2.21 ST\_NUMGEOMETRIES

### Syntax

```
ST_NumGeometries(gc)
NumGeometries(gc)
```

### Description

Returns the number of geometries in the GeometryCollection

gc

ST\_NumGeometries()  
and  
NumGeometries()  
are synonyms.

### Example

```
SET @gc = 'GeometryCollection(Point(1 1),LineString(2 2, 3 3))';

SELECT NUMGEOMETRIES(GeomFromText(@gc));
+-----+
| NUMGEOMETRIES(GeomFromText(@gc)) |
+-----+
|                           2 |
+-----+
```

## 1.1.12.9.3.2.22 ST\_RELATE

MariaDB starting with 10.1.2

The ST\_RELATE() function was introduced in MariaDB 10.1.2

## Syntax

```
ST_Relate(g1, g2, i)
```

## Description

Returns true if Geometry

g1  
is spatially related to Geometry  
g2  
by testing for intersections between the interior, boundary and exterior of the two geometries as specified by the values in intersection matrix  
pattern  
i  
.

## 1.1.12.9.3.2.23 ST\_SRID

## Syntax

```
ST_SRID(g)  
SRID(g)
```

## Description

Returns an integer indicating the Spatial Reference System ID for the geometry value g.

In MariaDB, the SRID value is just an integer associated with the geometry value. All calculations are done assuming Euclidean (planar) geometry.

ST\_SRID()  
and  
SRID()  
are synonyms.

## Examples

```
SELECT SRID(GeomFromText('LineString(1 1,2 2)',101));  
+-----+  
| SRID(GeomFromText('LineString(1 1,2 2)',101)) |  
+-----+  
| 101 |  
+-----+
```

## 1.1.12.9.3.3 Geometry Relations

### 1.1.12.9.3.3.1 CONTAINS

## Syntax

```
Contains(g1,g2)
```

## Description

Returns

1  
or  
0  
to indicate whether a geometry  
g1  
completely contains geometry  
g2  
. CONTAINS() is based on the original MySQL implementation and uses object bounding rectangles, while [ST\\_CONTAINS\(\)](#) uses object shapes.

This tests the opposite relationship to [Within\(\)](#) .

## 1.1.12.9.3.3.2 CROSSES

### Syntax

```
Crosses(g1,g2)
```

### Description

Returns

```
1  
if  
g1  
spatially crosses  
g2  
. Returns  
NULL  
if  
g1  
is a Polygon or a MultiPolygon , or if  
g2  
is a Point or a MultiPoint . Otherwise, returns  
0  
. .
```

The term spatially crosses denotes a spatial relation between two given geometries that has the following properties:

- The two geometries intersect
- Their intersection results in a geometry that has a dimension that is one less than the maximum dimension of the two given geometries
- Their intersection is not equal to either of the two given geometries

CROSSES() is based on the original MySQL implementation, and uses object bounding rectangles, while [ST\\_CROSSES\(\)](#) uses object shapes.

## 1.1.12.9.3.3.3 DISJOINT

### Syntax

```
Disjoint(g1,g2)
```

### Description

Returns

```
1  
or  
0  
to indicate whether  
g1  
is spatially disjoint from (does not intersect)  
g2  
. .
```

DISJOINT() tests the opposite relationship to [INTERSECTS\(\)](#) .

DISJOINT() is based on the original MySQL implementation and uses object bounding rectangles, while [ST\\_DISJOINT\(\)](#) uses object shapes.

## 1.1.12.9.3.3.4 EQUALS

### Syntax

```
Equals(g1,g2)
```

From [MariaDB 10.2.3](#) :

```
MBREQUALS(g1,g2)
```

## Description

Returns

1  
or  
0  
to indicate whether  
*g1*  
is spatially equal to  
*g2*

EQUALS() is based on the original MySQL implementation and uses object bounding rectangles, while [ST\\_EQUALS\(\)](#) uses object shapes.

From [MariaDB 10.2.3](#),

MBREQUALS  
is a synonym for  
Equals

## 1.1.12.9.3.3.5 INTERSECTS

### Syntax

```
INTERSECTS(g1,g2)
```

## Description

Returns

1  
or  
0  
to indicate whether geometry  
*g1*  
spatially intersects geometry  
*g2*

INTERSECTS() is based on the original MySQL implementation and uses object bounding rectangles, while [ST\\_INTERSECTS\(\)](#) uses object shapes.

INTERSECTS() tests the opposite relationship to [DISJOINT\(\)](#).

## 1.1.12.9.3.3.6 OVERLAPS

### Syntax

```
OVERLAPS(g1,g2)
```

## Description

Returns

1  
or  
0  
to indicate whether  
*g1*  
spatially overlaps  
*g2*  
. The term spatially overlaps is used if two geometries intersect and their intersection results in a geometry of the same dimension but not equal to either of the given geometries.

OVERLAPS() is based on the original MySQL implementation and uses object bounding rectangles, while [ST\\_OVERLAPS\(\)](#) uses object shapes.

## 1.1.12.9.3.3.7 ST\_CONTAINS

### Syntax

```
ST_CONTAINS(g1,g2)
```

## Description

Returns

```
1  
or  
0  
to indicate whether a geometry  
g1  
completely contains geometry  
g2  
.
```

ST\_CONTAINS() uses object shapes, while [CONTAINS\(\)](#) , based on the original MySQL implementation, uses object bounding rectangles.

ST\_CONTAINS tests the opposite relationship to [ST\\_WITHIN\(\)](#) .

## Examples

```
SET @g1 = ST_GEOFROMTEXT('POLYGON((175 150, 20 40, 50 60, 125 100, 175 150))');  
  
SET @g2 = ST_GEOFROMTEXT('POINT(174 149)');  
  
SELECT ST_CONTAINS(@g1,@g2);  
+-----+  
| ST_CONTAINS(@g1,@g2) |  
+-----+  
| 1 |  
+-----+  
  
SET @g2 = ST_GEOFROMTEXT('POINT(175 151)');  
  
SELECT ST_CONTAINS(@g1,@g2);  
+-----+  
| ST_CONTAINS(@g1,@g2) |  
+-----+  
| 0 |  
+-----+
```

## 1.1.12.9.3.3.8 ST\_CROSSES

### Syntax

```
ST_CROSSES(g1,g2)
```

## Description

Returns

```
1  
if geometry  
g1  
spatially crosses geometry  
g2  
. Returns  
NULL  
if  
g1  
is a Polygon or a MultiPolygon , or if  
g2  
is a Point or a MultiPoint . Otherwise, returns  
0  
.
```

The term spatially crosses denotes a spatial relation between two given geometries that has the following properties:

- The two geometries intersect
- Their intersection results in a geometry that has a dimension that is one less than the maximum dimension of the two given geometries

- Their intersection is not equal to either of the two given geometries

ST\_CROSSES() uses object shapes, while [CROSSES\(\)](#), based on the original MySQL implementation, uses object bounding rectangles.

## Examples

```
SET @g1 = ST_GEOFROMTEXT('LINESTRING(174 149, 176 151)');
SET @g2 = ST_GEOFROMTEXT('POLYGON((175 150, 20 40, 50 60, 125 100, 175 150))');

SELECT ST_CROSSES(@g1,@g2);
+-----+
| ST_CROSSES(@g1,@g2) |
+-----+
| 1 |
+-----+

SET @g1 = ST_GEOFROMTEXT('LINESTRING(176 149, 176 151)');
SELECT ST_CROSSES(@g1,@g2);
+-----+
| ST_CROSSES(@g1,@g2) |
+-----+
| 0 |
+-----+
```

### 1.1.12.9.3.3.9 ST\_DIFFERENCE

#### Syntax

```
ST_DIFFERENCE(g1,g2)
```

#### Description

Returns a geometry representing the point set difference of the given geometry values.

#### Example

```
SET @g1 = POINT(10,10), @g2 = POINT(20,20);
SELECT ST_AsText(ST_Difference(@g1, @g2));
+-----+
| ST_AsText(ST_Difference(@g1, @g2)) |
+-----+
| POINT(10 10) |
+-----+
```

### 1.1.12.9.3.3.10 ST\_DISJOINT

#### Syntax

```
ST_DISJOINT(g1,g2)
```

#### Description

Returns

1  
or  
0  
to indicate whether geometry  
*g1*  
is spatially disjoint from (does not intersect with) geometry  
*g2*  
.

`ST_DISJOINT()` uses object shapes, while `DISJOINT()` , based on the original MySQL implementation, uses object bounding rectangles.  
`ST_DISJOINT()` tests the opposite relationship to `ST_INTERSECTS()` .

## Examples

```
SET @g1 = ST_GEOFROMTEXT('POINT(0 0)');
SET @g2 = ST_GEOFROMTEXT('LINESTRING(2 0, 0 2)');
SELECT ST_DISJOINT(@g1,@g2);
+-----+
| ST_DISJOINT(@g1,@g2) |
+-----+
|          1 |
+-----+

SET @g2 = ST_GEOFROMTEXT('LINESTRING(0 0, 0 2)');
SELECT ST_DISJOINT(@g1,@g2);
+-----+
| ST_DISJOINT(@g1,@g2) |
+-----+
|          0 |
+-----+
```

## 1.1.12.9.3.3.11 ST\_DISTANCE

### Syntax

```
ST_DISTANCE(g1,g2)
```

### Description

Returns the distance between two geometries, or null if not given valid inputs.

### Example

```
SELECT ST_Distance(POINT(1,2),POINT(2,2));
+-----+
| ST_Distance(POINT(1,2),POINT(2,2)) |
+-----+
|          1 |
+-----+
```

## 1.1.12.9.3.3.12 ST\_DISTANCE\_SPHERE

MariaDB starting with 10.2.38

`ST_DISTANCE_SPHERE`  
was introduced in MariaDB 10.2.38 , MariaDB 10.3.29 , MariaDB 10.4.19 and MariaDB 10.5.10 .

### Syntax

```
ST_DISTANCE_SPHERE(g1,g2,[r])
```

### Description

Returns the spherical distance between two geometries (point or multipoint) on a sphere with the optional radius  $r$  (default is the Earth radius if  $r$  is not specified), or NULL if not given valid inputs.

## Example

```
set @zenica = ST_GeomFromText('POINT(17.907743 44.203438)');
set @sarajevo = ST_GeomFromText('POINT(18.413076 43.856258)');
SELECT ST_Distance_Sphere(@zenica, @sarajevo);
55878.59337591705
```

## 1.1.12.9.3.3.13 ST\_EQUALS

### Syntax

```
ST_EQUALS(g1,g2)
```

### Description

Returns

1  
or  
0  
to indicate whether geometry  
*g1*  
is spatially equal to geometry  
*g2*

ST\_EQUALS() uses object shapes, while [EQUALS\(\)](#), based on the original MySQL implementation, uses object bounding rectangles.

### Examples

```
SET @g1 = ST_GEOMFROMTEXT('LINESTRING(174 149, 176 151)');
SET @g2 = ST_GEOMFROMTEXT('LINESTRING(176 151, 174 149)');
SELECT ST_EQUALS(@g1,@g2);
+-----+
| ST_EQUALS(@g1,@g2) |
+-----+
|      1      |
+-----+
```

```
SET @g1 = ST_GEOMFROMTEXT('POINT(0 2)');
SET @g1 = ST_GEOMFROMTEXT('POINT(2 0)');
SELECT ST_EQUALS(@g1,@g2);
+-----+
| ST_EQUALS(@g1,@g2) |
+-----+
|      0      |
+-----+
```

## 1.1.12.9.3.3.14 ST\_INTERSECTS

### Syntax

```
ST_INTERSECTS(g1,g2)
```

### Description

Returns

1  
or  
0

to indicate whether geometry

*g1*

spatially intersects geometry

*g2*

.

ST\_INTERSECTS() uses object shapes, while [INTERSECTS\(\)](#), based on the original MySQL implementation, uses object bounding rectangles.

ST\_INTERSECTS() tests the opposite relationship to [ST\\_DISJOINT\(\)](#).

## Examples

```
SET @g1 = ST_GEOMFROMTEXT('POINT(0 0)');
SET @g2 = ST_GEOMFROMTEXT('LINESTRING(0 0, 0 2)');
SELECT ST_INTERSECTS(@g1,@g2);
+-----+
| ST_INTERSECTS(@g1,@g2) |
+-----+
| 1 |
+-----+
```

```
SET @g2 = ST_GEOMFROMTEXT('LINESTRING(2 0, 0 2)');
SELECT ST_INTERSECTS(@g1,@g2);
+-----+
| ST_INTERSECTS(@g1,@g2) |
+-----+
| 0 |
+-----+
```

## 1.1.12.9.3.3.15 ST\_LENGTH

### Syntax

```
ST_LENGTH(ls)
```

### Description

Returns as a double-precision number the length of the [LineString](#) value

*ls*

in its associated spatial reference.

## Examples

```
SET @ls = 'LineString(1 1,2 2,3 3)';
SELECT ST_LENGTH(ST_GeomFromText(@ls));
+-----+
| ST_LENGTH(ST_GeomFromText(@ls)) |
+-----+
| 2.82842712474619 |
+-----+
```

## 1.1.12.9.3.3.16 ST\_OVERLAPS

### Syntax

```
ST_OVERLAPS(g1,g2)
```

### Description

Returns

```
1  
or  
0  
to indicate whether geometry  
g1  
spatially overlaps geometry  
g2  
.
```

The term spatially overlaps is used if two geometries intersect and their intersection results in a geometry of the same dimension but not equal to either of the given geometries.

ST\_OVERLAPS() uses object shapes, while [OVERLAPS\(\)](#), based on the original MySQL implementation, uses object bounding rectangles.

## 1.1.12.9.3.3.17 ST\_TOUCHES

### Syntax

```
ST_TOUCHES(g1,g2)
```

### Description

Returns

```
1  
or  
0  
to indicate whether geometry  
g1  
spatially touches geometry  
g2  
. Two geometries spatially touch if the interiors of the geometries do not intersect, but the boundary of one of the geometries intersects either the boundary or the interior of the other.
```

ST\_TOUCHES() uses object shapes, while [TOUCHES\(\)](#), based on the original MySQL implementation, uses object bounding rectangles.

### Examples

```
SET @g1 = ST_GEOFROMTEXT('POINT(2 0)');  
  
SET @g2 = ST_GEOFROMTEXT('LINESTRING(2 0, 0 2)');  
  
SELECT ST_TOUCHES(@g1,@g2);  
+-----+  
| ST_TOUCHES(@g1,@g2) |  
+-----+  
| 1 |  
+-----+  
  
SET @g1 = ST_GEOFROMTEXT('POINT(2 1)');  
  
SELECT ST_TOUCHES(@g1,@g2);  
+-----+  
| ST_TOUCHES(@g1,@g2) |  
+-----+  
| 0 |  
+-----+
```

## 1.1.12.9.3.3.18 ST\_WITHIN

### Syntax

```
ST_WITHIN(g1,g2)
```

### Description

Returns

1  
or  
0  
to indicate whether geometry  
*g1*  
is spatially within geometry  
*g2*

This tests the opposite relationship as

[ST\\_CONTAINS\(\)](#)

ST\_WITHIN() uses object shapes, while [WITHIN\(\)](#), based on the original MySQL implementation, uses object bounding rectangles.

## Examples

```
SET @g1 = ST_GEOFROMTEXT('POINT(174 149)';

SET @g2 = ST_GEOFROMTEXT('POLYGON((175 150, 20 40, 50 60, 125 100, 175 150))');

SELECT ST_WITHIN(@g1,@g2);
+-----+
| ST_WITHIN(@g1,@g2) |
+-----+
|          1          |
+-----+

SET @g1 = ST_GEOFROMTEXT('POINT(176 151)';

SELECT ST_WITHIN(@g1,@g2);
+-----+
| ST_WITHIN(@g1,@g2) |
+-----+
|          0          |
+-----+
```

## 1.1.12.9.3.3.19 TOUCHES

### Syntax

`Touches(g1,g2)`

### Description

Returns

1  
or  
0  
to indicate whether  
*g1*  
spatially touches  
*g2*  
. Two geometries spatially touch if the interiors of the geometries do not intersect, but the boundary of one of the geometries intersects either the boundary or the interior of the other.

TOUCHES() is based on the original MySQL implementation and uses object bounding rectangles, while [ST\\_TOUCHES\(\)](#) uses object shapes.

## 1.1.12.9.3.3.20 WITHIN

### Syntax

`Within(g1,g2)`

## Description

Returns

1  
or  
0  
to indicate whether  
g1  
is spatially within  
g2  
. This tests the opposite relationship as

`Contains()`

`WITHIN()` is based on the original MySQL implementation, and uses object bounding rectangles, while `ST_WITHIN()` uses object shapes.

## Examples

```
SET @g1 = GEOMFROMTEXT('POINT(174 149)');
SET @g2 = GEOMFROMTEXT('POINT(176 151)');
SET @g3 = GEOMFROMTEXT('POLYGON((175 150, 20 40, 50 60, 125 100, 175 150))');

SELECT within(@g1,@g3);
+-----+
| within(@g1,@g3) |
+-----+
|           1 |
+-----+

SELECT within(@g2,@g3);
+-----+
| within(@g2,@g3) |
+-----+
|           0 |
+-----+
```

## 1.1.12.9.3.4 LineString Properties

### 1.1.12.9.3.4.1 ENDPOINT

A synonym for `ST_ENDPOINT`.

### 1.1.12.9.3.4.2 GLENGTH

## Syntax

```
GLength(ls)
```

## Description

Returns as a double-precision number the length of the `LineString` value

`ls`  
in its associated spatial reference.

## Examples

```
SET @ls = 'LineString(1 1,2 2,3 3)';

SELECT GLength(GeomFromText(@ls));
+-----+
| GLength(GeomFromText(@ls)) |
+-----+
|           2.82842712474619 |
+-----+
```

## See Also

- [ST\\_LENGTH\(\)](#) is the OpenGIS equivalent.

### 1.1.12.9.3.4.3 NumPoints

A synonym for [ST\\_NumPoints](#).

### 1.1.12.9.3.4.4 PointN

A synonym for [ST\\_PointN](#).

### 1.1.12.9.3.4.5 STARTPOINT

A synonym for [ST\\_STARTPOINT](#).

### 1.1.12.9.3.4.6 ST\_ENDPOINT

## Syntax

```
ST_EndPoint(ls)
EndPoint(ls)
```

## Description

Returns the [Point](#) that is the endpoint of the [LineString](#) value

ls

ST\_EndPoint()  
and  
EndPoint()  
are synonyms.

## Examples

```
SET @ls = 'LineString(1 1,2 2,3 3)';
SELECT AsText(EndPoint(GeomFromText(@ls)));
+-----+
| AsText(EndPoint(GeomFromText(@ls))) |
+-----+
| POINT(3 3)                         |
+-----+
```

### 1.1.12.9.3.4.7 ST\_NUMPOINTS

## Syntax

```
ST_NumPoints(ls)
NumPoints(ls)
```

## Description

Returns the number of [Point](#) objects in the [LineString](#) value

ls

ST\_NumPoints()  
and  
NumPoints()  
are synonyms.

## Examples

```
SET @ls = 'LineString(1 1,2 2,3 3)';

SELECT NumPoints(GeomFromText(@ls));
+-----+
| NumPoints(GeomFromText(@ls)) |
+-----+
|          3 |
+-----+
```

## 1.1.12.9.3.4.8 ST\_POINTN

### Syntax

```
ST_PointN(ls,N)
PointN(ls,N)
```

### Description

Returns the N-th [Point](#) in the [LineString](#) value

ls  
. Points are numbered beginning with  
1  
.

ST\_PointN()  
and  
PointN()  
are synonyms.

## Examples

```
SET @ls = 'LineString(1 1,2 2,3 3)';

SELECT AsText(PointN(GeomFromText(@ls),2));
+-----+
| AsText(PointN(GeomFromText(@ls),2)) |
+-----+
| POINT(2 2)                         |
+-----+
```

## 1.1.12.9.3.4.9 ST\_STARTPOINT

### Syntax

```
ST_StartPoint(ls)
StartPoint(ls)
```

### Description

Returns the [Point](#) that is the start point of the [LineString](#) value

ls  
.

ST\_StartPoint()  
and  
StartPoint()  
are synonyms.

## Examples

```
SET @ls = 'LineString(1 1,2 2,3 3)';

SELECT AsText(StartPoint(GeomFromText(@ls)));
+-----+
| AsText(StartPoint(GeomFromText(@ls))) |
+-----+
| POINT(1 1) |
+-----+
```

### 1.1.12.9.3.5 MBR (Minimum Bounding Rectangle)

#### 1.1.12.9.3.5.1 MBR Definition

##### Description

The MBR (Minimum Bounding Rectangle), or Envelope is the bounding geometry, formed by the minimum and maximum (X,Y) coordinates:

##### Examples

```
((MINX MINY, MAXX MINY, MAXX MAXY, MINX MAXY, MINX MINY))
```

### 1.1.12.9.3.5.2 MBRContains

##### Syntax

```
MBRContains(g1,g2)
```

##### Description

Returns 1 or 0 to indicate whether the Minimum Bounding Rectangle of g1 contains the Minimum Bounding Rectangle of g2. This tests the opposite relationship as [MBRWithin\(\)](#).

##### Examples

```
SET @g1 = GeomFromText('Polygon((0 0,0 3,3 3,3 0,0 0))';

SET @g2 = GeomFromText('Point(1 1)');

SELECT MBRContains(@g1,@g2), MBRContains(@g2,@g1);
+-----+
| MBRContains(@g1,@g2) | MBRContains(@g2,@g1) |
+-----+
| 1 | 0 |
+-----+
```

### 1.1.12.9.3.5.3 MBDisjoint

##### Syntax

```
MBDisjoint(g1,g2)
```

##### Description

Returns 1 or 0 to indicate whether the Minimum Bounding Rectangles of the two geometries g1 and g2 are disjoint. Two geometries are disjoint if they do not intersect, that is touch or overlap.

## Examples

```
SET @g1 = GeomFromText('Polygon((0 0,0 3,3 3,3 0,0 0))');
SET @g2 = GeomFromText('Polygon((4 4,4 7,7 7,7 4,4 4))');
SELECT mbrdisjoint(@g1,@g2);
+-----+
| mbrdisjoint(@g1,@g2) |
+-----+
|          1          |
+-----+  
  
SET @g1 = GeomFromText('Polygon((0 0,0 3,3 3,3 0,0 0))';
SET @g2 = GeomFromText('Polygon((3 3,3 6,6 6,6 3,3 3))');
SELECT mbrdisjoint(@g1,@g2);
+-----+
| mbrdisjoint(@g1,@g2) |
+-----+
|          0          |
+-----+
```

## 1.1.12.9.3.5.4 MBREqual

### Syntax

```
MBREqual(g1,g2)
```

### Description

Returns 1 or 0 to indicate whether the Minimum Bounding Rectangles of the two geometries g1 and g2 are the same.

## Examples

```
SET @g1=GEOMFROMTEXT('LINESTRING(0 0, 1 2)');
SET @g2=GEOMFROMTEXT('POLYGON((0 0, 0 2, 1 2, 1 0, 0 0))';
SELECT MbrEqual(@g1,@g2);
+-----+
| MbrEqual(@g1,@g2) |
+-----+
|          1          |
+-----+  
  
SET @g1=GEOMFROMTEXT('LINESTRING(0 0, 1 3)');
SET @g2=GEOMFROMTEXT('POLYGON((0 0, 0 2, 1 4, 1 0, 0 0))';
SELECT MbrEqual(@g1,@g2);
+-----+
| MbrEqual(@g1,@g2) |
+-----+
|          0          |
+-----+
```

## 1.1.12.9.3.5.5 MBRIntersects

### Syntax

```
MBRIntersects(g1,g2)
```

### Description

Returns 1 or 0 to indicate whether the Minimum Bounding Rectangles of the two geometries g1 and g2 intersect.

## Examples

```

SET @g1 = GeomFromText('Polygon((0 0,0 3,3 3,3 0,0 0))');
SET @g2 = GeomFromText('Polygon((3 3,3 6,6 6,6 3,3 3))');
SELECT mbrintersects(@g1,@g2);
+-----+
| mbrintersects(@g1,@g2) |
+-----+
|      1      |
+-----+

SET @g1 = GeomFromText('Polygon((0 0,0 3,3 3,3 0,0 0))');
SET @g2 = GeomFromText('Polygon((4 4,4 7,7 7,7 4,4 4))');
SELECT mbrintersects(@g1,@g2);
+-----+
| mbrintersects(@g1,@g2) |
+-----+
|      0      |
+-----+

```

## 1.1.12.9.3.5.6 MBROverlaps

### Syntax

```
MBROverlaps(g1,g2)
```

### Description

Returns 1 or 0 to indicate whether the Minimum Bounding Rectangles of the two geometries

g1  
and  
g2

overlap. The term spatially overlaps is used if two geometries intersect and their intersection results in a geometry of the same dimension but not equal to either of the given geometries.

### Examples

```

SET @g1 = GeomFromText('Polygon((0 0,0 3,3 3,3 0,0 0))';
SET @g2 = GeomFromText('Polygon((4 4,4 7,7 7,7 4,4 4))');
SELECT mbroverlaps(@g1,@g2);
+-----+
| mbroverlaps(@g1,@g2) |
+-----+
|      0      |
+-----+

SET @g1 = GeomFromText('Polygon((0 0,0 3,3 3,3 0,0 0))';
SET @g2 = GeomFromText('Polygon((3 3,3 6,6 6,6 3,3 3))';
SELECT mbroverlaps(@g1,@g2);
+-----+
| mbroverlaps(@g1,@g2) |
+-----+
|      0      |
+-----+

SET @g1 = GeomFromText('Polygon((0 0,0 4,4 4,4 0,0 0))';
SET @g2 = GeomFromText('Polygon((3 3,3 6,6 6,6 3,3 3))';
SELECT mbroverlaps(@g1,@g2);
+-----+
| mbroverlaps(@g1,@g2) |
+-----+
|      1      |
+-----+

```

## 1.1.12.9.3.5.7 MBRTouches

### Syntax

```
MBRTouches(g1,g2)
```

## Description

Returns 1 or 0 to indicate whether the Minimum Bounding Rectangles of the two geometries

g1

and

g2

touch. Two geometries spatially touch if the interiors of the geometries do not intersect, but the boundary of one of the geometries intersects either the boundary or the interior of the other.

## Examples

```
SET @g1 = GeomFromText('Polygon((0 0,0 3,3 3,3 0,0 0))');
SET @g2 = GeomFromText('Polygon((4 4,4 7,7 7,7 4,4 4))');
SELECT mbrtouches(@g1,@g2);
+-----+
| mbrtouches(@g1,@g2) |
+-----+
|          0          |
+-----+

SET @g1 = GeomFromText('Polygon((0 0,0 3,3 3,3 0,0 0))');
SET @g2 = GeomFromText('Polygon((3 3,3 6,6 6,6 3,3 3))');
SELECT mbrtouches(@g1,@g2);
+-----+
| mbrtouches(@g1,@g2) |
+-----+
|          1          |
+-----+

SET @g1 = GeomFromText('Polygon((0 0,0 4,4 4,4 0,0 0))');
SET @g2 = GeomFromText('Polygon((3 3,3 6,6 6,6 3,3 3))');
SELECT mbrtouches(@g1,@g2);
+-----+
| mbrtouches(@g1,@g2) |
+-----+
|          0          |
+-----+
```

## 1.1.12.9.3.5.8 MBRWithin

### Syntax

```
MBRWithin(g1,g2)
```

## Description

Returns 1 or 0 to indicate whether the Minimum Bounding Rectangle of g1 is within the Minimum Bounding Rectangle of g2. This tests the opposite relationship as [MBRContains\(\)](#).

## Examples

```
SET @g1 = GeomFromText('Polygon((0 0,0 3,3 3,3 0,0 0))');
SET @g2 = GeomFromText('Polygon((0 0,0 5,5 5,5 0,0 0))');
SELECT MBRWithin(@g1,@g2), MBRWithin(@g2,@g1);
+-----+
| MBRWithin(@g1,@g2) | MBRWithin(@g2,@g1) |
+-----+
|          1          |          0          |
+-----+
```

## 1.1.12.9.3.6 Point Properties

## 1.1.12.9.3.6.1 ST\_X

### Syntax

```
ST_X(p)
X(p)
```

### Description

Returns the X-coordinate value for the point

p  
as a double-precision number.

ST\_X()  
and  
X()  
are synonyms.

### Examples

```
SET @pt = 'Point(56.7 53.34)';

SELECT X(GeomFromText(@pt));
+-----+
| X(GeomFromText(@pt)) |
+-----+
|      56.7 |
+-----+
```

## 1.1.12.9.3.6.2 ST\_Y

### Syntax

```
ST_Y(p)
Y(p)
```

### Description

Returns the Y-coordinate value for the point p as a double-precision number.

ST\_Y()  
and  
Y()  
are synonyms.

### Examples

```
SET @pt = 'Point(56.7 53.34)';

SELECT Y(GeomFromText(@pt));
+-----+
| Y(GeomFromText(@pt)) |
+-----+
|      53.34 |
+-----+
```

## 1.1.12.9.3.6.3 X

A synonym for [ST\\_X](#).

## 1.1.12.9.3.6.4 Y

A synonym for [ST\\_Y](#).

## 1.1.12.9.3.7 Polygon Properties

### 1.1.12.9.3.7.1 AREA

A synonym for [ST\\_AREA](#).

### 1.1.12.9.3.7.2 CENTROID

A synonym for [ST\\_CENTROID](#).

### 1.1.12.9.3.7.3 ExteriorRing

A synonym for [ST\\_ExteriorRing](#).

### 1.1.12.9.3.7.4 InteriorRingN

A synonym for [ST\\_InteriorRingN](#).

### 1.1.12.9.3.7.5 NumInteriorRings

A synonym for [ST\\_NumInteriorRings](#).

### 1.1.12.9.3.7.6 ST\_AREA

#### Syntax

```
ST_Area(poly)
Area(poly)
```

#### Description

Returns as a double-precision number the area of the Polygon value

`poly`  
, as measured in its spatial reference system.

`ST_Area()`  
and  
`Area()`  
are synonyms.

#### Examples

```
SET @poly = 'Polygon((0 0,0 3,3 0,0 0),(1 1,1 2,2 1,1 1))';

SELECT Area(GeomFromText(@poly));
+-----+
| Area(GeomFromText(@poly)) |
+-----+
|          4          |
+-----+
```

### 1.1.12.9.3.7.7 ST\_CENTROID

#### Syntax

```
ST_Centroid(mpoly)
Centroid(mpoly)
```

#### Description

Returns a point reflecting the mathematical centroid (geometric center) for the [MultiPolygon](#) *mpoly*. The resulting point will not necessarily be on the MultiPolygon.

`ST_Centroid()`  
and  
`Centroid()`  
are synonyms.

## Examples

```
SET @poly = ST_GeomFromText('POLYGON((0 0,20 0,20 20,0 20,0 0))');
SELECT ST_AsText(ST_Centroid(@poly)) AS center;
+-----+
| center      |
+-----+
| POINT(10 10) |
+-----+
```

## 1.1.12.9.3.7.8 ST\_ExteriorRing

### Syntax

```
ST_ExteriorRing(poly)
ExteriorRing(poly)
```

### Description

Returns the exterior ring of the Polygon value

`poly`  
as a LineString.

`ST_ExteriorRing()`  
and  
`ExteriorRing()`  
are synonyms.

## Examples

```
SET @poly = 'Polygon((0 0,0 3,3 3,3 0,0),(1 1,1 2,2 2,2 1,1 1))';
SELECT AsText(ExteriorRing(GeomFromText(@poly)));
+-----+
| AsText(ExteriorRing(GeomFromText(@poly))) |
+-----+
| LINESTRING(0 0,0 3,3 3,3 0,0 0)           |
+-----+
```

## 1.1.12.9.3.7.9 ST\_InteriorRingN

### Syntax

```
ST_InteriorRingN(poly,N)
InteriorRingN(poly,N)
```

### Description

Returns the N-th interior ring for the Polygon value

`poly`  
as a LineString. Rings are numbered beginning with 1.

`ST_InteriorRingN()`

and  
InteriorRingN()  
are synonyms.

## Examples

```
SET @poly = 'Polygon((0 0,0 3,3 3,3 0,0 0),(1 1,1 2,2 2,2 1,1 1))';
SELECT AsText(InteriorRingN(GeomFromText(@poly),1));
+-----+
| AsText(InteriorRingN(GeomFromText(@poly),1)) |
+-----+
| LINESTRING(1 1,1 2,2 2,2 1,1 1)           |
+-----+
```

### 1.1.12.9.3.7.10 ST\_NumInteriorRings

#### Syntax

```
ST_NumInteriorRings(poly)
NumInteriorRings(poly)
```

#### Description

Returns an integer containing the number of interior rings in the Polygon value

poly

Note that according to the OpenGIS standard, a **POLYGON** should have exactly one ExteriorRing and all other rings should lie within that ExteriorRing and thus be the InteriorRings. Practically, however, some systems, including MariaDB's, permit polygons to have several 'ExteriorRings'. In the case of there being multiple, non-overlapping exterior rings **ST\_NumInteriorRings()** will return

1

ST\_NumInteriorRings()  
and  
NumInteriorRings()  
are synonyms.

## Examples

```
SET @poly = 'Polygon((0 0,0 3,3 3,3 0,0 0),(1 1,1 2,2 2,2 1,1 1))';
SELECT NumInteriorRings(GeomFromText(@poly));
+-----+
| NumInteriorRings(GeomFromText(@poly)) |
+-----+
|                               1 |
```

Non-overlapping 'polygon':

```
SELECT ST_NumInteriorRings(ST_PolyFromText('POLYGON((0 0,10 0,10 10,0 10,0 0),
(-1 -1,-5 -1,-5,-1 -5,-1 -1))')) AS NumInteriorRings;
+-----+
| NumInteriorRings |
+-----+
|               1 |
```

### 1.1.12.9.3.8 WKB

#### 1.1.12.9.3.8.1 Well-Known Binary (WKB) Format

WKB stands for Well-Known Binary, a format for representing geographical and geometrical data.

WKB uses 1-byte unsigned integers, 4-byte unsigned integers, and 8-byte double-precision numbers.

- The first byte indicates the byte order. 00 for big endian, or 01 for little endian.
- The next 4 bytes indicate the geometry type. Values from 1 to 7 indicate whether the type is Point, LineString, Polygon, MultiPoint, MultiLineString, MultiPolygon, or GeometryCollection respectively.
- The 8-byte floats represent the co-ordinates.

Take the following example, a sequence of 21 bytes each represented by two hex digits:

```
00000000140000000000000000401000000000000
```

- It's big endian
  - 00 **00000001** 4000000000000000401000000000000
- It's a POINT
  - 00 **00000001** 4000000000000000401000000000000
- The X co-ordinate is 2.0
  - 0000000001 **4000000000000000** 4010000000000000
- The Y-co-ordinate is 4.0
  - 0000000000140000000000000000 **4010000000000000**

## 1.1.12.9.3.8.2 AsBinary

A synonym for [ST\\_AsBinary\(\)](#).

## 1.1.12.9.3.8.3 AsWKB

A synonym for [ST\\_AsBinary\(\)](#).

## 1.1.12.9.3.8.4 MLineFromWKB

### Syntax

```
MLineFromWKB(wkb[,srid])
MultiLineStringFromWKB(wkb[,srid])
```

### Description

Constructs a **MULTILINESTRING** value using its [WKB](#) representation and [SRID](#).

`MLineFromWKB()`  
and  
`MultiLineStringFromWKB()`  
are synonyms.

### Examples

```
SET @g = ST_AsBinary(MLineFromText('MULTILINESTRING((10 48,10 21,10 0),(16 0,16 23,16 48))'));

SELECT ST_AsText(MLineFromWKB(@g));
+-----+
| ST_AsText(MLineFromWKB(@g))           |
+-----+
| MULTILINESTRING((10 48,10 21,10 0),(16 0,16 23,16 48)) |
+-----+
```

## 1.1.12.9.3.8.5 MPointFromWKB

### Syntax

```
MPointFromWKB(wkb[,srid])
MultiPointFromWKB(wkb[,srid])
```

### Description

Constructs a **MULTIPOINT** value using its [WKB](#) representation and [SRID](#) .

`MPointFromWKB()`  
and  
`MultiPointFromWKB()`  
are synonyms.

## Examples

```
SET @g = ST_AsBinary(MPointFromText('MultiPoint( 1 1, 2 2, 5 3, 7 2, 9 3, 8 4, 6 6, 6 9, 4 9, 1 5 )'));  
  
SELECT ST_AsText(MPointFromWKB(@g));  
+-----+  
| ST_AsText(MPointFromWKB(@g)) |  
+-----+  
| MULTIPOLYGON(1 1,2 2,5 3,7 2,9 3,8 4,6 6,6 9,4 9,1 5) |  
+-----+
```

## 1.1.12.9.3.8.6 MPolyFromWKB

### Syntax

```
MPolyFromWKB(wkb[,srid])  
MultiPolygonFromWKB(wkb[,srid])
```

### Description

Constructs a **MULTIPOLYGON** value using its [WKB](#) representation and [SRID](#) .

`MPolyFromWKB()`  
and  
`MultiPolygonFromWKB()`  
are synonyms.

## Examples

```
SET @g = ST_AsBinary(MPolyFromText('MULTIPOLYGON(((28 26,28 0,84 0,84 42,28 26),(52 18,66 23,73 9,48 6,52 18)),((59 18,67 18,67  
0,84 0,84 42,28 26),(52 18,66 23,73 9,48 6,52 18)),((59 18,67 18,67 13,59 13,59 18))) |  
+-----+  
| ST_AsText(MPolyFromWKB(@g)) |  
+-----+  
| MULTIPOLYGON(((28 26,28 0,84 0,84 42,28 26),(52 18,66 23,73 9,48 6,52 18)),((59 18,67 18,67 13,59 13,59 18))) |  
+-----+
```

## 1.1.12.9.3.8.7 GeomCollFromWKB

A synonym for [ST\\_GeomCollFromWKB](#) .

## 1.1.12.9.3.8.8 GeometryCollectionFromWKB

A synonym for [ST\\_GeomCollFromWKB](#) .

## 1.1.12.9.3.8.9 GeometryFromWKB

A synonym for [ST\\_GeomFromWKB](#) .

## 1.1.12.9.3.8.10 GeomFromWKB

A synonym for [ST\\_GeomFromWKB](#) .

## 1.1.12.9.3.8.11 LineFromWKB

A synonym for [ST\\_LineFromWKB](#) .

## 1.1.12.9.3.8.12 LineStringFromWKB

A synonym for [ST\\_LineFromWKB](#).

## 1.1.12.9.3.8.13 MultiLineStringFromWKB

A synonym for [MLineFromWKB\(\)](#).

## 1.1.12.9.3.8.14 MultiPointFromWKB

A synonym for [MPointFromWKB](#).

## 1.1.12.9.3.8.15 MultiPolygonFromWKB

Synonym for [MPolyFromWKB](#).

## 1.1.12.9.3.8.16 PointFromWKB

A synonym for [ST\\_PointFromWKB](#).

## 1.1.12.9.3.8.17 PolyFromWKB

A synonym for [ST\\_PolyFromWKB](#).

## 1.1.12.9.3.8.18 PolygonFromWKB

A synonym for [ST\\_PolyFromWKB](#).

## 1.1.12.9.3.8.19 ST\_AsBinary

### Syntax

```
ST_AsBinary(g)
AsBinary(g)
ST_AsWKB(g)
AsWKB(g)
```

### Description

Converts a value in internal geometry format to its [WKB](#) representation and returns the binary result.

`ST_AsBinary()`  
,

`AsBinary()`  
,

`ST_AsWKB()`  
and  
`AsWKB()`  
are synonyms,

### Examples

```
SET @poly = ST_GeomFromText('POLYGON((0 0,0 1,1 1,1 0,0 0))';
SELECT ST_AsBinary(@poly);

SELECT ST_AsText(ST_GeomFromWKB(ST_AsWKB(@poly)));
+-----+
| ST_AsText(ST_GeomFromWKB(ST_AsWKB(@poly))) |
+-----+
| POLYGON((0 0,0 1,1 1,1 0,0 0))               |
+-----+
```

## 1.1.12.9.3.8.20 ST\_AsWKB

A synonym for [ST\\_AsBinary\(\)](#).

## 1.1.12.9.3.8.21 ST\_GeomCollFromWKB

### Syntax

```
ST_GeomCollFromWKB(wkb[,srid])
ST_GeometryCollectionFromWKB(wkb[,srid])
GeomCollFromWKB(wkb[,srid])
GeometryCollectionFromWKB(wkb[,srid])
```

### Description

Constructs a GEOMETRYCOLLECTION value using its [WKB](#) representation and SRID.

ST\_GeomCollFromWKB()  
,  
ST\_GeometryCollectionFromWKB()  
,  
GeomCollFromWKB()  
and  
GeometryCollectionFromWKB()  
are synonyms.

### Examples

```
SET @g = ST_AsBinary(ST_GeomFromText('GEOMETRYCOLLECTION(POLYGON((5 5,10 5,10 10,5 5)),POINT(10 10))');

SELECT ST_AsText(ST_GeomCollFromWKB(@g));
+-----+
| ST_AsText(ST_GeomCollFromWKB(@g))           |
+-----+
| GEOMETRYCOLLECTION(POLYGON((5 5,10 5,10 10,5 5)),POINT(10 10)) |
+-----+
```

## 1.1.12.9.3.8.22 ST\_GeometryCollectionFromWKB

A synonym for [ST\\_GeomCollFromWKB](#).

## 1.1.12.9.3.8.23 ST\_GeometryFromWKB

A synonym for [ST\\_GeomFromWKB](#).

## 1.1.12.9.3.8.24 ST\_GeomFromWKB

### Syntax

```
ST_GeomFromWKB(wkb[,srid])
ST_GeometryFromWKB(wkb[,srid])
GeomFromWKB(wkb[,srid])
GeometryFromWKB(wkb[,srid])
```

### Description

Constructs a geometry value of any type using its [WKB](#) representation and SRID.

ST\_GeomFromWKB()  
,  
ST\_GeometryFromWKB()  
,  
GeomFromWKB()  
and  
GeometryFromWKB()  
are synonyms.

## Examples

```
SET @g = ST_AsBinary(ST_LineFromText('LINESTRING(0 4, 4 6)'));

SELECT ST_AsText(ST_GeomFromWKB(@g));
+-----+
| ST_AsText(ST_GeomFromWKB(@g)) |
+-----+
| LINESTRING(0 4,4 6)           |
+-----+
```

## 1.1.12.9.3.8.25 ST\_LineFromWKB

### Syntax

```
ST_LineFromWKB(wkb[,srid])
LineFromWKB(wkb[,srid])
ST_LineStringFromWKB(wkb[,srid])
LineStringFromWKB(wkb[,srid])
```

### Description

Constructs a LINESTRING value using its [WKB](#) representation and SRID.

`ST_LineFromWKB()`  
,  
`LineFromWKB()`  
,  
`ST_LineStringFromWKB()`  
, and  
`LineStringFromWKB()`  
are synonyms.

## Examples

```
SET @g = ST_AsBinary(ST_LineFromText('LineString(0 4,4 6)'));

SELECT ST_AsText(ST_LineFromWKB(@g)) AS l;
+-----+
| l          |
+-----+
| LINESTRING(0 4,4 6) |
+-----+
```

## 1.1.12.9.3.8.26 ST\_LineStringFromWKB

A synonym for [ST\\_LineFromWKB](#).

## 1.1.12.9.3.8.27 ST\_PointFromWKB

### Syntax

```
ST_PointFromWKB(wkb[,srid])
PointFromWKB(wkb[,srid])
```

### Description

Constructs a [POINT](#) value using its [WKB](#) representation and [SRID](#).

`ST_PointFromWKB()`  
and  
`PointFromWKB()`

are synonyms.

## Examples

```
SET @g = ST_AsBinary(ST_PointFromText('POINT(0 4)'));  
  
SELECT ST_AsText(ST_PointFromWKB(@g)) AS p;  
+-----+  
| p |  
+-----+  
| POINT(0 4) |  
+-----+
```

## 1.1.12.9.3.8.28 ST\_PolyFromWKB

### Syntax

```
ST_PolyFromWKB(wkb[,srid])  
ST_PolygonFromWKB(wkb[,srid])  
PolyFromWKB(wkb[,srid])  
PolygonFromWKB(wkb[,srid])
```

### Description

Constructs a **POLYGON** value using its **WKB** representation and **SRID**.

ST\_PolyFromWKB()  
,  
ST\_PolygonFromWKB()  
,  
PolyFromWKB()  
and  
PolygonFromWKB()  
are synonyms.

## Examples

```
SET @g = ST_AsBinary(ST_PolyFromText('POLYGON((1 1,1 5,4 9,6 9,9 3,7 2,1 1))'));  
  
SELECT ST_AsText(ST_PolyFromWKB(@g)) AS p;  
+-----+  
| p |  
+-----+  
| POLYGON((1 1,1 5,4 9,6 9,9 3,7 2,1 1)) |  
+-----+
```

## 1.1.12.9.3.8.29 ST\_PolyFromWKB

### Syntax

```
ST_PolyFromWKB(wkb[,srid])  
ST_PolygonFromWKB(wkb[,srid])  
PolyFromWKB(wkb[,srid])  
PolygonFromWKB(wkb[,srid])
```

### Description

Constructs a **POLYGON** value using its **WKB** representation and **SRID**.

ST\_PolyFromWKB()  
,  
ST\_PolygonFromWKB()

,  
PolyFromWKB()  
and  
PolygonFromWKB()  
are synonyms.

## Examples

```
SET @g = ST_AsBinary(ST_PolyFromText('POLYGON((1 1,1 5,4 9,6 9,9 3,7 2,1 1))');

SELECT ST_AsText(ST_PolyFromWKB(@g)) AS p;
+-----+
| p           |
+-----+
| POLYGON((1 1,1 5,4 9,6 9,9 3,7 2,1 1)) |
+-----+
```

### 1.1.12.9.3.9 WKT

#### 1.1.12.9.3.9.1 WKT Definition

#### Description

The Well-Known Text (WKT) representation of Geometry is designed to exchange geometry data in ASCII form. Examples of the basic geometry types include:

Geometry Types
POINT
LINESTRING
POLYGON
MULTIPOINT
MULTILINESTRING
MULTIPOLYGON
GEOMETRYCOLLECTION
GEOMETRY

#### See Also

- [Geometry Types](#)

#### 1.1.12.9.3.9.2 AsText

A synonym for [ST\\_AsText\(\)](#).

#### 1.1.12.9.3.9.3 AsWKT

A synonym for [ST\\_AsText\(\)](#).

#### 1.1.12.9.3.9.4 GeomCollFromText

A synonym for [ST\\_GeomCollFromText](#).

#### 1.1.12.9.3.9.5 GeometryCollectionFromText

A synonym for [ST\\_GeomCollFromText](#).

#### 1.1.12.9.3.9.6 GeometryFromText

A synonym for [ST\\_GeomFromText](#).

#### 1.1.12.9.3.9.7 GeomFromText

A synonym for [ST\\_GeomFromText](#).

## 1.1.12.9.3.9.8 LineFromText

A synonym for [ST\\_LineFromText](#) .

## 1.1.12.9.3.9.9 LineStringFromText

A synonym for [ST\\_LineFromText](#) .

## 1.1.12.9.3.9.10 MLineFromText

### Syntax

```
MLineFromText(wkt[,srid])
MultiLineStringFromText(wkt[,srid])
```

### Description

Constructs a [MULTILINESTRING](#) value using its [WKT](#) representation and [SRID](#) .

`MLineFromText()`  
and  
`MultiLineStringFromText()`  
are synonyms.

### Examples

```
CREATE TABLE gis_multi_line (g MULTILINESTRING);
SHOW FIELDS FROM gis_multi_line;
INSERT INTO gis_multi_line VALUES
  (MultiLineStringFromText('MULTILINESTRING((10 48,10 21,10 0),(16 0,16 23,16 48))')),
   (MLineFromText('MULTILINESTRING((10 48,10 21,10 0))')),
   (MLineFromWKB(AsWKB(MultiLineString(LineString(Point(1, 2), Point(3, 5)), LineString(Point(2, 5), Point(5, 8), Point(21, 7))))))
```

## 1.1.12.9.3.9.11 MPointFromText

### Syntax

```
MPointFromText(wkt[,srid])
MultiPointFromText(wkt[,srid])
```

### Description

Constructs a [MULTIPOINT](#) value using its [WKT](#) representation and [SRID](#) .

`MPointFromText()`  
and  
`MultiPointFromText()`  
are synonyms.

### Examples

```
CREATE TABLE gis_multi_point (g MULTIPOINT);
SHOW FIELDS FROM gis_multi_point;
INSERT INTO gis_multi_point VALUES
  (MultiPointFromText('MULTIPOINT(0 0,10 10,10 20,20 20)')),
   (MPointFromText('MULTIPOINT(1 1,11 11,11 21,21 21)')),
   (MPointFromWKB(AsWKB(MultiPoint(Point(3, 6), Point(4, 10))))));
```

## 1.1.12.9.3.9.12 MPolyFromText

## Syntax

```
MPolyFromText(wkt[,srid])
MultiPolygonFromText(wkt[,srid])
```

## Description

Constructs a **MULTIPOINT** value using its [WKT](#) representation and [SRID](#).

`MPolyFromText()`  
and  
`MultiPolygonFromText()`  
are synonyms.

## Examples

```
CREATE TABLE gis_multi_polygon  (g MULTIPOINT);
SHOW FIELDS FROM gis_multi_polygon;
INSERT INTO gis_multi_polygon VALUES
(MultiPolygonFromText('MULTIPOINT(((28 26,28 0,84 0,84 42,28 26),(52 18,66 23,73 9,48 6,52 18)),((59 18,67 18,67 13,59 13,
(MPolyFromText('MULTIPOINT(((28 26,28 0,84 0,84 42,28 26),(52 18,66 23,73 9,48 6,52 18)),((59 18,67 18,67 13,59 13,59 18))
(MPolyFromWKB(AsWKB(MultiPolygon(Polygon(LineString(Point(0, 3), Point(3, 3), Point(3, 0), Point(0, 3)))))));
```

## 1.1.12.9.3.9.13 MultiLineStringFromText

A synonym for [MLineFromText](#).

## 1.1.12.9.3.9.14 MultiPointFromText

A synonym for [MPointFromText](#).

## 1.1.12.9.3.9.15 MultiPolygonFromText

A synonym for [MPolyFromText](#).

## 1.1.12.9.3.9.16 PointFromText

A synonym for [ST\\_PointFromText](#).

## 1.1.12.9.3.9.17 PolyFromText

A synonym for [ST\\_PolyFromText](#).

## 1.1.12.9.3.9.18 PolygonFromText

A synonym for [ST\\_PolyFromText](#).

## 1.1.12.9.3.9.19 ST\_AsText

## Syntax

```
ST_AsText(g)
AsText(g)
ST_AsWKT(g)
AsWKT(g)
```

## Description

Converts a value in internal geometry format to its [WKT](#) representation and returns the string result.

`ST_AsText()`  
,

`AsText()`  
,

`ST_AsWKT()`  
and  
`AsWKT()`  
are all synonyms.

## Examples

```
SET @g = 'LineString(1 1,4 4,6 6)';

SELECT ST_AsText(ST_GeomFromText(@g));
+-----+
| ST_AsText(ST_GeomFromText(@g)) |
+-----+
| LINESTRING(1 1,4 4,6 6)      |
+-----+
```

## 1.1.12.9.3.9.20 `ST_ASWKT`

A synonym for [ST\\_ASTEXT\(\)](#).

## 1.1.12.9.3.9.21 `ST_GeomCollFromText`

### Syntax

```
ST_GeomCollFromText(wkt[,srid])
ST_GeometryCollectionFromText(wkt[,srid])
GeomCollFromText(wkt[,srid])
GeometryCollectionFromText(wkt[,srid])
```

### Description

Constructs a `GEOMETRYCOLLECTION` value using its [WKT](#) representation and [SRID](#).

`ST_GeomCollFromText()`  
,  
`ST_GeometryCollectionFromText()`  
,  
`GeomCollFromText()`  
and  
`GeometryCollectionFromText()`  
are all synonyms.

### Example

```
CREATE TABLE gis_geometrycollection  (g GEOMETRYCOLLECTION);
SHOW FIELDS FROM gis_geometrycollection;
INSERT INTO gis_geometrycollection VALUES
(GeomCollFromText('GEOMETRYCOLLECTION(POINT(0 0), LINESTRING(0 0,10 10)))'),
(GeometryFromWKB(AsWKB(GeometryCollection(Point(44, 6), LineString(Point(3, 6), Point(7, 9))))),
(GeomFromText('GeometryCollection()')),
(GeomFromText('GeometryCollection EMPTY')));
```

## 1.1.12.9.3.9.22 `ST_GeometryCollectionFromText`

A synonym for [ST\\_GeomCollFromText](#).

## 1.1.12.9.3.9.23 `ST_GeometryFromText`

A synonym for [ST\\_GeomFromText](#).

## 1.1.12.9.3.9.24 `ST_GeomFromText`

### Syntax

```
ST_GeomFromText(wkt[,srid])
ST_GeometryFromText(wkt[,srid])
GeomFromText(wkt[,srid])
GeometryFromText(wkt[,srid])
```

## Description

Constructs a geometry value of any type using its [WKT](#) representation and [SRID](#).

```
GeomFromText()
,
GeometryFromText()
,
ST_GeomFromText()
and
ST_GeometryFromText()
are all synonyms.
```

## Example

```
SET @g = ST_GEOMFROMTEXT('POLYGON((1 1,1 5,4 9,6 9,9 3,7 2,1 1));
```

## 1.1.12.9.3.9.25 ST\_LineFromText

### Syntax

```
ST_LineFromText(wkt[,srid])
ST_LineStringFromText(wkt[,srid])
LineFromText(wkt[,srid])
LineStringFromText(wkt[,srid])
```

## Description

Constructs a [LINESTRING](#) value using its [WKT](#) representation and [SRID](#).

```
ST_LineFromText()
,
ST_LineStringFromText()
,
ST_LineFromText()
and
ST_LineStringFromText()
are all synonyms.
```

## Examples

```
CREATE TABLE gis_line (g LINESTRING);
SHOW FIELDS FROM gis_line;
INSERT INTO gis_line VALUES
(LineFromText('LINESTRING(0 0,0 10,10 0)'),
(LineStringFromText('LINESTRING(10 10,20 10,20 20,10 20,10 10'))),
(LineStringFromWKB(AsWKB(LineString(Point(10, 10), Point(40, 10)))));
```

## 1.1.12.9.3.9.26 ST\_LineStringFromText

A synonym for [ST\\_LineFromText](#).

## 1.1.12.9.3.9.27 ST\_PointFromText

### Syntax

```
ST_PointFromText(wkt[,srid])
PointFromText(wkt[,srid])
```

## Description

Constructs a **POINT** value using its **WKT** representation and **SRID**.

ST\_PointFromText()  
and  
PointFromText()  
are synonyms.

## Examples

```
CREATE TABLE gis_point  (g POINT);
SHOW FIELDS FROM gis_point;
INSERT INTO gis_point VALUES
  (PointFromText('POINT(10 10'))),
  (PointFromText('POINT(20 10'))),
  (PointFromText('POINT(20 20'))),
  (PointFromWKB(PointFromText('POINT(10 20'))));
```

## 1.1.12.9.3.9.28 ST\_PolyFromText

### Syntax

```
ST_PolyFromText(wkt[,srid])
ST_PolygonFromText(wkt[,srid])
PolyFromText(wkt[,srid])
PolygonFromText(wkt[,srid])
```

## Description

Constructs a **POLYGON** value using its **WKT** representation and **SRID**.

ST\_PolyFromText()  
,  
ST\_PolygonFromText()  
,  
PolyFromText()  
and  
ST\_PolygonFromText()  
are all synonyms.

## Examples

```
CREATE TABLE gis_polygon  (g POLYGON);
INSERT INTO gis_polygon VALUES
  (PolygonFromText('POLYGON((10 10,20 10,20 20,10 20,10 10))')),
  (PolyFromText('POLYGON((0 0,50 0,50 50,0 50,0 0), (10 10,20 10,20 20,10 20,10 10))'));
```

## 1.1.12.9.3.9.29 ST\_PolygonFromText

A synonym for **ST\_PolyFromText**.

## 1.1.12.9.4 JSON Functions

### 1.1.12.9.4.1 Differences between JSON\_QUERY and JSON\_VALUE

MariaDB starting with 10.2.3

JSON functions were added in MariaDB 10.2.3.

The primary difference between the two functions is that `JSON_QUERY` returns an object or an array, while `JSON_VALUE` returns a scalar.

Take the following JSON document as an example

```
SET @json='{"x": [0,1], "y": "[0,1]", "z": "Monty"}';
```

Note that data member "x" is an array, and data members "y" and "z" are strings. The following examples demonstrate the differences between the two functions.

## 1.1.12.9.4.2 JSONPath Expressions

## Contents

1. JSON Path Syntax
    1. Object Member Selector
    2. Array Element Selector
    3. Wildcard
  2. Compatibility

A number of [JSON functions](#) accept JSON Path expressions. MariaDB defines this path as follows:

# JSON Path Syntax

path : ['lax'] '\$' [step]\*

The path starts with an optional *path mode*. At the moment, MariaDB supports only the "lax" mode, which is also the mode that is used when it is not explicitly specified.

The

4

symbol represents the context item. The search always starts from the context item; because of that, the path always starts with \$

Then, it is followed by zero or more steps, which select element(s) in the JSON document. A step may be one of the following:

- Object member selector
- Array element selector
- Wildcard selector

## Object Member Selector

To select member(s) in a JSON object, one can use one of the following:

- `.memberName`  
  selects the value of the member with name `memberName`.
- `."memberName"`  
  - the same as above but allows one to select a member with a name that's not a valid identifier (that is, has space, dot, and/or other characters)
- `.*`  
  - selects the values of all members of the object.

If the current item is an array (instead of an object), nothing will be selected.

## Array Element Selector

To select elements of an array, one can use one of the following:

- `[N]`  
  selects element number N in the array. The elements are counted from zero.
- `[*]`  
  selects all elements in the array.

If the current item is an object (instead of an array), nothing will be selected.

Starting from MariaDB server 10.9, JSON path also supports negative index in array and 'last' keyword for accessing array elements. Negative index starts from -1.

- `[-N]`  
  selects n th element from end.
- `[last-N]`  
  selects n th element from the last element.

Example:

```
SET @json='{
    "A": [0,
          [1, 2, 3],
          [4, 5, 6],
          "seven",
          0.8,
          true,
          false,
          "eleven",
          [12, [13, 14], {"key1":"value1"},[15]],
          true],
    "B": {"C": 1},
    "D": 2
}';

SELECT JSON_EXTRACT(@json, '$.A[-8][1]');

+-----+
| JSON_EXTRACT(@json, '$.A[-8][1]') |
+-----+
| 5                                     |
+-----+

SELECT JSON_EXTRACT(@json, '$.A[last-7][1]');

+-----+
| SELECT JSON_EXTRACT(@json, '$.A[last-7][1]'); |
+-----+
| 5                                     |
+-----+
```

This will produce output for first index of eighth from last element of a two dimensional array.

## Wildcard

The wildcard step,

\*\*

, recursively selects all child elements of the current element. Both array elements and object members are selected.

The wildcard step must not be the last step in the JSONPath expression. It must be followed by an array or object member selector step.

For example:

```
select json_extract(@json_doc, '$**.price');
```

will select all object members in the document that are named

    price  
    , while

```
select json_extract(@json_doc, '$**[2]');
```

will select the second element in each of the arrays present in the document.

## Compatibility

MariaDB's JSONPath syntax supports a subset of JSON Path's definition in the SQL Standard. The most notable things not supported are the

    strict  
    mode and filters.

MariaDB's JSONPath is close to MySQL's JSONPath. The wildcard step (

\*\*

) is a non-standard extension that has the same meaning as in MySQL. The differences between MariaDB and MySQL's JSONPath are: MySQL supports

    [last]  
    and  
    [M to N]  
    as array element selectors; MySQL doesn't allow one to specify the mode explicitly (but uses  
    lax  
    mode implicitly).

### 1.1.12.9.4.3 JSON\_ARRAY

MariaDB starting with [10.2.3](#)

JSON functions were added in [MariaDB 10.2.3](#).

## Syntax

```
JSON_ARRAY([value[, value2] ...])
```

## Description

Returns a JSON array containing the listed values. The list can be empty.

## Example

```
SELECT Json_Array(56, 3.1416, 'My name is "Foo"', NULL);
+-----+
| Json_Array(56, 3.1416, 'My name is "Foo"', NULL) |
+-----+
| [56, 3.1416, "My name is \"Foo\"", null]         |
+-----+
```

## See also

- [JSON\\_MAKE\\_ARRAY](#), the CONNECT storage engine function

## 1.1.12.9.4.4 JSON\_ARRAYAGG

## 1.1.12.9.4.5 JSON\_ARRAY\_APPEND

MariaDB starting with 10.2.3

JSON functions were added in MariaDB 10.2.3 .

### Syntax

```
JSON_ARRAY_APPEND(json_doc, path, value[, path, value] ...)
```

### Description

Appends values to the end of the specified arrays within a JSON document, returning the result, or NULL if any of the arguments are NULL.

Evaluation is performed from left to right, with the resulting document from the previous pair becoming the new value against which the next pair is evaluated.

If the

```
json_doc  
is not a valid JSON document, or if any of the paths are not valid, or contain a  
*  
or  
**  
wildcard, an error is returned.
```

### Examples

```
SET @json = '[1, 2, [3, 4]]';  
  
SELECT JSON_ARRAY_APPEND(@json, '$[0]', 5)  
+-----+  
| JSON_ARRAY_APPEND(@json, '$[0]', 5) |  
+-----+  
| [[1, 5], 2, [3, 4]] |  
+-----+  
  
SELECT JSON_ARRAY_APPEND(@json, '$[1]', 6);  
+-----+  
| JSON_ARRAY_APPEND(@json, '$[1]', 6) |  
+-----+  
| [1, [2, 6], [3, 4]] |  
+-----+  
  
SELECT JSON_ARRAY_APPEND(@json, '$[1]', 6, '$[2]', 7);  
+-----+  
| JSON_ARRAY_APPEND(@json, '$[1]', 6, '$[2]', 7) |  
+-----+  
| [1, [2, 6], [3, 4, 7]] |  
+-----+  
  
SELECT JSON_ARRAY_APPEND(@json, '$', 5);  
+-----+  
| JSON_ARRAY_APPEND(@json, '$', 5) |  
+-----+  
| [1, 2, [3, 4], 5] |  
+-----+  
  
SET @json = '{"A": 1, "B": [2], "C": [3, 4]}';  
  
SELECT JSON_ARRAY_APPEND(@json, '$.B', 5);  
+-----+  
| JSON_ARRAY_APPEND(@json, '$.B', 5) |  
+-----+  
| [{"A": 1, "B": [2, 5], "C": [3, 4]}] |  
+-----+
```

## 1.1.12.9.4.6 JSON\_ARRAY\_INSERT

MariaDB starting with 10.2.3

JSON functions were added in MariaDB 10.2.3 .

### Syntax

```
JSON_ARRAY_INSERT(json_doc, path, value[, path, value] ...)
```

### Description

Inserts a value into a JSON document, returning the modified document, or NULL if any of the arguments are NULL.

Evaluation is performed from left to right, with the resulting document from the previous pair becoming the new value against which the next pair is evaluated.

If the

```
json_doc  
is not a valid JSON document, or if any of the paths are not valid, or contain a  
*  
or  
**  
wildcard, an error is returned.
```

### Examples

```
SET @json = '[1, 2, [3, 4]]';  
  
SELECT JSON_ARRAY_INSERT(@json, '$[0]', 5);  
+-----+  
| JSON_ARRAY_INSERT(@json, '$[0]', 5) |  
+-----+  
| [5, 1, 2, [3, 4]] |  
+-----+  
  
SELECT JSON_ARRAY_INSERT(@json, '$[1]', 6);  
+-----+  
| JSON_ARRAY_INSERT(@json, '$[1]', 6) |  
+-----+  
| [1, 6, 2, [3, 4]] |  
+-----+  
  
SELECT JSON_ARRAY_INSERT(@json, '$[1]', 6, '$[2]', 7);  
+-----+  
| JSON_ARRAY_INSERT(@json, '$[1]', 6, '$[2]', 7) |  
+-----+  
| [1, 6, 7, 2, [3, 4]] |  
+-----+
```

## 1.1.12.9.4.7 JSON\_COMPACT

MariaDB starting with 10.2.4

This function was added in MariaDB 10.2.4 .

### Syntax

```
JSON_COMPACT(json_doc)
```

## Contents

1. [Syntax](#)
2. [Description](#)
3. [Example](#)
4. [See Also](#)

## Description

Removes all unnecessary spaces so the json document is as short as possible.

## Example

```
SET @j = '{ "A": 1, "B": [2, 3]}';  
  
SELECT JSON_COMPACT(@j), @j;  
+-----+-----+  
| JSON_COMPACT(@j) | @j  
+-----+-----+  
| {"A":1,"B":[2,3]} | { "A": 1, "B": [2, 3]} |  
+-----+-----+
```

## See Also

- [JSON video tutorial covering JSON\\_COMPACT](#).

## 1.1.12.9.4.8 JSON\_CONTAINS

MariaDB starting with [10.2.3](#)

JSON functions were added in [MariaDB 10.2.3](#).

## Syntax

```
JSON_CONTAINS(json_doc, val[, path])
```

## Description

Returns whether or not the specified value is found in the given JSON document or, optionally, at the specified path within the document. Returns

1  
if it does,  
0  
if not and NULL if any of the arguments are null. An error occurs if the document or path is not valid, or contains the  
\*  
or  
\*\*  
wildcards.

## Examples

```

SET @json = '{"A": 0, "B": {"C": 1}, "D": 2}';

SELECT JSON_CONTAINS(@json, '2', '$.A');
+-----+
| JSON_CONTAINS(@json, '2', '$.A') |
+-----+
|          0          |
+-----+

SELECT JSON_CONTAINS(@json, '2', '$.D');
+-----+
| JSON_CONTAINS(@json, '2', '$.D') |
+-----+
|          1          |
+-----+

SELECT JSON_CONTAINS(@json, '{"C": 1}', '$.A');
+-----+
| JSON_CONTAINS(@json, '{"C": 1}', '$.A') |
+-----+
|          0          |
+-----+

SELECT JSON_CONTAINS(@json, '{"C": 1}', '$.B');
+-----+
| JSON_CONTAINS(@json, '{"C": 1}', '$.B') |
+-----+
|          1          |
+-----+

```

## 1.1.12.9.4.9 JSON\_CONTAINS\_PATH

MariaDB starting with 10.2.3

JSON functions were added in MariaDB 10.2.3 .

### Syntax

```
JSON_CONTAINS_PATH(json_doc, return_arg, path[, path] ...)
```

### Description

Indicates whether the given JSON document contains data at the specified path or paths. Returns

- 1  
if it does,
- 0  
if not and NULL if any of the arguments are null.

The *return\_arg* can be

- one
- or
- all
- :
- - one
    - Returns
  - 1  
if at least one path exists within the JSON document.
- - all
    - Returns
  - 1  
only if all paths exist within the JSON document.

### Examples

```

SET @json = '{"A": 1, "B": [2], "C": [3, 4]}';

SELECT JSON_CONTAINS_PATH(@json, 'one', '$.A', '$.D');
+-----+
| JSON_CONTAINS_PATH(@json, 'one', '$.A', '$.D') |
+-----+
|          1          |
+-----+
1 row in set (0.00 sec)

SELECT JSON_CONTAINS_PATH(@json, 'all', '$.A', '$.D');
+-----+
| JSON_CONTAINS_PATH(@json, 'all', '$.A', '$.D') |
+-----+
|          0          |
+-----+

```

## 1.1.12.9.4.10 JSON\_DEPTH

MariaDB starting with [10.2.3](#)

JSON functions were added in [MariaDB 10.2.3](#).

### Syntax

```
JSON_DEPTH(json_doc)
```

### Description

Returns the maximum depth of the given JSON document, or NULL if the argument is null. An error will occur if the argument is an invalid JSON document.

- Scalar values or empty arrays or objects have a depth of 1.
- Arrays or objects that are not empty but contain only elements or member values of depth 1 will have a depth of 2.
- In other cases, the depth will be greater than 2.

### Examples

```

SELECT JSON_DEPTH('[]'), JSON_DEPTH('true'), JSON_DEPTH('{}');
+-----+-----+-----+
| JSON_DEPTH('[]') | JSON_DEPTH('true') | JSON_DEPTH('{}') |
+-----+-----+-----+
|      1      |         1        |       1       |
+-----+-----+-----+

SELECT JSON_DEPTH('[1, 2, 3]'), JSON_DEPTH('[], {}, []');
+-----+-----+
| JSON_DEPTH('[1, 2, 3]') | JSON_DEPTH('[], {}, []') |
+-----+-----+
|      2      |         2        |
+-----+-----+

SELECT JSON_DEPTH('[1, 2, [3, 4, 5, 6], 7]');
+-----+
| JSON_DEPTH('[1, 2, [3, 4, 5, 6], 7]') |
+-----+
|      3      |
+-----+

```

## 1.1.12.9.4.11 JSON\_DETAILED

MariaDB starting with [10.2.4](#)

This function was added in [MariaDB 10.2.4](#).

### Syntax

```
JSON_DETAILED(json_doc[, tab_size])
```

## Contents

1. [Syntax](#)
2. [Description](#)
3. [Example](#)
4. [See Also](#)

## Description

Represents JSON in the most understandable way emphasizing nested structures.

## Example

```
SET @j = '{ "A":1,"B":[2,3]}';

SELECT @j;
+-----+
| @j      |
+-----+
| { "A":1,"B":[2,3]} |
+-----+

SELECT JSON_DETAILED(@j);
+-----+
| JSON_DETAILED(@j)          |
+-----+
| {                           |
|   "A": 1,                   |
|   "B": [                     |
|     2,                      |
|     3                       |
|   ]                         |
| } |                         |
+-----+
```

## See Also

- [JSON video tutorial covering JSON\\_DETAILED.](#)

## 1.1.12.9.4.12 JSON\_EQUALS

MariaDB starting with [10.7.0](#)

JSON\_EQUALS was added in [MariaDB 10.7.0](#).

## Syntax

```
JSON_EQUALS(json1, json2)
```

## Description

Checks if there is equality between two json objects. Returns

1  
if it there is,  
0  
if not, or NULL if any of the arguments are null.

## Examples

```

SELECT JSON_EQUALS('{"a": [1, 2, 3], "b": [4]}', '{"b": [4], "a": [1, 2, 3.0]}');
+-----+
| JSON_EQUALS('{"a": [1, 2, 3], "b": [4]}', '{"b": [4], "a": [1, 2, 3.0]}') |
+-----+
|                               1 |
+-----+

SELECT JSON_EQUALS('{"a": [1, 2, 3]}', '{"a": [1, 2, 3.01]}');
+-----+
| JSON_EQUALS('{"a": [1, 2, 3]}', '{"a": [1, 2, 3.01]}') |
+-----+
|                               0 |
+-----+

```

## See Also

- [JSON\\_NORMALIZE](#)

## 1.1.12.9.4.13 JSON\_EXISTS

MariaDB starting with [10.2.3](#)

JSON functions were added in [MariaDB 10.2.3](#).

## Syntax

### Description

Determines whether a specified JSON value exists in the given data. Returns

```

1
if found,
0
if not, or
NULL
if any of the inputs were NULL.

```

## Examples

```

SELECT JSON_EXISTS('{"key1": "xxxx", "key2": [1, 2, 3]}', "$.key2");
+-----+
| JSON_EXISTS('{"key1": "xxxx", "key2": [1, 2, 3]}', "$.key2") |
+-----+
|                               1 |
+-----+

SELECT JSON_EXISTS('{"key1": "xxxx", "key2": [1, 2, 3]}', "$.key3");
+-----+
| JSON_EXISTS('{"key1": "xxxx", "key2": [1, 2, 3]}', "$.key3") |
+-----+
|                               0 |
+-----+

SELECT JSON_EXISTS('{"key1": "xxxx", "key2": [1, 2, 3]}', "$.key2[1]");
+-----+
| JSON_EXISTS('{"key1": "xxxx", "key2": [1, 2, 3]}', "$.key2[1]") |
+-----+
|                               1 |
+-----+

SELECT JSON_EXISTS('{"key1": "xxxx", "key2": [1, 2, 3]}', "$.key2[10]");
+-----+
| JSON_EXISTS('{"key1": "xxxx", "key2": [1, 2, 3]}', "$.key2[10]") |
+-----+
|                               0 |
+-----+

```

## 1.1.12.9.4.14 JSON\_EXTRACT

MariaDB starting with 10.2.3

JSON functions were added in MariaDB 10.2.3 .

## Contents

1. [Syntax](#)
2. [Description](#)
3. [Examples](#)
4. [See Also](#)

## Syntax

```
JSON_EXTRACT(json_doc, path[, path] ...)
```

## Description

Extracts data from a JSON document. The extracted data is selected from the parts matching the path arguments. Returns all matched values; either as a single matched value, or, if the arguments could return multiple values, a result autowrapped as an array in the matching order.

Returns NULL if no paths match or if any of the arguments are NULL.

An error will occur if any path argument is not a valid path, or if the json\_doc argument is not a valid JSON document.

The path expression be a [JSONPath expression](#) as supported by MariaDB

## Examples

```
SET @json = '[1, 2, [3, 4]]';

SELECT JSON_EXTRACT(@json, '$[1]');
+-----+
| JSON_EXTRACT(@json, '$[1]') |
+-----+
| 2 |
+-----+

SELECT JSON_EXTRACT(@json, '$[2]');
+-----+
| JSON_EXTRACT(@json, '$[2]') |
+-----+
| [3, 4] |
+-----+

SELECT JSON_EXTRACT(@json, '$[2][1]');
+-----+
| JSON_EXTRACT(@json, '$[2][1]') |
+-----+
| 4 |
+-----+
```

## See Also

- [JSON video tutorial covering JSON\\_EXTRACT.](#)

## 1.1.12.9.4.15 JSON\_INSERT

MariaDB starting with 10.2.3

JSON functions were added in MariaDB 10.2.3 .

## Syntax

```
JSON_INSERT(json_doc, path, val[, path, val] ...)
```

## Contents

1. [Syntax](#)
2. [Description](#)
3. [Examples](#)
4. [See Also](#)

## Description

Inserts data into a JSON document, returning the resulting document or NULL if any argument is null.

An error will occur if the JSON document is not invalid, or if any of the paths are invalid or contain a

\*  
or  
\*\*  
wildcard.

`JSON_INSERT` can only insert data while `JSON_REPLACE` can only update. `JSON_SET` can update or insert data.

## Examples

```
SET @json = '{ "A": 0, "B": [1, 2]}';  
  
SELECT JSON_INSERT(@json, '$.C', '[3, 4]');  
+-----+  
| JSON_INSERT(@json, '$.C', '[3, 4]') |  
+-----+  
| { "A": 0, "B": [1, 2], "C": "[3, 4]" } |  
+-----+
```

## See Also

- [JSON video tutorial](#) covering `JSON_INSERT`.

## 1.1.12.9.4.16 JSON\_KEYS

MariaDB starting with [10.2.3](#)

JSON functions were added in [MariaDB 10.2.3](#).

## Syntax

```
JSON_KEYS(json_doc[, path])
```

## Description

Returns the keys as a JSON array from the top-level value of a JSON object or, if the optional path argument is provided, the top-level keys from the path.

Excludes keys from nested sub-objects in the top level value. The resulting array will be empty if the selected object is empty.

Returns NULL if any of the arguments are null, a given path does not locate an object, or if the json\_doc argument is not an object.

An error will occur if JSON document is invalid, the path is invalid or if the path contains a

\*  
or  
\*\*  
wildcard.

## Examples

```
SELECT JSON_KEYS('{"A": 1, "B": {"C": 2}}');
+-----+
| JSON_KEYS('{"A": 1, "B": {"C": 2}}') |
+-----+
| ["A", "B"] |
+-----+

SELECT JSON_KEYS('{"A": 1, "B": 2, "C": {"D": 3}}', '$.C');
+-----+
| JSON_KEYS('{"A": 1, "B": 2, "C": {"D": 3}}', '$.C') |
+-----+
| ["D"] |
+-----+
```

## 1.1.12.9.4.17 JSON\_LENGTH

MariaDB starting with 10.2.3

JSON functions were added in MariaDB 10.2.3 .

### Syntax

```
JSON_LENGTH(json_doc[, path])
```

### Description

Returns the length of a JSON document, or, if the optional path argument is given, the length of the value within the document specified by the path.

Returns NULL if any of the arguments argument are null or the path argument does not identify a value in the document.

An error will occur if the JSON document is invalid, the path is invalid or if the path contains a

- \*
- or
- \*\*
- wildcard.

Length will be determined as follow:

- A scalar's length is always 1.
- If an array, the number of elements in the array.
- If an object, the number of members in the object.

The length of nested arrays or objects are not counted.

### Examples

## 1.1.12.9.4.18 JSON\_LOOSE

MariaDB starting with 10.2.4

This function was added in MariaDB 10.2.4 .

### Syntax

```
JSON_LOOSE(json_doc)
```

### Description

Adds spaces to a JSON document to make it look more readable.

### Example

```
SET @j = '{ "A":1,"B":[2,3]}';

SELECT JSON_LOOSE(@j), @j;
+-----+-----+
| JSON_LOOSE(@j) | @j           |
+-----+-----+
| {"A": 1, "B": [2, 3]} | { "A":1,"B":[2,3]} |
+-----+-----+
```

## 1.1.12.9.4.19 JSON\_MERGE

MariaDB starting with 10.2.3

JSON functions were added in MariaDB 10.2.3 .

### Syntax

```
JSON_MERGE(json_doc, json_doc[, json_doc] ...)
```

### Description

Merges the given JSON documents.

Returns the merged result, or NULL if any argument is NULL.

An error occurs if any of the arguments are not valid JSON documents.

JSON\_MERGE

has been deprecated since MariaDB 10.2.25 , MariaDB 10.3.16 and MariaDB 10.4.5 . JSON\_MERGE\_PATCH is an RFC 7396-compliant replacement, and JSON\_MERGE\_PRESERVE is a synonym.

### Example

```
SET @json1 = '[1, 2]';
SET @json2 = '[3, 4]';

SELECT JSON_MERGE(@json1,@json2);
+-----+
| JSON_MERGE(@json1,@json2) |
+-----+
| [1, 2, 3, 4]             |
+-----+
```

### See Also

- [JSON\\_MERGE\\_PATCH](#)
- [JSON\\_MERGE\\_PRESERVE](#)

## 1.1.12.9.4.20 JSON\_MERGE\_PATCH

MariaDB starting with 10.2.25

JSON\_MERGE\_PATCH  
was introduced in MariaDB 10.2.25 , MariaDB 10.3.16 and MariaDB 10.4.5 .

### Syntax

```
JSON_MERGE_PATCH(json_doc, json_doc[, json_doc] ...)
```

### Description

Merges the given JSON documents, returning the merged result, or NULL if any argument is NULL.

`JSON_MERGE_PATCH`  
is an RFC 7396-compliant replacement for [JSON\\_MERGE](#), which has been deprecated.

## Example

```
SET @json1 = '[1, 2]';  
SET @json2 = '[2, 3]';  
SELECT JSON_MERGE_PATCH(@json1,@json2),JSON_MERGE_PRESERVE(@json1,@json2);  
+-----+  
| JSON_MERGE_PATCH(@json1,@json2) | JSON_MERGE_PRESERVE(@json1,@json2) |  
+-----+  
| [2, 3] | [1, 2, 2, 3] |  
+-----+
```

## 1.1.12.9.4.21 JSON\_MERGE\_PRESERVE

MariaDB starting with [10.2.25](#)

`JSON_MERGE_PRESERVE`  
was introduced in [MariaDB 10.2.25](#), [MariaDB 10.3.16](#) and [MariaDB 10.4.5](#).

## Syntax

```
JSON_MERGE_PRESERVE(json_doc, json_doc[, json_doc] ...)
```

## Description

Merges the given JSON documents, returning the merged result, or NULL if any argument is NULL.

`JSON_MERGE_PRESERVE`  
was introduced in [MariaDB 10.2.25](#), [MariaDB 10.3.16](#) and [MariaDB 10.4.5](#) as a synonym for [JSON\\_MERGE](#), which has been deprecated.

## Example

```
SET @json1 = '[1, 2]';  
SET @json2 = '[2, 3]';  
SELECT JSON_MERGE_PATCH(@json1,@json2),JSON_MERGE_PRESERVE(@json1,@json2);  
+-----+  
| JSON_MERGE_PATCH(@json1,@json2) | JSON_MERGE_PRESERVE(@json1,@json2) |  
+-----+  
| [2, 3] | [1, 2, 2, 3] |  
+-----+
```

## See Also

- [JSON\\_MERGE\\_PATCH](#)

## 1.1.12.9.4.22 JSON\_NORMALIZE

MariaDB starting with [10.7.0](#)

`JSON_NORMALIZE` was added in [MariaDB 10.7.0](#).

## Syntax

```
JSON_NORMALIZE(json1, json2)
```

## Description

Recursively sorts keys and removes spaces, allowing comparison of json documents for equality.

## Examples

We may wish our application to use the database to enforce a unique constraint on the JSON contents, and we can do so using the `JSON_NORMALIZE` function in combination with a unique key.

For example, if we have a table with a JSON column:

```
CREATE TABLE t1 (
    id BIGINT UNSIGNED NOT NULL AUTO_INCREMENT,
    val JSON,
    /* other columns here */
    PRIMARY KEY (id)
);
```

Add a unique constraint using `JSON_NORMALIZE` like this:

```
ALTER TABLE t1
    ADD COLUMN jnorm JSON AS (JSON_NORMALIZE(val)) VIRTUAL,
    ADD UNIQUE KEY (jnorm);
```

We can test this by first inserting a row as normal:

```
INSERT INTO t1 (val) VALUES ('{"name": "alice", "color": "blue"}');
```

And then seeing what happens with a different string which would produce the same JSON object:

```
INSERT INTO t1 (val) VALUES ('{ "color": "blue", "name": "alice" }');
ERROR 1062 (23000): Duplicate entry '{"color":"blue","name":"alice"}' for key 'jnorm'
```

## See Also

- [JSON\\_EQUALS](#)

## 1.1.12.9.4.23 JSON\_OBJECT

MariaDB starting with 10.2.3

JSON functions were added in [MariaDB 10.2.3](#).

## Syntax

```
JSON_OBJECT([key, value[, key, value] ...])
```

## Description

Returns a JSON object containing the given key/value pairs. The key/value list can be empty.

An error will occur if there are an odd number of arguments, or any key name is NULL.

## Example

```
SELECT JSON_OBJECT("id", 1, "name", "Monty");
+-----+
| JSON_OBJECT("id", 1, "name", "Monty") |
+-----+
| {"id": 1, "name": "Monty"}           |
+-----+
```

## See also

- [JSON\\_MAKE\\_OBJECT](#), the CONNECT storage engine function

## 1.1.12.9.4.24 JSON\_OBJECTAGG

## 1.1.12.9.4.25 JSON\_OVERLAPS

MariaDB starting with 10.9

JSON\_OVERLAPS is added in MariaDB starting from 10.9.

### Syntax

```
JSON_OVERLAPS(json_doc1, json_doc2)
```

### Description

JSON\_OVERLAPS() compares two json documents and returns true if they have at least one common key-value pair between two objects, array element common between two arrays, or array element common with scalar if one of the arguments is a scalar and other is an array. If two json documents are scalars, it returns true if they have same type and value.

If none of the above conditions are satisfied then it returns false.

### Examples

```
SELECT JSON_OVERLAPS('false', 'false');
+-----+
| JSON_OVERLAPS('false', 'false') |
+-----+
| 1 |
+-----+

SELECT JSON_OVERLAPS('true', '[{"abc": 1, "2": true, "false": false}]');
+-----+
| JSON_OVERLAPS('true', '[{"abc": 1, "2": true, "false": false}]') |
+-----+
| 1 |
+-----+

SELECT JSON_OVERLAPS('{"A": 1, "B": {"C": 2}}', '{"A": 2, "B": {"C": 2}}') AS is_overlap;
+-----+
| is_overlap |
+-----+
| 1 |
+-----+
```

Partial match is considered as no-match.

### Examples

```
SELECT JSON_OVERLAPS('[1, 2, true, false, null]', '[3, 4, [1]]) AS is_overlap;
+-----+
| is_overlap |
+-----+
| 0 |
+-----+
```

## 1.1.12.9.4.26 JSON\_QUERY

MariaDB starting with 10.2.3

JSON functions were added in [MariaDB 10.2.3](#).

### Syntax

```
JSON_QUERY(json_doc, path)
```

## Description

Given a JSON document, returns an object or array specified by the path. Returns NULL if not given a valid JSON document, or if there is no match.

## Examples

```
select json_query('{"key1":{"a":1, "b":[1,2]}}', '$.key1');
+-----+
| json_query('{"key1":{"a":1, "b":[1,2]}}', '$.key1') |
+-----+
| {"a":1, "b":[1,2]} |
+-----+

select json_query('{"key1":123, "key1": [1,2,3]}', '$.key1');
+-----+
| json_query('{"key1":123, "key1": [1,2,3]}', '$.key1') |
+-----+
| [1,2,3] |
+-----+
```

## 1.1.12.9.4.27 JSON\_QUOTE

MariaDB starting with 10.2.3

JSON functions were added in MariaDB 10.2.3 .

## Syntax

```
JSON_QUOTE(json_value)
```

## Description

Quotes a string as a JSON value, usually for producing valid JSON string literals for inclusion in JSON documents. Wraps the string with double quote characters and escapes interior quotes and other special characters, returning a utf8mb4 string.

Returns NULL if the argument is NULL.

## Examples

```
SELECT JSON_QUOTE('A'), JSON_QUOTE("B"), JSON_QUOTE('"C"');
+-----+-----+-----+
| JSON_QUOTE('A') | JSON_QUOTE("B") | JSON_QUOTE('"C"') |
+-----+-----+-----+
| "A"           | "B"          | "\"C\""      |
+-----+-----+-----+
```

## 1.1.12.9.4.28 JSON\_REMOVE

MariaDB starting with 10.2.3

JSON functions were added in MariaDB 10.2.3 .

## Syntax

```
JSON_REMOVE(json_doc, path[, path] ...)
```

## Contents

1. [Syntax](#)
2. [Description](#)
3. [Examples](#)
4. [See Also](#)

# Description

Removes data from a JSON document returning the result, or NULL if any of the arguments are null. If the element does not exist in the document, no changes are made.

An error will occur if JSON document is invalid, the path is invalid or if the path contains a

- \*
- or
- \*\*
- wildcard.

Path arguments are evaluated from left to right, with the result from the earlier evaluation being used as the value for the next.

## Examples

```
SELECT JSON_REMOVE('{"A": 1, "B": 2, "C": {"D": 3}}', '$.C');
+-----+
| JSON_REMOVE('{"A": 1, "B": 2, "C": {"D": 3}}', '$.C') |
+-----+
| {"A": 1, "B": 2} |
+-----+  
  
SELECT JSON_REMOVE('["A", "B", ["C", "D"], "E"]', '$[1]');
+-----+
| JSON_REMOVE('["A", "B", ["C", "D"], "E"]', '$[1]') |
+-----+
| ["A", ["C", "D"], "E"] |
+-----+
```

## See Also

- [JSON video tutorial](#) covering JSON\_REMOVE.

## 1.1.12.9.4.29 JSON\_REPLACE

MariaDB starting with [10.2.3](#)

JSON functions were added in [MariaDB 10.2.3](#).

## Syntax

```
JSON_REPLACE(json_doc, path, val[, path, val] ...)
```

### Contents

1. [Syntax](#)
2. [Description](#)
3. [Examples](#)
4. [See Also](#)

## Description

Replaces existing values in a JSON document, returning the result, or NULL if any of the arguments are NULL.

An error will occur if the JSON document is invalid, the path is invalid or if the path contains a

- \*
- or
- \*\*
- wildcard.

Paths and values are evaluated from left to right, with the result from the earlier evaluation being used as the value for the next.

JSON\_REPLACE can only update data, while [JSON\\_INSERT](#) can only insert. [JSON\\_SET](#) can update or insert data.

## Examples

```
SELECT JSON_REPLACE('{ "A": 1, "B": [2, 3]}', '$.B[1]', 4);
+-----+
| JSON_REPLACE('{ "A": 1, "B": [2, 3]}', '$.B[1]', 4) |
+-----+
| { "A": 1, "B": [2, 4]} |
+-----+
```

## See Also

- [JSON video tutorial covering JSON\\_REPLACE.](#)

## 1.1.12.9.4.30 JSON\_SEARCH

MariaDB starting with [10.2.3](#)

JSON functions were added in [MariaDB 10.2.3](#).

## Syntax

```
JSON_SEARCH(json_doc, return_arg, search_str[, escape_char[, path] ...])
```

## Description

Returns the path to the given string within a JSON document, or NULL if any of `json_doc`, `search_str` or a path argument is NULL; if the search string is not found, or if no path exists within the document.

A warning will occur if the JSON document is not valid, any of the path arguments are not valid, if `return_arg` is neither `one` nor `all`, or if the escape character is not a constant. NULL will be returned.

`return_arg` can be one of two values:

- - 'one': Terminates after finding the first match, so will return one path string. If there is more than one match, it is undefined which is considered first.
  - 'all': Returns all matching path strings, without duplicates. Multiple strings are autowrapped as an array. The order is undefined.

## Examples

```
SET @json = '[{"A": [{"B": "1"}], {"C":"AB"}, {"D":"BC"}]';

SELECT JSON_SEARCH(@json, 'one', 'AB');
+-----+
| JSON_SEARCH(@json, 'one', 'AB') |
+-----+
| "$[2].C" |
+-----+
```

## 1.1.12.9.4.31 JSON\_SET

MariaDB starting with [10.2.3](#)

JSON functions were added in [MariaDB 10.2.3](#).

## Syntax

```
JSON_SET(json_doc, path, val[, path, val] ...)
```

## Description

Updates or inserts data into a JSON document, returning the result, or NULL if any of the arguments are NULL or the optional path fails to find an object.

An error will occur if the JSON document is invalid, the path is invalid or if the path contains a \* or **wildcard**.

JSON\_SET can update or insert data, while **JSON\_REPLACE** can only update, and **JSON\_INSERT** only insert.

## Examples

```
SELECT JSON_SET(Priv, '$.locked', 'true') FROM mysql.global_priv
```

## 1.1.12.9.4.32 JSON\_TABLE

MariaDB starting with **10.6.0**

JSON\_TABLE was added in **MariaDB 10.6.0**.

JSON\_TABLE is a table function that converts JSON data into a relational form.

## Syntax

```
JSON_TABLE(json_doc,
           context_path COLUMNS (column_list)
) [AS] alias
```

```
column_list:
    column[, column][, ...]
```

```
column:
    name FOR ORDINALITY
    | name type PATH path_str [on_empty] [on_error]
    | name type EXISTS PATH path_str
    | NESTED PATH path_str COLUMNS (column_list)
```

```
on_empty:
    {NULL | DEFAULT string | ERROR} ON EMPTY
```

```
on_error:
    {NULL | DEFAULT string | ERROR} ON ERROR
```

## Contents

1. [Syntax](#)
2. [Description](#)
  1. [Column Definitions](#)
    1. [Path Columns](#)
    2. [ORDINALITY Columns](#)
    3. [EXISTS PATH Columns](#)
    4. [NESTED PATHs](#)
  2. [ON EMPTY and ON ERROR Clauses](#)
  3. [Replication](#)
  3. [See Also](#)

## Description

JSON\_TABLE can be used in contexts where a table reference can be used; in the FROM clause of a **SELECT** statement, and in multi-table **UPDATE** / **DELETE** statements.

json\_doc

is the JSON document to extract data from. In the simplest case, it is a string literal containing JSON. In more complex cases it can be an arbitrary expression returning JSON. The expression may have references to columns of other tables. However, one can only refer to tables that precede this JSON\_TABLE invocation. For RIGHT JOIN, it is assumed that its outer side precedes the inner. All tables in outer selects are also considered preceding.

context\_path

is a [JSON Path](#) expression pointing to a collection of nodes in json\_doc

that will be used as the source of rows.

The

COLUMNS

clause declares the names and types of the columns that JSON\_TABLE returns, as well as how the values of the columns are produced.

## Column Definitions

The following types of columns are supported:

### Path Columns

```
name type PATH path_str [on_empty] [on_error]
```

Locates the JSON node pointed to by

path\_str

and returns its value. The path\_str is evaluated using the current row source node as the context node.

```
set @json='
[
  {"name":"Laptop", "color":"black", "price":"1000"},
  {"name":"Jeans", "color":"blue"}
]';

select * from json_table(@json, '$[*]')
columns(
  name varchar(10) path '$.name',
  color varchar(10) path '$.color',
  price decimal(8,2) path '$.price' )
) as jt;
+-----+-----+
| name | color | price |
+-----+-----+
| Laptop | black | 1000.00 |
| Jeans | blue |     NULL |
+-----+-----+
```

The

on\_empty

and

on\_error

clauses specify the actions to be performed when the value was not found or there was an error condition. See the ON EMPTY and ON ERROR clauses section for details.

### ORDINALITY Columns

```
name FOR ORDINALITY
```

Counts the rows, starting from 1.

Example:

```
set @json='
[
  {"name":"Laptop", "color":"black"},
  {"name":"Jeans", "color":"blue"}
]';

select * from json_table(@json, '$[*]')
columns(
  id for ordinality,
  name varchar(10) path '$.name')
) as jt;
+-----+
| id   | name   |
+-----+
| 1    | Laptop |
| 2    | Jeans  |
+-----+
```

### EXISTS PATH Columns

```
name type EXISTS PATH path_str
```

Checks whether the node pointed to by

value\_path  
exists. The  
value\_path  
is evaluated using the current row source node as the context node.

```
set @json='
[
  {"name":"Laptop", "color":"black", "price":1000},
  {"name":"Jeans", "color":"blue"}
]';

select * from json_table(@json, '$[*]')
  columns(
    name varchar(10) path '$.name',
    has_price integer exists path '$.price')
) as jt;
+-----+
| name | has_price |
+-----+
| Laptop |      1 |
| Jeans  |      0 |
+-----+
```

## NESTED PATHs

NESTED PATH converts nested JSON structures into multiple rows.

```
NESTED PATH path COLUMNS (column_list)
```

It finds the sequence of JSON nodes pointed to by

path  
and uses it to produce rows. For each found node, a row is generated with column values as specified by the NESTED PATH's COLUMNS clause. If  
path  
finds no nodes, only one row is generated with all columns having NULL values.

For example, consider a JSON document that contains an array of items, and each item, in turn, is expected to have an array of its available sizes:

```
set @json='
[
  {"name":"Jeans", "sizes": [32, 34, 36]},
  {"name":"T-Shirt", "sizes":["Medium", "Large"]},
  {"name":"Cellphone"}
]';
```

NESTED PATH allows one to produce a separate row for each size each item has:

```
select * from json_table(@json, '$[*]')
  columns(
    name varchar(10) path '$.name',
    nested path '$.sizes[*]' columns (
      size varchar(32) path '$'
    )
  )
) as jt;
+-----+
| name | size |
+-----+
| Jeans | 32  |
| Jeans | 34  |
| Jeans | 36  |
| T-Shirt | Medium |
| T-Shirt | Large |
| Cellphone | NULL |
+-----+
```

NESTED PATH clauses can be nested within one another. They can also be located next to each other. In that case, the nested path clauses will produce records one at a time. The ones that are not producing records will have all columns set to NULL.

Example:

```

set @json='
[{"name":"Jeans", "sizes": [32, 34, 36], "colors":["black", "blue"]}
]';

select * from json_table(@json, '$[*]')
columns(
    name varchar(10) path '$.name',
    nested path '$.sizes[*]' columns (
        size varchar(32) path '$'
    ),
    nested path '$.colors[*]' columns (
        color varchar(32) path '$'
    )
)
) as jt;

+-----+-----+-----+
| name | size | color |
+-----+-----+-----+
| Jeans | 32 | NULL |
| Jeans | 34 | NULL |
| Jeans | 36 | NULL |
| Jeans | NULL | black |
| Jeans | NULL | blue |
+-----+-----+-----+

```

## ON EMPTY and ON ERROR Clauses

The ON EMPTY clause specifies what will be done when the element specified by the search path is missing in the JSON document.

```

on_empty:
{NULL | DEFAULT string | ERROR} ON EMPTY

```

When

```

ON EMPTY
clause is not present,
NULL ON EMPTY
is implied.

```

```

on_error:
{NULL | DEFAULT string | ERROR} ON ERROR

```

The ON ERROR clause specifies what should be done if a JSON structure error occurs when trying to extract the value pointed to by the path expression. A JSON structure error here occurs only when one attempts to convert a JSON non-scalar (array or object) into a scalar value. When the

```

ON ERROR
clause is not present,
NULL ON ERROR
is implied.

```

**Note :** A datatype conversion error (e.g. attempt to store a non-integer value into an `integer` field, or a `varchar` column being truncated) is not considered a JSON error and so will not trigger the

```

ON ERROR
behavior. It will produce warnings, in the same way as CAST(value AS datatype) would.

```

## Replication

In the current code, evaluation of JSON\_TABLE is deterministic, that is, for a given input string JSON\_TABLE will always produce the same set of rows in the same order. However, one can think of JSON documents that one can consider identical which will produce different output. In order to be future-proof and withstand changes like:

- sorting JSON object members by name (like MySQL does)
- changing the way duplicate object members are handled the function is marked as `unsafe for statement-based replication`.

## See Also

- [JSON Support \(video\)](#)

## 1.1.12.9.4.33 JSON\_TYPE

MariaDB starting with 10.2.3

JSON functions were added in MariaDB 10.2.3 .

## Syntax

```
JSON_TYPE(json_val)
```

## Description

Returns the type of a JSON value (as a string), or NULL if the argument is null.

An error will occur if the argument is an invalid JSON value.

The following is a complete list of the possible return types:

Return type	Value	Example
ARRAY	JSON array	[1, 2, {"key": "value"}]
OBJECT	JSON object	{"key": "value"}
BOOLEAN	JSON true/false literals	true, false
DOUBLE	A number with at least one floating point decimal.	1.2
INTEGER	A number without a floating point decimal.	1
NULL	JSON null literal (this is returned as a string, not to be confused with the SQL NULL value!)	null
STRING	JSON String	"a sample string"

## Examples

```
SELECT JSON_TYPE('{"A": 1, "B": 2, "C": 3}');
+-----+
| JSON_TYPE('{"A": 1, "B": 2, "C": 3}') |
+-----+
| OBJECT |
+-----+
```

## 1.1.12.9.4.34 JSON\_UNQUOTE

MariaDB starting with 10.2.3

JSON functions were added in MariaDB 10.2.3 .

## Syntax

```
JSON_UNQUOTE(val)
```

## Description

Unquotes a JSON value, returning a string, or NULL if the argument is null.

An error will occur if the given value begins and ends with double quotes and is an invalid JSON string literal.

If the given value is not a JSON string, value is passed through unmodified.

Certain character sequences have special meanings within a string. Usually, a backslash is ignored, but the escape sequences in the table below are recognised by MariaDB, unless the [SQL Mode](#) is set to NO\_BACKSLASH\_ESCAPES SQL.

Escape sequence	Character
\"	Double quote ("")

\b	Backslash
\f	Formfeed
\n	Newline (linefeed)
\r	Carriage return
\t	Tab
\\	Backslash ()
\uXXXX	UTF-8 bytes for Unicode value XXXX

## Examples

```
SELECT JSON_UNQUOTE('"Monty"');
+-----+
| JSON_UNQUOTE('"Monty") |
+-----+
| Monty |
+-----+
```

With the default [SQL Mode](#) :

```
SELECT JSON_UNQUOTE('Si\bng\ting');
+-----+
| JSON_UNQUOTE('Si\bng\ting') |
+-----+
| Sng ing |
+-----+
```

Setting NO\_BACKSLASH\_ESCAPES:

```
SET @@sql_mode = 'NO_BACKSLASH_ESCAPES';

SELECT JSON_UNQUOTE('Si\bng\ting');
+-----+
| JSON_UNQUOTE('Si\bng\ting') |
+-----+
| Si\bng\ting |
+-----+
```

## 1.1.12.9.4.35 JSON\_VALID

MariaDB starting with [10.2.3](#)

JSON functions were added in [MariaDB 10.2.3](#).

## Syntax

```
JSON_VALID(value)
```

## Contents

1. [Syntax](#)
2. [Description](#)
3. [Examples](#)
4. [See Also](#)

## Description

Indicates whether the given value is a valid JSON document or not. Returns

```
1  
if valid,  
0  
if not, and NULL if the argument is NULL.
```

From [MariaDB 10.4.3](#), the JSON\_VALID function is automatically used as a [CHECK constraint](#) for the [JSON data type alias](#) in order to ensure that a valid json document is inserted.

## Examples

```
SELECT JSON_VALID('{"id": 1, "name": "Monty"}');  
+-----+  
| JSON_VALID('{"id": 1, "name": "Monty"}') |  
+-----+  
| 1 |  
+-----+  
  
SELECT JSON_VALID('{"id": 1, "name": "Monty", "oddfield"}');  
+-----+  
| JSON_VALID('{"id": 1, "name": "Monty", "oddfield"}') |  
+-----+  
| 0 |  
+-----+
```

## See Also

- [JSON video tutorial covering JSON\\_VALID.](#)

## 1.1.12.9.4.36 JSON\_VALUE

MariaDB starting with [10.2.3](#)

JSON functions were added in [MariaDB 10.2.3](#).

## Syntax

```
JSON_VALUE(json_doc, path)
```

## Description

Given a JSON document, returns the scalar specified by the path. Returns NULL if not given a valid JSON document, or if there is no match.

## Examples

```

select json_value('{"key1":123}', '$.key1');
+-----+
| json_value('{"key1":123}', '$.key1') |
+-----+
| 123 |
+-----+

select json_value('{"key1": [1,2,3], "key1":123}', '$.key1');
+-----+
| json_value('{"key1": [1,2,3], "key1":123}', '$.key1') |
+-----+
| 123 |
+-----+

```

## 1.1.12.9.5 Spider Functions

### 1.1.12.9.5.1 SPIDER\_BG\_DIRECT\_SQL

#### Syntax

```
SPIDER_BG_DIRECT_SQL('sql', 'tmp_table_list', 'parameters')
```

#### Description

Executes the given SQL statement in the background on the remote server, as defined in the parameters listing. If the query returns a result-set, it stores the results in the given temporary table. When the given SQL statement executes successfully, this function returns the number of called UDF's. It returns

- 0  
when the given SQL statement fails.

This function is a [UDF](#) installed with the [Spider](#) storage engine.

#### Examples

```

SELECT SPIDER_BG_DIRECT_SQL('SELECT * FROM example_table', '',
    'srv "node1", port "8607"' ) AS "Direct Query";
+-----+
| Direct Query |
+-----+
|          1 |
+-----+

```

#### Parameters

`error_rw_mode`

- **Description:** Returns empty results on network error.
  - 0 : Return error on getting network error.
  - 1 : Return 0 records on getting network error.
- **Default Table Value:**
  - 0
- **DSN Parameter Name:**
  - erwm

#### See also

- [SPIDER\\_DIRECT\\_SQL](#)

## 1.1.12.9.5.2 SPIDER\_COPY\_TABLES

### Syntax

```
SPIDER_COPY_TABLES(spider_table_name,  
    source_link_id, destination_link_id_list [,parameters])
```

### Description

A [UDF](#) installed with the [Spider Storage Engine](#), this function copies table data from

```
source_link_id  
to  
destination_link_id_list  
. The service does not need to be stopped in order to copy.
```

If the Spider table is partitioned, the name must be of the format

```
table_name#P#partition_name  
. The partition name can be viewed in the  
mysql.spider_tables  
table, for example:
```

```
SELECT table_name FROM mysql.spider_tables;  
+-----+  
| table_name |  
+-----+  
| spt_a#P#pt1 |  
| spt_a#P#pt2 |  
| spt_a#P#pt3 |  
+-----+
```

#### Returns

```
1  
if the data was copied successfully, or  
0  
if copying the data failed.
```

## 1.1.12.9.5.3 SPIDER\_DIRECT\_SQL

### Syntax

```
SPIDER_DIRECT_SQL('sql', 'tmp_table_list', 'parameters')
```

### Description

A [UDF](#) installed with the [Spider Storage Engine](#), this function is used to execute the SQL string

```
sql  
on the remote server, as defined in  
parameters  
. If any resultsets are returned, they are stored in the  
tmp_table_list  
.
```

The function returns

```
1  
if the SQL executes successfully, or  
0  
if it fails.
```

### Examples

```
SELECT SPIDER_DIRECT_SQL('SELECT * FROM s', '', 'srv "node1", port "8607"');
+-----+
| SPIDER_DIRECT_SQL('SELECT * FROM s', '', 'srv "node1", port "8607"') |
+-----+
|                               1 |
+-----+
```

## See also

- [SPIDER\\_BG\\_DIRECT\\_SQL](#)

## 1.1.12.9.5.4 SPIDER\_FLUSH\_TABLE\_MON\_CACHE

### Syntax

```
SPIDER_FLUSH_TABLE_MON_CACHE()
```

### Description

A UDF installed with the [Spider Storage Engine](#), this function is used for refreshing monitoring server information. It returns a value of

1

.

### Examples

```
SELECT SPIDER_FLUSH_TABLE_MON_CACHE();
+-----+
| SPIDER_FLUSH_TABLE_MON_CACHE() |
+-----+
|                               1 |
+-----+
```

## 1.1.12.9.6 Window Functions

### 1.1.12.9.6.1 Window Functions Overview

#### Contents

1. [Introduction](#)
  1. [Syntax](#)
  2. [Description](#)
2. [Scope](#)
3. [Links](#)
4. [Examples](#)
5. [See Also](#)

MariaDB starting with [10.2](#)

Window functions were introduced in [MariaDB 10.2](#).

### Introduction

Window functions allow calculations to be performed across a set of rows related to the current row.

### Syntax

```

function (expression) OVER (
    [ PARTITION BY expression_list ]
    [ ORDER BY order_list [ frame_clause ] ] )

function:
A valid window function

expression_list:
expression | column_name [, expr_list ]

order_list:
expression | column_name [ ASC | DESC ]
[, ...]

frame_clause:
{ROWS | RANGE} {frame_border | BETWEEN frame_border AND frame_border}

frame_border:
| UNBOUNDED PRECEDING
| UNBOUNDED FOLLOWING
| CURRENT ROW
| expr PRECEDING
| expr FOLLOWING

```

## Description

In some ways, window functions are similar to [aggregate functions](#) in that they perform calculations across a set of rows. However, unlike aggregate functions, the output is not grouped into a single row.

Non-aggregate window functions include

- [CUME\\_DIST](#)
- [DENSE\\_RANK](#)
- [FIRST\\_VALUE](#)
- [LAG](#)
- [LAST\\_VALUE](#)
- [LEAD](#)
- [MEDIAN](#)
- [NTH\\_VALUE](#)
- [NTILE](#)
- [PERCENT\\_RANK](#)
- [PERCENTILE\\_CONT](#)
- [PERCENTILE\\_DISC](#)
- [RANK , ROW\\_NUMBER](#)

[Aggregate functions](#) that can also be used as window functions include

- [AVG](#)
- [BIT\\_AND](#)
- [BIT\\_OR](#)
- [BIT\\_XOR](#)
- [COUNT](#)
- [MAX](#)
- [MIN](#)
- [STD](#)
- [STDDEV](#)
- [STDDEV\\_POP](#)
- [STDDEV\\_SAMP](#)
- [SUM](#)
- [VAR\\_POP](#)
- [VAR\\_SAMP](#)
- [VARIANCE](#)

Window function queries are characterised by the OVER keyword, following which the set of rows used for the calculation is specified. By default, the set of rows used for the calculation (the "window") is the entire dataset, which can be ordered with the ORDER BY clause. The PARTITION BY clause is used to reduce the window to a particular group within the dataset.

For example, given the following data:

```

CREATE TABLE student (name CHAR(10), test CHAR(10), score TINYINT);

INSERT INTO student VALUES
('Chun', 'SQL', 75), ('Chun', 'Tuning', 73),
('Esben', 'SQL', 43), ('Esben', 'Tuning', 31),
('Kaolin', 'SQL', 56), ('Kaolin', 'Tuning', 88),
('Tatiana', 'SQL', 87), ('Tatiana', 'Tuning', 83);

```

the following two queries return the average partitioned by test and by name respectively:

```

SELECT name, test, score, AVG(score) OVER (PARTITION BY test)
  AS average_by_test FROM student;

+-----+-----+-----+-----+
| name | test | score | average_by_test |
+-----+-----+-----+-----+
| Chun | SQL | 75 | 65.2500 |
| Chun | Tuning | 73 | 68.7500 |
| Esben | SQL | 43 | 65.2500 |
| Esben | Tuning | 31 | 68.7500 |
| Kaolin | SQL | 56 | 65.2500 |
| Kaolin | Tuning | 88 | 68.7500 |
| Tatiana | SQL | 87 | 65.2500 |
| Tatiana | Tuning | 83 | 68.7500 |
+-----+-----+-----+-----+

SELECT name, test, score, AVG(score) OVER (PARTITION BY name)
  AS average_by_name FROM student;

+-----+-----+-----+-----+
| name | test | score | average_by_name |
+-----+-----+-----+-----+
| Chun | SQL | 75 | 74.0000 |
| Chun | Tuning | 73 | 74.0000 |
| Esben | SQL | 43 | 37.0000 |
| Esben | Tuning | 31 | 37.0000 |
| Kaolin | SQL | 56 | 72.0000 |
| Kaolin | Tuning | 88 | 72.0000 |
| Tatiana | SQL | 87 | 85.0000 |
| Tatiana | Tuning | 83 | 85.0000 |
+-----+-----+-----+-----+

```

It is also possible to specify which rows to include for the window function (for example, the current row and all preceding rows). See [Window Frames](#) for more details.

## Scope

Window functions were introduced in SQL:2003, and their definition was expanded in subsequent versions of the standard. The last expansion was in the latest version of the standard, SQL:2011.

Most database products support a subset of the standard, they implement some functions defined as late as in SQL:2011, and at the same time leave some parts of SQL:2008 unimplemented.

MariaDB:

- Supports ROWS and RANGE-type frames
  - All kinds of frame bounds are supported, including
 

```
RANGE PRECEDING|FOLLOWING n
frame bounds (unlike PostgreSQL or MS SQL Server)
```
  - Does not yet support DATE[TIME] datatype and arithmetic for RANGE-type frames ( [MDEV-9727](#) )
- Does not support GROUPS-type frames (it seems that no popular database supports it, either)
- Does not support frame exclusion (no other database seems to support it, either) ( [MDEV-9724](#) )
- Does not support explicit
 

```
NULLS FIRST
or
NULLS LAST
```
- Does not support nested navigation in window functions (this is
 

```
VALUE_OF(expr AT row_marker [, default_value)
syntax)
```
- The following window functions are supported:
  - "Streamable" window functions: [ROW\\_NUMBER](#) , [RANK](#) , [DENSE\\_RANK](#) ,
  - Window functions that can be streamed once the number of rows in partition is known: [PERCENT\\_RANK](#) , [CUME\\_DIST](#) , [NTILE](#)
- Aggregate functions that are currently supported as window functions are: [COUNT](#) , [SUM](#) , [AVG](#) , [BIT\\_OR](#) , [BIT\\_AND](#) , [BIT\\_XOR](#) .

- Aggregate functions with the DISTINCT specifier (e.g. COUNT( DISTINCT x) ) are not supported as window functions.

## Links

- [MDEV-6115](#) is the main jira task for window functions development. Other tasks are attached as sub-tasks
- [bb-10.2-mdev9543](#) is the feature tree for window functions. Development is ongoing, and this tree has the newest changes.
- Testcases are in mysql-test/t/win\*.test

## Examples

Given the following sample data:

```
CREATE TABLE users (
  email VARCHAR(30),
  first_name VARCHAR(30),
  last_name VARCHAR(30),
  account_type VARCHAR(30)
);

INSERT INTO users VALUES
  ('admin@boss.org', 'Admin', 'Boss', 'admin'),
  ('bob.carlsen@foo.bar', 'Bob', 'Carlsen', 'regular'),
  ('eddie.stevens@data.org', 'Eddie', 'Stevens', 'regular'),
  ('john.smith@xyz.org', 'John', 'Smith', 'regular'),
  ('root@boss.org', 'Root', 'Chief', 'admin')
```

First, let's order the records by email alphabetically, giving each an ascending *rnum* value starting with 1. This will make use of the [ROW\\_NUMBER](#) window function:

```
SELECT row_number() OVER (ORDER BY email) AS rnum,
       email, first_name, last_name, account_type
  FROM users ORDER BY email;
```

rnum	email	first_name	last_name	account_type
1	admin@boss.org	Admin	Boss	admin
2	bob.carlsen@foo.bar	Bob	Carlsen	regular
3	eddie.stevens@data.org	Eddie	Stevens	regular
4	john.smith@xyz.org	John	Smith	regular
5	root@boss.org	Root	Chief	admin

We can generate separate sequences based on account type, using the PARTITION BY clause:

```
SELECT row_number() OVER (PARTITION BY account_type ORDER BY email) AS rnum,
       email, first_name, last_name, account_type
  FROM users ORDER BY account_type,email;
```

rnum	email	first_name	last_name	account_type
1	admin@boss.org	Admin	Boss	admin
2	root@boss.org	Root	Chief	admin
1	bob.carlsen@foo.bar	Bob	Carlsen	regular
2	eddie.stevens@data.org	Eddie	Stevens	regular
3	john.smith@xyz.org	John	Smith	regular

Given the following structure and data, we want to find the top 5 salaries from each department.

```

CREATE TABLE employee_salaries (dept VARCHAR(20), name VARCHAR(20), salary INT(11));

INSERT INTO employee_salaries VALUES
('Engineering', 'Dharma', 3500),
('Engineering', 'Binh', 3000),
('Engineering', 'Adalynn', 2800),
('Engineering', 'Samuel', 2500),
('Engineering', 'Cveta', 2200),
('Engineering', 'Ebele', 1800),
('Sales', 'Carbry', 500),
('Sales', 'Clytemnestra', 400),
('Sales', 'Juraj', 300),
('Sales', 'Kalpana', 300),
('Sales', 'Svantepolk', 250),
('Sales', 'Angelo', 200);

```

We could do this without using window functions, as follows:

```

select dept, name, salary
from employee_salaries as t1
where (select count(t2.salary)
      from employee_salaries as t2
      where t1.name != t2.name and
            t1.dept = t2.dept and
            t2.salary > t1.salary) < 5
order by dept, salary desc;

+-----+-----+-----+
| dept      | name       | salary |
+-----+-----+-----+
| Engineering | Dharma     | 3500  |
| Engineering | Binh       | 3000  |
| Engineering | Adalynn    | 2800  |
| Engineering | Samuel     | 2500  |
| Engineering | Cveta      | 2200  |
| Sales      | Carbry     | 500   |
| Sales      | Clytemnestra | 400   |
| Sales      | Juraj      | 300   |
| Sales      | Kalpana    | 300   |
| Sales      | Svantepolk | 250   |
+-----+-----+-----+

```

This has a number of disadvantages:

- if there is no index, the query could take a long time if the employee\_salary\_table is large
- Adding and maintaining indexes adds overhead, and even with indexes on `dept` and `salary`, each subquery execution adds overhead by performing a lookup through the index.

Let's try achieve the same with window functions. First, generate a rank for all employees, using the `RANK` function.

```

select rank() over (partition by dept order by salary desc) as ranking,
       dept, name, salary
  from employee_salaries
 order by dept, ranking;

+-----+-----+-----+
| ranking | dept      | name       | salary |
+-----+-----+-----+
|      1 | Engineering | Dharma     | 3500  |
|      2 | Engineering | Binh       | 3000  |
|      3 | Engineering | Adalynn    | 2800  |
|      4 | Engineering | Samuel     | 2500  |
|      5 | Engineering | Cveta      | 2200  |
|      6 | Engineering | Ebele      | 1800  |
|      1 | Sales      | Carbry     | 500   |
|      2 | Sales      | Clytemnestra | 400   |
|      3 | Sales      | Juraj      | 300   |
|      3 | Sales      | Kalpana    | 300   |
|      5 | Sales      | Svantepolk | 250   |
|      6 | Sales      | Angelo     | 200   |
+-----+-----+-----+

```

Each department has a separate sequence of ranks due to the `PARTITION BY` clause. This particular sequence of values for `rank()` is given by the `ORDER BY` clause inside the window function's `OVER` clause. Finally, to get our results in a readable format we order the data by `dept` and the newly generated `ranking` column.

Now, we need to reduce the results to find only the top 5 per department. Here is a common mistake:

```
select
rank() over (partition by dept order by salary desc) as ranking,
dept, name, salary
from employee_salaries
where ranking <= 5
order by dept, ranking;

ERROR 1054 (42S22): Unknown column 'ranking' in 'where clause'
```

Trying to filter only the first 5 values per department by putting a where clause in the statement does not work, due to the way window functions are computed. The computation of window functions happens after all WHERE, GROUP BY and HAVING clauses have been completed, right before ORDER BY, so the WHERE clause has no idea that the ranking column exists. It is only present after we have filtered and grouped all the rows.

To counteract this problem, we need to wrap our query into a derived table. We can then attach a where clause to it:

```
select * from (select rank() over (partition by dept order by salary desc) as ranking,
dept, name, salary
from employee_salaries) as salary_ranks
where (salary_ranks.ranking <= 5)
order by dept, ranking;
+-----+-----+-----+
| ranking | dept      | name       | salary   |
+-----+-----+-----+
| 1 | Engineering | Dharma    | 3500    |
| 2 | Engineering | Binh      | 3000    |
| 3 | Engineering | Adalynn   | 2800    |
| 4 | Engineering | Samuel    | 2500    |
| 5 | Engineering | Cveta     | 2200    |
| 1 | Sales      | Carbry    | 500     |
| 2 | Sales      | Clytemnestra | 400    |
| 3 | Sales      | Juraj     | 300     |
| 3 | Sales      | Kalpana   | 300     |
| 5 | Sales      | Svantepolk | 250    |
+-----+-----+-----+
```

## 2 MariaDB Administration

### 2.1 Getting, Installing and Upgrading MariaDB

#### 2.1.1 Where to Download MariaDB

#### Contents

- 1. [The Latest Packages](#)
- 2. [Distributions Which Include MariaDB](#)
- 3. [Pre-Release Binaries](#)
- 4. [Getting the Source](#)
- 5. [Old Versions](#)

### The Latest Packages

Tarballs, binaries (Linux, Solaris, and Windows), and packages for some Linux distributions are available at [mariadb.com/downloads/](#) or [downloads.mariadb.org](#) .

We hope that interested [community](#) package maintainers will step forward, as others already have, to build packages for their distributions. We ask for strict adherence to your packaging system's best practices and invite you to create a [bug report](#) if our project impedes this in any way.

Instructions how to install the packages can be found [here](#) .

### Distributions Which Include MariaDB

- Most distributions already include MariaDB. See [Distributions Which Include MariaDB](#) .

### Pre-Release Binaries

Binaries from our [Buildbot](#) system (see also the [Buildbot](#) page), are available at <http://hasky.askmonty.org/archive> . They are not suitable for use in production systems but may be of use for debugging.

Once at the above URL you will need to click on the MariaDB tree you are interested in, and then the build. The build number corresponds to the `tarbuildnum` variable in Buildbot.

For example, if you were interested in the bsd9-64 build of the [MariaDB 5.5](#) tree, revision 3497, the `tarbuildnum` is listed in the "Build Properties" table of the [Buildbot build report](#) . In this case, the value is "2434".

### Getting the Source

You can find all the source code at <https://github.com/MariaDB/server>

To retrieve the code, the [Git](#) source control software offers the path of least resistance. If you are unfamiliar with git, please refer to the [git documentation](#) for an understanding of version control with git.

For instructions on creating a local branch of MariaDB, see the [Getting the MariaDB Source Code](#) page.

See the [Generic Build Instructions](#) page for general instructions on compiling MariaDB from the source. The [source](#) page has links to platform and distribution-specific information, including information on how we build the release packages.

## 2.1.2 MariaDB Binary Packages

### 2.1.2.1 Installing MariaDB RPM Files

MariaDB provides RPM packages for several RPM-based Linux distributions. MariaDB also provides YUM/DNF and ZYpp repositories for these Linux distributions. The articles here provide information and instructions on using the RPM packages and the related repositories.

#### About the MariaDB RPM Files

4. See also

## Available RPM Packages

The available RPM packages depend on the specific MariaDB release series.

## Available RPM Packages in MariaDB 10.4

MariaDB starting with [10.4](#)

In [MariaDB 10.4](#), the following RPMs are available:

Package Name	Description
galera-4	The WSREP provider for <a href="#">Galera 4</a> .
MariaDB-backup	<a href="#">Mariabackup</a>
MariaDB-backup-debuginfo	Debuginfo for <a href="#">Mariabackup</a>
MariaDB-client	Client tools like mysql CLI, mysqldump , and others.
MariaDB-client-debuginfo	Debuginfo for client tools like mysql CLI, mysqldump , and others.
MariaDB-common	Character set files and <code>/etc/my.cnf</code>
MariaDB-common-debuginfo	Debuginfo for character set files and <code>/etc/my.cnf</code>
MariaDB-compat	Old shared client libraries, may be needed by old MariaDB or MySQL clients
MariaDB-connect-engine	The <a href="#">CONNECT</a> storage engine.
MariaDB-connect-engine-debuginfo	Debuginfo for the <a href="#">CONNECT</a> storage engine.
MariaDB-cracklib-password-check	The <a href="#">cracklib_password_check</a> password validation plugin.
MariaDB-cracklib-password-check	Debuginfo for the <a href="#">cracklib_password_check</a> password validation plugin.
MariaDB-devel	Development headers and static libraries.
MariaDB-devel-debuginfo	Debuginfo for development headers and static libraries.

MariaDB-gssapi-server	The <a href="#">gssapi</a> authentication plugin.
MariaDB-gssapi-server-debuginfo	Debuginfo for the <a href="#">gssapi</a> authentication plugin.
MariaDB-rocksdb-engine	The <a href="#">MyRocks</a> storage engine.
MariaDB-rocksdb-engine-debuginfo	Debuginfo for the <a href="#">MyRocks</a> storage engine.
MariaDB-server	The server and server tools, like <a href="#">myisamchk</a> and <a href="#">mysqlhotcopy</a> are here.
MariaDB-server-debuginfo	Debuginfo for the server and server tools, like <a href="#">myisamchk</a> and <a href="#">mysqlhotcopy</a> are here.
MariaDB-shared	Dynamic client libraries.
MariaDB-shared-debuginfo	Debuginfo for dynamic client libraries.
MariaDB-test	<a href="#">mysql-client-test</a> executable, and <b>mysql-test</b> framework with the tests.
MariaDB-test-debuginfo	Debuginfo for <a href="#">mysql-client-test</a> executable, and <b>mysql-test</b> framework with the tests.
MariaDB-tokudb-engine	The <a href="#">TokuDB</a> storage engine.
MariaDB-tokudb-engine-debuginfo	Debuginfo for the <a href="#">TokuDB</a> storage engine.

## Available RPM Packages in [MariaDB 10.2](#) and [MariaDB 10.3](#)

MariaDB starting with [10.2](#)

In [MariaDB 10.2](#) and [MariaDB 10.3](#), the following RPMs are available:

Package Name	Description
galera	The WSREP provider for <a href="#">Galera 3</a> .
MariaDB-backup	<a href="#">Mariabackup</a>
MariaDB-backup-debuginfo	Debuginfo for <a href="#">Mariabackup</a>

MariaDB-client	Client tools like mysql CLI, mysqldump , and others.
MariaDB-client-debuginfo	Debuginfo for client tools like mysql CLI, mysqldump , and others.
MariaDB-common	Character set files and /etc/my.cnf
MariaDB-common-debuginfo	Debuginfo for character set files and /etc/my.cnf
MariaDB-compat	Old shared client libraries, may be needed by old MariaDB or MySQL clients
MariaDB-connect-engine	The <a href="#">CONNECT</a> storage engine.
MariaDB-connect-engine-debuginfo	Debuginfo for the <a href="#">CONNECT</a> storage engine.
MariaDB-cracklib-password-check	The <a href="#">cracklib_password_check</a> password validation plugin.
MariaDB-cracklib-password-check	Debuginfo for the <a href="#">cracklib_password_check</a> password validation plugin.
MariaDB-devel	Development headers and static libraries.
MariaDB-devel-debuginfo	Debuginfo for development headers and static libraries.
MariaDB-gssapi-server	The <a href="#">gssapi</a> authentication plugin.
MariaDB-gssapi-server-debuginfo	Debuginfo for the <a href="#">gssapi</a> authentication plugin.
MariaDB-rocksdb-engine	The <a href="#">MyRocks</a> storage engine.
MariaDB-rocksdb-engine-debuginfo	Debuginfo for the <a href="#">MyRocks</a> storage engine.

MariaDB-server	The server and server tools, like <a href="#">myisamchk</a> and <a href="#">mysqlhotcopy</a> are here.
MariaDB-server-debuginfo	Debuginfo for the server and server tools, like <a href="#">myisamchk</a> and <a href="#">mysqlhotcopy</a> are here.
MariaDB-shared	Dynamic client libraries.
MariaDB-shared-debuginfo	Debuginfo for dynamic client libraries.
MariaDB-test	<a href="#">mysql-client-test</a> executable, and <b>mysql-test</b> framework with the tests.
MariaDB-test-debuginfo	Debuginfo for <a href="#">mysql-client-test</a> executable, and <b>mysql-test</b> framework with the tests.
MariaDB-tokudb-engine	The <a href="#">TokuDB</a> storage engine.
MariaDB-tokudb-engine-debuginfo	Debuginfo for the <a href="#">TokuDB</a> storage engine.

## Available RPM Packages in MariaDB 10.1

MariaDB starting with [10.1](#)

In [MariaDB 10.1](#), the following RPMs are available:

Package Name	Description
galera	The WSREP provider for <a href="#">Galera</a> 3.
MariaDB-backup	<a href="#">Mariabackup</a>
MariaDB-backup-debuginfo	Debuginfo for <a href="#">Mariabackup</a>
MariaDB-client	Client tools like <a href="#">mysql</a> <a href="#">CLI</a> , <a href="#">mysqldump</a> , and others.
MariaDB-client-debuginfo	Debuginfo for client tools like <a href="#">mysql</a> <a href="#">CLI</a> , <a href="#">mysqldump</a> , and others.
MariaDB-common	Character set files and <code>/etc/my.cnf</code>
MariaDB-common-debuginfo	Debuginfo for character set files and <code>/etc/my.cnf</code>
MariaDB-compat	Old shared client libraries, may be needed by old MariaDB or MySQL clients

MariaDB-connect-engine	The  CONNECT  storage engine.
MariaDB-connect-engine-debuginfo	Debuginfo for the  CONNECT  storage engine.
MariaDB-cracklib-password-check	The  cracklib_password_check  password validation plugin.
MariaDB-cracklib-password-check	Debuginfo for the  cracklib_password_check  password validation plugin.
MariaDB-devel	Development headers and static libraries.
MariaDB-devel-debuginfo	Debuginfo for development headers and static libraries.
MariaDB-gssapi-server	The  gssapi  authentication plugin.
MariaDB-gssapi-server-debuginfo	Debuginfo for the  gssapi  authentication plugin.
MariaDB-server	The server and server tools, like <a href="#">myisamchk</a> and <a href="#">mysqlhotcopy</a> are here.
MariaDB-server-debuginfo	Debuginfo for the server and server tools, like <a href="#">myisamchk</a> and <a href="#">mysqlhotcopy</a> are here.
MariaDB-shared	Dynamic client libraries.
MariaDB-shared-debuginfo	Debuginfo for dynamic client libraries.
MariaDB-test	<a href="#">mysql-client-test</a> executable, and <b>mysql-test</b> framework with the tests.
MariaDB-test-debuginfo	Debuginfo for  <a href="#">mysql-client-test</a> executable, and <b>mysql-test</b> framework with the tests.
MariaDB-tokudb-engine	The <a href="#">TokuDB</a> storage engine.
MariaDB-tokudb-engine-debuginfo	Debuginfo for the <a href="#">TokuDB</a> storage engine.

## Available RPM Packages in MariaDB 5.5

MariaDB starting with 5.5

In MariaDB 5.5 , the following RPMs are available:

Package Name	Description
MariaDB-client	Client tools like mysql CLI, mysqldump , and others.
MariaDB-client-debuginfo	Debuginfo for client tools like mysql CLI, mysqldump , and others.
MariaDB-common	Character set files and /etc/my.cnf
MariaDB-common-debuginfo	Debuginfo for character set files and /etc/my.cnf
MariaDB-compat	Old shared client libraries, may be needed by old MariaDB or MySQL clients
MariaDB-devel	Development headers and static libraries.
MariaDB-devel-debuginfo	Debuginfo for development headers and static libraries.
MariaDB-server	The server and server tools, like myisamchk and mysqlhotcopy are here.
MariaDB-server-debuginfo	Debuginfo for the server and server tools, like myisamchk and mysqlhotcopy are here.
MariaDB-shared	Dynamic client libraries.
MariaDB-shared-debuginfo	Debuginfo for dynamic client libraries.
MariaDB-test	mysql-client-test executable, and mysql-test framework with the tests.
MariaDB-test-debuginfo	Debuginfo for mysql-client-test executable, and mysql-test framework with the tests.

## Installing RPM Packages

Preferably, you should install MariaDB RPM packages using the package manager of your Linux distribution, for example

yum  
or  
zypper  
. But you can also use the lower-level  
rpm  
tool.

# Actions Performed by RPM Packages

## Users and Groups Created

When the

`MariaDB-server`  
RPM package is installed, it will create a user and group named  
`mysql`  
, if it does not already exist.

## See also

- [Installing MariaDB with yum](#)

### 2.1.2.1.2 Installing MariaDB with yum/dnf

On RHEL, CentOS, Fedora, and other similar Linux distributions, it is highly recommended to install the relevant [RPM packages](#) from MariaDB's repository using

`yum`

or

`dnf`

. Starting with RHEL 8 and Fedora 22,

`yum`  
has been replaced by  
`dnf`  
, which is the next major version of  
`yum`  
. However,  
`yum`  
commands still work on many systems that use  
`dnf`

This page walks you through the simple installation steps using

`yum`

.

## Contents

1. Adding the MariaDB YUM repository

  2. Using the MariaDB Repository Configuration Tool
  3. Pinning the MariaDB Repository to a Specific Minor Release
2. Updating the MariaDB YUM repository to a New Major Release
  1. Updating the Major Release with the MariaDB Package Repository Setup Script
  2. Updating the Major Release with the MariaDB Repository Configuration Tool
3. Importing the MariaDB GPG Public Key
4. Installing MariaDB Packages with YUM
  1. Installing the Most Common Packages with YUM
  2. Installing MariaDB Server with YUM
  3. Installing MariaDB Galera Cluster with YUM
  4. Installing MariaDB Clients and Client Libraries with YUM
  5. Installing Mariabackup with YUM
  6. Installing Plugins with YUM
  7. Installing Debug Info Packages with YUM
    1. Installing Debug Info for the Most Common Packages with YUM
    2. Installing Debug Info for MariaDB Server with YUM
    3. Installing Debug Info for MariaDB Clients and Client Libraries with YUM
    4. Installing Debug Info for Mariabackup with YUM
    5. Installing Debug Info for Plugins with YUM
  8. Installing Older Versions from the Repository
5. After Installation

## Adding the MariaDB YUM repository

We currently have YUM repositories for the following Linux distributions:

- Red Hat Enterprise Linux (RHEL) 6
- Red Hat Enterprise Linux (RHEL) 7
- CentOS 6
- CentOS 7
- Fedora 27
- Fedora 28
- Fedora 29

## Using the MariaDB Package Repository Setup Script

If you want to install MariaDB with

```
yum  
, then you can configure  
yum  
to install from MariaDB Corporation's MariaDB Package Repository by using the MariaDB Package Repository setup script.
```

MariaDB Corporation provides a MariaDB Package Repository for several Linux distributions that use

```
yum  
to manage packages. This repository contains software packages related to MariaDB Server, including the server itself, clients and utilities, client libraries, plugins, and Mariabackup. The MariaDB Package Repository setup script automatically configures your system to install packages from the MariaDB Package Repository.
```

To use the script, execute the following command:

```
curl -sS https://downloads.mariadb.com/MariaDB/mariadb_repo_setup | sudo bash
```

Note that this script also configures a repository for [MariaDB MaxScale](#) and a repository for MariaDB Tools, which currently only contains [Percona XtraBackup](#) and its dependencies.

See [MariaDB Package Repository Setup and Usage](#) for more information.

## Using the MariaDB Repository Configuration Tool

If you want to install MariaDB with

```
yum  
, then you can configure  
yum  
to install from MariaDB Foundation's MariaDB Repository by using the MariaDB Repository Configuration Tool.
```

The MariaDB Foundation provides a MariaDB repository for several Linux distributions that use

```
yum  
to manage packages. This repository contains software packages related to MariaDB Server, including the server itself, clients and utilities, client libraries, plugins, and Mariabackup. The MariaDB Repository Configuration Tool can easily generate the appropriate configuration file to add the repository for your distribution.
```

Once you have the appropriate repository configuration section for your distribution, add it to a file named

```
MariaDB.repo  
under  
/etc/yum.repos.d/  
:
```

For example, if you wanted to use the repository to install [MariaDB 10.3](#) on CentOS 7, then you could use the following

```
yum  
repository configuration in  
/etc/yum.repos.d/MariaDB.repo  
:  
[mariadb]  
name = MariaDB  
baseurl = http://yum.mariadb.org/10.3/centos7-amd64  
gpgkey=https://yum.mariadb.org/RPM-GPG-KEY-MariaDB  
gpgcheck=1
```

The example file above includes a

```
gpgkey  
line to automatically fetch the GPG public key that is used to verify the digital signatures of the packages in our repositories. This allows the the  
yum  
,  
dnf  
, and  
rpm  
utilities to verify the integrity of the packages that they install.
```

## Pinning the MariaDB Repository to a Specific Minor Release

If you wish to pin the

```
yum  
repository to a specific minor release, or if you would like to do a  
yum downgrade  
to a specific minor release, then you can create a  
yum  
repository configuration with a  
baseurl  
option set to that specific minor release.
```

The MariaDB Foundation archives repositories of old minor releases at the following URL:

- <http://archive.mariadb.org/>

So if you can't find the repository of a specific minor release at

```
yum.mariadb.org  
, then it would be a good idea to check the archive.
```

For example, if you wanted to pin your repository to [MariaDB 10.3.14](#) on CentOS 7, then you could use the following

```
yum  
repository configuration in  
/etc/yum.repos.d/MariaDB.repo
```

```
[mariadb]
name = MariaDB-10.3.14
baseurl=http://yum.mariadb.org/10.3.14/centos7-amd64
# alternative: baseurl=http://archive.mariadb.org/mariadb-10.3.14/yum/centos7-amd64
gpgkey=https://yum.mariadb.org/RPM-GPG-KEY-MariaDB
gpgcheck=1
```

Note that if you change an existing repository configuration, then you need to execute the following:

```
sudo yum clean all
```

## Updating the MariaDB YUM repository to a New Major Release

MariaDB's

yum

repository can be updated to a new major release. How this is done depends on how you originally configured the repository.

### Updating the Major Release with the MariaDB Package Repository Setup Script

If you configured

yum

to install from MariaDB Corporation's MariaDB Package Repository by using the [MariaDB Package Repository setup script](#), then you can update the major release that the repository uses by running the script again.

### Updating the Major Release with the MariaDB Repository Configuration Tool

If you configured

yum

to install from MariaDB Foundation's MariaDB Repository by using the [MariaDB Repository Configuration Tool](#), then you can update the major release that the repository uses by updating the

yum

repository configuration file in-place. For example, if you wanted to change the repository from [MariaDB 10.2](#) to [MariaDB 10.3](#), and if the repository configuration file was at

/etc/yum.repos.d/MariaDB.repo

, then you could execute the following:

```
sudo sed -i 's/10.2/10.3/' /etc/yum.repos.d/MariaDB.repo
```

After that, the repository should refer to [MariaDB 10.3](#).

If the

yum

repository is pinned to a specific minor release, then the above

sed

command can result in an invalid repository configuration. In that case, the recommended options are:

- Edit the

MariaDB.repo

repository file manually.

- Or delete the

MariaDB.repo

repository file, and then install the repository of the new version with the more robust [MariaDB Package Repository setup script](#).

## Importing the MariaDB GPG Public Key

Before MariaDB can be installed, you also have to import the GPG public key that is used to verify the digital signatures of the packages in our repositories. This allows the

yum

,

dnf

and

rpm

utilities to verify the integrity of the packages that they install.

The id of our GPG public key is

0xcbcb082a1bb943db

. The short form of the id is

0x1BB943DB

. The full key fingerprint is:

```
1993 69E5 404B D5FC 7D2F E43B CBCB 082A 1BB9 43DB
```

yum

should prompt you to import the GPG public key the first time that you install a package from MariaDB's repository. However, if you like, the

rpm

utility can be used to manually import this key instead. For example:

```
sudo rpm --import https://yum.mariadb.org/RPM-GPG-KEY-MariaDB
```

Once the GPG public key is imported, you are ready to install packages from the repository.

## Installing MariaDB Packages with YUM

After the

yum

repository is configured, you can install MariaDB by executing the

yum

command. The specific command that you would use would depend on which specific packages that you want to install.

## Installing the Most Common Packages with YUM

MariaDB starting with 10.4

In [MariaDB 10.4](#) and later, to Install the most common packages, execute the following command:

```
sudo yum install MariaDB-server galera-4 MariaDB-client MariaDB-shared MariaDB-backup MariaDB-common
```

MariaDB until 10.3

In [MariaDB 10.3](#) and before, to Install the most common packages, execute the following command:

```
sudo yum install MariaDB-server galera MariaDB-client MariaDB-shared MariaDB-backup MariaDB-common
```

## Installing MariaDB Server with YUM

To Install MariaDB Server, execute the following command:

```
sudo yum install MariaDB-server
```

## Installing MariaDB Galera Cluster with YUM

The process to install MariaDB Galera Cluster with the MariaDB

yum

repository is practically the same as installing standard MariaDB Server.

In [MariaDB 10.1](#) and later, Galera Cluster support has been included in the standard MariaDB Server packages, so you will need to install the  
MariaDB-server  
package, as you normally would.

In [MariaDB 10.4](#) and later, you also need to install the  
galera-4  
package to obtain the [Galera 4 wsrep provider library](#).

In [MariaDB 10.3](#) and before, you also need to install the  
galera  
package to obtain the [Galera 3 wsrep provider library](#).

MariaDB starting with [10.4](#)

In [MariaDB 10.4](#) and later, to install MariaDB Galera Cluster, you could execute the following command:

```
sudo yum install MariaDB-server MariaDB-client galera-4
```

MariaDB until [10.3](#)

In [MariaDB 10.3](#) and before, to install MariaDB Galera Cluster, you could execute the following command:

```
sudo yum install MariaDB-server MariaDB-client galera
```

If you haven't yet imported the MariaDB GPG public key, then

`yum`

will prompt you to import it after it downloads the packages, but before it prompts you to install them.

See [MariaDB Galera Cluster](#) for more information on MariaDB Galera Cluster.

## Installing MariaDB Clients and Client Libraries with YUM

In [MariaDB 10.2](#) and later, [MariaDB Connector/C](#) has been included as the client library. However, the package name for the client library has not been changed.

To Install the clients and client libraries, execute the following command:

```
sudo yum install MariaDB-client MariaDB-shared
```

## Installing Mariabackup with YUM

To install [Mariabackup](#), execute the following command:

```
sudo yum install MariaDB-backup
```

## Installing Plugins with YUM

Some [plugins](#) may also need to be installed.

For example, to install the

`cracklib_password_check`

password validation plugin, execute the following command:

```
sudo yum install MariaDB-cracklib-password-check
```

## Installing Debug Info Packages with YUM

MariaDB starting with [5.5.64](#)

The MariaDB

`yum`

repository first added

`debuginfo`

packages in [MariaDB 5.5.64](#) , [MariaDB 10.1.39](#) , [MariaDB 10.2.23](#) , [MariaDB 10.3.14](#) , and [MariaDB 10.4.4](#) .

The MariaDB

`yum`

repository also contains

`debuginfo`

packages. These package may be needed when [debugging a problem](#) .

## Installing Debug Info for the Most Common Packages with YUM

To install

[debuginfo](#)

for the most common packages, execute the following command:

```
sudo yum install MariaDB-server-debuginfo MariaDB-client-debuginfo MariaDB-shared-debuginfo MariaDB-backup-debuginfo MariaDB-com
```

## Installing Debug Info for MariaDB Server with YUM

To install

[debuginfo](#)

for MariaDB Server, execute the following command:

```
sudo yum install MariaDB-server-debuginfo
```

## Installing Debug Info for MariaDB Clients and Client Libraries with YUM

In [MariaDB 10.2](#) and later, [MariaDB Connector/C](#) has been included as the client library. However, the package name for the client library has not been changed.

To install

[debuginfo](#)

for the clients and client libraries, execute the following command:

```
sudo yum install MariaDB-client-debuginfo MariaDB-shared-debuginfo
```

## Installing Debug Info for Mariabackup with YUM

To install

[debuginfo](#)

for [Mariabackup](#), execute the following command:

```
sudo yum install MariaDB-backup-debuginfo
```

## Installing Debug Info for Plugins with YUM

For some [plugins](#),

[debuginfo](#)

may also need to be installed.

For example, to install

[debuginfo](#)

for the

[cracklib\\_password\\_check](#)

password validation plugin, execute the following command:

```
sudo yum install MariaDB-cracklib-password-check-debuginfo
```

## Installing Older Versions from the Repository

The MariaDB

[yum](#)

repository contains the last few versions of MariaDB. To show what versions are available, use the following command:

```
yum list --showduplicates MariaDB-server
```

In the output you will see the available versions. For example:

```
$ yum list --showduplicates MariaDB-server
Loaded plugins: fastestmirror
Loading mirror speeds from cached hostfile
 * base: centos.mirrors.ovh.net
 * extras: centos.mirrors.ovh.net
 * updates: centos.mirrors.ovh.net
Available Packages
MariaDB-server.x86_64    10.3.10-1.el7.centos      mariadb
MariaDB-server.x86_64    10.3.11-1.el7.centos      mariadb
MariaDB-server.x86_64    10.3.12-1.el7.centos      mariadb
mariadb-server.x86_64    1:5.5.60-1.el7_5          base
```

The MariaDB

```
yum
repository in this example contains MariaDB 10.3.10, MariaDB 10.3.11, and MariaDB 10.3.12. The CentOS base
yum
repository also contains MariaDB 5.5.60.
```

To install an older version of a package instead of the latest version we just need to specify the package name, a dash, and then the version number. And we only need to specify enough of the version number for it to be unique from the other available versions.

However, when installing an older version of a package, if

```
yum
has to install dependencies, then it will automatically choose to install the latest versions of those packages. To ensure that all MariaDB
packages are on the same version in this scenario, it is necessary to specify them all.
```

The packages that the MariaDB-server package depend on are: MariaDB-client, MariaDB-shared, and MariaDB-common. Therefore, to install [MariaDB 10.3.11](#) from this

```
yum
repository, we would do the following:
```

```
sudo yum install MariaDB-server-10.3.11 MariaDB-client-10.3.11 MariaDB-shared-10.3.11 MariaDB-backup-10.3.11 MariaDB-common-10.3
```

The rest of the install and setup process is as normal.

## After Installation

After the installation is complete, you can [start MariaDB](#).

If you are using [MariaDB Galera Cluster](#), then keep in mind that the first node will have to be [bootstrapped](#).

### 2.1.2.1.3 Installing MariaDB with zypper

On SLES, OpenSUSE, and other similar Linux distributions, it is highly recommended to install the relevant [RPM packages](#) from MariaDB's repository using

```
zypper
```

This page walks you through the simple installation steps using

```
zypper
```

## Contents

    5. Installing Debug Info for Plugins with ZYpp
  8. Installing Older Versions from the Repository
5. After Installation

## Adding the MariaDB ZYpp repository

We currently have ZYpp repositories for the following Linux distributions:

- SUSE Linux Enterprise Server (SLES) 12
- SUSE Linux Enterprise Server (SLES) 15
- OpenSUSE 15
- OpenSUSE 42

## Using the MariaDB Package Repository Setup Script

If you want to install MariaDB with

zypper  
, then you can configure  
zypper  
to install from MariaDB Corporation's MariaDB Package Repository by using the [MariaDB Package Repository setup script](#).

MariaDB Corporation provides a MariaDB Package Repository for several Linux distributions that use

zypper  
to manage packages. This repository contains software packages related to MariaDB Server, including the server itself, [clients and utilities](#), [client libraries](#), [plugins](#), and [Mariabackup](#). The MariaDB Package Repository setup script automatically configures your system to install packages from the MariaDB Package Repository.

To use the script, execute the following command:

```
curl -sS https://downloads.mariadb.com/MariaDB/mariadb_repo_setup | sudo bash
```

Note that this script also configures a repository for [MariaDB MaxScale](#) and a repository for MariaDB Tools, which currently only contains [Percona](#)

[XtraBackup](#) and its dependencies.

See [MariaDB Package Repository Setup and Usage](#) for more information.

## Using the MariaDB Repository Configuration Tool

If you want to install MariaDB with

```
zypper  
, then you can configure  
zypper  
to install from MariaDB Foundation's MariaDB Repository by using the MariaDB Repository Configuration Tool.
```

The MariaDB Foundation provides a MariaDB repository for several Linux distributions that use

```
zypper  
to manage packages. This repository contains software packages related to MariaDB Server, including the server itself, clients and utilities, client libraries, plugins, and Mariabackup. The MariaDB Repository Configuration Tool can easily generate the appropriate commands to add the repository for your distribution.
```

For example, if you wanted to use the repository to install [MariaDB 10.3](#) on SLES 15, then you could use the following commands to add the MariaDB

```
zypper  
repository:
```

```
sudo zypper addrepo --gpgcheck --refresh https://yum.mariadb.org/10.3/sles/15/x86_64 mariadb  
sudo zypper --gpg-auto-import-keys refresh
```

## Pinning the MariaDB Repository to a Specific Minor Release

If you wish to pin the

```
zypper  
repository to a specific minor release, or if you would like to downgrade to a specific minor release, then you can create a  
zypper  
repository with the URL hard-coded to that specific minor release.
```

The MariaDB Foundation archives repositories of old minor releases at the following URL:

- <http://archive.mariadb.org/>

So if you can't find the repository of a specific minor release at

```
yum.mariadb.org  
, then it would be a good idea to check the archive.
```

For example, if you wanted to pin your repository to [MariaDB 10.3.14](#) on SLES 15, then you could use the following commands to add the MariaDB

```
zypper  
repository:
```

```
sudo zypper removerepo mariadb  
sudo zypper addrepo --gpgcheck --refresh https://yum.mariadb.org/10.3.14/sles/15/x86_64 mariadb
```

## Updating the MariaDB ZYpp repository to a New Major Release

MariaDB's

```
zypper  
repository can be updated to a new major release. How this is done depends on how you originally configured the repository.
```

## Updating the Major Release with the MariaDB Package Repository Setup Script

If you configured

```
zypper  
to install from MariaDB Corporation's MariaDB Package Repository by using the MariaDB Package Repository setup script, then you can update  
the major release that the repository uses by running the script again.
```

## Updating the Major Release with the MariaDB Repository Configuration Tool

If you configured

```
zypper  
to install from MariaDB Foundation's MariaDB Repository by using the MariaDB Repository Configuration Tool, then you can update the major  
release that the repository uses by removing the repository for the old version and adding the repository for the new version.
```

First, you can remove the repository for the old version by executing the following command:

```
sudo zypper removerepo mariadb
```

After that, you can add the repository for the new version. For example, if you wanted to use the repository to install [MariaDB 10.3](#) on SLES 15, then you could use the following commands to add the MariaDB

```
zypper  
repository:
```

```
sudo zypper addrepo --gpgcheck --refresh https://yum.mariadb.org/10.3/sles/15/x86_64 mariadb  
sudo zypper --gpg-auto-import-keys refresh
```

After that, the repository should refer to [MariaDB 10.3](#).

## Importing the MariaDB GPG Public Key

Before MariaDB can be installed, you also have to import the GPG public key that is used to verify the digital signatures of the packages in our repositories. This allows the the

```
zypper  
and  
rpm  
utilities to verify the integrity of the packages that they install.
```

The id of our GPG public key is

```
0xcbcb082a1bb943db  
. The short form of the id is  
0x1BB943DB  
. The full key fingerprint is:
```

```
1993 69E5 404B D5FC 7D2F E43B CBCB 082A 1BB9 43DB
```

The

```
rpm
```

utility can be used to import this key. For example:

```
sudo rpm --import https://yum.mariadb.org/RPM-GPG-KEY-MariaDB
```

Once the GPG public key is imported, you are ready to install packages from the repository.

## Installing MariaDB Packages with ZYpp

After the

```
zypper  
repository is configured, you can install MariaDB by executing the
```

```
zypper
```

command. The specific command that you would use would depend on which specific packages that you want to install.

## Installing the Most Common Packages with ZYpp

MariaDB starting with [10.4](#)

In [MariaDB 10.4](#) and later, to Install the most common packages, execute the following command:

```
sudo zypper install MariaDB-server galera-4 MariaDB-client MariaDB-shared MariaDB-backup MariaDB-common
```

MariaDB until [10.3](#)

In [MariaDB 10.3](#) and before, to Install the most common packages, execute the following command:

```
sudo zypper install MariaDB-server galera MariaDB-client MariaDB-shared MariaDB-backup MariaDB-common
```

## Installing MariaDB Server with ZYpp

To Install MariaDB Server, execute the following command:

```
sudo zypper install MariaDB-server
```

## Installing MariaDB Galera Cluster with ZYpp

The process to install MariaDB Galera Cluster with the MariaDB

```
zypper  
repository is practically the same as installing standard MariaDB Server.
```

In [MariaDB 10.1](#) and later, Galera Cluster support has been included in the standard MariaDB Server packages, so you will need to install the  
MariaDB-server  
package, as you normally would.

In [MariaDB 10.4](#) and later, you also need to install the  
galera-4  
package to obtain the [Galera 4 wsrep provider library](#).

In [MariaDB 10.3](#) and before, you also need to install the  
galera  
package to obtain the [Galera 3 wsrep provider library](#).

MariaDB starting with [10.4](#)

In [MariaDB 10.4](#) and later, to install MariaDB Galera Cluster, you could execute the following command:

```
sudo zypper install MariaDB-server MariaDB-client galera-4
```

MariaDB until [10.3](#)

In [MariaDB 10.3](#) and before, to install MariaDB Galera Cluster, you could execute the following command:

```
sudo zypper install MariaDB-server MariaDB-client galera
```

If you haven't yet imported the MariaDB GPG public key, then

```
zypper  
will prompt you to import it after it downloads the packages, but before it prompts you to install them.
```

See [MariaDB Galera Cluster](#) for more information on MariaDB Galera Cluster.

## Installing MariaDB Clients and Client Libraries with ZYpp

In [MariaDB 10.2](#) and later, [MariaDB Connector/C](#) has been included as the client library. However, the package name for the client library has not been changed.

To Install the clients and client libraries, execute the following command:

```
sudo zypper install MariaDB-client MariaDB-shared
```

## Installing Mariabackup with ZYpp

To install [Mariabackup](#), execute the following command:

```
sudo zypper install MariaDB-backup
```

## Installing Plugins with ZYpp

Some [plugins](#) may also need to be installed.

For example, to install the

```
cracklib_password_check
```

password validation plugin, execute the following command:

```
sudo zypper install MariaDB-cracklib-password-check
```

## Installing Debug Info Packages with ZYpp

MariaDB starting with [5.5.64](#)

#### The MariaDB

```
zypper  
repository first added
```

```
debuginfo
```

packages in [MariaDB 5.5.64](#) , [MariaDB 10.1.39](#) , [MariaDB 10.2.23](#) , [MariaDB 10.3.14](#) , and [MariaDB 10.4.4](#) .

#### The MariaDB

```
zypper  
repository also contains
```

```
debuginfo
```

packages. These package may be needed when [debugging a problem](#) .

### Installing Debug Info for the Most Common Packages with ZYpp

To install

```
debuginfo
```

for the most common packages, execute the following command:

```
sudo zypper install MariaDB-server-debuginfo MariaDB-client-debuginfo MariaDB-shared-debuginfo MariaDB-backup-debuginfo MariaDB-
```

### Installing Debug Info for MariaDB Server with ZYpp

To install

```
debuginfo
```

for MariaDB Server, execute the following command:

```
sudo zypper install MariaDB-server-debuginfo
```

### Installing Debug Info for MariaDB Clients and Client Libraries with ZYpp

In [MariaDB 10.2](#) and later, [MariaDB Connector/C](#) has been included as the client library. However, the package name for the client library has not been changed.

To install

```
debuginfo
```

for the clients and client libraries, execute the following command:

```
sudo zypper install MariaDB-client-debuginfo MariaDB-shared-debuginfo
```

### Installing Debug Info for Mariabackup with ZYpp

To install

```
debuginfo
```

for [Mariabackup](#) , execute the following command:

```
sudo zypper install MariaDB-backup-debuginfo
```

### Installing Debug Info for Plugins with ZYpp

For some [plugins](#) ,

```
debuginfo
```

may also need to be installed.

For example, to install

```
debuginfo
```

for the

```
cracklib_password_check
```

password validation plugin, execute the following command:

```
sudo zypper install MariaDB-cracklib-password-check-debuginfo
```

## Installing Older Versions from the Repository

The MariaDB

```
zypper
```

repository contains the last few versions of MariaDB. To show what versions are available, use the following command:

```
zypper search --details MariaDB-server
```

In the output you will see the available versions.

To install an older version of a package instead of the latest version we just need to specify the package name, a dash, and then the version number. And we only need to specify enough of the version number for it to be unique from the other available versions.

However, when installing an older version of a package, if

```
zypper
```

has to install dependencies, then it will automatically choose to install the latest versions of those packages. To ensure that all MariaDB packages are on the same version in this scenario, it is necessary to specify them all.

The packages that the MariaDB-server package depend on are: MariaDB-client, MariaDB-shared, and MariaDB-common. Therefore, to install [MariaDB 10.3.14](#) from this

```
zypper
```

repository, we would do the following:

```
sudo zypper install MariaDB-server-10.3.14 MariaDB-client-10.3.14 MariaDB-shared-10.3.14 MariaDB-backup-10.3.14 MariaDB-common-1
```

The rest of the install and setup process is as normal.

## After Installation

After the installation is complete, you can [start MariaDB](#).

If you are using [MariaDB Galera Cluster](#), then keep in mind that the first node will have to be [bootstrapped](#).

### 2.1.2.1.4 Installing MariaDB With the rpm Tool

This article describes how to download the RPM files and install them using the

```
rpm
```

command.

It is highly recommended to [Install MariaDB with yum](#) where possible.

Navigate to <http://downloads.mariadb.org> and choose the desired database version and then select the RPMs that match your Linux distribution and architecture.

Clicking those links takes you to a local mirror. Choose the rpms link and download the desired packages. The packages will be similar to the following:

```
MariaDB-client-5.2.5-99.el5.x86_64.rpm  
MariaDB-debuginfo-5.2.5-99.el5.x86_64.rpm  
MariaDB-devel-5.2.5-99.el5.x86_64.rpm  
MariaDB-server-5.2.5-99.el5.x86_64.rpm  
MariaDB-shared-5.2.5-99.el5.x86_64.rpm  
MariaDB-test-5.2.5-99.el5.x86_64.rpm
```

For a standard server installation you will need to download at least the *client*, *shared*, and *server* RPM files. See [About the MariaDB RPM Files](#) for more information about what is included in each RPM package.

After downloading the MariaDB RPM files, you might want to check their signatures. See [Checking MariaDB RPM Package Signatures](#) for more information about checking signatures.

```
rpm --checksig $(find . -name '*.rpm')
```

Prior to installing MariaDB, be aware that it will conflict with an existing installation of MySQL. To check whether MySQL is already installed, issue the command:

```
rpm -qa 'mysql*'
```

If necessary, you can remove found MySQL packages before installing MariaDB.

To install MariaDB, use the command:

```
rpm -ivh MariaDB-*
```

You should see output such as the following:

```
Preparing...                                           ###### [100%]
1:MariaDB-shared                                     ##### [ 14%]
2:MariaDB-client                                     ##### [ 29%]
3:MariaDB-client                                     ##### [ 43%]
4:MariaDB-debuginfo                                  ##### [ 57%]
5:MariaDB-devel                                       ##### [ 71%]
6:MariaDB-server                                     ##### [ 86%]
```

PLEASE REMEMBER TO SET A PASSWORD FOR THE MariaDB root USER !

To do so, start the server, then issue the following commands:

```
/usr/bin/mysqladmin -u root password 'new-password'
/usr/bin/mysqladmin -u root -h hostname password 'new-password'
```

Alternatively you can run:

```
/usr/bin/mysql_secure_installation
```

which will also give you the option of removing the test databases and anonymous user created by default. This is strongly recommended for production servers.

See the MySQL manual for more instructions.

Please report any problems with the /usr/bin/mysqlbug script!

The latest information about MariaDB is available at <http://www.askmonty.org/>.

You can find additional information about the MySQL part at:

<http://dev.mysql.com>

Support MariaDB development by buying support/new features from

Monty Program Ab. You can contact us about this at [sales@askmonty.org](mailto:sales@askmonty.org).

Alternatively consider joining our community based development effort:

[http://askmonty.org/wiki/index.php/MariaDB#How\\_can\\_I\\_participate\\_in\\_the\\_development\\_of\\_MariaDB](http://askmonty.org/wiki/index.php/MariaDB#How_can_I_participate_in_the_development_of_MariaDB)

Starting MySQL....[ OK ]

Giving mysqld 2 seconds to start

```
7:MariaDB-test                                     ##### [100%]
```

Be sure to follow the instructions given in the preceding output and create a password for the root user either by using mysqladmin or by running the /usr/bin/mysql\_secure\_installation script.

Installing the MariaDB RPM files installs the MySQL tools in the

```
/usr/bin
directory. You can confirm that MariaDB has been installed by using the MySQL client program. Issuing the command
mysql
should give you the MariaDB cursor.
```

## See Also

- [Installing MariaDB with yum](#)
- [Troubleshooting MariaDB Installs on RedHat/CentOS](#)
- [Checking MariaDB RPM Package Signatures](#)

## 2.1.2.1.5 Checking MariaDB RPM Package Signatures

MariaDB RPM packages since [MariaDB 5.1.55](#) are signed.

The key we use has an id of

1BB943DB

and the key fingerprint is:

```
1993 69E5 404B D5FC 7D2F E43B CBCB 082A 1BB9 43DB
```

To check the signature you first need to import the public part of the key like so:

```
gpg --keyserver hkp://pgp.mit.edu --recv-keys 1BB943DB
```

Next you need to let pgp know about the key like so:

```
gpg --export --armour 1BB943DB > mariadb-signing-key.asc
sudo rpm --import mariadb-signing-key.asc
```

You can check to see if the key was imported with:

```
rpm -qa gpg-pubkey*
```

Once the key is imported, you can check the signature of the MariaDB RPM files by running the something like the following in your download directory:

```
rpm --checksig $(find . -name '*.rpm')
```

The output of the above will look something like this (make sure gpg shows up on each OK line):

```
me@desktop:~$ rpm --checksig $(find . -name '*.rpm')
./kvm-rpm-centos5-amd64/rpms/MariaDB-test-5.1.55-98.el5.x86_64.rpm: (sha1) dsa sha1 md5 gpg OK
./kvm-rpm-centos5-amd64/rpms/MariaDB-server-5.1.55-98.el5.x86_64.rpm: (sha1) dsa sha1 md5 gpg OK
./kvm-rpm-centos5-amd64/rpms/MariaDB-client-5.1.55-98.el5.x86_64.rpm: (sha1) dsa sha1 md5 gpg OK
./kvm-rpm-centos5-amd64/rpms/MariaDB-shared-5.1.55-98.el5.x86_64.rpm: (sha1) dsa sha1 md5 gpg OK
./kvm-rpm-centos5-amd64/rpms/MariaDB-devel-5.1.55-98.el5.x86_64.rpm: (sha1) dsa sha1 md5 gpg OK
./kvm-rpm-centos5-amd64/rpms/MariaDB-debuginfo-5.1.55-98.el5.x86_64.rpm: (sha1) dsa sha1 md5 gpg OK
./kvm-rpm-centos5-amd64/srpms/MariaDB-5.1.55-98.el5.src.rpm: (sha1) dsa sha1 md5 gpg OK
```

## See Also

- [Installing MariaDB RPM Files](#)
- [Troubleshooting MariaDB Installs on RedHat/CentOS](#)

## 2.1.2.1.6 Troubleshooting MariaDB Installs on Red Hat/CentOS

The following article is about different issues people have encountered when installing MariaDB on Red Hat / CentOS.

It is highly recommended to [install with yum](#) where possible.

In Red Hat / CentOS it is also possible to install a [RPM](#) or a [tar ball](#). The RPM is the preferred version, except if you want to install many versions of MariaDB or install MariaDB in a non standard location.

## Replacing MySQL

If you removed an MySQL RPM to install MariaDB, note that the MySQL RPM on uninstall renames /etc/my.cnf to /etc/my.cnf.rpmsave.

After installing MariaDB you should do the following to restore your configuration options:

```
mv /etc/my.cnf.rpmsave /etc/my.cnf
```

## Unsupported configuration options

If you are using any of the following options in your /etc/my.cnf or other my.cnf file you should remove them. This is also true for MySQL 5.1 or newer:

```
skip-bdb
```

## See also

- [Installing with yum \(recommended\)](#)
- [Installing MariaDB RPM Files](#)
- [Checking MariaDB RPM Package Signatures](#)

## 2.1.2.1.7 MariaDB for DirectAdmin Using RPMs

If you are using DirectAdmin and you encounter any issues with [Installing MariaDB with YUM](#), then the directions below may help. The process is very straightforward.

**Note:** Installing with YUM is preferable to installing the MariaDB RPM packages manually, so only do this if you are having issues such as:

```
Starting httpd:  
httpd:  
Syntax error on line 18 of /etc/httpd/conf/httpd.conf:  
Syntax error on line 1 of /etc/httpd/conf/extrahttpd-phpmodules.conf:  
Cannot load /usr/lib/apache/libphp5.so into server:  
libmysqlclient.so.18: cannot open shared object file: No such file or directory
```

Or:

```
Starting httpd:  
httpd:  
Syntax error on line 18 of /etc/httpd/conf/httpd.conf:  
Syntax error on line 1 of /etc/httpd/conf/extrahttpd-phpmodules.conf:  
Cannot load /usr/lib/apache/libphp5.so into server:  
/usr/lib/apache/libphp5.so: undefined symbol: client_errors
```

## RPM Installation

To install the RPMs, there is a quick and easy guide to [Installing MariaDB with the RPM Tool](#). Follow the instructions there.

## Necessary Edits

We do not want DirectAdmin's custombuild to remove/overwrite our MariaDB installation whenever an update is performed. To rectify this, disable automatic MySQL installation.

Edit

```
/usr/local/directadmin/custombuild/options.conf
```

Change:

```
mysql_inst=yes
```

To:

```
mysql_inst=no
```

**Note:** When MariaDB is installed manually (i.e. not using YUM), updates are not automatic. You will need to update the RPMs yourself.

## 2.1.2.1.8 MariaDB Installation (Version 10.1.21) via RPMs on CentOS 7

Here are the detailed steps for installing MariaDB (version 10.1.21) via RPMs on CentOS 7.

The RPM's needed for the installation are all available on the MariaDB website and are given below:

- jemalloc-3.6.0-1.el7.x86\_64.rpm
- MariaDB-10.1.21-centos7-x86\_64-client.rpm
- MariaDB-10.1.21-centos7-x86\_64-compat.rpm
- galera-25.3.19-1.rhel7.el7.centos.x86\_64.rpm
- jemalloc-devel-3.6.0-1.el7.x86\_64.rpm
- MariaDB-10.1.21-centos7-x86\_64-common.rpm
- MariaDB-10.1.21-centos7-x86\_64-server.rpm

Step by step installation:

- 1) First install all of the dependencies needed. Its easy to do this via YUM packages: yum install rsync nmap lsof perl-DBI nc
- 2) rpm -ivh jemalloc-3.6.0-1.el7.x86\_64.rpm
- 3) rpm -ivh jemalloc-devel-3.6.0-1.el7.x86\_64.rpm
- 4) rpm -ivh MariaDB-10.1.21-centos7-x86\_64-common.rpm MariaDB-10.1.21-centos7-x86\_64-compat.rpm MariaDB-10.1.21-centos7-x86\_64-client.rpm galera-25.3.19-1.rhel7.el7.centos.x86\_64.rpm MariaDB-10.1.21-centos7-x86\_64-server.rpm

While installing MariaDB-10.1.21-centos7-x86\_64-common.rpm there might be a conflict with older MariaDB packages. we need to remove them and install the original rpm again.

Here is the error message for dependencies:

```
# rpm -ivh MariaDB-10.1.21-centos7-x86_64-common.rpm
warning: MariaDB-10.1.21-centos7-x86_64-common.rpm: Header V4 DSA/SHA1 Signature, key ID 1bb943db: NOKEY
error: Failed dependencies:
        mariadb-libs < 1:10.1.21-1.el7.centos conflicts with MariaDB-common-10.1.21-1.el7.centos.x86_64
```

Solution: search for this package:

```
# rpm -qa | grep mariadb-libs
mariadb-libs-5.5.52-1.el7.x86_64
```

Remove this package:

```
# rpm -ev --nodeps mariadb-libs-5.5.52-1.el7.x86_64
Preparing packages...
mariadb-libs-1:5.5.52-1.el7.x86_64
```

While installing the Galera package there might be a conflict in installation for a dependency package. Here is the error message:

```
[root@centos-2 /]# rpm -ivh galera-25.3.19-1.rhel7.el7.centos.x86_64.rpm
error: Failed dependencies:
        libboost_program_options.so.1.53.0()(64bit) is needed by galera-25.3.19-1.rhel7.el7.centos.x86_64

The dependencies for Galera package is: libboost_program_options.so.1.53.0
```

Solution:

```
yum install boost-devel.x86_64
```

Another warning message while installing Galera package is as shown below:

```
warning: galera-25.3.19-1.rhel7.el7.centos.x86_64.rpm: Header V4 DSA/SHA1 Signature, key ID 1bb943db: NOKEY
```

The solution for this is to import the key:

```
#rpm --import http://yum.mariadb.org/RPM-GPG-KEY-MariaDB
```

After step 4, the installation will be completed. The last step will be to run [mysql\\_secure\\_installation](#) to secure the production server by dis allowing remote login for root, creating root password and removing the test database.

- 5) mysql\_secure\_installation

## 2.1.2.1.9 Why Source RPMs (SRPMs) Aren't Packaged For Some Platforms

MariaDB source RPMs (SRPMs) are not packaged on all platforms for which MariaDB RPMs are packaged.

The reason is that MariaDB's build process relies heavily on

[cmake](#)

for a lot of things. In this specific case, MariaDB's build process relies on [CMake CPack Package Generators](#) to build RPMs. The specific package generator that it uses to build RPMs is called

[CPackRPM](#)

Support for source RPMs in

[CPackRPM](#)

became usable with MariaDB's build system starting from around [cmake 3.10](#). This means that we do not produce source RPMs on platforms where the installed

[cmake](#)

version is older than that.

See also [Building MariaDB from a Source RPM](#).

## 2.1.2.1.10 Building MariaDB from a Source RPM

For some distributions you can build MariaDB from a source RPM. (See also [Why Source RPMs \(SRPMs\) Aren't Packaged For Some Platforms](#)).

You can build it as follows:

### using dnf

On RHEL8 you might need to start with:

```
sudo dnf config-manager --set-enabled codeready-builder-beta-for-rhel-8-x86_64-rpms
```

Then, on all dnf distributions:

```
sudo dnf install rpm-build perl-generators
dnf download --source MariaDB
sudo dnf builddep MariaDB-*.src.rpm
rpmbuild --rebuild MariaDB-*.src.rpm
```

### using yum

```
sudo yum install rpm-build yum-utils
yumdownloader --source MariaDB
sudo yum-builddep MariaDB-*.src.rpm
rpmbuild --rebuild MariaDB-*.src.rpm
```

### using zypper

```
sudo zypper in rpm-build
sudo zypper si MariaDB
sudo rpmbuild -bb /usr/src/packages/SPECS/MariaDB.spec
```

Or (to avoid building as root):

```
sudo zypper in rpm-build
sudo zypper si -d MariaDB
zypper --pkg-cache-dir=`pwd` si --download-only MariaDB
rpmbuild --rebuild mariadb/srpms/MariaDB-*.src.rpm
```

## Installing MariaDB with APT

On Debian, Ubuntu, and other similar Linux distributions, it is highly recommended to install the relevant

.deb

packages from MariaDB's repository using

apt

`aptitude`

, [Ubuntu Software Center](#) , [Synaptic Package Manager](#) , or another package manager.

This page walks you through the simple installation steps using

`apt`

## Adding the MariaDB APT repository

We currently have APT repositories for the following Linux distributions:

- Debian 9 (Jessie)
- Debian 10 (Buster)
- Debian Unstable (Sid)
- Ubuntu 18.04 LTS (Bionic)
- Ubuntu 20.04 LTS (Focal)
- Ubuntu 20.10 (Groovy)
- Ubuntu 21.04 (Hirsute)

## Using the MariaDB Package Repository Setup Script

If you want to install MariaDB with

`apt`

, then you can configure

`apt`

to install from MariaDB Corporation's MariaDB Package Repository by using the [MariaDB Package Repository setup script](#) .

MariaDB Corporation provides a MariaDB Package Repository for several Linux distributions that use

`apt`

to manage packages. This repository contains software packages related to MariaDB Server, including the server itself, [clients and utilities](#) , [client libraries](#) , [plugins](#) , and [Mariabackup](#) . The MariaDB Package Repository setup script automatically configures your system to install packages from the MariaDB Package Repository.

To use the script, execute the following command:

```
curl -sS https://downloads.mariadb.com/MariaDB/mariadb_repo_setup | sudo bash
```

Note that this script also configures a repository for [MariaDB MaxScale](#) and a repository for MariaDB Tools, which currently only contains [Percona XtraBackup](#) and its dependencies.

See [MariaDB Package Repository Setup and Usage](#) for more information.

## Using the MariaDB Repository Configuration Tool

If you want to install MariaDB with

`apt`

, then you can configure

`apt`

to install from MariaDB Foundation's MariaDB Repository by using the [MariaDB Repository Configuration Tool](#) .

The MariaDB Foundation provides a MariaDB repository for several Linux distributions that use

`apt-get`

to manage packages. This repository contains software packages related to MariaDB Server, including the server itself, [clients and utilities](#) , [client libraries](#) , [plugins](#) , and [Mariabackup](#) . The MariaDB Repository Configuration Tool can easily generate the appropriate commands to add the repository for your distribution.

There are several ways to add the repository.

Executing add-apt-repository

One way to add an

`apt`

repository is by using the

`add-apt-repository`

command. This command will add the repository configuration to  
`/etc/apt/sources.list`

For example, if you wanted to use the repository to install [MariaDB 10.3](#) on Ubuntu 18.04 LTS (Bionic), then you could use the following commands to add

the MariaDB

apt  
repository:

```
sudo apt-get install software-properties-common
sudo add-apt-repository 'deb [arch=amd64,arm64,ppc64el] http://sfo1.mirrors.digitalocean.com/mariadb/repo/10.3/ubuntu bionic main'
```

And then you would have to update the package cache by executing the following command:

```
sudo apt update
```

## Creating a Source List File

Another way to add an

apt  
repository is by creating a [source list](#) file in  
`/etc/apt/sources.list.d/`

For example, if you wanted to use the repository to install [MariaDB 10.3](#) on Ubuntu 18.04 LTS (Bionic), then you could create the

MariaDB.list  
file in  
`/etc/apt/sources.list.d/`  
with the following contents to add the MariaDB  
apt  
repository:

```
# MariaDB 10.3 repository list - created 2019-01-27 09:50 UTC
# http://downloads.mariadb.org/mariadb/repositories/
deb [arch=amd64,arm64,ppc64el] http://sfo1.mirrors.digitalocean.com/mariadb/repo/10.3/ubuntu bionic main
deb-src http://sfo1.mirrors.digitalocean.com/mariadb/repo/10.3/ubuntu bionic main
```

And then you would have to update the package cache by executing the following command:

```
sudo apt update
```

## Using Ubuntu Software Center

Another way to add an

apt  
repository is by using [Ubuntu Software Center](#).

You can do this by going to the **Software Sources** window. This window can be opened either by navigating to **Edit > Software Sources** or by navigating to **System > Administration > Software Sources**.

Once the **Software Sources** window is open, go to the **Other Software** tab, and click the **Add** button. At that point, you can input the repository information provided by the [MariaDB Repository Configuration Tool](#).

See [here](#) for more information.

## Using Synaptic Package Manager

Another way to add an

apt  
repository is by using [Synaptic Package Manager](#).

You can do this by going to the **Software Sources** window. This window can be opened either by navigating to **System > Administrator > Software Sources** or by navigating to **Settings > Repositories**.

Once the **Software Sources** window is open, go to the **Other Software** tab, and click the **Add** button. At that point, you can input the repository information provided by the [MariaDB Repository Configuration Tool](#).

See [here](#) for more information.

## Pinning the MariaDB Repository to a Specific Minor Release

If you wish to pin the

apt  
repository to a specific minor release, or if you would like to downgrade to a specific minor release, then you can create a  
apt  
repository with the URL hard-coded to that specific minor release.

The MariaDB Foundation archives repositories of old minor releases at the following URL:

- <http://archive.mariadb.org/>

Archives are only of the distros and architectures supported at the time of release. For example [MariaDB 10.0.38](#) exists for Ubuntu

```
precise
,
trusty
,
xenial
,
wily
, and
yakkety
```

obtained looking in <https://archive.mariadb.org/mariadb-10.0.38/repo/ubuntu/dists>.

For example, if you wanted to pin your repository to [MariaDB 10.5.9](#) on Ubuntu 20.04 LTS (Focal), then you would have to first remove any existing MariaDB repository source list file from

```
/etc/apt/sources.list.d/
. And then you could use the following commands to add the MariaDB
apt-get
repository:
```

```
sudo add-apt-repository 'deb [arch=amd64,arm64,ppc64el,s390x] http://archive.mariadb.org/mariadb-10.5.9/repo/ubuntu/ focal main'
```

Ensure you have the [signing key installed](#).

Ubuntu Xenial and older will need:

```
sudo apt-get install -y apt-transport-https
```

And then you would have to update the package cache by executing the following command:

```
sudo apt update
```

## Updating the MariaDB APT repository to a New Major Release

MariaDB's

```
apt
repository can be updated to a new major release. How this is done depends on how you originally configured the repository.
```

### Updating the Major Release with the MariaDB Package Repository Setup Script

If you configured

```
apt
to install from MariaDB Corporation's MariaDB Package Repository by using the MariaDB Package Repository setup script, then you can update the major release that the repository uses by running the script again.
```

### Updating the Major Release with the MariaDB Repository Configuration Tool

If you configured

```
apt
to install from MariaDB Foundation's MariaDB Repository by using the MariaDB Repository Configuration Tool, then you can update the major release in various ways, depending on how you originally added the repository.
```

Updating a Repository with add-apt-repository

If you added the

```
apt
repository by using the
add-apt-repository
```

command, then you can update the major release that the repository uses by using the the

```
add-apt-repository
```

command again.

First, look for the repository string for the old version in

```
/etc/apt/sources.list
```

And then, you can remove the repository for the old version by executing the

```
add-apt-repository
```

command and providing the

```
--remove
```

option. For example, if you wanted to remove a [MariaDB 10.2](#) repository, then you could do so by executing something like the following:

```
sudo add-apt-repository --remove 'deb [arch=amd64,arm64,ppc64el] http://sfo1.mirrors.digitalocean.com/mariadb/repo/10.2/ubuntu b'.
```

After that, you can add the repository for the new version with the

```
add-apt-repository
```

command. For example, if you wanted to use the repository to install [MariaDB 10.3](#) on Ubuntu 18.04 LTS (Bionic), then you could use the following commands to add the MariaDB

```
apt
```

```
repository:
```

```
sudo apt-get install software-properties-common  
sudo add-apt-repository 'deb [arch=amd64,arm64,ppc64el] http://sfo1.mirrors.digitalocean.com/mariadb/repo/10.3/ubuntu bionic mai'.
```

And then you would have to update the package cache by executing the following command:

```
sudo apt update
```

After that, the repository should refer to [MariaDB 10.3](#).

Updating a Source List File

If you added the

```
apt
```

```
repository by creating a source list file in
```

```
/etc/apt/sources.list.d/
```

, then you can update the major release that the repository uses by updating the source list file in-place. For example, if you wanted to change the repository from [MariaDB 10.2](#) to [MariaDB 10.3](#), and if the source list file was at

```
/etc/apt/sources.list.d/MariaDB.list  
, then you could execute the following:
```

```
sudo sed -i 's/10.2/10.3/' /etc/apt/sources.list.d/MariaDB.list
```

And then you would have to update the package cache by executing the following command:

```
sudo apt update
```

After that, the repository should refer to [MariaDB 10.3](#).

## Importing the MariaDB GPG Public Key

Before MariaDB can be installed, you also have to import the GPG public key that is used to verify the digital signatures of the packages in our repositories. This allows the

```
apt
```

```
utility to verify the integrity of the packages that it installs.
```

- Prior to Debian 9 (Stretch), and Debian Unstable (Sid), and Ubuntu 16.04 LTS (Xenial), the id of our GPG public key is 0xcbcb082a1bb943db. The full key fingerprint is:

```
1993 69E5 404B D5FC 7D2F E43B CBCB 082A 1BB9 43DB
```

The

```
apt-key
```

utility can be used to import this key. For example:

```
sudo apt-key adv --recv-keys --keyserver hkp://keyserver.ubuntu.com:80 0xcbcb082a1bb943db
```

- Starting with Debian 9 (Stretch) and Ubuntu 16.04 LTS (Xenial), the id of our GPG public key is 0xF1656F24C74CD1D8 . The full key fingerprint is:

```
177F 4010 FE56 CA33 3630 0305 F165 6F24 C74C D1D8
```

The

[apt-key](#)

utility can be used to import this key. For example:

```
sudo apt-key adv --recv-keys --keyserver hkp://keyserver.ubuntu.com:80 0xF1656F24C74CD1D8
```

Starting with Debian 9 (Stretch), the

[dirmngr](#)

package needs to be installed before the GPG public key can be imported. To install it, execute:

```
sudo apt install dirmngr
```

If you are unsure which GPG public key you need, then it is perfectly safe to import both keys.

The command used to import the GPG public key is the same on both Debian and Ubuntu. For example:

```
$ sudo apt-key adv --recv-keys --keyserver hkp://keyserver.ubuntu.com:80 0xcbcb082a1bb943db
Executing: gpg --ignore-time-conflict --no-options --no-default-keyring --secret-keyring /tmp/tmp.ASyOPV87XC --trustdb-name /etc
gpg: requesting key 1BB943DB from hkp server keyserver.ubuntu.com
gpg: key 1BB943DB: "MariaDB Package Signing Key <package-signing-key@mariadb.org>" imported
gpg: no ultimately trusted keys found
gpg: Total number processed: 1
gpg:           imported: 1
```

Once the GPG public key is imported, you are ready to install packages from the repository.

## Installing MariaDB Packages with APT

After the

[apt](#)

repository is configured, you can install MariaDB by executing the

[apt-get](#)

command. The specific command that you would use would depend on which specific packages that you want to install.

### Installing the Most Common Packages with APT

To Install the most common packages, first you would have to update the package cache by executing the following command:

```
sudo apt update
```

MariaDB starting with 10.4

In [MariaDB 10.4](#) and later, to Install the most common packages, execute the following command:

```
sudo apt-get install mariadb-server galera-4 mariadb-client libmariadb3 mariadb-backup mariadb-common
```

MariaDB 10.2 - 10.3

In [MariaDB 10.2](#) and [MariaDB 10.3](#) , to Install the most common packages, execute the following command:

```
sudo apt-get install mariadb-server galera mariadb-client libmariadb3 mariadb-backup mariadb-common
```

MariaDB until 10.1

In [MariaDB 10.1](#) and before, to Install the most common packages, execute the following command:

```
sudo apt-get install mariadb-server galera mariadb-client libmysqlclient18 mariadb-backup mariadb-common
```

## Installing MariaDB Server with APT

To Install MariaDB Server, first you would have to update the package cache by executing the following command:

```
sudo apt update
```

Then, execute the following command:

```
sudo apt-get install mariadb-server
```

## Installing MariaDB Galera Cluster with APT

The process to install MariaDB Galera Cluster with the MariaDB

```
apt-get  
repository
```

is practically the same as installing standard MariaDB Server.

In [MariaDB 10.1](#) and later, Galera Cluster support has been included in the standard MariaDB Server packages, so you will need to install the  
`mariadb-server`  
package, as you normally would.

In [MariaDB 10.4](#) and later, you also need to install the

```
galera-4  
package
```

to obtain the [Galera 4 wsrep provider library](#).

In [MariaDB 10.3](#) and before, you also need to install the

```
galera-3  
package
```

to obtain the [Galera 3 wsrep provider library](#).

To install MariaDB Galera Cluster, first you would have to update the package cache by executing the following command:

```
sudo apt update
```

### MariaDB starting with 10.4

In [MariaDB 10.4](#) and later, to install MariaDB Galera Cluster, you could execute the following command:

```
sudo apt-get install mariadb-server mariadb-client galera-4
```

### MariaDB until 10.3

In [MariaDB 10.3](#) and before, to install MariaDB Galera Cluster, you could execute the following command:

```
sudo apt-get install mariadb-server mariadb-client galera-3
```

MariaDB Galera Cluster also has a separate package that can be installed on arbitrator nodes. In [MariaDB 10.4](#) and later, the package is called

```
galera-arbitrator-4
```

In [MariaDB 10.3](#) and before, the package is called

```
galera-arbitrator-3
```

. This package should be installed on whatever node you want to serve as the arbitrator. It can either run on a separate server that is not acting as a cluster node, which is the recommended configuration, or it can run on a server that is also acting as an existing cluster node.

### MariaDB starting with 10.4

In [MariaDB 10.4](#) and later, to install the arbitrator package, you could execute the following command:

```
sudo apt-get install galera-arbitrator-4
```

### MariaDB until 10.3

In [MariaDB 10.3](#) and before, to install the arbitrator package, you could execute the following command:

```
sudo apt-get install galera-arbitrator-3
```

See [MariaDB Galera Cluster](#) for more information on MariaDB Galera Cluster.

## Installing MariaDB Clients and Client Libraries with APT

In [MariaDB 10.2](#) and later, [MariaDB Connector/C](#) has been included as the client library.

To Install the clients and client libraries, first you would have to update the package cache by executing the following command:

```
sudo apt update
```

Then, in [MariaDB 10.2](#) and later, execute the following command:

```
sudo apt-get install mariadb-client libmariadb3
```

Or in [MariaDB 10.1](#) and before, execute the following command:

```
sudo apt-get install mariadb-client libmysqlclient18
```

## Installing Mariabackup with APT

To install [Mariabackup](#), first you would have to update the package cache by executing the following command:

```
sudo apt update
```

Then, execute the following command:

```
sudo apt-get install mariadb-backup
```

## Installing Plugins with APT

Some [plugins](#) may also need to be installed.

For example, to install the

```
cracklib_password_check
```

password validation plugin, first you would have to update the package cache by executing the following command:

```
sudo apt update
```

Then, execute the following command:

```
sudo apt-get install mariadb-cracklib-password-check
```

## Installing Older Versions from the Repository

The MariaDB

```
apt
```

repository contains the last few versions of MariaDB. To show what versions are available, use the

```
apt-cache
```

command:

```
sudo apt-cache showpkg mariadb-server
```

In the output you will see the available versions.

To install an older version of a package instead of the latest version we just need to specify the package name, an equal sign, and then the version number.

However, when installing an older version of a package, if

```
apt-get
```

has to install dependencies, then it will automatically choose to install the latest versions of those packages. To ensure that all MariaDB packages are on the same version in this scenario, it is necessary to specify them all. Therefore, to install [MariaDB 10.3.14](#) from this

```
apt
```

repository, we would do the following:

```
sudo apt-get install mariadb-server=10.3.14-1 mariadb-client=10.3.14-1 libmariadb3=10.3.14-1 mariadb-backup=10.3.14-1 mariadb-co
```

The rest of the install and setup process is as normal.

## Installing MariaDB with dpkg

While it is not recommended, it is possible to download and install the

```
.deb  
packages manually. However, it is generally recommended to use a package manager like  
apt-get
```

A tarball that contains the

```
.deb  
packages can be downloaded from the following URL:
```

- <https://downloads.mariadb.com>

For example, to install the [MariaDB 10.4.8](#)

```
.deb  
packages on Ubuntu 18.04 LTS (Bionic), you could execute the following:
```

```
sudo apt-get update  
sudo apt-get install libdbi-perl libdbd-mysql-perl psmisc libaio1 socat  
wget https://downloads.mariadb.com/MariaDB/mariadb-10.4.8/repo/ubuntu/mariadb-10.4.8-ubuntu-bionic-amd64-debs.tar  
tar -xvf mariadb-10.4.8-ubuntu-bionic-amd64-debs.tar  
cd mariadb-10.4.8-ubuntu-bionic-amd64-debs/  
sudo dpkg --install ./mariadb-common*.deb \  
./mysql-common*.deb \  
./mariadb-client*.deb \  
./libmariadb3*.deb \  
./libmysqlclient18*.deb  
sudo dpkg --install ./mariadb-server*.deb \  
./mariadb-backup*.deb \  
./galera-4*.deb
```

## After Installation

After the installation is complete, you can [start MariaDB](#).

If you are using [MariaDB Galera Cluster](#), then keep in mind that the first node will have to be [bootstrapped](#).

## Installation Issues

MariaDB starting with 5.5

### Upgrading

mariadb-server  
and  
mariadb-client  
packages

As noted in [MDEV-4266](#), the

```
mariadb-server  
and  
mariadb-client  
packages have a minor upgrade issue if you use '  
apt-get install mariadb-server  
' or '  
apt-get install mariadb-client  
' to upgrade them instead of the more common '  
apt-get upgrade  
'. This is because those two packages depend on  
mariadb-server-5.5  
and  
mariadb-client-5.5  
with no specific version of those packages. For example, if you have the  
mariadb-server
```

package installed, version 5.5.29 and you install version 5.5.30 of that package it will not automatically upgrade the mariadb-server-5.5 package to version 5.5.30 like you would expect because the 5.5.29 version of that package satisfies the dependency.

The

```
mariadb-server  
and  
mariadb-client  
packages are virtual packages, they only exist to require the installation of the  
mariadb-server-5.5  
and  
mariadb-client-5.5  
packages, respectively. MariaDB will function normally with a, for example, version 5.5.30 version of the  
mariadb-server  
package and a version 5.5.29 version of the  
mariadb-server-5.5  
package. No data is at risk. However, expected behavior is for '  
apt-get install mariadb-server  
' to upgrade everything to the latest version (if a new version is available), so this is definitely a bug.
```

A fix is planned for this bug in a future version of MariaDB. In the mean time, when upgrading MariaDB, use '

```
apt-get upgrade  
' or '  
apt-get install mariadb-server-5.5  
'
```

## MariaDB 5.1 - 5.5

### Version Mismatch Between MariaDB and Ubuntu/Debian Repositories

As mentioned [here](#) (and in [MDEV-4080](#) and [MDEV-3882](#)) sometimes APT will refuse to install MariaDB. Or, if MariaDB is already installed, suggest the removal of MariaDB to apply an upgrade to the

```
mysql-common  
or  
libmysqlclient  
packages. This happens whenever the version number of those two packages is higher in the distribution repositories than the versions in the MariaDB repositories. Most MariaDB packages have different names than their MySQL counterparts, but in order for upgrades from MySQL to MariaDB to be successful in APT, those two packages must be named the same. Because they have the same names, APT just checks the version numbers and tries to install what it considers to be the most recent.
```

It is rare for the version numbers of

```
mysql-common  
or  
libmysqlclient  
to be higher in the official Ubuntu or Debian repositories than they are in the MariaDB repositories, but it has happened. Whenever it has it has been because of critical bug fix releases for bugs that existed in the version of MySQL in the distribution repositories but which had already been fixed in the version of MariaDB in the MariaDB repositories.
```

If a situation as described above exists when you try to install MariaDB you will get an error like this:

```
The following packages have unmet dependencies:  
mariadb-server : Depends: mariadb-server-5.5 but it is not going to be installed  
E: Unable to correct problems, you have held broken packages.
```

There are three primary ways of fixing this issue:

1. [Pinning the MariaDB Repository](#)
2. [Specifying Specific Versions to Install](#)
3. [Holding Packages](#)

Click on the links above to jump to directions for each (or simply scroll down).

#### Pinning the MariaDB Repository

It is possible to *pin* the MariaDB repository used so the packages it provides will always have an higher priority over the ones from the system repositories.

This is done by creating a file with the '

```
.pref  
' extension under'  
/etc/apt/preferences.d/  
' with the following contents:
```

```
Package: *  
Pin: origin <mirror-domain>  
Pin-Priority: 1000
```

```
Replace '  
<mirror-domain>  
' with the domain name of the MariaDB mirror you use. For example '  
ftp.osuosl.org  
'
```

## Specifying Specific Versions to Install

A way to fix this is to specify the exact version of the two packages that you want to install. To do this, first determine the full version numbers of the affected packages. An easy way to do so is with

```
'apt-cache show'  
:  
  
apt-cache show mysql-common | grep Version  
apt-cache show libmysqlclient18 | grep Version
```

For each of the above you will be given a list of versions. The ones in the MariaDB repositories will have "mariadb" in the version strings and are the ones you want. With the version numbers in hand you will be able to install MariaDB by explicitly specifying the version numbers like so:

```
apt-get install mariadb-server-5.5 mariadb-client-5.5 \  
libmysqlclient18=<version-number> \  
mysql-common=<version-number>
```

Replace the two instances of

```
<version-number>  
in the example above with the actual version number of MariaDB that you want to install.
```

Even after having installed these specific packages versions, running '

```
apt-get dist-upgrade  
' will still try to upgrade the packages to the highest version available.
```

## Holding Packages

After MariaDB is installed, and as long as the version number issue exists, an '

```
apt-get dist-upgrade  
' will try to remove MariaDB in order to install the "upgraded"  
libmysqlclient  
and  
mysql-common  
packages. To prevent this from happening you can hold them so that apt doesn't try to upgrade them. To do so, open a terminal, become root with '  
sudo -s  
' , and then enter the following:
```

```
echo libmysqlclient18 hold | dpkg --set-selections  
echo mysql-common hold | dpkg --set-selections
```

The holds will prevent you from upgrading MariaDB, so when you want to remove the holds, open a terminal, become root with '

```
sudo -s  
' , and then enter the following:
```

```
echo libmysqlclient18 install | dpkg --set-selections  
echo mysql-common install | dpkg --set-selections
```

You will then be able to upgrade MariaDB as normal (e.g. with '

```
sudo apt-get update; sudo apt-get upgrade  
').
```

# Available DEB Packages

The available DEB packages depend on the specific MariaDB release series.

## Available DEB Packages in MariaDB 10.4

MariaDB starting with [10.4](#)

In [MariaDB 10.4](#) , the following DEBs are available:

Package Name	Description
--------------	-------------

galera-4	The WSREP provider for <a href="#">Galera 4</a> .
libmariadb3	Dynamic client libraries.
libmariadb-dev	Development headers and static libraries.
libmariadbclient18	Virtual package to satisfy external depends
libmysqlclient18	Virtual package to satisfy external depends
mariadb-backup	<a href="#">Mariabackup</a>
mariadb-client	Client tools like <code>mysql</code> CLI, <code>mysqldump</code> , and others.
mariadb-client-core	Core client tools
mariadb-common	Character set files and <code>/etc/my.cnf</code>
mariadb-plugin-connect	The <code>CONNECT</code> storage engine.
mariadb-plugin-cracklib-password-check	The <code>cracklib_password_check</code> password validation plugin.
mariadb-plugin-gssapi-client	The client-side component of the <code>gssapi</code> authentication plugin.
mariadb-plugin-gssapi-server	The server-side component of the <code>gssapi</code> authentication plugin.
mariadb-plugin-rocksdb	The <a href="#">MyRocks</a> storage engine.
mariadb-plugin-spider	The <code>SPIDER</code> storage engine.
mariadb-plugin-tokudb	The <a href="#">TokuDB</a> storage engine.

mariadb-server	The server and server tools, like <code>myisamchk</code> and <code>mysqlhotcopy</code> are here.
mariadb-server-core	The core server.
mariadb-test	<code>mysql-client-test</code> executable, and <b>mysql-test</b> framework with the tests.
mariadb-test-data	MariaDB database regression test suite - data files

## Available DEB Packages in MariaDB 10.2 and MariaDB 10.3

MariaDB starting with 10.2

In MariaDB 10.2 and MariaDB 10.3 , the following DEBs are available:

Package Name	Description
galera	The WSREP provider for Galera 3.
libmariadb3	Dynamic client libraries.
libmariadb-dev	Development headers and static libraries.
libmariadbclient18	Virtual package to satisfy external depends
libmysqlclient18	Virtual package to satisfy external depends
mariadb-backup	<b>Mariabackup</b>
mariadb-client	Client tools like <code>mysql</code> CLI, <code>mysqldump</code> , and others.
mariadb-client-core	Core client tools
mariadb-common	Character set files and <code>/etc/my.cnf</code>
mariadb-plugin-connect	The <code>CONNECT</code> storage engine.
mariadb-plugin-cracklib-password-check	The <code>cracklib_password_check</code> password validation plugin.

<code>mariadb-plugin-gssapi-client</code>	The client-side component of the <code>gssapi</code> authentication plugin.
<code>mariadb-plugin-gssapi-server</code>	The server-side component of the <code>gssapi</code> authentication plugin.
<code>mariadb-plugin-rocksdb</code>	The <code>MyRocks</code> storage engine.
<code>mariadb-plugin-spider</code>	The <code>SPIDER</code> storage engine.
<code>mariadb-plugin-tokudb</code>	The <code>TokuDB</code> storage engine.
<code>mariadb-server</code>	The server and server tools, like <code>myisamchk</code> and <code>mysqlhotcopy</code> are here.
<code>mariadb-server-core</code>	The core server.
<code>mariadb-test</code>	<code>mysql-client-test</code> executable, and <code>mysql-test</code> framework with the tests.
<code>mariadb-test-data</code>	MariaDB database regression test suite - data files

## Available DEB Packages in MariaDB 10.1

MariaDB starting with [10.1](#)

In [MariaDB 10.1](#), the following DEBs are available:

Package Name	Description
<code>galera</code>	The WSREP provider for <a href="#">Galera 3</a> .
<code>libmysqlclient18</code>	Dynamic client libraries.
<code>mariadb-backup</code>	<a href="#">Mariabackup</a>
<code>mariadb-client</code>	Client tools like <code>mysql</code> CLI, <code>mysqldump</code> , and others.
<code>mariadb-client-core</code>	Core client tools
<code>mariadb-common</code>	Character set files and <code>/etc/my.cnf</code>

mariadb-plugin-connect	The  CONNECT  storage engine.
mariadb-plugin-cracklib-password-check	The  cracklib_password_check  password validation plugin.
mariadb-plugin-gssapi-client	The client-side component of the  gssapi  authentication plugin.
mariadb-plugin-gssapi-server	The server-side component of the  gssapi  authentication plugin.
mariadb-plugin-spider	The  SPIDER  storage engine.
mariadb-plugin-tokudb	The TokuDB storage engine.
mariadb-server	The server and server tools, like myisamchk and mysqlhotcopy are here.
mariadb-server-core	The core server.
mariadb-test	mysql-client-test executable, and mysql-test framework with the tests.
mariadb-test-data	MariaDB database regression test suite - data files

## Available DEB Packages in MariaDB 5.5

MariaDB starting with 5.5

In MariaDB 5.5 , the following DEBs are available:

Package Name	Description
libmysqlclient18	Dynamic client libraries.
mariadb-client	Client tools like  mysql CLI, mysqldump , and others.
mariadb-client-core	Core client tools
mariadb-common	Character set files and  /etc/my.cnf

mariadb-server	The server and server tools, like <code>myisamchk</code> and <code>mysqlhotcopy</code> are here.
mariadb-server-core	The core server.
mariadb-test	<code>mysql-client-test</code> executable, and <b>mysql-test</b> framework with the tests.
mariadb-test-data	MariaDB database regression test suite - data files

## Actions Performed by DEB Packages

### Users and Groups Created

When the

`mariadb-server`  
DEB package is installed, it will create a user and group named  
`mysql`, if they do not already exist.

## 2.1.2.3 Installing MariaDB MSI Packages on Windows

MSI packages are available for both x86 (32 bit) and x64 (64 bit) processor architectures. We'll use screenshots from an x64 installation below (the 32 bit installer is very similar).

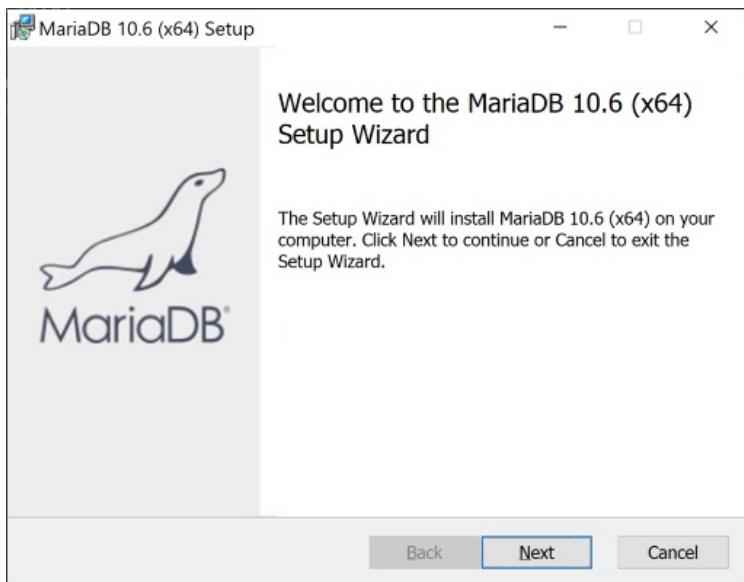

### Contents

1. Installation UI
  1. Welcome
  2. License Agreement
  3. Custom Setup
  4. Database Authentication/Security Related Properties
  5. Other Database Properties
  6. Ready to Install
  7. End
2. New Entries in Start Menu
3. Uninstall UI
4. Silent Installation
  1. Properties
  2. Features
  3. Silent Installation Examples
  4. Silent Uninstall
5. Installation Logs
6. Running 32 and 64 Bit Distributions on the Same Machine

### Installation UI

This is the typical mode of installation. To start the installer, just click on the `mariadb-<major>.<minor>.<patch>.msi`

### Welcome

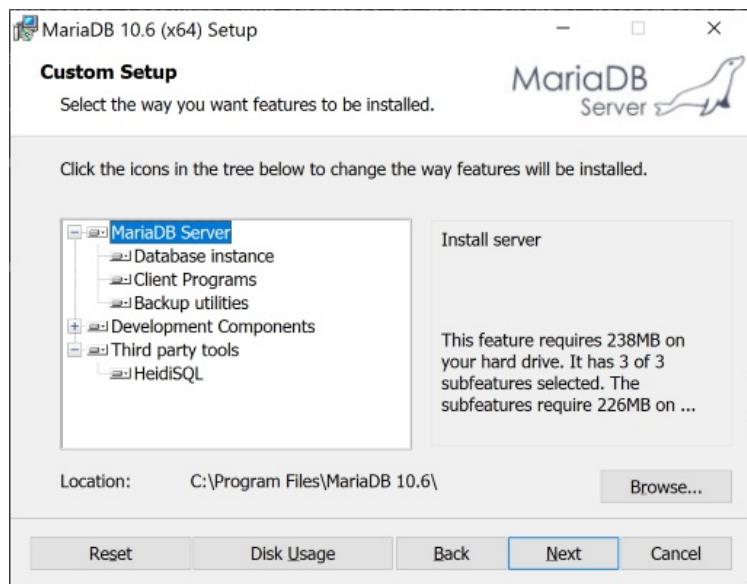

## License Agreement

Click on "I accept the terms"

## Custom Setup

Here, you can choose what features to install. By default, all features are installed with the exception of the debug symbols. If the "Database instance" feature is selected, the installer will create a database instance, by default running as a service. In this case the installer will present additional dialogs to control various database properties. Note that you do not necessarily have to create an instance at this stage. For example, if you already have MySQL or

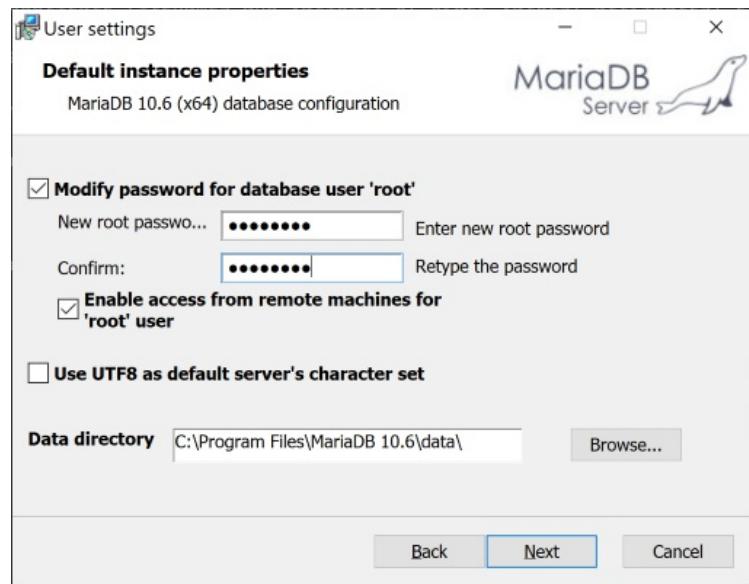

MariaDB databases running as services, you can just upgrade them during the installation. Also, you can create additional database instances after the installation, with the

`mysql_install_db.exe`

utility.

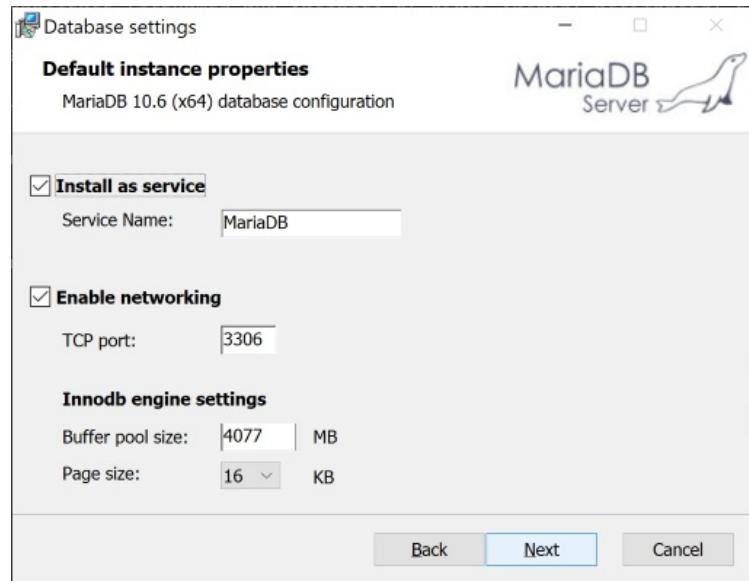

**NOTE :** By default, if you install a database instance, the data directory will be in the "data" folder under the installation root. To change the data directory location, select "Database instance" in the feature tree, and use the "Browse" button to point to another place.

## Database Authentication/Security Related Properties

This dialog is shown if you selected the "Database instance" feature. Here, you can set the password for the "root" database user and specify whether root can access database from remote machines. The "Create anonymous account" setting allows for anonymous (non-authenticated) users. It is off by default and it is not recommended to change this setting.

## Other Database Properties

- Install as service

Defines whether the database should be run as a service. If it should be run as a service, then it also defines the service name. It is recommended to run your database instance as a service as it greatly simplifies database management. In [MariaDB 10.4](#) and later, the default service name used by the MSI installer is "MariaDB". In 10.3 and before, the default service name used by the MSI installer is "MySQL". Note that the default service name for the

`--install`

and

--install-manual

options for  
mysqld.exe  
is "MySQL" in all versions of MariaDB.

- Enable Networking

Whether to enable TCP/IP (recommended) and which port MariaDB should listen to. If security is a concern, you can change the [bind-address](#) parameter post-installation to bind to only local addresses. If the "Enable networking" checkbox is deselected, the database will use named pipes for communication.

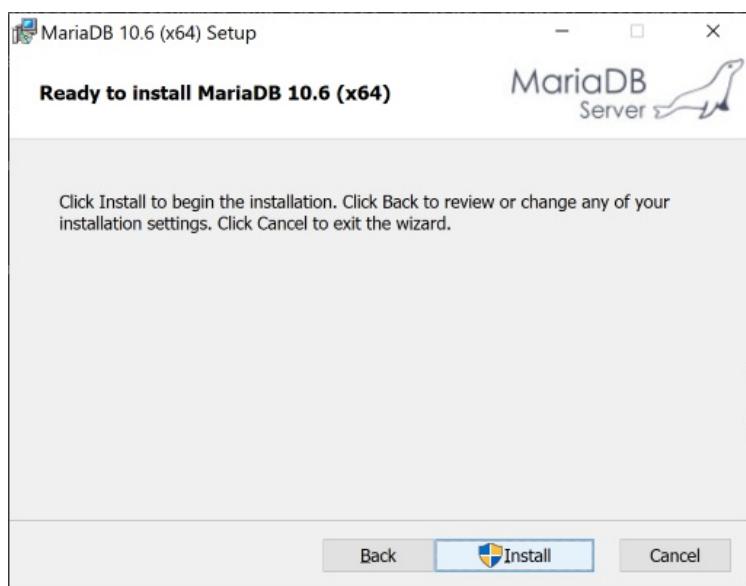

- Optimize for Transactions

If this checkbox is selected, the default storage engine is set to InnoDB (or XtraDB) and the

`sql_mode`  
parameter is set to "  
`NO_ENGINE_SUBSTITUTION,STRICT_TRANS_TABLES`

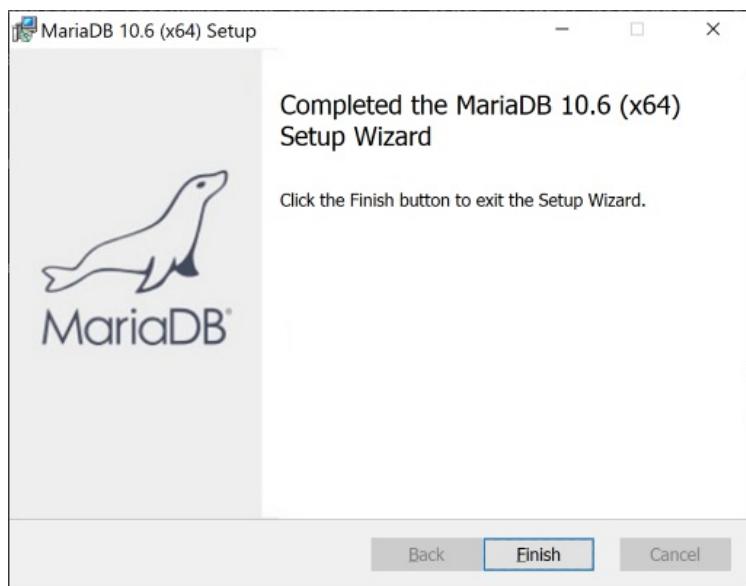

". You can also define the InnoDB/Xtradb buffer pool size. The default buffer pool size is 12.5% of RAM and depending on your requirements you can give InnoDB more (up to 70-80% RAM). 32 bit versions of MariaDB have restrictions on maximum buffer pool size, which is approximately 1GB, due to virtual address space limitations for 32bit processes.

## Ready to Install

At this point, all installation settings are collected. Click on the "Install" button.

## End

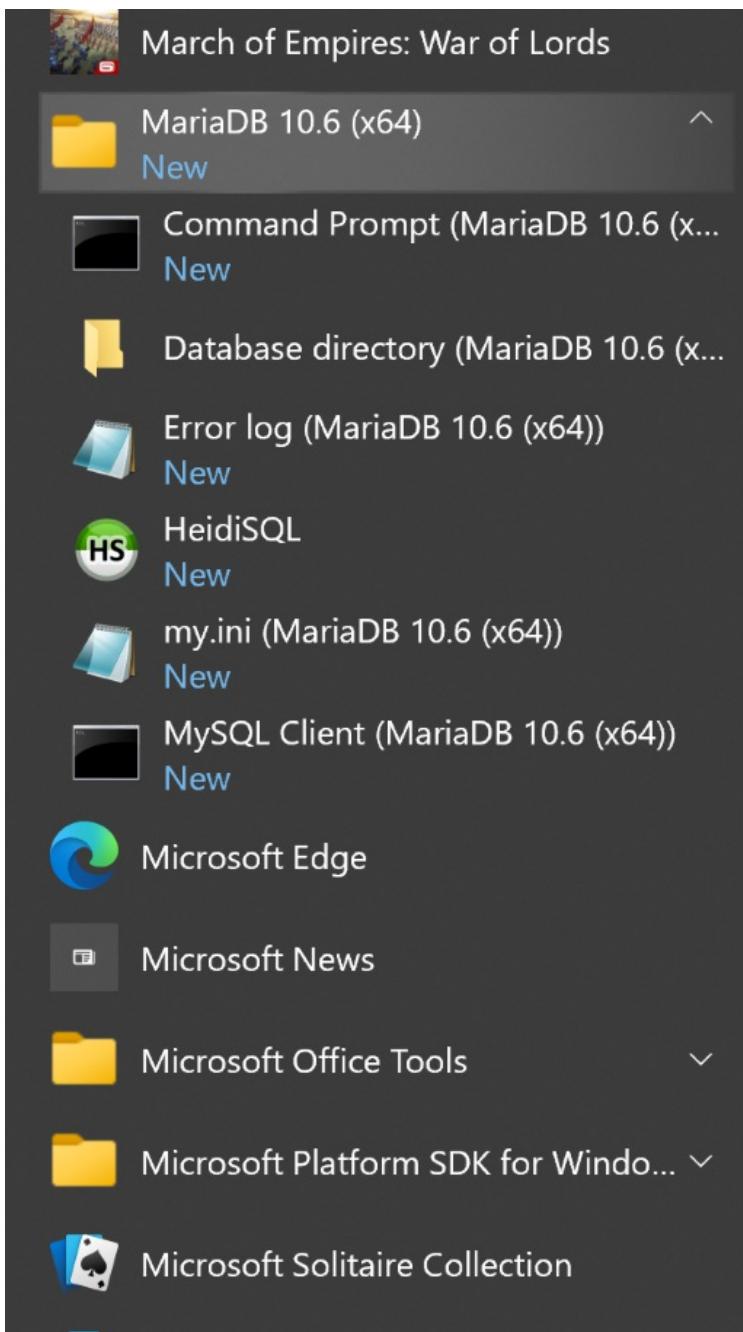

Installation is finished now. If you have upgradable instances of MariaDB/MySQL, running as services, this dialog will present a "Do you want to upgrade existing instances" checkbox (if selected, it launches the Upgrade Wizard post-installation).

If you installed a database instance as service, the service will be running already.

## New Entries in Start Menu

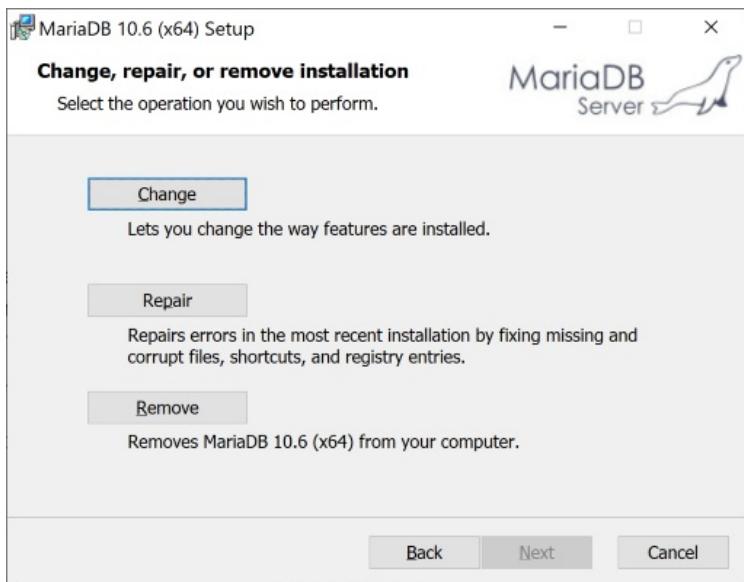

Installation will add some entries in the Start Menu:

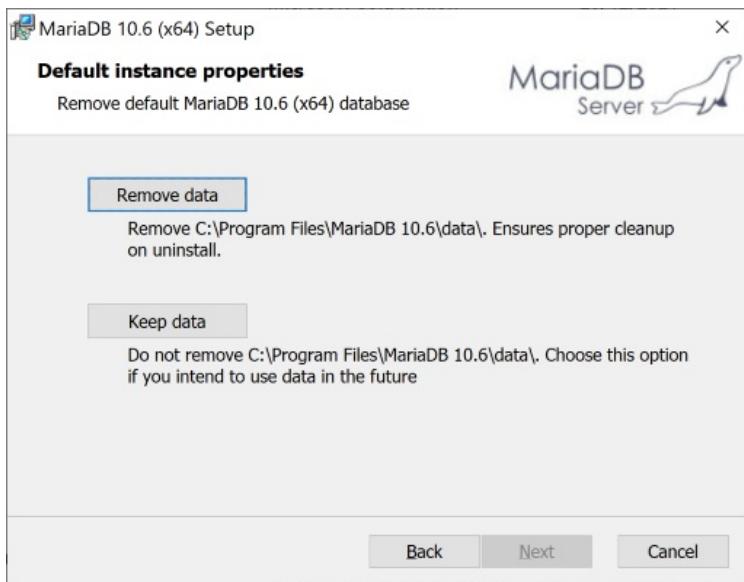

- MariaDB Client - Starts command line client mysql.exe
- Command Prompt - Starts a command prompt. Environment is set such that "bin" directory of the installation is included into PATH environment variable, i.e you can use this command prompt to issue MariaDB commands (mysqldadmin, mysql etc...)
- Database directory - Opens the data directory in Explorer.
- Error log - Opens the database error log in Notepad.
- my.ini - Opens the database configuration file my.ini in Notepad.
- Upgrade Wizard - Starts the Wizard to upgrade an existing MariaDB/MySQL database instance to this MariaDB version.

## Uninstall UI

In the Explorer applet "Programs and Features" (or "Add/Remove programs" on older Windows), find the entry for MariaDB, choose Uninstall/Change and click on the "Remove" button in the dialog below.

If you installed a database instance, you will need to decide if you want to remove or keep the data in the database directory.

## Silent Installation

The MSI installer supports silent installations as well. In its simplest form silent installation with all defaults can be performed from an elevated command prompt like this:

```
msiexec /i path-to-package.msi /qn
```

**Note:** the installation is silent due to msiexec.exe's /qn switch (no user interface), if you omit the switch, the installation will have the full UI.

## Properties

Silent installations also support installation properties (a property would correspond for example to checked/unchecked state of a checkbox in the UI, user password, etc). With properties the command line to install the MSI package would look like this:

```
msiexec /i path-to-package.msi [PROPERTY_1=VALUE_1 ... PROPERTY_N=VALUE_N] /qn
```

The MSI installer package requires property names to be all capitals and contain only English letters. By convention, for a boolean property, an empty value means "false" and a non-empty is "true".

MariaDB installation supports the following properties:

Property name	Default value	Description
INSTALLDIR	%ProgramFiles%\MariaDB<version>\	Installation root

PORT	3306	--port parameter for the server
ALLOWREMOTEROOTACCESS		Allow remote access for root user
BUFFERPOOLSIZEx	RAM/8	Bufferpoolsize for innodb
CLEANUPDATA	1	Remove the data directory (uninstall only)
DATADIR	INSTALLDIR\data	Location of the data directory
DEFAULTUSER		Allow anonymous users
PASSWORD		Password of the root user
SERVICENAME		Name of the Windows service. A service is not created if this value is empty.
SKIPNETWORKING		Skip networking
STDCONFIG	1	Corresponds to "optimize for transactions" in the GUI, default engine innodb, strict sql mode
UTF8		if set, adds character-set-server=utf8 to my.ini file (added in <a href="#">MariaDB 5.5.29</a> )
PAGESIZE	16K	page size for innodb

## Features

*Feature* is a Windows installer term for a unit of installation. Features can be selected and deselected in the UI in the feature tree in the "Custom Setup" dialog.

Silent installation supports adding features with the special property

```
ADDLOCAL=Feature_1,...,Feature_N
```

and removing features with

```
REMOVE=Feature_1,..., Feature_N
```

Features in the MariaDB installer:

Feature id	Installed by default?	Description
DBInstance	yes	Install database instance
Client	yes	Command line client programs
MYSQLSERVER	yes	Install server
SharedLibraries	yes	Install client shared library
DEVEL	yes	install C/C++ header files and client libraries
HeidiSQL	yes	Installs HeidiSQL

## Silent Installation Examples

All examples here require running as administrator (and elevated command line in Vista and later)

- Install default features, database instance as service, non-default datadir and port

```
msiexec /i path-to-package.msi SERVICENAME=MySQL DATADIR=C:\mariadb5.2\data PORT=3307 /qn
```

- Install service, add debug symbols, do not add development components (client libraries and headers)

```
msiexec /i path-to-package.msi SERVICENAME=MySQL ADDLOCAL=DEBUGSYMBOLS REMOVE=DEVEL /qn
```

## Silent Uninstall

To uninstall silently, use the

```
REMOVE=ALL
```

property with msiexec:

```
msiexec /i path-to-package.msi REMOVE=ALL /qn
```

To keep the data directory during an uninstall, you will need to pass an additional parameter:

```
msiexec /i path-to-package.msi REMOVE=ALL CLEANUPDATA="" /qn
```

# Installation Logs

If you encounter a bug in the installer, the installer logs should be used for diagnosis. Please attach verbose logs to the bug reports you create. To create a verbose installer log, start the installer from the command line with the

```
/1*v  
switch, like so:
```

```
msiexec.exe /i path-to-package.msi /1*v path-to-logfile.txt
```

## Running 32 and 64 Bit Distributions on the Same Machine

It is possible to install 32 and 64 bit packages on the same Windows x64.

Apart from testing, an example where this feature can be useful is a development scenario, where users want to run a 64 bit server and develop both 32 and 64 bit client components. In this case the full 64 bit package can be installed, including a database instance plus development-related features (headers and libraries) from the 32 bit package.

## 2.1.2.4 Installing MariaDB Server PKG packages on macOS

### Contents

1. [Installer behavior](#)
2. [launchd behavior](#)
3. [Uninstalling MariaDB Server](#)
4. [See Also](#)

MariaDB starting with 10.2.5

Starting with MariaDB 10.2.5, a .pkg installer for macOS is available from <http://mariadb.com/downloads>

The .pkg installer installs MariaDB Server and, optionally, a launchd service definition to allow the OS to automatically start and manage MariaDB Server.

## Installer behavior

The installer installs MariaDB Server in a subdirectory of /usr/local/mariadb.

You can place /usr/local/mariadb/server/bin in your PATH to always have access to executables distributed in the MariaDB Server package. The basedir of the MariaDB Server installation will depend on the version installed; for 10.2.6, it will be /usr/local/mariadb/mariadb-10.2.6-osx10.12-x86\_64, to which a symlink /usr/local/mariadb/server will be created.

The MariaDB Server binaries distributed in this package do not read from .cnf files in /etc/. Instead, put .cnf files in /usr/local/mariadb/etc/.

If there's an existing service listening on port 3306, the installer will create /usr/local/mariadb/etc/my.cnf with

```
skip-networking  
. You can edit this file to set an alternate port for MariaDB Server to listen on, or you can remove  
skip-networking  
if you have disabled the daemon that had bound port 3306.
```

MariaDB Server will place its socket file at /usr/local/mariadb/data/mariadb.sock and the client tools included in the package will by default look for a socket file at that location.

After installation, your MariaDB Server instance will have a "root" user account and a user account named after the username of the user who ran the installer. Both of these accounts use the [UNIX\\_SOCKET Authentication Plugin](#), which means no password is required to log in.

To log in to MariaDB as root, you will need to become root on the OS; the preferred mechanism for this is to use

```
sudo  
, like this:
```

```
sudo /usr/local/mariadb/server/bin/mariadb
```

If you want to be able to connect to MariaDB Server using TCP, you will need to create a new user and give it a password.

The daemon's executable is

```
mariadb  
, not  
mysqld  
. You should take this into account if you have scripts, tools, or workflows that look for processes named "mysqld". You can also invoke  
mysqld  
to start the server; edit /Library/LaunchDaemons/com.mariadb.server.plist if you want to do that permanently.
```

## launchd behavior

The installer can install a launchd service configuration. This is optional, but it is enabled by default.

The service definition causes launchd to automatically start MariaDB Server after installation and when the OS boots.

The launchd service configuration file installed by the installer is located at /Library/LaunchDaemons/com.mariadb.server.plist. The service definition file uses command-line arguments to

```
mariadb  
to control some of its behavior. These will override changes you make in option (.cnf) files.
```

To stop MariaDB Server using launchd, execute

```
sudo launchctl stop com.mariadb.server
```

To start MariaDB Server using launchd, execute

```
sudo launchctl start com.mariadb.server
```

## Uninstalling MariaDB Server

To remove MariaDB Server, follow these steps:

First, stop MariaDB Server and remove the files associated with launchd support, if you installed it (you'll need to do this as root or under sudo):

- ```
launchctl stop com.mariadb.server
```
- ```
launchctl unload /Library/LaunchDaemons/com.mariadb.server.plist
```
- ```
rm /Library/LaunchDaemons/com.mariadb.server.plist /usr/local/mariadb/server
```
- ```
pkgutil --forget com.mariadb.mariadb-server-launchd
```

Now, remove files associated with the MariaDB Server package:

- ```
rm -r /usr/local/mariadb/server/ /usr/local/mariadb/server
```
- If you also want to remove config files, remove  

```
/usr/local/mariadb/etc/
```
- If you want to remove the MariaDB Server data directory, remove  

```
/usr/local/mariadb/data/
```

You can also consult the output of

```
pkgutil --files com.mariadb.mariadb-server-files  
to see the specific list of files installed by the package.
```

After removing the files you wish to remove, tell pkgutil to forget the MariaDB Server package:

- ```
pkgutil --forget com.mariadb.mariadb-server-files
```

## See Also

- [MariaDB Server on macOS: Does it even make sense to try? \(video\)](#)

### 2.1.2.5 Installing MariaDB Binary Tarballs

#### Contents

1. [Ensure You Use the Correct my.cnf Files](#)
2. [Installing MariaDB as root in /usr/local/mysql](#)
3. [Installing MariaDB as Not root in Any Directory](#)
4. [Auto Start of mysqld](#)
5. [Post Installation](#)

MariaDB Binary tarballs are named following the pattern: mariadb-VERSION-OS.tar.gz. Be sure to [download](#) the correct version for your machine.

**Note:** Some binary tarballs are marked '(GLIBC\_2.14)' or '(requires GLIBC\_2.14+)'. These binaries are built the same as the others, but on a newer build host, and they require GLIBC 2.14 or higher. Use the other binaries for machines with older versions of GLIBC installed. Run

```
ldd --version  
to see which version is running on your distribution.
```

Others are marked 'systemd', which are for systems with

```
systemd  
and GLIBC 2.19 or higher.
```

To install the [binaries](#), unpack the distribution into the directory of your choice and run the

```
mysql_install_db
```

script.

In the example below we install MariaDB in the

```
/usr/local/mysql  
directory (this is the default location for MariaDB for many platforms). However any other directory should work too.
```

We install the binary with a symlink to the original name. This is done so that you can easily change MariaDB versions just by moving the symlink to point to another directory.

**NOTE:** For MariaDB 5.1.32 *only* the line "

```
./scripts/mysql_install_db --user=mysql  
" should be changed to "  
./bin/mysql_install_db --user=mysql  
"
```

## Ensure You Use the Correct my.cnf Files

MariaDB searches for the configuration files '

```
/etc/my.cnf  
' (on some systems '  
/etc/mysql/my.cnf  
) and '  
~/.my.cnf  
' If you have an old  
my.cnf  
file (maybe from a system installation of MariaDB or MySQL) you need to take care that you don't accidentally use the old one with your new  
binary .tar installation.
```

The normal solution for this is to ignore the

```
.my.cnf  
file in  
/etc  
when you use the programs in the tar file.
```

This is done by [creating your own .my.cnf file](#) in your home directory and telling

```
mysql_install_db  
, mysqld_safe and possibly mysql (the command-line client utility) to only use this one with the option '  
--defaults-file=~/.my.cnf  
' Note that this has to be first option for the above commands!
```

## Installing MariaDB as root in /usr/local/mysql

If you have root access to the system, you probably want to install MariaDB under the user and group 'mysql' (to keep compatibility with MySQL installations):

```
groupadd mysql  
useradd -g mysql mysql  
cd /usr/local  
tar -zxvf /path-to/mariadb-VERSION-OS.tar.gz  
ln -s mariadb-VERSION-OS mysql  
cd mysql  
./scripts/mysql_install_db --user=mysql  
chown -R root .  
chown -R mysql data
```

The symlinking with

```
ln -s  
is recommended as it makes it easy to install many MariaDB version at the same time (for easy testing, upgrading, downgrading etc).
```

If you are installing MariaDB to replace MySQL, then you can leave out the call to

```
mysql_install_db  
. Instead shut down MySQL. MariaDB should find the path to the data directory from your old  
/etc/my.cnf  
file (path may vary depending on your system).
```

To start mysqld you should now do:

```
./bin/mysqld_safe --user=mysql &  
or  
.bin/mysqld_safe --defaults-file=~/my.cnf --user=mysql &
```

To test connection, modify your \$PATH so you can invoke client such as [mysql](#), [mysqldump](#), etc.

```
export PATH=$PATH:/usr/local/mysql/bin/
```

You may want to modify your .bashrc or .bash\_profile to make it permanent.

## Installing MariaDB as Not root in Any Directory

Below, change /usr/local to the directory of your choice.

```
cd /usr/local  
gunzip < /path-to/mariadb-VERSION-OS.tar.gz | tar xf -  
ln -s mariadb-VERSION-OS mysql  
cd mysql  
.scripts/mysql_install_db --defaults-file=~/my.cnf
```

If you have problems with the above gunzip command line, you can instead, if you have gnu tar, do:

```
tar xfz /path-to/mariadb-VERSION-OS.tar.gz
```

To start mysqld you should now do:

```
./bin/mysqld_safe --defaults-file=~/my.cnf &
```

## Auto Start of mysqld

You can get mysqld (the MariaDB server) to autostart by copying the file

```
mysql.server  
file to the right place.
```

```
cp support-files/mysql.server /etc/init.d/mysql.server
```

The exact place depends on your system. The

```
mysql.server  
file contains instructions of how to use and fine tune it.
```

For systemd installation the mariadb.service file will need to be copied from the support-files/systemd folder to the /usr/lib/systemd/system/ folder.

```
cp support-files/systemd/mariadb.service /usr/lib/systemd/system/mariadb.service
```

Note that by default the /usr/ directory is write protected by systemd though, so when having the data directory in /usr/local/mysql/data as per the instructions above you also need to make that directory writable. You can do so by adding an extra service include file:

```
mkdir /etc/systemd/system/mariadb.service.d/  
  
cat > /etc/systemd/system/mariadb.service.d/datadir.conf <<EOF  
[Service]  
ReadWritePaths=/usr/local/mysql/data  
EOF  
  
systemctl daemon-reload
```

After this you can start and stop the service using

```
systemctl start mariadb.service
```

and

```
systemctl stop mariadb.service
```

respectively.

Please refer to the [systemd](#) page for further information.

## Post Installation

After this, remember to set proper passwords for all accounts accessible from untrusted sources, to avoid exposing the host to security risks!

Also consider using the [mysql.server](#) to [start MariaDB automatically](#) when your system boots.

On systems using systemd you can instead enable automatic startup during system boot with

```
systemctl enable mariadb.service
```

instead.

Our MariaDB binaries are similar to the Generic binaries available for the MySQL binary distribution. So for more options on using these binaries, the MySQL 5.5 manual entry on [installing generic binaries](#) can be consulted.

For details on the exact steps used to build the binaries, see the [compiling MariaDB section](#) of the KB.

## 2.1.2.6 Installing MariaDB Server on macOS Using Homebrew

### Contents

1. [Upgrading MariaDB](#)
2. [Building MariaDB Server from source](#)
3. [Other resources](#)

MariaDB Server is available for installation on macOS (formerly Mac OS X) via the [Homebrew](#) package manager.

MariaDB Server is available as a Homebrew "bottle", a pre-compiled package. This means you can install it without having to build from source yourself. This saves time.

After installing Homebrew, MariaDB Server can be installed with this command:

```
brew install mariadb
```

After installation, start MariaDB Server:

```
mysql.server start
```

To auto-start MariaDB Server, use Homebrew's services functionality, which configures auto-start with the launchctl utility from [launchd](#) :

```
brew services start mariadb
```

After MariaDB Server is started, you can log in as your user:

```
mysql
```

Or log in as root:

```
sudo mysql -u root
```

## Upgrading MariaDB

First you may need to update your brew installation:

```
brew update
```

Then, to upgrade MariaDB Server:

```
brew upgrade mariadb
```

## Building MariaDB Server from source

In addition to the "bottled" MariaDB Server package available from Homebrew, you can use Homebrew to build MariaDB from source. This is useful if you want to use a different version of the server or enable some different capabilities that are not included in the bottle package.

Two components not included in the bottle package (as of MariaDB Server 10.1.19) are the CONNECT and OQGRAPH engines, because they have non-standard dependencies. To build MariaDB Server with these engines, you must first install

```
boost  
and  
judy
```

. As of December 2016, judy is in the Homebrew "boneyard", but the old formula still works on macOS Sierra. Follow these steps to install the dependencies and build the server:

```
brew install boost homebrew/boneyard/judy  
brew install mariadb --build-from-source
```

You can also use Homebrew to build and install a pre-release version of MariaDB Server (for example MariaDB Server 10.2, when the highest GA version is MariaDB Server 10.1). Use this command to build and install a "development" version of MariaDB Server:

```
brew install mariadb --devel
```

## Other resources

- [mariadb.rb on github](#)
- [Terin Stock \(terinjokes\)](#) who is the packager for Homebrew
- [MariaDB Server on macOS: Does it even make sense to try?](#) (video)

## 2.1.2.7 Installing MariaDB Windows ZIP Packages

Getting started with ZIP packages on Windows is very straightforward - this distribution includes pre-built database files that can be used right after unpacking the ZIP.

You can run mysqld.exe from the command prompt like this:

```
cd <directory-where-zip-was-unpacked>  
bin\mysqld --console
```

However, running MariaDB from the command line in a user session like this covers only the simplest testing scenarios.

For any serious purpose, use [mysql\\_install\\_db.exe](#) to create database instances - it is more secure (disables anonymous user by default, allows setting root password during database creation), and more convenient (can create Windows service, supports user-specified data directory).

Note : Starting with [MariaDB 10.4.3](#), a pre-built data directory is no longer provided, and users need to run [mysql\\_install\\_db.exe](#) to create a data directory.

For older MariaDB releases, you can follow the instructions in [MySQL documentation on ZIP distributions](#) - this describes the manual process for registering a service and securing the database.

## 2.1.2.8

### 2.1.2.8.1 Get, Build and Test Latest MariaDB the Lazy Way

The intention of this documentation is show all the steps of getting, building and testing the latest MariaDB server (10.5 at time of writing) from GitHub. Each stage links to the full documentation for that step if you need to find out more.

#### Install all tools needed to build MariaDB

##### OpenSuse

```
sudo zypper install git gcc gcc-c++ make bison ncurses ncurses-devel zlib-devel libevent-devel cmake openssl
```

##### Debian

```
apt install -y build-essential bison  
apt build-dep mariadb-server
```

## Set Up git

Fetch and checkout the MariaDB source to a subdirectory of the current directory

```
git clone https://github.com/MariaDB/server.git mariadb  
cd mariadb  
git checkout 10.5
```

## Build It

The following command builds a server the same way that is used for building releases. Use

```
cmake . -DCMAKE_BUILD_TYPE=Debug  
to build for debugging.
```

```
cmake . -DBUILD_CONFIG=mysql_release && make -j8
```

## Check the Server (If You Want To)

```
cd mysql-test  
mtr --parallel=8 --force
```

## Install the Default Databases

```
./scripts/mariadb-install-db --srcdir=.
```

(Older MariaDB version use [mysql\\_install\\_db](#) )

## Install the Server (If needed)

You can also [run and test mariadb directly from the build directory](#) , in which case you can skip the rest of the steps below.

```
make install
```

## Start the Server

Start the server in it's own terminal window for testing. Note that the directory depends on your system!

```
/usr/sbin/mysqld
```

## 2.1.2.8.2 MariaDB Source Code

### Checking out the Source with Git

The MariaDB source is hosted on GitHub: <https://github.com/MariaDB/server>

If you want a source tarball for a specific released MariaDB version, you can find it at <http://downloads.mariadb.org> .

At any given time, developers will be working on their own branches locally or on GitHub, with the main MariaDB branches receiving pushes less often.

The main MariaDB branches are:

- [10.6](#)
- [10.5](#)
- [10.4](#)
- [10.3](#)
- [10.2](#)

Source repositories for the MariaDB Connectors are:

- [MariaDB Connector/C](#)
- [MariaDB Connector/J](#)
- [MariaDB Connector/Node.js](#)
- [MariaDB Connector/ODBC](#)
- [MariaDB Connector/Python](#)

See the [Using git](#) page for instructions on how to use git to check out the source code and switch between the various branches.

## 2.1.2.8.3 Build Environment Setup for Linux

### Contents

1. [Required Tools](#)
2. [See Also](#)

## Required Tools

The following is a list of tools that are required for building MariaDB on Linux and Mac OS X. Most, if not all, of these will exist as packages in your distribution's package repositories, so check there first. See [Building MariaDB on Ubuntu](#), [Building MariaDB on CentOS](#), and [Building MariaDB on Gentoo](#) pages for specific requirements for those platforms.

- [git](#)
- [gunzip](#)
- [GNU tar](#)
- [gcc/g++ 4.8.5 or later, recommend above 9 or clang/clang++](#)
- [GNU make 3.75 or later or Ninja](#)
- [bison \(3.0\)](#)
- [libncurses](#)
- [zlib-dev](#)
- [libevent-dev](#)
- [cmake above 2.8.7 though preferably above 3.3](#)
- [gnutls or openssl](#)
- [jemalloc \(optional\)](#)
- [valgrind \(only needed if running mysql-test-run --valgrind \)](#)
- [libcurl \(only needed if you want to use the S3 storage engine \)](#)

You can install these programs individually through your package manager.

In addition, some package managers support the use a build dependency command. When using this command, the package manager retrieves a list of build dependencies and install them for you, making it much easier to get started on the compile. The actual option varies, depending on the distribution you use.

On Ubuntu and Debian you can use the

```
build-dep  
command.
```

```
# apt build-dep mariadb-server
```

Fedora uses the  
`builddep`  
command with DNF.

```
# dnf builddep mariadb-server
```

CentOS has a separate utility

```
yum-builddep  
, which is part of the  
yum-utils  
package. This works like the DNF  
builddep  
command.
```

```
# yum install yum-utils  
# yum-builddep mariadb-server
```

With openSUSE and SUSE, you can use the source-install command.

```
# zypper source-install -d mariadb
```

Each of these commands works off of the release of MariaDB provided in the official software repositories of the given distribution. In some instances and especially in older versions of Linux, MariaDB may not be available in the official repositories. In these cases you can use the MariaDB repositories as an alternative.

Bear in mind, the release of MariaDB provided by your distribution may not be the same as the version you are trying to install. Additionally, the package managers don't always retrieve all of the packages you need to compile MariaDB. There may be some missed or unlisted in the process. When this is the case, CMake fails during checks with an error message telling you what's missing.

Note: On Debian-based distributions, you may receive a "You must put some 'source' URLs in your sources.list" error. To avoid this, ensure that /etc/apt/sources.list contains the source repositories.

For example, for Debian buster:

```
deb http://ftp.debian.org/debian buster main contrib  
deb http://security.debian.org buster/updates main contrib  
deb-src http://ftp.debian.org/debian buster main contrib  
deb-src http://security.debian.org buster/updates main contrib
```

Refer to the documentation for your Linux distribution for how to do this on your system.

After editing the sources.list, do:

```
sudo apt update
```

...and then the above mentioned

```
build-dep  
command.
```

Note: On openSUSE the source package repository may be disabled. The following command will enable it:

```
sudo zypper mr -er repo-source
```

After enabling it, you will be able to run the zypper command to install the build dependencies.

You should now have your build environment set up and can proceed to [Getting the MariaDB Source Code](#) and then using the [Generic Build Instructions](#) to build Mariadb (or following the steps for your Linux distribution or [Creating a MariaDB Binary Tarball](#) ).

## See Also

- [Installing Galera from source](#)

### 2.1.2.8.4 Generic Build Instructions

#### Contents

1. [Using cmake](#)
2. [Using BUILD Scripts](#)
3. [Starting MariaDB for the First Time](#)
4. [Testing MariaDB](#)
5. [Increasing Version Number or Tagging a Version](#)
6. [Non-ascii Symbols](#)
7. [Post-install Tasks](#)

The instructions on this page will help you compile [MariaDB](#) from source. Links to more complete instructions for specific platforms can be found on the [source](#) page.

First, [get a copy of the MariaDB source](#).

Next, [prepare your system to be able to compile the source](#).

If you don't want to run MariaDB as yourself, then you should create a

```
mysql  
user. The example below uses this user.
```

## Using cmake

[MariaDB 5.5](#) and above is compiled using [cmake](#).

It is recommended to create a build directory **beside** your source directory

```
mkdir build-mariadb  
cd build-mariadb
```

**NOTE** If you have built MariaDB in the past and have recently updated the repository, you should perform a complete cleanup of old artifacts (such as cmake configured files). In the base repository run:

```
git clean -xffd && git submodule foreach --recursive git clean -xffd
```

You can configure your build simply by running [cmake](#) without any special options, like

```
cmake .. /server
```

where

server  
is where you installed MariaDB. If you are building in the source directory, just omit  
.. /server

If you want it to be configured exactly as a normal MariaDB server release is built, use

```
cmake .. /server -DBUILD_CONFIG=mysql_release
```

This will configure the build to generate binary tarballs similar to release tarballs from downloads.mariadb.org. Unfortunately this doesn't work on old platforms, like OpenSuse Leap 15.0, because MariaDB binary tarballs are built to minimize external dependencies, and that needs static libraries that might not be provided by the platform by default, and would need to be installed manually.

To do a build suitable for debugging use:

```
cmake .. /server -DCMAKE_BUILD_TYPE=Debug
```

By default, MariaDB is compiled with the

-Werror  
flag, which causes compiling to abort if there is a compiler warning. You can disable that by configuring with  
-DMYSQL\_MAINTAINER\_MODE=OFF

```
cmake .. /server -DCMAKE_BUILD_TYPE=Debug -DMYSQL_MAINTAINER_MODE=OFF .
```

All *cmake* configuration options for MariaDB can be displayed with:

```
cmake .. /server -LH
```

To build and install MariaDB after running *cmake* use

```
cmake --build .  
sudo cmake --install .
```

If the commands above fail, you can enable more compilation information by doing:

```
cmake --build . --verbose
```

If you want to generate a binary tarball, run

```
cpack
```

## Using BUILD Scripts

There are also

BUILD

scripts for the most common systems for those that doesn't want to dig into *cmake* options. These are optimized for in source builds.

The scripts are of type 'compile-#cpu#-how\_to\_build'. Some common scripts-are

Script	Description
compile-pentium64	Compile an optimized binary optimized for 64 bit pentium (works also for amd64)
compile-pentium-debug	Compile a debug binary optimized for 64 bit pentium
compile-pentium-valgrind-max	Compile a debug binary that can be used with <a href="#">valgrind</a> to find wrong memory accesses and memory leaks. Should be used if one want's to run the <code>mysql-test-run</code> test suite with the <code>--valgrind</code> option

Some common suffixes used for the scripts:

Suffix	Description
--------	-------------

32	Compile for 32 bit cpu's
64	Compile for 64 bit cpu's
-max	Enable (almost) all features and plugins that MariaDB supports
-gprof	binary is compiled with profiling (gcc --pg)
-gcov	binary is compiled with code coverage (gcc -fprofile-arcs -ftest-coverage)
-valgrind	The binary is compiled for debugging and optimized to be used with <a href="#">valgrind</a> .
-debug	The binary is compiled with all symbols (gcc -g) and the <a href="#">DBUG</a> log system is enabled.

All

BUILD

scripts support the following options:

Suffix	Description
-h, --help	Show this help message.
-n, --just-print	Don't actually run any commands; just print them.
-c, --just-configure	Stop after running configure. Combined with --just-print shows configure options.
--extra-configs=xxx	Add this to configure options
--extra-flags=xxx	Add this C and CXX flags
--extra-cflags=xxx	Add this to C flags
--extra-cxxflags=xxx	Add this to CXX flags
--verbose	Print out full compile lines
--with-debug=full	Build with full debug(no optimizations, keep call stack).

A typical compilation used by a developer would be:

```
shell> ./BUILD/compile-pentium64-debug
```

This configures the source for debugging and runs make. The server binary will be

```
sql/mariadb  
or  
sql/mysql
```

## Starting MariaDB for the First Time

After installing MariaDB (using

```
sudo make install  
)
```

, but prior to starting MariaDB for the first time, one should:

1. ensure the directory where you installed MariaDB is owned by the mysql user (if the user doesn't exist, you'll need to create it)
2. run the

```
mysql_install_db  
script to generate the needed system tables
```

Here is an example:

```
# The following assumes that the 'mysql' user exists and that we installed MariaDB  
# in /usr/local/mysql  
chown -R mysql /usr/local/mysql/  
cd /usr/local/mysql/  
scripts/mysql_install_db --user=mysql  
/usr/local/mysql/bin/mysqld_safe --user=mysql &
```

## Testing MariaDB

If you want to test your compiled MariaDB, you can do either of:

Run unit tests:

```
cmake --build . --target test
```

Or run mtr tests:

```
mysql-test/mysql-test-run --force
```

Each of the above are run from the build directory. There is no need to '

```
make install  
/  
cmake --install .  
' MariaDB prior to running them.
```

**NOTE:** If you are doing more extensive testing or debugging of MariaDB (like with real application data and workloads) you may want to start and run MariaDB directly from the source directory instead of installing it with '

```
sudo make install  
' If so, see Running MariaDB from the Source Directory.
```

## Increasing Version Number or Tagging a Version

If you have made code changes and want to increase the version number or tag our version with a specific tag you can do this by editing the

```
VERSION  
file. Tags are shown when running the '  
mysqld --version  
' command.
```

## Non-ascii Symbols

MariaDB builds with

```
readline  
; using an alternative such as  
Editline  
may result in problems with non-ascii symbols.
```

## Post-install Tasks

- [Installing system tables \(mysql\\_install\\_db\)](#)
- [Starting and Stopping MariaDB Automatically](#)

### 2.1.2.8.5 Compiling MariaDB with Extra Modules/Options

#### 2.1.2.8.5.1 Compiling MariaDB with TCMalloc

[TCMalloc](#) is a malloc replacement library optimized for multi-threaded usage. It also features a built-in heap debugger and profiler.

To build [MariaDB 5.5](#) with

```
TCMalloc  
, you need to use the following command
```

```
cmake -DCMAKE_EXE_LINKER_FLAGS='`ltcmalloc` -DWITH_SAFEMALLOC=OFF'
```

Many other malloc replacement libraries (as well as heap debuggers and profilers) can be used with MariaDB in a similar fashion.

You can also start a standard MariaDB server with

TCmalloc  
with:

```
/usr/sbin/mysqld_safe --malloc-lib=tcmalloc
```

## See Also

- [Debugging a running server on Linux](#)

## 2.1.2.8.5.2 Compiling MariaDB with Vanilla XtraDB

Sometimes, one needs to have MariaDB compiled with Vanilla XtraDB. This page describes the process to do this. The process is rather crude, as my goal was just a once-off compile for testing (that is, not packaging or shipping) purposes.

The process is applicable to [MariaDB 5.3.4](#) and XtraDB from Percona Server 5.1.61.

```
wget http://s.petrunia.net/scratch/make-vanilla-xtradb-work-with-mariadb.diff
bzr branch /path/to/mariadb-5.3 5.3-vanilla-xtradb-r3
cd 5.3-vanilla-xtradb-r3/storage/
tar czf innodb_plugin.tgz innodb_plugin/
rm -rf innodb_plugin
tar czf xtradb.tgz xtradb/
rm -rf xtradb
cd ../../
tar zxvf ~/Percona-Server-5.1.61.tar.gz
cp -r Percona-Server-5.1.61/storage/innodb_plugin 5.3-vanilla-xtradb-r3/storage/
patch -p1 -d 5.3-vanilla-xtradb-r3/storage/innodb_plugin/ < make-vanilla-xtradb-work-with-mariadb.diff
cd 5.3-vanilla-xtradb-r3/
BUILD/autorun.sh
./configure --with-plugin-innodb_plugin
make
```

## 2.1.2.8.5.3 Specifying Which Plugins to Build

By default all plugins are enabled and built as dynamic

.so  
(or  
.dll  
) modules. If a plugin does not support dynamic builds, it is not built at all.

### MariaDB 5.5 - 10.0

To specify that a specific plugin should be enabled and built statically into the server executable, use the

-DWITH\_xxx=1  
cmake option (where  
xxx  
is the plugin name). Of course, static linking only works if the plugin itself supports it — some plugins can only be built as dynamic modules.  
A plugin will automatically be skipped by cmake if it cannot be built; for example, if some required libraries are missing or if you want to statically link a plugin that only supports dynamic linking.

If you want to avoid building some specific plugin, specify the

-DWITHOUT\_xxx=1  
cmake option.

### MariaDB starting with 10.1

Use

PLUGIN\_xxx  
cmake variables. They can be set on the command line with  
-DPLUGIN\_xxx=  
  
value

or in the cmake gui. Supported values are

Value	Effect
-------	--------

<b>NO</b>	the plugin will be not compiled at all
<b>STATIC</b>	the plugin will be compiled statically, if supported. Otherwise it will be not compiled.
<b>DYNAMIC</b>	the plugin will be compiled dynamically, if supported. Otherwise it will be not compiled. This is the default behavior.
<b>AUTO</b>	the plugin will be compiled statically, if supported. Otherwise it will be compiled dynamically.
<b>YES</b>	same as <b>AUTO</b> , but if plugin prerequisites (for example, specific libraries) are missing, it will not be skipped, it will abort cmake with an error.

Note that unlike autotools, cmake tries to configure and build incrementally. You can modify one configuration option and cmake will only rebuild the part of the tree affected by it. For example, when you do

```
cmake -DWITH_EMBEDDED_SERVER=1
```

in the already-built tree, it will make libmysqld to be built, but no other configuration options will be changed or reset to their default values.

In particular this means that if you have run, for example

MariaDB 5.5 - 10.0

```
cmake -DWITHOUT_OQGRAPH=1
```

MariaDB starting with 10.1

```
cmake -DPLUGIN_OQGRAPH=NO
```

and later you want to restore the default behavior (with OQGraph being built) in the same build tree, you would need to run

MariaDB 5.5 - 10.0

```
cmake -UWITHOUT_OQGRAPH
```

MariaDB starting with 10.1

```
cmake -DPLUGIN_OQGRAPH=DYNAMIC
```

Alternatively, you might simply delete the

CMakeCache.txt

file — this is the file where cmake stores current build configuration — and rebuild everything from scratch.

## 2.1.2.8.6 Creating the MariaDB Source Tarball

How to create a source tar.gz file.

First [Setup your build environment](#).

Then use automake/configure/make to generate the tar file:

```
BUILD/autorun.sh
./configure --with-plugin-xtradb
make dist
```

This creates a source file with a name like

```
mysql-5.3.2-MariaDB-beta.tar.gz
```

See also [the generic build instructions](#).

## 2.1.2.8.7 Creating the MariaDB Binary Tarball

How to generate binary tar.gz files.

- [Setup your build environment](#).
- [Build binaries](#) with your preferred options/plugins.

### MariaDB until 5.3

- Use

```
make_binary_distribution  
to generate a binary tar file:
```

```
cd mariadb-source  
../scripts/make_binary_distribution
```

This creates a source file with a name like

```
mariadb-5.3.2-MariaDB-beta-linux-x86_64.tar.gz  
in your current directory.
```

The other option is to use the bakery scripts. In this case you don't have to compile MariaDB source first.

```
cd $PACKAGING_WORK  
bakery/preheat.sh  
cd bakery_{number}  
bakery/tarbake51.sh last:1 $MARIA_WORK  
bakery/autobake51-bintar.sh mariadb-{version_num}-maria-beta-ourdelta{number}.tar.gz
```

### MariaDB starting with 5.5

If the binaries are already built, you can generate a binary tarball with

```
make package
```

## 2.1.2.8.8 Build Environment Setup for Mac

### XCode

- Install Xcode from Apple (free registration required): <https://developer.apple.com/xcode/> or from your Mac OS X installation disk (macports needs XCode >= 3.1, so if you do not have that version or greater you will need to download the latest version, which is 900+ MB)

You can install the necessary dependencies using either MacPorts or Homebrew.

### Using MacPorts

- Download and install the MacPorts dmg image from <http://www.macports.org>
- After installing, update it from the terminal:  

```
sudo port -v selfupdate
```

```
sudo port install cmake jemalloc Judy openssl boost gnutls
```

### Using Homebrew

- Download and install Homebrew from <https://brew.sh>

```
brew install cmake jemalloc trailldb/Judy Judy openssl boost gnutls
```

Your Mac should now have everything it needs to get, compile, and otherwise work with the MariaDB source code. The next step is to actually get a copy of the code. For help with this see the [Getting the MariaDB Source Code](#) page.

When building with Mac, you'll need

```
-DOPENSSL_ROOT_DIR=/usr/local/openssl  
passed as a  
cmake  
argument to build against openssl correctly.
```

## 2.1.2.8.9 Building MariaDB From a Source RPM

## 2.1.2.8.10 Building MariaDB on CentOS

### Contents

1. [Installing Build Dependencies](#)
2. [Building MariaDB](#)
3. [Creating MariaDB-compat package](#)
4. [Additional Dependencies](#)
5. [More about CMake and CPackRPM](#)

In the event that you are using the Linux-based operating system CentOS or any of its derivatives, you can optionally compile MariaDB from source code. This is useful in cases where you want use a more advanced release than the one that's available in the official repositories, or when you want to enable certain feature that are not otherwise accessible.

### Installing Build Dependencies

Before you start building MariaDB, you first need to install the build dependencies required to run the compile. CentOS provides a tool for installing build dependencies. The

```
yum-builddep
```

utility reads a package and generates a list of the packages required to build from source, then calls YUM to install them for you. In the event that this utility is not available on your system, you can install it through the

```
yum-utils
```

package. Once you have it, install the MariaDB build dependencies.

```
# yum-builddep mariadb-server
```

Running this command installs many of the build dependencies, but it doesn't install all of them. Not all the required packages are noted and it's run against the official CentOS package of MariaDB, not necessarily the version that you want to install. Use YUM to install the remaining packages.

```
# yum install git \
  gcc \
  gcc-c++ \
  bison \
  libxml2-devel \
  libevent-devel \
  rpm-build
```

In addition to these, you also need to install

```
gnutls
or
openssl
, depending on the TLS implementation you want to use.
```

For more information on dependencies, see [Linux Build Environment](#).

### Building MariaDB

Once you have the base dependencies installed, you can retrieve the source code and start building MariaDB. The source code is available on GitHub. Use the

```
--branch
option to specify the particular version of MariaDB you want to build.
```

```
$ git clone --branch 10.3 https://github.com/MariaDB/server.git
```

With the source repository cloned onto your system, you can start building MariaDB. Run CMake to read MariaDB for the build,

```
$ cmake -DRPM=centos7 server/
```

Once CMake readies the relevant Makefile for your system, use Make to build MariaDB.

```
$ make package
```

This generates an RPM file, which you can then install on your system or copy over to install on other CentOS hosts.

### Creating MariaDB-compat package

MariaDB-compat package contains libraries from older MariaDB releases. They cannot be built from the current source tree, so cpack creates them by repackaging old MariaDB-shared packages. If you want to have -compat package created, you need to download MariaDB-shared-5.3 and MariaDB-

shared-10.1 rpm packages for your architecture (any minor version will do) and put them *one level above* the source tree you're building. CMake will pick them up and create a MariaDB-compat package. CMake reports it as

```
$ ls ../*.rpm
./MariaDB-shared-10.1.17-centos7-x86_64.rpm
./MariaDB-shared-5.3.12-122.el5.x86_64.rpm
$ cmake -DRPM=centos7 .
...
Using ../MariaDB-shared-5.3.12-122.el5.x86_64.rpm to build MariaDB-compat
Using ../MariaDB-shared-10.1.17-centos7-x86_64.rpm to build MariaDB-compat
```

## Additional Dependencies

In the event that you miss a package while installing build dependencies, CMake may continue to fail after you install the necessary packages. If this happens to you, delete the CMake cache then run the above command again:

```
$ rm CMakeCache.txt
```

When CMake runs through the tests again, it should now find the packages it needs, instead of the cache telling it they're unavailable.

## More about CMake and CPackRPM

See also [building RPM packages from source](#)

### 2.1.2.8.11 Building MariaDB on Fedora

In the event that you are using the Linux-based operating system Fedora or any of its derivatives and would like to compile MariaDB from source code, you can do so using the MariaDB build in the official repositories.

## Installing Build Dependencies

MariaDB requires a number of packages to compile from source. Fortunately, you can use the package in the Fedora repository to retrieve most of the relevant build dependencies through DNF.

```
# dnf builddep mariadb-server
```

Running DNF in this way pulls the build dependencies for the release of MariaDB compiled by your version of Fedora. These may not be all the dependencies you need to build the particular version of MariaDB you want to use, but it will retrieve most of them.

You'll also need to install Git to retrieve the source repository:

```
# dnf install git
```

## Building MariaDB

Once you have the base dependencies installed, you can retrieve the source code and start building MariaDB. The source code is available on GitHub. Use the

```
--branch  
option to specify the particular version of MariaDB you want to build.
```

```
$ git clone --branch 10.3 https://github.com/MariaDB/server.git mariadb-server
```

With the source repository cloned onto your system, you can start building MariaDB. Change into the new `mariadb-server/` directory and run CMake to prepare the build.

```
$ mkdir mariadb-build
$ cd mariadb-build
$ cmake -DRPM=fedora ../mariadb-server
```

Once CMake readies the relevant Makefile for your system, use Make to build MariaDB.

```
$ make package
```

### 2.1.2.8.12 Building MariaDB on Debian

## Contents

1. [Installing Build Dependencies](#)
2. [Building MariaDB](#)
  1. [After Building](#)

In the event that you are using the Linux-based operating system Debian or any of its direct derivatives and would like to compile MariaDB from source code, you can do so using the MariaDB source repository for the release that interests you. For Ubuntu and its derivatives, see [Building on Ubuntu](#).

Before you begin, install the

software-properties-common  
and  
devscripts  
packages:

```
$ sudo apt-get install -y software-properties-common \
  devscripts
```

## Installing Build Dependencies

MariaDB requires a number of packages to compile from source. Fortunately, you can use the MariaDB repositories to retrieve the necessary code for the version you want. Use the [Repository Configuration](#) tool to determine how to set up the MariaDB repository for your release of Debian, the version of MariaDB that you want to install, and the mirror that you want to use.

First add the authentication key for the repository, then add the repository.

```
$ sudo apt-key adv --recv-keys \
  --keyserver hkp://keyserver.ubuntu.com:80 \
  0xF1656F24C74CD1D8
$ sudo add-apt-repository 'deb [arch=amd64] http://nyc2.mirrors.digitalocean.com/mariadb/repo/10.3/debian stretch main'
```

The second command added text to the

/etc/apt/sources.list

file. One of these lines is the repository containing binary packages for MariaDB, the other contains the source packages. The line for the source packages is commented out by default. This can be scripted:

```
sed -e '/^# deb-src.*mariadb/s/^# //' -i /etc/apt/sources.list
```

Alternately, open the file using your preferred text editor and uncomment the source repository.

```
$ sudo vim /etc/apt/sources.list
...
deb [arch=amd64] http://nyc2.mirrors.digitalocean.com/mariadb/repo/10.3/debian stretch main
deb-src [arch=amd64] http://nyc2.mirrors.digitalocean.com/mariadb/repo/10.3/debian stretch main
```

Once the repository is set up, you can use

apt-get

to retrieve the build dependencies. MariaDB packages supplied by Ubuntu and packages supplied by the MariaDB repository have the same base name of

mariadb-server

. You need to specify the specific version you want to retrieve.

```
$ sudo apt-get update
$ sudo apt-get build-dep -y mariadb-server-10.3
```

## Building MariaDB

Once you have the base dependencies installed, you can retrieve the source code and start building MariaDB. The source code is available on GitHub. Use the

--branch

option to specify the particular version of MariaDB you want to build.

```
$ git clone --branch 10.3 https://github.com/MariaDB/server.git
```

The source code includes scripts to install the remaining build dependencies. For Ubuntu, they're located in the

debian/

directory. Navigate into the repository and run the

autobake-deb.sh

script. Then use

```
$ export DEB_BUILD_OPTIONS=parallel=$(nproc)
$ cd server/
$ ./debian/autobake-deb.sh
```

## After Building

After building the packages, it is a good idea to put them in a repository. See the [Creating a Debian Repository](#) page for instructions.

### 2.1.2.8.13 Building MariaDB on FreeBSD

#### Contents

- 1. [Using Ports](#)
  - 1. [Building MariaDB from Ports](#)
- 2. [Using Poudriere](#)
  - 1. [Building MariaDB](#)
  - 2. [Using Poudriere Repositories](#)

It is relatively straightforward to build MariaDB from source on FreeBSD. When working with an individual host, you can use Ports to compile particular or multiple versions of MariaDB. When working with multiple hosts, you can use Poudriere to build MariaDB once, then serve it as a package to multiple FreeBSD hosts.

## Using Ports

The FreeBSD Ports Collection provides a series of Makefiles that you can use to retrieve source code, configure builds, install dependencies and compile software. This allows you to use more advanced releases than what is normally available through the package managers as well as enable any additional features that interest you.

In the event that you have not used Ports before on your system, you need to first fetch and extract the Ports tree. This downloads the Ports tree from FreeBSD and extracts it onto your system, placing the various Makefiles, patches and so on in the

```
/usr/ports/  
directory.
```

```
# portsnap fetch extract
```

In the event that you have used Ports before on this system, run Portsnap again to download and install any updates to the Ports tree.

```
# portsnap fetch update
```

This ensures that you are using the most up to date release of the Ports tree that is available on your system.

## Building MariaDB from Ports

Once Portsnap has installed or updated your Ports tree, you can change into the relevant directory and install MariaDB. Ports for MariaDB are located in the

```
/usr/ports/databases/  
directory.
```

```
$ ls /usr/ports/databases | grep mariadb

mariadb-connector-c
mariadb-connector-odbc
mariadb100-client
mariadb100-server
mariadb101-client
mariadb101-server
mariadb102-client
mariadb102-server
mariadb103-client
mariadb103-server
mariadb55-client
mariadb55-server
```

Note that FreeBSD treats the Server and Client as separate packages. The Client is a dependency of the Server, so you only need to build the Server to get both. It also provides a number of different versions. You can search the available ports from [Fresh Ports](#). Decide what version of MariaDB you want to install, then change into the relevant directory. Once in the directory, run Make to build MariaDB.

```
# cd /usr/ports/databases/mariadb103-server  
# make
```

In addition to downloading and building MariaDB, Ports also downloads and build any libraries on which MariaDB depends. Each port it builds will take you to a GUI window where you can select various build options. In the case of MariaDB, this includes various storage engines and specific features you need in your build.

Once you finish building the ports, install MariaDB on your system and clean the directory to free up disk space.

```
# make install clean
```

This installs FreeBSD on your server. You can now enable, configure and start the service as you normally would after installing MariaDB from a package.

## Using Poudriere

Poudriere is a utility for building FreeBSD packages. It allows you to build MariaDB from a FreeBSD Jail, then serve it as a binary package to other FreeBSD hosts. You may find this is particularly useful when building to deploy multiple MariaDB servers on FreeBSD, such as with Galera Cluster or similar deployments.

### Building MariaDB

Once you've configured your host to use Jails and Poudriere, initialize a jail to use in building packages and a jail for managing ports.

```
# poudriere jail -c -j package-builder -v 11.2-RELEASE  
# poudriere ports -c -p local-ports
```

This creates two jails,

package-builder  
and  
local-ports

, which you can then use to build MariaDB. Create a text file to define the packages you want to build. Poudriere will build these packages as well as their dependencies. MariaDB is located at

databases/mariadb103-server  
. Adjust the path to match the version you want to install.

```
$ vi mariadb-package-builder.txt  
  
databases/mariadb103-server
```

Use the

options  
command to initialize the build options for the packages you want Poudriere to compile.

```
# poudriere options -j package-builder -p local-ports -z mariadb-builder -f mariadb-package-builder.txt
```

Lastly, use the

bulk  
command to compile the packages.

```
# poudriere bulk -j package-builder -p local-ports -z mariadb-builder -f mariadb-package-builder.txt
```

## Using Poudriere Repositories

In order to use Poudriere, you need to set up and configure a web server, such as Nginx or Apache to serve the directory that Poudriere built. For instance, in the case of the above example, you would map to the

package-builder  
jail:  
/usr/local/poudriere/data/packages/package-builder/  
. You may find it useful to map this directory to a sub-domain, for instance  
https

*pkg.example.com*

or something similar.

Lastly, you need to configure the FreeBSD hosts to use the Poudriere repository you just created. On each host, disable the FreeBSD official repositories and enable the Poudriere repository as an alternative.

```
# vi /usr/local/etc/pkg/repos/FreeBSD.conf

FreeBSD: {
    enabled: no
}
```

Then add the URL for your Poudriere repository to configuration file:

```
# vi /usr/local/etc/pkg/repos/mariadb.conf

custom: {
    url: "https://pkg.example.com",
    enabled: yes
}
```

You can then install MariaDB from Poudriere using the package manager.

```
# pkg install mariadb103-server
```

## 2.1.2.8.14 Building MariaDB on Gentoo

MariaDB is in Gentoo, so the steps to build it are:

1. Synchronize your tree with

```
emerge --sync
```

2. Build MariaDB using

```
emerge mariadb
```

## 2.1.2.8.15 Building MariaDB on Solaris and OpenSolaris

The following two articles should help you get your Solaris machine prepared to build MariaDB (just ignore the parts about installing buildbot):

- [Buildbot Setup for Solaris Sparc](#)
- [Buildbot Setup for Solaris x86](#)

## Notes

- The BUILD dir contains various scripts for compiling MariaDB on Solaris. The  
BUILD/compile-solaris-amd64  
and  
BUILD/compile-solaris-amd64-debug  
are probably the most useful.
- The scripts do not play nice with non-bash shells such as the Korn Shell (ksh). So if your /bin/sh is pointing at ksh or ksh93, you'll want to change it so that it points at bash.

## 2.1.2.8.16 Building MariaDB on Ubuntu

### Contents

1. [Installing Build Dependencies](#)
2. [Building MariaDB](#)
  1. [Further Dependencies](#)
  2. [After Building](#)

In the event that you are using the Linux-based operating system Ubuntu or any of its derivatives and would like to compile MariaDB from source code, you can do so using the MariaDB source repository for the release that interests you.

Before you begin, install the

```
software-properties-common
,
devscripts
and
equivs
packages.
```

```
$ sudo apt-get install software-properties-common \
  devscripts \
  equivs
```

## Installing Build Dependencies

MariaDB requires a number of packages to compile from source. Fortunately, you can use the MariaDB repositories to retrieve the necessary code for the version you want. Use the [Repository Configuration](#) tool to determine how to set up the MariaDB repository for your release of Ubuntu, the version of MariaDB that you want to install, and the mirror that you want to use.

First add the authentication key for the repository, then add the repository.

```
$ sudo apt-key adv --recv-keys \
  --keyserver hkp://keyserver.ubuntu.com:80 \
  0xF1656F24C74CD1D8
$ sudo add-apt-repository --update --yes --enable-source \
  'deb [arch=amd64] http://nyc2.mirrors.digitalocean.com/mariadb/repo/10.3/ubuntu \'$(lsb_release -sc)\' main'
```

Once the repository is set up, you can use

`apt-get`

to retrieve the build dependencies. MariaDB packages supplied by Ubuntu and packages supplied by the MariaDB repository have the same base name of

`mariadb-server`

. You need to specify the specific version you want to retrieve.

```
$ sudo apt-get build-dep mariadb-10.3
```

## Building MariaDB

Once you have the base dependencies installed, you can retrieve the source code and start building MariaDB. The source code is available on GitHub. Use the

`--branch`

option to specify the particular version of MariaDB you want to build.

```
$ git clone --branch 10.3 https://github.com/MariaDB/server.git
```

The source code includes scripts to install the remaining build dependencies. For Ubuntu, they're located in the

`debian/`

directory. Navigate into the repository and run the

`autobake-deb.sh`

script. Then use

```
$ cd server/
$ ./debian/autobake-deb.sh
```

## After Building

After building the packages, it is a good idea to put them in a repository. See the [Creating a Debian Repository](#) page for instructions.

### 2.1.2.8.17 Building MariaDB on Windows

## Contents

- 1. Build Requirements
- 2. Building Windows Binaries
- 3. Build Variations
  - 1. Debug Builds
  - 2. 32bit and 64 bit Builds
    - 1. Build 64 bit binary
    - 2. Build 32 bit binary
  - 3. IDE Builds
- 4. Building the ZIP Package
- 5. Building the MSI Package
- 6. Including HeidiSQL in the MSI Installer
- 7. Code Signing Support for MariaDB Release Processing
- 8. Building Packages for MariaDB Releases
- 9. Running Tests
  - 1. Running a Test Under Debugger

## Build Requirements

To build MariaDB you need the following:

- **Visual C++** : We currently support Visual Studio 2019 and 2022. Generally we try to support the two most recent VS versions, but build ourselves using the last one. Community editions will work fine; we only use them in our builds. While installing Visual Studio, make sure to [add "Desktop Development with C++"](#).
- **CMake** : We recommend the latest release. Older releases might not support your version of Visual Studio. Visual Studio 2019 requires cmake 3.14 at least.
- **Git** : Required to build newer versions from the source tree.
  - NOTE: run

```
git config --global core.autocrlf input
```

after the installation, otherwise some mtr tests will fail

In the "Adjusting your PATH" dialog, choose "Use Git from Windows command prompt", otherwise wrong (mingw64) git and perl will be in your PATH

- **Bison from GnuWin32** : Bison creates parts of the SQL parser. Choose "Complete package except sources" when downloading.
  - NOTE: **Do not** install this into your default path with spaces (e.g. under  
C:\Program Files\GnuWin32  
); the build will break due to [this bison bug](#). Instead, install into  
C:\GnuWin32
  - Add  
C:\GnuWin32\bin  
to your system  
PATH  
after installation.
- **Strawberry perl** : Used to run the test suite. [ActiveState Perl](#) is another Win32 Perl distribution and should work as well (but it is not as well tested).  
NOTE: Cygwin or mingw Perl versions **will not work** for testing. Use Windows native Perl, please.
- Optional: If you intend to build the MSI packages, install [[ <https://wixtoolset.org/releases/>] Windows Installer XML] . If you build MSI with 10.4, also modify your Visual Studio installation, add "Redistributable MSMs" (see [MDEV-22555](#) )
- **Gnu Diff** , needed if you run mysql-test-run.pl tests.

Verify that bison.exe, bsr.exe or git.exe, cmake.exe and perl.exe can be found in the PATH environment variable with "

```
where bison
",
where git
",
where perl
" etc. from the command line prompt.
```

## Building Windows Binaries

The above instructions assume [MariaDB 10.2](#) or higher.

Branch the MariaDB bsr repository, or unpack the source archive. On the command prompt, switch to your source directory, then execute:

```
mkdir bld  
cd bld  
cmake ..  
cmake --build . --config RelWithDebInfo
```

The above example builds a release configured for 64 bit systems in a subdirectory named

```
bld  
."  
cmake ...  
" is the configuration step,  
cmake --build . --config Relwithdebinfo  
" is the build step.
```

## Build Variations

### Debug Builds

Building Debug version is done with:

```
cmake --build . --config Debug
```

### 32bit and 64 bit Builds

#### Build 64 bit binary

Visual Studio 2019-2022 cmake generator will use host architecture by default, that is, with the steps above, cmake will build x64 binaries on x64 machine.

#### Build 32 bit binary

pass -A Win32 parameter for CMake, like this

```
cmake .. -A Win32
```

Historical note: With Visual Studio 2017 and earlier, one had to pass the name of 32bit generator ,e.g cmake .. -G "Visual Studio 15 2017"

For a complete list of available generators, call "cmake" without any parameters.

### IDE Builds

Instead of calling "

```
cmake --build  
" as above, open  
MySQL.sln  
. When Visual Studio starts, choose Build/Compile.
```

## Building the ZIP Package

```
cmake --build . --config relwithdebinfo --target package
```

This is how it is "done by the book", standard cmake target.

MariaDB however uses non-standard target "win\_package" for the packaging for its releases, it generates 2 ZIPs, a slim one with executables, and another one with debuginfo (.PDB files). The debuginfo is important to be able to debug released binaries, and to analyze crashes.

```
cmake --build . --config relwithdebinfo --target win_package
```

## Building the MSI Package

```
cmake --build . --config relwithdebinfo  
cmake --build . --config relwithdebinfo --target MSI
```

## Including HeidiSQL in the MSI Installer

Starting with MariaDB 5.2.7 , it is possible to build an installer which includes 3rd party products, as described in [MWL#200](#) . Currently only HeidiSQL support is implemented; it is also included in the official builds. Use the CMake parameter

-DWITH\_THIRD\_PARTY=HeidiSQL  
to include it in the installer.

## Code Signing Support for MariaDB Release Processing

MariaDB builds optionally support authenticode code signing with an optional parameter

SIGNCODE  
. Use  
cmake -DSIGNCODE=1  
during the configuration step to sign the binaries in the  
ZIP  
and  
MSI  
packages.

**Important:** for

SIGNCODE=1  
to work, the user that runs the build needs to install a valid authenticode digital certificate into their certificate store, otherwise the packaging step will fail.

## Building Packages for MariaDB Releases

The full script to create the release in an out-of-source build with Visual Studio with signed binaries might look like:

```
mkdir bld
cd bld
cmake .. -DSIGNCODE=1 -DWITH_THIRD_PARTY=HeidiSQL
cmake --build . --config relwithdebinfo --target win_package
cmake --build . --config relwithdebinfo --target MSI
```

This command sequence will produce a ZIP package (e.g mariadb-5.2.6-win32.zip) and MSI package (e.g mariadb-5.2.6-win32.msi) in the  
bld  
directory.

## Running Tests

- **Important: Do not use Cygwin bash, MinGW bash, Git bash, WSL bash, or any other bash when running the test suite. You will then very likely use the wrong version of Perl too (a "Unix-flavoured" one on Windows), and spend a lot of time trying to figure out why this version of Perl does not work for the test suite. Use native perl, in cmd.exe , or powershell instead,**
- Switch mysql-test subdirectory of the build directory

```
cd C:\server\bld\mysql-test
```

- Run the test suite

```
perl mysql-test-run.pl --suite=main --parallel=auto
```

## Running a Test Under Debugger

Assuming VS is installed on the machine

```
perl mysql-test-run.pl <test_name> --vsjitdebugger
```

If vsjitdebugger does not start, you can edit AeDebug registry key as mentioned in

[https://docs.microsoft.com/en-us/visualstudio/debugger/debug-using-the-just-in-time-debugger?view=vs-2019#jit\\_errors](https://docs.microsoft.com/en-us/visualstudio/debugger/debug-using-the-just-in-time-debugger?view=vs-2019#jit_errors)

Alternatively:

```
perl mysql-test-run.pl <test_name> --devenv
```

(devenv.exe needs to be in PATH)

or, if you prefer WinDBG

```
perl mysql-test-run.pl <test_name> --windbg
```

## 2.1.2.8.18 Installing MariaDB Server on macOS Using Homebrew

### Contents

1. [Upgrading MariaDB](#)
2. [Building MariaDB Server from source](#)
3. [Other resources](#)

MariaDB Server is available for installation on macOS (formerly Mac OS X) via the [Homebrew](#) package manager.

MariaDB Server is available as a Homebrew "bottle", a pre-compiled package. This means you can install it without having to build from source yourself. This saves time.

After installing Homebrew, MariaDB Server can be installed with this command:

```
brew install mariadb
```

After installation, start MariaDB Server:

```
mysql.server start
```

To auto-start MariaDB Server, use Homebrew's services functionality, which configures auto-start with the launchctl utility from [launchd](#) :

```
brew services start mariadb
```

After MariaDB Server is started, you can log in as your user:

```
mysql
```

Or log in as root:

```
sudo mysql -u root
```

## Upgrading MariaDB

First you may need to update your brew installation:

```
brew update
```

Then, to upgrade MariaDB Server:

```
brew upgrade mariadb
```

## Building MariaDB Server from source

In addition to the "bottled" MariaDB Server package available from Homebrew, you can use Homebrew to build MariaDB from source. This is useful if you want to use a different version of the server or enable some different capabilities that are not included in the bottle package.

Two components not included in the bottle package (as of MariaDB Server 10.1.19) are the CONNECT and OQGRAPH engines, because they have non-standard dependencies. To build MariaDB Server with these engines, you must first install

```
boost  
and  
judy
```

. As of December 2016, judy is in the Homebrew "boneyard", but the old formula still works on macOS Sierra. Follow these steps to install the dependencies and build the server:

```
brew install boost homebrew/boneyard/judy  
brew install mariadb --build-from-source
```

You can also use Homebrew to build and install a pre-release version of MariaDB Server (for example MariaDB Server 10.2, when the highest GA version is MariaDB Server 10.1). Use this command to build and install a "development" version of MariaDB Server:

```
brew install mariadb --devel
```

## Other resources

- mariadb.rb on [github](#)
- Terin Stock ([terinjokes](#)) who is the packager for Homebrew
- MariaDB Server on macOS: [Does it even make sense to try?](#) (video)

## 2.1.2.8.19 Creating a Debian Repository

Below are instructions for creating your own Debian repository. The instructions are based on <http://www.debian.org/doc/manuals/repository-howto/repository-howto.en.html>

```
REPO_DIR={pick some location}
mkdir $REPO_DIR
mkdir $REPO_DIR/binary
mkdir $REPO_DIR/source
cp *.deb *.ddeb $REPO_DIR/binary
cd $REPO_DIR
dpkg-scanpackages binary /dev/null | gzip -9c > binary/Packages.gz
dpkg-scansources source /dev/null | gzip -9c > source/Sources.gz
```

## Using the Debian repository you just created

One needs to add a new file to the

```
/etc/apt/sources.list.d/
directory. For instance a new file called
mariadb.list
```

```
# sergey's MariaDB repository
#
deb file:///home/psergey/testrepo binary/
deb-src file:///home/psergey/testrepo source/
```

after which one can run

```
apt-get update # Let apt learn about the new repository
apt-get install mariadb-server
```

and collect bugs :-).

"apt-get install" will spray output of scripts and servers all over /var/log. It is also possible to set DEBIAN\_SCRIPT\_DEBUG=1 to get some (not all) of it to stdout.

## Cleaning up after failed installation

Run

```
dpkg --get-selections | grep mariadb
dpkg --get-selections | grep mysql
```

to see what is installed, and then

```
dpkg --purge <packages>
```

until the former produces empty output. Note: after some failures, /etc/mysql and /var/lib/mysql are not cleaned and still need to be removed manually.

## 2.1.2.8.20 Building MariaDB From Source Using musl-based GNU/Linux

### Instructions on compiling MariaDB on musl-based operating systems (Alpine)

#### Contents

1. [Instructions on compiling MariaDB on musl-based operating systems \(Alpine\)](#)
2. [Using cmake](#)

The instructions on this page will help you compile [MariaDB](#) from source. Links to more complete instructions for specific platforms can be found on the

[source](#) page.

- First, [get a copy of the MariaDB source](#) .
- Next, [prepare your system to be able to compile the source](#) .

## Using cmake

MariaDB 10.1 and above is compiled using `cmake` . You can configure your build simply by running `cmake` using special option, i.e.

```
cmake . -DWITHOUT_TOKUDB=1
```

To build and install MariaDB after running `cmake` use

```
make  
sudo make install
```

Note that building with MariaDB this way will disable tokuDB, till tokuDB becomes fully supported on musl.

### 2.1.2.8.21 Compiling MariaDB for Debugging

#### Contents

1. [Compiling MariaDB for Debugging Using the CMAKE\\_BUILD\\_TYPE Option](#)
2. [Compiling MariaDB for Debugging Using Build Scripts](#)
  1. [Example of Compiling MariaDB for Debugging Using Build Scripts](#)
  3. [Building Optimized Build With Debug Symbols](#)
  4. [Doing a Debug Build on Debian/Ubuntu](#)
    1. [Temporarily Installing your Debug Build](#)
    2. [Reinstalling your Release Build](#)
  5. [Different Compilation Options](#)
    1. [Changing DBUG\\_ASSERT to Print to Error Log](#)
  6. [See Also](#)

Compiling MariaDB with full debug information includes all code symbols and also new code to do internal testing of structures and allow one to trace MariaDB execution. A full debug binary will be notably slower than a normal binary (30%).

## Compiling MariaDB for Debugging Using the CMAKE\_BUILD\_TYPE Option

On Unix systems, you can build a debug build by executing

```
cmake  
and by setting the  
CMAKE_BUILD_TYPE  
option to  
Debug  
. For example:
```

```
cmake -DCMAKE_BUILD_TYPE=Debug .
```

## Compiling MariaDB for Debugging Using Build Scripts

The other option is to use the scripts in the BUILD directory that will compile MariaDB with most common debug options and plugins:

```
./BUILD/compile-pentium64-debug-max
```

or alternatively if you want to use the [Valgrind](#) memory checking tool with the [MariaDB test system](#) :

```
./BUILD/compile-pentium64-valgrind-max
```

There are separate build scripts for different configurations in the BUILD directory.

You can find a list of the needed packages/libraries for building on Linux [here](#).

## Example of Compiling MariaDB for Debugging Using Build Scripts

- Scripts containing "debug" in the name are for developers that want to build, develop and test MariaDB.
- Scripts containing "valgrind" in the name are for running mysqld under [http://valgrind.org/valgrind]. Compiling for valgrind means that we are using another implementation of MEM\_ROOT to allow valgrind to better detect memory overruns. In addition, some memory areas are marked as used/not used to remove some false positives.
- Scripts containing "max" in the name include all normal plugins.

Here is an example of how to compile MariaDB for debugging in your home directory with [MariaDB 5.2.9](#) as an example:

```
cd ~  
mkdir mariadb  
cd mariadb  
tar xvf mariadb-5.2.9.tar.gz  
ln -s mariadb-5.2.9 current  
cd current  
.BUILD/compile-pentium64-debug-max
```

The last command will produce a debug version of

```
sql/mysqld  
. If you have a system other than 64 bit Intel/AMD on Linux you can use a different  
BUILD/...-debug-max  
file. If this fails, you can try with:
```

```
cmake --build . --config Debug  
make -j4
```

## Building Optimized Build With Debug Symbols

To build MariaDB with symbols, to get better stack traces and to be able to debug the binary with

```
gdb  
, you need to supply the  
-g3  
option to the  
gcc  
compiler.
```

Just compiling with

```
-g3  
will make the binary much bigger but the slowdown of the server should be negligible.
```

One way to do this is to edit the script

```
BUILD/compile-pentium64-max
```

and add the -g3 last on the line with

```
extra_flags  
, like this:
```

```
extra_flags="$pentium64_cflags $fast_cflags -g3"
```

After that you can compile MariaDB with debugging symbols by just execution the above script.

## Doing a Debug Build on Debian/Ubuntu

To build a "mysqld" binary with debugging enabled that uses the same parameters as the ones used in Debian/Ubuntu binary packages, you must do as follows (you must have a deb-src line of one of the MariaDB repositories on your /etc/apt/sources.list in order to do that):

```
apt-get build-dep mariadb-10.2  
apt-get install cmake libaio1 libaio-dev  
apt-get source mariadb-10.2  
cd mariadb-10.2*  
.debian/rules configure  
.BUILD/compile-pentium64-debug-all
```

Then you will have your "debugging enabled" mysqld binary in the sql/ directory.

This binary can directly replace the one provided by the binary package that is placed on "/usr/bin/mysqld".

## Temporarily Installing your Debug Build

The commands shown below replace the release

```
mysqld  
binary with the debug  
mysqld  
binary that you compiled. Most importantly, they replace the binary in a way which makes it trivial to revert back to the original release  
mysqld  
binary.
```

First, [stop MariaDB](#).

Then, use the

```
mv  
utility to rename the release  
mysqld  
binary:
```

```
sudo mv /usr/sbin/mysqld /usr/sbin/mysqld-orig
```

Note: Do not use the

```
cp  
utility because that will change the file modification timestamp.
```

Then, install the debug

```
mysqld  
binary from your source tree:
```

```
sudo install ~/mariadb-10.3.14/sql/mysqld /usr/sbin/mysqld-debug
```

Then, link the

```
mysqld  
path to the path of your debug  
mysqld  
binary:
```

```
sudo ln -s /usr/sbin/mysqld-debug /usr/sbin/mysqld
```

Then, [start MariaDB](#).

Be sure to replace

```
/usr/sbin/mysqld  
with the path to your  
mysqld  
binary and to also replace
```

~

```
/mariadb-10.3.14/sql/mysqld  
with the path to your debug  
mysqld  
binary.
```

## Reinstalling your Release Build

If you want to restore your original

```
mysqld  
binary, you can do it with the following process::
```

First, [stop MariaDB](#).

Then, execute the following command to delete the symbolic link:

```
sudo rm /usr/sbin/mysqld
```

Then, execute the following command to move the original

```
mysqld  
release binary back into place:
```

```
sudo mv /usr/sbin/mysqld-orig /usr/sbin/mysqld
```

Then, [start MariaDB](#).

Be sure to replace

```
/usr/sbin/mysqld  
with the path to your  
mysqld  
binary
```

Notice that the debug

```
mysqld  
binary located at  
/usr/sbin/mysqld-debug  
was not deleted. Only the symbolic link to this file was deleted. The debug  
mysqld  
binary is still present if it is needed again in the future.
```

## Different Compilation Options

### Changing DBUG\_ASSERT to Print to Error Log

A debug binary has lots of code checks and asserts, that are not checked in production. This is done to get more performance when running in production. In some cases, when one is trying to find a hard-to-repeat bug, it could be beneficial to have these checks in production builds too.

Compiling with

```
-DDBUG_ASSERT_AS_PRINTF  
will change DBUG_ASSERT() to print any failed check to the error log.
```

```
cmake . -DDBUG_ASSERT_AS_PRINTF
```

Enabling the above option should not have any notable impact on performance (probably < 1% slowdown). This is achieved by grouping asserts in MariaDB server code into two groups:

- Fast checks, using  
`DBUG_ASSERT()`  
: These are converted to printing to error log.
- Slow checks, using  
`DBUG_SLOW_ASSERT()`  
. These will always be removed in production builds.

### 2.1.2.8.22 Cross-compiling MariaDB

#### Buildroot

[Buildroot](#) is a way to cross compile MariaDB and other packages into a root filesystem. In the menuconfig you need to enable "Enable C++ Support" first under "Toolchain". After C++ is enabled MariaDB is an option under "Target Packages" ->"Libraries" -> "Databases" -> "mysql support" -> "mysql variant" -> "mariadb". Also enable the "mariadb server" below the "mysql support" option.

#### Details

To cross-compile with cmake you will need a toolchain file. See, for example, [here](#). Besides cmake specific variables it should have, at least

```
SET(STACK_DIRECTION -1)  
SET(HAVE_IB_GCC_ATOMIC_BUILTINS 1)
```

with appropriate values for your target architecture. Normally these MariaDB configuration settings are detected by running a small test program, and it cannot be done when cross-compiling.

Note that during the build few helper tools are compiled and then immediately used to generate more source files for this very build. When cross-compiling these tools naturally should be built for the host architecture, not for the target architecture. Do it like this (assuming you're in the mariadb source tree):

```
$ mkdir host
$ cd host
$ cmake ..
$ make import_executables
$ cd ..
```

Now the helpers are built and you can cross-compile:

```
$ mkdir target
$ cd target
$ cmake .. -DCMAKE_TOOLCHAIN_FILE=/path/to/toolchain/file.cmake -DIMPORT_EXECUTABLES=../host/import_executables.cmake
$ make
```

Here you invoke cmake, specifying the path to your toolchain file and the path to the

`import_executables.cmake`

that you have just built on the previous step. Of course, you can also specify any other cmake parameters that could be necessary for this build, for example, enable or disable specific storage engines.

## 2.1.2.8.23 MariaDB Source Configuration Options

### Contents

#### 1. See Also

All CMake configuration options for MariaDB can be displayed with:

```
cmake . -LH
```

## See Also

- [Get the Code, Build it, Test it](#) (mariadb.org)
- [Generic Build Instructions](#)

## 2.1.2.8.24 Building RPM Packages From Source

To generate RPM packages from the build, supply the

`-DRPM=yes`

flag to CMake.

The value

`yes`

(or whatever) will build generic RPM packages. It is also possible to use one of these special values that will slightly modify what kind of layout the resulting RPM packages will have:

- `fedora`
- `centos7/rhel7`
- `centos8/rhel8`
- `sles`

What these do are controlled in the following CMake files:

- `cmake/cpack_rpm.cmake`
- `cmake/build_configurations/mysql_release.cmake`
- `cmake/mariadb_connector_c.cmake`

- [MariaDB RPM Packages](#)

## 2.1.2.8.25 Compile and Using MariaDB with

# AddressSanitizer (ASAN)

## Contents

1. [What is AddressSanitizer \(ASAN\)](#)
2. [How to Compile MariaDB for ASAN](#)
3. [Running an ASAN Build](#)
4. [Other Things](#)
  - 1. [Using Valgrind](#)
5. [See Also](#)

## What is AddressSanitizer (ASAN)

[AddressSanitizer \(aka ASan\)](#) is a memory error detector for C/C++. It finds a lot of the same things as [valgrind](#), but with a lot less overhead.

- Use after free (dangling pointer dereference)
- Heap buffer overflow
- Stack buffer overflow
- Global buffer overflow
- Use after return
- Use after scope
- Initialization order bugs
- Memory leaks

To use ASAN you need a gcc version that supports ASAN. gcc 4.8.5 and up are known to work.

## How to Compile MariaDB for ASAN

ASAN is supported in [MariaDB 10.1](#) and up.

You can use one of the two following build commands:

```
cmake . -DWITH_ASAN=ON
```

or from [MariaDB 10.2](#) and up:

```
./BUILD/compile-pentium64-asan-max
```

## Running an ASAN Build

To run mysqld with instrumentation you have to set the

```
ASAN_OPTIONS  
environment variable before starting  
mysqld  
. Either in your shell or in your mysqld\_safe script.
```

```
export ASAN_OPTIONS=abort_on_error=1:leak_check_at_exit=0
```

The above command will abort mysqld if any errors are found, which is good for debugging. If you set `abort_on_error=0` all errors are logged to your error log file (`mysqld.err`).

## Other Things

A side effect of using ASAN builds is that you will not get any core file if your server crashes.

## Using Valgrind

The [MariaDB test system](#) can use [Valgrind](#) for finding memory leaks and wrong memory accesses. Valgrind is an instrumentation framework for building dynamic analysis tools. If Valgrind is installed on your system, you can simply use `mysql-test-run --valgrind` to run the test under Valgrind.

## 2.1.2.9 Distributions Which Include MariaDB

## Contents

1. Linux Distributions
2. BSD Distributions
3. macOS

The following is a partial list of distributions which include MariaDB in their package repositories. For these you can use the distribution's management system to install MariaDB.

The term "default" in the list below refers to the distribution's default relational or MySQL-type database.

## Linux Distributions

- [Alpine Linux](#) — Defaults to MariaDB. [MariaDB 10.5](#) has been available 3.13.5
- [4mLinux](#) — Defaults to MariaDB. [MariaDB 10.3](#) has been available since 26.0
- [ALT Linux](#) — [MariaDB 5.5](#) included in 7.0.0, MariaDB is default from 8.1, which includes [MariaDB 10.1](#), 9.1 includes [MariaDB 10.4](#)
- [Arch Linux](#) — Features [MariaDB 10.5](#), and replaced MySQL as a default
- [Asianux](#) — [MariaDB 5.5](#) replaced MySQL in 7.
- [Austrumi](#) — Defaulted to [MariaDB 5.3](#) in 2.4.8, 3.5.8 includes [MariaDB 10.1](#)
- [BlackArch](#) — Defaulted to [MariaDB 5.5](#) in 2014.07.01, 2020.06.01 includes [MariaDB 10.4](#)
- [BlueOnyx](#) — 5209 defaults to [MariaDB 5.5](#), 5210R to [MariaDB 10.3](#)
- [BlueStar](#) — 4.8.4 defaults to [MariaDB 10.1](#), 5.4.2 to [MariaDB 10.5](#)
- [CentOS](#) — [MariaDB 5.5](#) replaced MySQL in CentOS 7
- [The Chakra Project](#) — MariaDB replaced MySQL as default in 2013.05. 2016.02 includes [MariaDB 10.1](#)
- [Debian](#) — Debian 8 "Jessie" includes [MariaDB 10.0](#), Debian 9 "Stretch" [MariaDB 10.1](#), Debian 10 "Buster" [MariaDB 10.3](#), Debian 11 "Bullseye" [MariaDB 10.5](#) as default.
- [Elastix](#) — Defaulted to [MariaDB 5.5](#) in 4.0.76
- [Exherbo](#) — Includes [MariaDB 10.4](#)
- [Fedora](#) — [MariaDB 5.5](#) became the default relational database in Fedora 19. Fedora 30 includes [MariaDB 10.3](#), Fedora 34 includes [MariaDB 10.5](#).
- [Funtoo](#) — Includes [MariaDB 5.5](#)
- [Gentoo Linux](#)
- [Guix](#) — 11.2.0 includes [MariaDB 10.1](#)
- [Hanthana](#) — 19.1 defaulted to [MariaDB 5.5](#), 21 includes [MariaDB 10.0](#), 28.1.2 includes [MariaDB 10.2](#), 30 includes [MariaDB 10.3](#)
- [KaOS](#) — Defaulted to [MariaDB 5.5](#) in 2014.12, 2019.04 includes [MariaDB 10.3](#)
- [Kali Linux](#) — 2017.3 Included [MariaDB 10.1](#), 2021.1 includes [MariaDB 10.5](#)
- [GNU/Linux KDu](#) — [MariaDB 5.5](#) replaced MySQL as a default in 2.0 Final.
- [Korora](#) — Defaulted to MariaDB in 19.1, 26 includes [MariaDB 10.1](#)
- [Linux from Scratch](#) — 10.1-BLFS defaults to [MariaDB 10.5](#)
- [Lunar](#) — 1.7.0 includes [MariaDB 5.5](#), Moonbase includes [MariaDB 10.5](#)
- [Mageia](#) — [MariaDB 5.5](#) replaced MySQL as default in version 3, [MariaDB 10.3](#) from version 7.1, [MariaDB 10.5](#) from 8.
- [Manjaro Linux](#) — Defaulted to [MariaDB 5.5](#) in 0.8.11, 16.10.3 includes [MariaDB 10.1](#).
- [NixOS](#) — 14.0.4.630 included [MariaDB 10.0](#), 18.09 includes [MariaDB 10.2](#), Stable includes [MariaDB 10.5](#)
- [Network Security Toolkit](#) — 20-5663 defaulted to [MariaDB 5.5](#), 32-11992 includes [MariaDB 10.4](#)
- [NuTyX](#) — 14.11 included [MariaDB 10.0](#), defaulted to [MariaDB 10.1](#) in 8.2.1, 20.12.1 includes [MariaDB 10.5](#)
- [OpenELEC](#)
- [OpenEuler](#) — 21.9 includes [10.5](#), 20.03 LTS includes [MariaDB 10.3](#), as does 21.03
- [Open Mandriva](#) — Defaulted to [MariaDB 10.0](#) in 2014.2, includes [MariaDB 10.5](#) in 4.2
- [openSUSE](#) — [MariaDB 5.5](#) became the default relational database in [openSUSE 12.3](#), and [MariaDB 10.4](#) the default since 15.2
- [Oracle Linux](#) — 7.3 includes [MariaDB 5.5](#). 8.0 includes [MariaDB 10.3](#)
- [Paldo](#) — Defaults to [MariaDB 10.5](#) in Stable
- [Parabola GNU/Linux](#) — Includes [MariaDB 10.1](#) since 3.7
- [Parrot Security](#) — Based on Debian's testing branch (stretch), Parrot Security switched from MySQL to [MariaDB 10.0](#) in 3.1, 4.7 includes [MariaDB 10.3](#)
- [Parted Magic](#) — Defaulted to [MariaDB 5.5](#) in 2015\_11\_13
- [PCLinuxOS](#) — Replaced MySQL with [MariaDB 10.1](#) in 2017.03
- [Pisi Linux](#) — Defaulted to [MariaDB 10.0](#) in 1.1
- [Plamo](#) — Defaulted to [MariaDB 5.5](#) in 5.3.1, 7.3 includes [MariaDB 10.2](#)
- [PoliArch](#) — Defaulted to [MariaDB 5.5](#) in 13.1, 15.1 includes [MariaDB 10.0](#)
- [Red Hat Enterprise Linux](#) — [MariaDB 5.5](#) was included as the default "MySQL" database since RHEL 7, RHEL 8 includes [MariaDB 10.3](#)
- [ROSA](#) — Defaulted to [MariaDB 10.0](#) in R4 and [MariaDB 10.1](#) in R9.
- [Sabayon](#) — Included [MariaDB 10.0](#) in 14.12, includes [MariaDB 10.3](#) since 19.03
- [Scientific Linux](#) — Defaulted to [MariaDB 5.5](#) in 7.3
- [Slackware](#) — [MariaDB 5.5](#) replaced MySQL as default in 14.1. 14.2 includes [MariaDB 10.0](#), current includes [MariaDB 10.5](#)
- [SliTaz GNU/Linux](#) — Includes [MariaDB 10.0](#) in 5.0-rolling
- [SME Server](#) — started to use [MariaDB 5.5](#) from 10.0
- [Springdale Linux](#) — Defaulted to [MariaDB 5.5](#) in 7.2, 8.1 includes [MariaDB 10.3](#)
- [SuliX](#) — Defaults to [MariaDB 5.5](#) in 8.
- [SUSE Linux Enterprise](#) — [MariaDB 10.0](#) is the default relational database option on 12-SP2, 15-SP2 includes [MariaDB 10.4](#)
- [Ubuntu](#) — [MariaDB 5.5](#) was included in Trusty Tahr 14.04. 20.04 includes [MariaDB 10.3](#).
- [Void](#) — Includes [MariaDB 10.5](#) in current
- [Wifislax](#) — Defaulted to [MariaDB 10.0](#) in 4.11.1

## BSD Distributions

- **Dragonfly BSD** — 3.8 included [MariaDB 5.5](#) . 5.8.0 includes [MariaDB 10.4](#) .
- **FreeBSD** — MariaDB is available in the ports tree and the FreeBSD Manual has instructions on [Installing Applications: Packages and Ports](#) . [MariaDB 10.5](#) is included in 12.2
  - [MariaDB on FreshPorts](#)
- **NetBSD** — 6.1 and 7.0 include [MariaDB 5.5](#) .
- **OpenBSD** — [MariaDB 10.0](#) was included in 5.7, 6.8 includes [MariaDB 10.5](#) .

## macOS

- [Homebrew](#) — If you have Homebrew installed, you can install MariaDB Server by executing  

```
brew install mariadb
```

 . Find out more at [Installing MariaDB Server on macOS Using Homebrew](#) .
- [MacPorts](#) — This provides [mariadb](#) and [mariadb-server](#) . A [quick guide](#) on how to install it.

## 2.1.2.10 Running Multiple MariaDB Server Processes

### Contents

1. [Configuring Multiple MariaDB Server Processes](#)
2. [Starting Multiple MariaDB Server Processes](#)
  1. [Service Managers](#)
    1. [Systemd](#)
  2. [Starting the Server Process Manually](#)
    1. [mysqld](#)
    2. [mysqld\\_safe](#)
    3. [mysqld\\_multi](#)
  3. [Other Options](#)

It is possible to run multiple MariaDB Server processes on the same server, but there are certain things that need to be kept in mind. This page will go over some of those things.

## Configuring Multiple MariaDB Server Processes

If multiple MariaDB Server process are running on the same server, then at minimum, you will need to ensure that the different instances do not use the same

`datadir`

,

`port`

, and

`socket`

. The following example shows these options set in an [option file](#) :

```
[client]
# TCP port to use to connect to mysqld server
port=3306
# Socket to use to connect to mysqld server
socket=/tmp/mysql.sock
[mariadb]
# TCP port to make available for clients
port=3306
# Socket to make available for clients
socket=/tmp/mysql.sock
# Where MariaDB should store all its data
datadir=/usr/local/mysql/data
```

The above values are the defaults. If you would like to run multiple MariaDB Server instances on the same server, then you will need to set unique values for each instance.

There may be additional options that also need to be changed for each instance. Take a look at the full list of options for

`mysqld`

To see the current values set for an instance, see [Checking Program Options](#) for how to do so.

To list the default values, check the end of:

```
mysqld --help --verbose
```

## Starting Multiple MariaDB Server Processes

There are several different methods to start or stop the MariaDB Server process. There are two primary categories that most of these methods fall into: starting the process with the help of a service manager, and starting the process manually. See [Starting and Stopping MariaDB](#) for more information.

### Service Managers

[sysVinit](#) and [systemd](#) are the most common Linux service managers. [launchd](#) is used in MacOS X. [Upstart](#) is a less common service manager.

#### Systemd

RHEL/CentOS 7 and above, Debian 8 Jessie and above, and Ubuntu 15.04 and above use [systemd](#) by default.

For information on how to start and stop multiple MariaDB Server processes on the same server with this service manager, see [systemd: Interacting with Multiple MariaDB Server Processes](#).

### Starting the Server Process Manually

#### mysqld

[mysqld](#)

is the actual MariaDB Server binary. It can be started manually on its own.

If you want to force each instance to read only a single [option file](#), then you can use the

[--defaults-file](#)

option:

```
mysqld --defaults-file=/etc/my_instance1.cnf
```

#### mysqld\_safe

[mysqld\\_safe](#)

is a wrapper that can be used to start the

[mysqld](#)

server process. The script has some built-in safeguards, such as automatically restarting the server process if it dies. See [mysqld\\_safe](#) for more information.

If you want to force each instance to read only a single [option file](#), then you can use the

[--defaults-file](#)

option:

```
mysqld_safe --defaults-file=/etc/my_instance1.cnf
```

#### mysqld\_multi

[mysqld\\_multi](#)

is a wrapper that can be used to start the

[mysqld](#)

## Other Options

In some cases, there may be easier ways to run multiple MariaDB Server instances on the same server, such as:

- Using [dbdeployer](#).
- Starting multiple [Docker](#) containers.

### 2.1.2.11 Installing MariaDB Alongside MySQL

MariaDB was designed as a drop-in replacement of MySQL, with more features, new storage engines, fewer bugs, and better performance, but you can also install it alongside MySQL. (This can be useful, for example, if you want to migrate databases/applications one by one.)

Here are the steps to install MariaDB near an existing MySQL installation.

- Download the compiled binary tar.gz that contains the latest version ([mariadb-5.5.24-linux-x86\\_64.tar.gz](#) - as of writing this article) and extract the files in a directory of your choice. I will assume for this article that the directory was `/opt`.

```
[root@mariadb-near-mysql ~]# cat /etc/issue
CentOS release 6.2 (Final)

[root@mariadb-near-mysql ~]# rpm -qa mysql*
mysql-5.1.61-1.el6_2.1.x86_64
mysql-libs-5.1.61-1.el6_2.1.x86_64
mysql-server-5.1.61-1.el6_2.1.x86_64

[root@mariadb-near-mysql ~]# ps axf | grep mysqld
2072 pts/0    S+      0:00          \_ grep mysqld
1867 ?        S      0:01 /bin/sh /usr/bin/mysqld_safe --datadir=/var/lib/mysql --socket=/var/lib/mysql/mysql.sock ...
1974 ?        S1      0:06  \_ /usr/libexec/mysqld --basedir=/usr --datadir=/var/lib/mysql --user=mysql ...
```

- Create data directory and symlinks as below:

```
[root@mariadb-near-mysql opt]# mkdir mariadb-data
[root@mariadb-near-mysql opt]# ln -s mariadb-5.5.24-linux-x86_64 mariadb
[root@mariadb-near-mysql opt]# ls -al
total 20
drwxr-xr-x.  5 root root 4096 2012-06-06 07:27 .
dr-xr-xr-x. 23 root root 4096 2012-06-06 06:38 ..
lrwxrwxrwx.  1 root root   27 2012-06-06 07:27 mariadb -> mariadb-5.5.24-linux-x86_64
drwxr-xr-x. 13 root root 4096 2012-06-06 07:07 mariadb-5.5.24-linux-x86_64
drwxr-xr-x.  2 root root 4096 2012-06-06 07:26 mariadb-data
```

- Create group **mariadb** and user **mariadb** and set correct ownerships:

```
[root@mariadb-near-mysql opt]# groupadd --system mariadb
[root@mariadb-near-mysql opt]# useradd -c "MariaDB Server" -d /opt/mariadb -g mariadb --system mariadb
[root@mariadb-near-mysql opt]# chown -R mariadb:mariadb mariadb-5.5.24-linux-x86_64/
[root@mariadb-near-mysql opt]# chown -R mariadb:mariadb mariadb-data/
```

- Create a new **my.cnf** in `/opt/mariadb` from support files:

```
[root@mariadb-near-mysql opt]# cp mariadb/support-files/my-medium.cnf mariadb-data/my.cnf
[root@mariadb-near-mysql opt]# chown mariadb:mariadb mariadb-data/my.cnf
```

- Edit the file `/opt/mariadb-data/my.cnf` and add custom paths, socket, port, user and the most important of all: data directory and base directory. Finally the file should have at least the following:

```
[client]
port = 3307
socket = /opt/mariadb-data/mariadb.sock

[mysqld]
datadir      = /opt/mariadb-data
basedir      = /opt/mariadb
port = 3307
socket = /opt/mariadb-data/mariadb.sock
user        = mariadb
```

- Copy the init.d script from support files in the right location:

```
[root@mariadb-near-mysql opt]# cp mariadb/support-files/mysql.server /etc/init.d/mariadb
[root@mariadb-near-mysql opt]# chmod +x /etc/init.d/mariadb
```

- Edit **/etc/init.d/mariadb** replacing **mysql** with **mariadb** as below:

```
- # Provides: mysql
+ # Provides: mariadb
- basedir=
+ basedir=/opt/mariadb
- datadir=
+ datadir=/opt/mariadb-data
- lock_file_path="$lockdir/mysql"
+ lock_file_path="$lockdir/mariadb"
```

The trickiest part will be the last changes to this file. You need to tell mariadb to use only one cnf file. In the **start** section after **\$bindir/mysqld\_safe** add **--defaults-file=/opt/mariadb-data/my.cnf**. Finally the lines should look like:

```
# Give extra arguments to mysqld with the my.cnf file. This script
# may be overwritten at next upgrade.
$bindir/mysqld_safe --defaults-file=/opt/mariadb-data/my.cnf --datadir="$datadir" --pid-file="$mysqld_pid_file_path" $other_args
```

The same change needs to be made to the mysqladmin command below in the **wait\_for\_ready()** function so that the mariadb start command can properly listen for the server start. In the **wait\_for\_ready()** function, after **\$bindir/mysqladmin** add **--defaults-file=/opt/mariadb-data/my.cnf**. The lines should look like:

```
wait_for_ready () {
[...]
if $bindir/mysqladmin --defaults-file=/opt/mariadb-data/my.cnf ping >/dev/null 2>&1; then
```

- Run **mysql\_install\_db** by explicitly giving it the my.cnf file as argument:

```
[root@mariadb-near-mysql opt]# cd mariadb
[root@mariadb-near-mysql mariadb]# scripts/mysql_install_db --defaults-file=/opt/mariadb-data/my.cnf
```

- Now you can start MariaDB by

```
[root@mariadb-near-mysql opt]# /etc/init.d/mariadb start
Starting MySQL... [ OK ]
```

- Make MariaDB start at system start:

```
[root@mariadb-near-mysql opt]# cd /etc/init.d
[root@mariadb-near-mysql init.d]# chkconfig --add mariadb
[root@mariadb-near-mysql init.d]# chkconfig --levels 3 mariadb on
```

- Finally test that you have both instances running:

```
[root@mariadb-near-mysql ~]# mysql -e "SELECT VERSION();"
+-----+
| VERSION() |
+-----+
| 5.1.61    |
+-----+

## What about MariaDB Upgrades ?

By having the **mariadb.socket** , **my.cnf** file and **databases** in **/opt/mariadb-data** if you want to upgrade the MariaDB version you will only need to:

- extract the new version from the archive in **/opt** near the current version
- stop MariaDB
- change the symlink **mariadb** to point to the new directory
- start MariaDB
- run upgrade script... but remember you will need to provide the socket option **--socket=/opt/mariadb-data/mariadb.sock**

## 2.1.2.12 GPG

### Contents

1. [New key](#)
2. [Old key](#)
3. [Configuring](#)

The MariaDB project signs their MariaDB packages for Debian, Ubuntu, Fedora, CentOS, and Red Hat.

### New key

Our repositories for Debian "Sid" and the Ubuntu 16.04 and beyond "Xenial" use a new GPG signing key. As detailed in [MDEV-9781](#), APT 1.2.7 (and later) prefers SHA2 GPG keys and now prints warnings when a repository is signed using a SHA1 key like our previous GPG key. We have created a new SHA2 key for use with these affected repositories.

Information about this key:

- The short Key ID is:  
0xC74CD1D8
- The long Key ID is:  
0xF1656F24C74CD1D8
- The full fingerprint of the key is:  
177F 4010 FE56 CA33 3630 0305 F165 6F24 C74C D1D8
- The key can be added on Debian-based systems using the following command:

```
sudo apt-key adv --recv-keys --keyserver hkp://keyserver.ubuntu.com:80 0xF1656F24C74CD1D8
```

The instructions in the repository configuration tool for Ubuntu 16.04 "Xenial" and Debian "Stretch" and higher have been updated to reference this new key. Repositories for previous versions of Debian and Ubuntu still use the old key, so no changes are needed there.

### Old key

The GPG Key ID of the MariaDB signing key is

0xCBCB082A1BB943DB

. The short form of the id is

0x1BB943DB

and the full key fingerprint is:

```
1993 69E5 404B D5FC 7D2F E43B CBCB 082A 1BB9 43DB
```

This key is still used by the yum/dnf/zypper repositories for RedHat, CentOS, Fedora, openSUSE, and SLES.

If you configure the mariadb.org rpm repositories using the repository configuration tool (see below) then your package manager will prompt you to import the key the first time you install a package from the repository.

You can also import the key directly using the following command:

```
sudo rpmkeys --import https://yum.mariadb.org/RPM-GPG-KEY-MariaDB
```

### Configuring

See the [repository configuration tool](#) for details on configuring repositories that use these keys.

## 2.1.2.13 MariaDB Deprecation Policy

### Contents

1. [Current Package Platforms](#)
2. [Deprecated Package Platforms](#)
3. [Support for Deprecated Platforms](#)
4. [See Also](#)

The [MariaDB Foundation](#) tries to support as many different Operating Systems, Linux Distributions, and processor architectures as possible. However, when a distribution or OS stops receiving security and other updates it becomes difficult for the MariaDB project to provide freely packages for that platform. In such cases, our policy is to deprecate the platform and stop providing binary packages for it.

This policy and related deprecated dates are from the [MariaDB Foundation](#). For information on the MariaDB Corporation's policies related to supporting

software, see the [Engineering Policies](#) page.

## Current Package Platforms

The MariaDB project builds packages for the following:

Platform	Planned Deprecation Date
Debian 9 "Stretch"	Jun 2022
Windows 8.1	Jan 2023
Ubuntu 18.04 "Bionic"	Apr 2023
Windows Server 2012 R2	Oct 2023
Red Hat Enterprise Linux 7.x	Jun 2024
CentOS 7.x	Jun 2024
Debian 10 "Buster"	Jun 2024
SLES 12.x	Oct 2024
Ubuntu 20.04 "Focal"	Apr 2025
Debian 11 "Bullseye"	Jun 2026
SLES 15.x	Jul 2028
Red Hat Enterprise Linux 8.x	Jun 2029
Fedora 34	approximately 1 month after release of Fedora 36
Fedora 35	approximately 1 month after release of Fedora 37
SLES 12.5	6 months after release of SLES 12.6
SLES 15.0	6 months after release of SLES 15.1
Arch Linux	N/A - rolling distribution
Mageia	N/A - rolling distribution

- [Ubuntu Release Information](#) (End of Standard Support)
- [Debian LTS information](#)
- [General Debian release information](#)
- [Red Hat Release Information](#)
- [Fedora Release Information](#)
- [FreeBSD Security Information](#)
- [openSUSE Lifetime Information](#)
- [SLES Lifecycle Information](#)
- [Windows client lifecycle info](#)
- [Windows server lifecycle info](#)

## Deprecated Package Platforms

The MariaDB project no longer builds packages for the following Operating Systems and Linux Distributions:

Platform	Deprecation Date	Final MariaDB Version(s)
Ubuntu 21.04 "Hirsute"	Feb 2022	<a href="#">MariaDB 10.7.2</a> , <a href="#">MariaDB 10.6.6</a> , <a href="#">MariaDB 10.5.14</a>
Fedora 33	Feb 2022	<a href="#">MariaDB 10.7.2</a> , <a href="#">MariaDB 10.6.6</a> , <a href="#">MariaDB 10.5.14</a> , <a href="#">MariaDB 10.4.23</a>
CentOS 8.x	Feb 2022	<a href="#">MariaDB 10.7.2</a> , <a href="#">MariaDB 10.6.6</a> , <a href="#">MariaDB 10.5.14</a> , <a href="#">MariaDB 10.4.23</a> , <a href="#">MariaDB 10.3.33</a>
Ubuntu 20.10 "Groovy"	Jul 2021	<a href="#">MariaDB 10.6.4</a> , <a href="#">MariaDB 10.5.12</a> , <a href="#">MariaDB 10.4.21</a> , <a href="#">MariaDB 10.3.31</a>
Fedora 32	Apr 2021	<a href="#">MariaDB 10.5.10</a> , <a href="#">MariaDB 10.4.19</a> , <a href="#">MariaDB 10.3.29</a>
Ubuntu 16.04 LTS "Xenial"	Apr 2021	<a href="#">MariaDB 10.5.10</a> , <a href="#">MariaDB 10.4.19</a> , <a href="#">MariaDB 10.3.29</a> , <a href="#">MariaDB 10.2.38</a>
Mint 18 LTS "Serena"	Apr 2021	<a href="#">MariaDB 10.5.10</a> , <a href="#">MariaDB 10.4.19</a> , <a href="#">MariaDB 10.3.29</a> , <a href="#">MariaDB 10.2.38</a>
Fedora 31	Nov 2020	<a href="#">MariaDB 10.5.7</a> , <a href="#">MariaDB 10.4.16</a> , <a href="#">MariaDB 10.3.26</a>
Red Hat Enterprise Linux 6.x	Nov 2020	<a href="#">MariaDB 10.4.16</a> , <a href="#">MariaDB 10.3.26</a> , <a href="#">MariaDB 10.2.35</a> , <a href="#">MariaDB 10.1.48</a>
CentOS 6.x	Nov 2020	<a href="#">MariaDB 10.4.16</a> , <a href="#">MariaDB 10.3.26</a> , <a href="#">MariaDB 10.2.35</a> , <a href="#">MariaDB 10.1.48</a>
Fedora 30	Aug 2020	<a href="#">MariaDB 10.5.5</a> , <a href="#">MariaDB 10.4.14</a> , <a href="#">MariaDB 10.3.24</a>

Ubuntu 19.10 "Eoan"	Jul 2020	<a href="#">MariaDB 10.5.5</a> , <a href="#">MariaDB 10.4.14</a> , <a href="#">MariaDB 10.3.24</a>
Debian 8 "Jessie"	Jun 2020	<a href="#">MariaDB 10.4.13</a> , <a href="#">MariaDB 10.3.23</a> , <a href="#">MariaDB 10.2.32</a> , <a href="#">MariaDB 10.1.45</a>
Ubuntu 19.04 "Disco"	Jan 2020	<a href="#">MariaDB 10.4.12</a> , <a href="#">MariaDB 10.3.22</a>
Windows Server 2008	Jan 2020	<a href="#">MariaDB 10.4.12</a> , <a href="#">MariaDB 10.3.22</a>
Windows Server 2008 R2	Jan 2020	<a href="#">MariaDB 10.4.12</a> , <a href="#">MariaDB 10.3.22</a>
Windows 7	Jan 2020	<a href="#">MariaDB 10.4.12</a> , <a href="#">MariaDB 10.3.22</a>
Fedora 29	Dec 2019	<a href="#">MariaDB 10.4.11</a> , <a href="#">MariaDB 10.3.21</a>
Ubuntu 18.10 "Cosmic"	Jul 2019	<a href="#">MariaDB 10.4.7</a> , <a href="#">MariaDB 10.3.17</a> , <a href="#">MariaDB 10.2.26</a> , <a href="#">MariaDB 10.1.41</a>
openSUSE 42.3	Jun 2019	<a href="#">MariaDB 10.4.7</a> , <a href="#">MariaDB 10.3.16</a> , <a href="#">MariaDB 10.2.25</a> , <a href="#">MariaDB 10.1.41</a>
Fedora 28	May 2019	<a href="#">MariaDB 10.4.5</a> , <a href="#">MariaDB 10.3.15</a> , <a href="#">MariaDB 10.2.24</a>
Ubuntu 14.04 LTS "Trusty"	Apr 2019	<a href="#">MariaDB 10.4.4</a> , <a href="#">MariaDB 10.3.14</a> , <a href="#">MariaDB 10.2.23</a> , <a href="#">MariaDB 10.1.40</a> , <a href="#">MariaDB 5.5.64</a>

Debian 5 "Lenny"	Jan 2013	<a href="#">MariaDB 10.0.1</a> , <a href="#">MariaDB 5.5.29</a>
Debian 4 "Etch"		
Ubuntu 9.10 "Karmic"		
Ubuntu 9.04 "Jaunty"		
Ubuntu 8.10 "Intrepid"		

## Support for Deprecated Platforms

If your chosen Linux Distribution or Operating System is deprecated, packages or support are not completely unavailable. The [MariaDB Corporation](#) provides support for all versions of MariaDB back to even very old MySQL versions. This includes packaged binaries. For specific dates related to each version and more details on the MariaDB Corporation's policies, see the [Engineering Policies](#) page.

## 2.1.2.14 Automated MariaDB Deployment and Administration

It is possible to automate the deployment and administration of MariaDB servers and related technologies by using third-party software. This is especially useful when deploying and administering a large number of servers, but it also has benefits for small environments.

This section describes some automation technologies from MariaDB users perspective.

### Why to Automate MariaDB Deployments and Management

## 2.1.2.14.1 Why to Automate MariaDB Deployments and Management

MariaDB includes a powerful [configuration system](#). This is enough when we need to deploy a single MariaDB instance, or a small number of instances. But many modern organisations have many database servers. Deploying and upgrading them manually could require too much time, and would be error-prone.

### Contents

1. [Infrastructure as Code](#)
2. [Automated Failover](#)
3. [Resources](#)

## Infrastructure as Code

Several tools exist to deploy and manage several servers automatically. These tools operate at a higher level, and execute tasks like installing MariaDB, running queries, or generating new configuration files based on a template. Instead of upgrading servers manually, users can launch a command to upgrade a group of servers, and the automation software will run the necessary tasks.

Servers can be described in a code repository. This description can include MariaDB version, its configuration, users, backup jobs, and so on. This code is human-readable, and can serve as a documentation of which servers exist and how they are configured. The code is typically versioned in a repository, to allow collaborative development and track the changes that occurred over time. This is a paradigm called **Infrastructure as Code**.

Automation code is high-level and one usually doesn't care how operations are implemented. Their implementation is delegated to modules that handle specific components of the infrastructure. For example a module could equally work with apt and yum package managers. Other modules can implement operations for a specific cloud vendor, so we declare we want a snapshot to be done, but we don't need to write the commands to make it happen. For special cases, it is of course possible to write Bash commands, or scripts in every language, and declare that they must be run.

Manual interventions on the servers will still be possible. This is useful, for example, to investigate performance problems. But it is important to leave the servers in the state that is described by the code.

This code is not something you write once and never touch again. It is periodically necessary to modify infrastructures to update some software, add new replicas, and so on. Once the base code is in place, making such changes is often trivial and potentially it can be done in minutes.

## Automated Failover

Once [replication](#) is in place, two important aspects to automate are load balancing and failover.

Proxies can implement load balancing, redirecting the queries they receive to different server, trying to distribute the load equally. They can also monitor that MariaDB servers are running and in good health, thus avoiding sending queries to a server that is down or struggling.

However, this does not solve the problem with replication: if a primary server crashes, its replicas should point to another server. Usually this means that an existing replica is promoted to a master. This kind of changes are possible thanks to MariaDB [GTID](#).

One can promote a replica to a primary by making change to existing automation code. This is typically simple and relatively quick to do for a human operator. But this operation takes time, and in the meanwhile the service could be down.

Automating failover will minimise the time to recover. A way to do it is to use Orchestrator, a tool that can automatically promote a replica to a primary. The choice of the replica to promote is done in a smart way, keeping into account things like the servers versions and the [binary log](#) format.

## Code Structure Differences

Different automation systems provide different ways to describe our infrastructure. Understanding how they work is the first step to evaluate them and choose one for our organization.

### Ansible Code Structure

Ansible code consists of the following components:

- An **inventory** determines which **hosts** Ansible should be able to deploy. Each host may belong to one or more **groups** . Groups may have **children** , forming a hierarchy. This is useful because it allows us to deploy on a group, or to assign variables to a group.
- A **role** describes the state that a host, or group of hosts, should reach after a deploy.
- A **play** associates hosts or groups to their roles. Each role/group can have more than one role.
- A role consists of a list of **tasks** . Despite its name a task is not necessarily something to do, but something that must exist in a certain state.
- Tasks can use **variables** . They can affect how a task is executed (for example a variable could be a file name), or even whether a task is executed or not. Variables exist at role, group or host level. Variables can also be passed by the user when a play is applied.
- **Playbooks** are the code that is used to define tasks and variables.
- **Facts** are data that Ansible retrieves from remote hosts before deploying. This is a very important step, because facts may determine which tasks are executed or how they are executed. Facts include, for example, the operating system family or its version. A playbook sees facts as pre-set variables.
- **Modules** implement **actions** that tasks can use. Action examples are **file** (to declare that files and directories must exist) or **mysql\_variables** (to declare MySQL/MariaDB variables that need to be set).

See [Ansible Overview - concepts](#) for more details and an example.

### Puppet Code Structure

Puppet code consists of the following components:

- An **inventory file** defines a set of **groups** and their **targets** (the members of a group). **plugins** can be used to retrieve groups and target dynamically, so they are equivalent to Ansible dynamic inventories.
- A **manifest** is a file that describes a configuration.
- A **resource** is a component that should run on a server. For example, "file" and "service" are existing support types.
- An **attribute** relates to a resource and affects the way it is applied. For example, a resource of type "file" can have attributes like "owner" and "mode".
- A **class** groups resources and variables, describing a logical part of server configuration. A class can be associated to several servers. A class is part of a manifest.
- A **module** is a set of manifests and describes an infrastructure or a part of it.
- Classes can have typed **parameters** that affect how they are applied.
- **Properties** are variables that are read from the remote server, and cannot be arbitrarily assigned.
- **Facts** are pre-set variables collected by Puppet before applying or compiling a manifest.

## Architectural Differences

The architecture of the various systems is different. Their architectures determine how a deploy physically works, and what is needed to be able to deploy.

## Ansible Architecture

Ansible architecture is simple. Ansible can run from any host, and can apply its playbooks on remote hosts. To do this, it runs commands via SSH. In practice, in most cases the commands will be run as superuser via

```
sudo  
, though this is not always necessary.
```

Inventories can be dynamic. In this case, when we apply a playbook Ansible connects to remote services to discover hosts.

Ansible playbooks are applied via the

```
ansible-playbook  
binary. Changes to playbooks are only applied when we perform this operation.
```

To recap, Ansible does not need to be installed on the server it administers. It needs an SSH access, and normally its user needs to be able to run

```
sudo  
. It is also possible to configure a dynamic inventory, and a remote service to be used for this purpose.
```

## Puppet Architecture

Puppet supports two types of architecture: agent-master or standalone. The agent-master architecture is recommended by Puppet Labs, and it is the most popular among Puppet users. For this reason, those who prefer a standalone architecture tend to prefer Ansible.

### Agent-Master Architecture

When this architecture is chosen, manifests are sent to the **Puppet master**. There can be more than one master, for high availability reasons. All target hosts run a **Puppet agent**. Normally this is a service that automatically starts at system boot. The agent contacts a master at a given interval. It sends facts, and uses them to compile a **catalog** from the manifests. A catalog is a description of what exactly an individual server should run. The agent receives the catalog and checks if there are differences between its current configuration and the catalog. If differences are found, the agent applies the relevant parts of the catalog.

An optional component is **PuppetDB**. This is a central place where some data are stored, including manifests, retrieved facts and logs. PuppetDB is based on PostgreSQL and there are no plans to support MariaDB or other DBMSs.

If a manual change is made to a remote server, it will likely be overwritten the next time Puppet agent runs. To avoid this, the Puppet agent service can be stopped.

### Standalone Architecture

As mentioned, this architecture is not recommended by Puppet Labs nor popular amongst Puppet users. It is similar to Ansible architecture.

Users can apply manifests from any host with Puppet installed. This could be their laptop but, in order to emulate the behavior of an agent-master architecture, normally Puppet runs on a dedicated node as a cronjob. The **Puppet apply** application will require facts from remote hosts, it will compile a catalog for each host, will check which parts of it need to be applied, and will apply them remotely.

If a manual change is made to a remote server, it will be overwritten the next time Puppet apply runs. To avoid this, comment out any cron job running Puppet apply, or comment out the target server in the inventory.

### Inventory

As mentioned, Puppet supports plugins to retrieve the inventory dynamically from remote services. In an agent-master architecture, one has to make sure that each target host has access to these services. In a standalone architecture, one has to make sure that the hosts running Puppet apply have access to these services.

## Storing Secrets

Often our automation repositories need to contain secrets, like MariaDB user passwords or private keys for SSH authentication.

Both Ansible and Puppet support integration with secret stores, like Hashicorp Vault. For Puppet integration, see [Integrations with secret stores](#).

In the simplest case, Ansible allows encrypting secrets in playbooks and decrypting them during execution using **ansible-vault**. This implies a minimal effort to handle secrets. However, it is not the most secure way to store secrets. The passwords to disclose certain secrets need to be shared with the users who have the right to use them. Also, brute force attacks are possible.

## Ecosystems and Communities

Automation software communities are very important, because they make available a wide variety of modules to handle specific software.

### Ansible Ecosystem

Ansible is open source, released under the terms of the GNU GPL. It is produced by RedHat. RedHat has a page about [Red Hat Ansible Automation Platform Partners](#), who can provide support and consulting.

[Ansible Galaxy](#) is a big repository of Ansible roles produced by both the vendor and the community. Ansible comes with

`ansible-galaxy`

, a tool that can be used to create roles and upload them to Ansible Galaxy.

At the time of this writing, Ansible does not have specific MariaDB official modules. MySQL official modules can be used. However, be careful not try to use features that only apply to MySQL. There are several community-maintained MariaDB roles.

## Puppet Ecosystem

Puppet is open source, released under the GNU GPL. It is produced by a homonym company. The page [Puppet Partners](#) lists partners that can provide support and consulting about Puppet.

[Puppet Forge](#) is a big repository of modules produced by the vendor and by the community, as well as how-to guides.

Currently Puppet has many MariaDB modules.

## 2.1.2.14.3.1 Ansible Overview for MariaDB Users

Ansible is a tool to automate servers configuration management. It is produced by Red Hat and it is open source software released under the terms of the GNU GPL.

It is entirely possible to use Ansible to automate MariaDB deployments and configuration. This page contains generic information for MariaDB users who want to learn, or evaluate, Ansible.

For information about how to install Ansible, see [Installing Ansible](#) in Ansible documentation.

### Contents

1. [Automation Hubs](#)
2. [Design Principles](#)
3. [Concepts](#)
  1. [Example](#)
4. [Architecture](#)
5. [Ansible Resources and References](#)

## Automation Hubs

Normally, Ansible can run from any computer that has access to the target hosts to be automated. It is not uncommon that all members of a team has Ansible installed on their own laptop, and use it to deploy.

Red Hat offers a commercial version of Ansible called [Ansible Tower](#). It consists of a REST API and a web-based interface that work as a hub that handles all normal Ansible operations.

An alternative is [AWX](#). AWX is the open source upstream project from which many Ansible Tower features are originally developed. AWX is released under the terms of the Apache License 2.0. However, Red Hat does not recommend to run AWX in production.

AWX development is fast. It has several features that may or may not end up in Ansible Tower. Ansible Tower is more focused on making AWS features more robust, providing a stable tool to automate production environments.

## Design Principles

Ansible allows us to write **playbooks** that describe how our servers should be configured. Playbooks are lists of **tasks**.

Tasks are usually **declarative**. You don't explain *how* to do something, you declare *what* should be done.

Playbooks are **idempotent**. When you apply a playbook, tasks are only run if necessary.

Here is a task example:

```
- name: Install Perl
  package:
    name: perl
    state: present
```

"Install Perl" is just a description that will appear on screen when the task is applied. Then we use the `package` module to declare that a package called "perl" should be installed. When we apply the playbook, if Perl is already installed nothing happens. Otherwise, Ansible installs it.

When we apply a playbook, the last information that appears on the screen is a recap like the following:

```
PLAY RECAP ****
mariadb-01 : ok=6    changed=2    unreachable=0    failed=0    skipped=0    rescued=0    ignored=0
```

This means that six tasks were already applied (so no action was taken), and two tasks were applied.

As the above example shows, Ansible playbooks are written in YAML.

Modules (like

`package`) can be written in any language, as long as they are able to process a JSON input and produce a JSON output. However the Ansible community prefers to write them in Python, which is the language Ansible is written in.

## Concepts

A piece of Ansible code that can be applied to a server is called a **playbook**.

A **task** is the smallest brick of code in a playbook. The name is a bit misleading, though, because an Ansible task should not be seen as "something to do". Instead, it is a minimal description of a component of a server. In the example above, we can see a task.

A task uses a single **module**, which is an interface that Ansible uses to interact with a specific system component. In the example, the module is "package".

A task also has attributes, that describe what should be done with that module, and how. In the example above, "name" and "state" are both tasks. The `state`

attribute exists for every module, by convention (though there may be exceptions). Typically, it has at least the "present" and "absent" state, to indicate if an object should exist or not.

Other important code concepts are:

- An **inventory** determines which **hosts** Ansible should be able to deploy. Each host may belong to one or more **groups**. Groups may have **children**, forming a hierarchy. This is useful because it allows us to deploy on a group, or to assign variables to a group.
- A **role** describes the state that a host, or group of hosts, should reach after a deploy.
- A **play** associates hosts or groups to their roles. Each role/group can have more than one role.
- A **playbook** is a playbook that describes how certain servers should be configured, based on the logical role they have in the infrastructure. Servers can have multiple roles, for example the same server could have both the "mariadb" and the "mydumper" role, meaning that they run MariaDB and they have mydumper installed (as shown later).
- Tasks can use **variables**. They can affect how a task is executed (for example a variable could be a file name), or even whether a task is executed or not. Variables exist at role, group or host level. Variables can also be passed by the user when a play is applied.
- **Facts** are data that Ansible retrieves from remote hosts before deploying. This is a very important step, because facts may determine which tasks are executed or how they are executed. Facts include, for example, the operating system family or its version. A playbook sees facts as pre-set variables.
- **Modules** implement **actions** that tasks can use. Action examples are **file** (to declare that files and directories must exist) or **mysql\_variables** (to declare MySQL/MariaDB variables that need to be set).

## Example

Let's describe a hypothetical infrastructure to find out how these concepts can apply to MariaDB.

The **inventory** could define the following groups:

- "db-main" for the cluster used by our website. All nodes belong to this group.
- "db-analytics" for our replicas used by data analysts.
- "dump" for one or more servers that take dumps from the replicas.
- "proxysql" for one or more hosts that run ProxySQL.

Then we'll need the following nodes:

- "mariadb-node" for the nodes in "db-main". This role describes how to setup nodes of a cluster using Galera.
- "mariadb-replica" for the members of "db-analytics". It describes a running replica, and it includes the tasks that are necessary to provision the node if the data directory is empty when the playbook is applied. The hostname of the primary server is defined in a variable.
- "mariadb". The aforementioned "mariadb-node" and "mariadb-replica" can be children of this group. They have many things in common (filesystem for the data directory, some basic MariaDB configuration, some installed tools...), so it could make sense to avoid duplication and describe the common traits in a super-role.
- A "mariabackup" role to take backups with [Mariabackup](#), running jobs during the night. We can associate this role to the "db-main" group, or we could create a child group for servers that will take the backups.
- "mariadb-dump" for the server that takes dumps with [mariadb-dump](#). Note that we may decide to take dumps on a replica, so the same host may belong to "db-analytics" and "mariadb-dump".
- "proxysql" for the namesake group.

## Architecture

Ansible architecture is extremely simple. Ansible can run on any host. To apply playbooks, it connects to the target hosts and runs system commands. By default the connection happens via ssh, though it is possible to develop connection plugins to use different methods. Applying playbooks locally without establishing a connection is also possible.

Modules can be written in any language, though Python is the most common choice in the Ansible community. Modules receive JSON "requests" and facts from Ansible core, they are supposed to run useful commands on a target host, and then they should return information in JSON. Their output informs Ansible whether something has changed on the remote server and if the operations succeeded.

Ansible is not centralized. It can run on any host, and it is common for a team to run it from several laptops. However, to simplify things and improve security, it may be desirable to run it from a dedicated host. Users will connect to that host, and apply Ansible playbooks.

## 2.1.2.14.3.2 Deploying to Remote Servers with Ansible

If we manage several remote servers, running commands on them manually can be frustrating and time consuming. Ansible allows one to run commands on a whole group of servers.

This page shows some examples of ansible-playbook invocations. We'll see how to deploy roles or parts of them to remote servers. Then we'll see how to run commands on remote hosts, and possibly to get information from them. Make sure to read [Ansible Overview](#) first, to understand Ansible general concepts.

### Contents

1. [Pinging Remote Servers](#)
2. [Running Commands on Remote Servers](#)
3. [Applying Roles to Remote Servers](#)
  1. [Check mode](#)
4. [References](#)

# Pinging Remote Servers

Let's start with the simplest example: we just want our local Ansible to ping remote servers to see if they are reachable. Here's how to do it:

```
ansible -i production-mariadb all -m ping
```

Before proceeding with more useful examples, let's discuss this syntax.

- **ansible** is the executable we can call to run a command from remote servers.
- **-i production-mariadb** means that the servers must be read from an inventory called production-mariadb.
- **all** means that the command must be executed against all servers from the above inventory.
- **-m ping** specifies that we want to run the ping module. This is not the ping Linux command. It tells us if Ansible is able to connect a remote server and run a simple commands on them.

To run ping on a specific group or host, we can just replace "all" with a group name or host name from the inventory:

```
ansible -i production-mariadb main_cluster -m ping
```

## Running Commands on Remote Servers

The previous examples show how to run an Ansible module on remote servers. But it's also possible to run custom commands over SSH. Here's how:

```
ansible -i production-mariadb all -a 'echo $PATH'
```

This command shows the value of

\$PATH  
on all servers in the inventory "production-mariadb".

We can also run commands as root by adding the

-b  
(or  
--become  
) option:

```
# print a MariaDB variable
ansible -i production-mariadb all -b -a 'mysql -e "SHOW GLOBAL VARIABLES LIKE \'innodb_buffer_pool_size\';"'

# reboot servers
ansible -i production-mariadb all -b -a 'reboot'
```

## Applying Roles to Remote Servers

We saw how to run commands on remote hosts. Applying roles to remote hosts is not much harder, we just need to add some information. An example:

```
ansible-playbook -i production-mariadb production-mariadb.yml
```

Let's see what changed:

- **ansible-playbook** is the executable file that we need to call to apply playbooks and roles.
- **production-mariadb.yml** is the play that associates the servers listed in the inventory to their roles.

If we call ansible-playbook with no additional arguments, we will apply all applicable roles to all the servers mentioned in the play.

To only apply roles to certain servers, we can use the

-l  
parameter to specify a group, an individual host, or a pattern:

```
# Apply to the mariadb-main role role
ansible-playbook -i production-mariadb -l mariadb-main production-mariadb.yml

# Apply to the mariadb-main-01 host
ansible-playbook -i production-mariadb -l mariadb-main-01 production-mariadb.yml

# Apply to multiple hosts whose name starts with "mariadb-main-"
ansible-playbook -i production-mariadb -l mariadb-main-* production-mariadb.yml
```

We can also apply tasks from roles selectively. Tasks may optionally have tags, and each tag corresponds to an operation that we may want to run on our remote hosts. For example, a "mariadb" role could have the "timezone-update" tag, to update the contents of the [timezone tables](#). To only apply the tasks with the "timezone-update" tag, we can use this command:

```
ansible-playbook -i production-mariadb --tag timezone-update production-mariadb.yml
```

Using tags is especially useful for database servers. While most of the technologies typically managed by Ansible are stateless (web servers, load balancers, etc.) database servers are not. We must pay special attention not to run tasks that could cause a database server outage, for example destroying its data directory or restarting the service when it is not necessary.

## Check mode

We should always test our playbooks and roles on test servers before applying them to production. However, if test servers and production servers are not exactly in the same state (which means, some facts may differ) it is still possible that applying roles will fail. If it fails in the initial stage, Ansible will not touch the remote hosts at all. But there are cases where Ansible could successfully apply some tasks, and fail to apply another task. After the first failure, `ansible-playbook` will show errors and exit. But this could leave a host in an inconsistent state.

Ansible has a *check mode* that is meant to greatly reduce the chances of a failure. When run in check mode, `ansible-playbook` will read the inventory, the play and roles; it will figure out which tasks need to be applied; then it will connect to target hosts, read facts, and value all the relevant variables. If all these steps succeed, it is unlikely that running `ansible-playbook` without check mode will fail.

To run `ansible-playbook` in check mode, just add the

```
--check  
(or  
-C  
) parameter.
```

## 2.1.2.14.3.3 Deploying Docker Containers with Ansible

Ansible can be used to manage Docker container upgrades and configuration changes. Docker has native ways to do this, namely [Dockerfiles](#) and [Docker Compose](#) . But sometimes there are reasons to start basic containers from an image and then manage configuration with Ansible or similar software. See [Benefits of Managing Docker Containers with Automation Software](#) .

In this page we'll discuss how to use Ansible to manage Docker containers.

### Contents

1. [How to Deploy a Container with Ansible](#)
2. [References](#)

## How to Deploy a Container with Ansible

Ansible has modules to manage the Docker server, Docker containers, and Docker Compose. These modules are maintained by the community.

A dynamic inventory plugin for Docker exists. It retrieves the list of existing containers from Docker.

Docker modules and the Docker inventory plugin communicate with Docker using its API. The connection to the API can use a TSL connection and supports key authenticity verification.

To communicate with Docker API, Ansible needs a proper Python module installed on the Ansible node (

```
docker  
or  
docker-py  
().
```

Several roles exist to deploy Docker and configure it. They can be found in Ansible Galaxy.

## 2.1.2.14.3.4 Installing MariaDB .deb Files with Ansible

This page refers to the operations described in [Installing MariaDB .deb Files](#). Refer to that page for a complete list and explanation of the tasks that should be performed.

Here we discuss how to automate such tasks using Ansible. For example, here we show how to install a package or how to import a GPG key; but for an updated list of the necessary packages and for the keyserver to use, you should refer to [Installing MariaDB .deb Files](#).

### Adding apt Repositories

To add a repository :

```
- name: Add specified repository into sources list
ansible.builtin.apt_repository:
  repo: deb [arch=amd64,arm64,ppc64el] http://sfo1.mirrors.digitalocean.com/mariadb/repo/10.3/ubuntu bionic main
  state: present
```

If you prefer to keep the repository information in a [source list file](#) in the Ansible repository, you can upload that file to the target hosts in this way:

```
- name: Create a symbolic link
ansible.builtin.file:
  src: ./file/mariadb.list
  dest: /etc/apt/sources.list.d/
  owner: root
  group: root
  mode: 644
  state: file
```

### Updating the Repository Cache

Both the Ansible modules `ansible.builtin.apt` and `ansible.builtin.apt_repository` have an

`update_cache` attribute. In `ansible.builtin.apt` it is set to "no" by default. Whenever a task sets it to 'yes', `apt-get update` is run on the target system. You have three ways to make sure that repositories are updated.

The first is to use `ansible.builtin.apt_repository` to add the desired repository, as shown above. So you only need to worry about updating repositories if you use the file method.

The second is to make sure that

`update_cache` is set to 'yes' when you install a repository:

```
- name: Install foo
apt:
  name: foo
  update_cache: yes
```

But if you run certain tasks conditionally, this option may not be very convenient. So the third option is to update the repository cache explicitly as a separate task:

```
- name: Update repositories
apt:
  - update_cache: yes
```

### Importing MariaDB GPG Key

To [import the GPG key](#) for MariaDB we can use the `ansible.builtin.apt_key` Ansible module. For example:

```
- name: Add an apt key by id from a keyserver
ansible.builtin.apt_key:
  keyserver: hkp://keyserver.ubuntu.com:80
  id: 0xF1656F24C74CD1D8
```

### Installing Packages

To install Deb packages into a system:

```
- name: Install software-properties-common
  apt:
    name: software-properties-common
    state: present
```

To make sure that a specific version is installed, performing an upgrade or a downgrade if necessary:

```
- name: Install foo 1.0
  apt:
    name: foo=1.0
```

To install a package or upgrade it to the latest version, use:

```
state: latest
```

To install multiple packages at once:

```
- name: Install the necessary packages
  apt:
    pkg:
      - pkg1
      - pkg2=1.0
```

If all your servers run on the same system, you will always use `ansible.builtin.apt` and the names and versions of the packages will be the same for all servers. But suppose you have some servers running systems from the Debian family, and others running systems from the Red Hat family. In this case, you may find convenient to use two different task files for two different types of systems. To include the proper file for the target host's system:

```
- include: mariadb-debian.yml
when: "{{ ansible_facts['os_family'] }} == 'Debian'
```

The variables you can use to run the tasks related to the proper system are:

- `ansible_fact['distribution']`
- `ansible_fact['distribution_major_version']`
- `ansible_fact['os_family']`

There is also a system-independent [package module](#), but if the package names depend on the target system using it may be of very little benefit.

## See Also

- [Installing MariaDB .deb Files](#)

---

Content initially contributed by [Vettabase Ltd](#).

### 2.1.2.14.3.5 Running mariadb-tzinfo-to-sql with Ansible

For documentation about the

`mariadb-tzinfo-to-sql` utility, see [mysql\\_tzinfo\\_to\\_sql](#). This page is about running it using Ansible.

## Installing or Upgrading the Package

First, we should install

`mariadb-tzinfo-to-sql`

if it is available on our system. For example, to install it on Ubuntu, we can use this task. For other systems, use the proper module and package name.

```
- name: Update timezone info
  tags: [ timezone-update ]
  apt:
    name: tzdata
    state: latest
    install_recommends: no
  register: timezone_info
```

This task installs the latest version of the

`tzdata`

, unless it is already installed and up to date. We register the

`timezone_info`

variables, so we can only run the next task if the package was installed or updated.

We also specify a

`timezone-update`  
tag, so we can apply the role to only update the timezone tables.

## Running the Script

The next task runs

```
mariadb-tzinfo-to-sql
```

```
- name: Move system timezone info into MariaDB
tags: [ timezone-update ]
shell: >
  mysql_tzinfo_to_sql /usr/share/zoneinfo \
    | grep -v "Warning" \
    | mysql --database=mysql
when: timezone_info.changed
```

We use the

```
shell
module to run the command. Running a command in this way is not idempotent, so we specify
when: timezone_info.changed
to only run it when necessary. Some warnings may be generated, so we pipe the output of
mysql_tzinfo_to_sql
to
grep
to filter warnings out.
```

## Using Galera

If we're using [MariaDB Galera Cluster](#) we'll want to only update the timezone tables in one node, because the other nodes will replicate the changes. For our convenience, we can run this operation on the first node. If the nodes hostnames are defined in a list called

```
cluster_hosts
, we can check if the current node is the first in this way:
```

```
when: timezone_info.changed and inventory_hostname == cluster_hosts[0].hostname
```

---

Content initially contributed by [Vettabase Ltd](#).

### 2.1.2.14.3.6 Managing Secrets in Ansible

An Ansible role often runs commands that require certain privileges, so it must perform some forms of login, using passwords or key pairs. In the context of database automation, we normally talk about: SSH access, sudo access, and access to MariaDB. If we write these secrets (passwords or private keys) in clear text in an Ansible repository, anyone who has access to the repository can access them, and this is not what we want.

Let's see how we can manage secrets.

#### Contents

1. [The SSH Password or Keys](#)
2. [Avoiding Sharing Secrets](#)
3. [ansible-vault](#)

## The SSH Password or Keys

Most of the times, Ansible connects to the target hosts via SSH. It is common to use the system username and the SSH keys installed in

```
/.ssh
```

, which is the SSH clients default. In this case, nothing has to be done on the clients to be able to allow Ansible to use SSH, as long as they are already able to connect to the target hosts.

It is also possible to specify a different username as

```
ANSIBLE_REMOTE_USER
```

and an SSH configuration file as

```
ANSIBLE_NETCONF_SSH_CONFIG
```

. These settings can be specified in Ansible configuration file or as environment variables.

#### [ANSIBLE\\_ASK\\_PASS](#)

can be specified. If this is the case, Ansible will prompt the user asking to type an SSH password.

## Avoiding Sharing Secrets

As a general rule, any configuration that implies communicating sensible information to the persons who will connects to a system implies some degree of risk. Therefore, the most common choice is to allow users to login into remote systems with their local usernames, using SSH keys.

Once Ansible is able to connect remote hosts, it can also be used to install the public keys of some users to grant them access. Sharing these keys implies no risk. Sharing private keys is never necessary, and must be avoided.

MariaDB has a [UNIX\\_SOCKET](#) plugin that can be used to let some users avoid entering a password, as far as they're logged in the operating system. This authentication method is used by default for the root user. This is a good way to avoid having one more password and possibly writing to a

`.my.cnf`  
file so that the user doesn't have to type it.

Even for users who connect remotely, it is normally not necessary to insert passwords in an Ansible file. When we create a user with a password, a hash of the original password is stored in MariaDB. That hash can be found in the [mysql.user table](#). To know the hash of a password without even creating a user, we can use the [PASSWORD\(\)](#) function:

```
SELECT PASSWORD('my_password12') AS hash;
```

When we create a user, we can actually specify a hash instead of the password the user will have to type:

```
CREATE USER user@host IDENTIFIED BY PASSWORD '*54958E764CE10E50764C2EECB71D01F08549980';
```

## ansible-vault

Even if you try to avoid sharing secrets, it's likely you'll have to keep some in Ansible. For example, MariaDB users that connect remotely have passwords, and if we want Ansible to create and manage those users, the hashes must be placed somewhere in our Ansible repository. While a hash cannot be converted back to a password, treating hashes as secrets is usually a good idea. Ansible provides a native way to handle secrets: [ansible-vault](#).

In the simplest case, we can manage all our passwords with a single ansible-vault password. When we add or change a new password in some file (typically a file in

`host_vars`  
or  
`group_vars`

) we'll use ansible-vault to crypt this password. While doing so, we'll be asked to insert our ansible-vault password. When we apply a role and Ansible needs to decrypt this password, it will ask us to enter again our ansible-vault password.

ansible-vault can use more than one password. Each password can manage a different set of secrets. So, for example, some users may have the password to manage regular MariaDB users passwords, and only one may have the password that is needed to manage the root user.

### 2.1.2.14.4 Puppet and MariaDB

General information and hints on how to automate MariaDB deployments and configuration with Puppet.

Puppet is an open source tool deployment, configuration and operations.

#### **Puppet Overview for MariaDB Users**

[Overview of Puppet and how it works with MariaDB.](#)

#### **Bolt Examples**

[How to invoke Bolt to run commands or apply roles on remote hosts.](#)

[Using hiera to handle Puppet configuration files.](#)

#### **Deploying Docker Containers with Puppet**

[How to deploy and manage Docker containers with Puppet.](#)

#### **Existing Puppet Modules for MariaDB**

[Links to existing Puppet modules for MariaDB.](#)

## 2.1.2.14.4.1 Puppet Overview for MariaDB Users

Puppet is a tool to automate servers configuration management. It is produced by Puppet Inc, and released under the terms of the Apache License, version 2.

It is entirely possible to use Ansible to automate MariaDB deployments and configuration. This page contains generic information for MariaDB users who want to learn, or evaluate, Puppet.

Puppet modules can be searched using [Puppet Forge](#). Most of them are also published on GitHub with open source licenses. Puppet Forge allows filtering modules to only view the most reliable: supported by Puppet, supported by a Puppet partner, or approved.

For information about installing Puppet, see [Installing and upgrading](#) in Puppet documentation.

### Contents

- 1. [Design Principles](#)
  - 1. [Defining Resources](#)
  - 2. [Defining Nodes](#)
- 2. [Concepts](#)
- 3. [Architecture](#)
  - 1. [Agent-master Architecture](#)

  - 3. [PuppetDB](#)
  - 4. [External Node Classifiers](#)
  - 5. [Bolt](#)
- 4. [hiera](#)
- 5. [Puppet Resources](#)

## Design Principles

With Puppet, you write **manifests** that describe the resources you need to run on certain servers and their **attributes**.

Therefore manifests are **declarative**. You don't write the steps to achieve the desired result. Instead, you describe the desired result. When Puppet detects differences between your description and the current state of a server, it decides what to do to fix those differences.

Manifests are also **idempotent**. You don't need to worry about the effects of applying a manifest twice. This may happen (see Architecture below) but it won't have any side effects.

## Defining Resources

Here's an example of how to describe a resource in a manifest:

```
file { '/etc/motd':  
  content => '',  
  ensure => present,  
}
```

This block describes a resource. The resource type is

file  
, while the resource itself is  
/etc/motd  
. The description consists of a set of attributes. The most important is  
ensure  
, which in this case states that the file must exist. It is also common to use this resource to indicate that a file (probably created by a previous version of the manifest) doesn't exist.

These classes of resource types exist:

- **Built-in resources**, or **Puppet core resources**: Resources that are part of Puppet, maintained by the Puppet team.
- **Defined resources**: Resources that are defined as a combination of other resources. They are written in the Puppet domain-specific language.
- **Custom resources**: Resources that are written by users, in the Ruby language.

To obtain information about resources:

```
# list existing resource types  
puppet resource --types  
# print information about the file resource type  
puppet describe file
```

To group several resources in a reusable class:

```

class ssh_server {
  file { '/etc/motd':
    content => '',
    ensure => present,
  }
  file { '/etc/issue.net':
    content => '',
    ensure => present,
  }
}

```

There are several ways to include a class. For example:

```
include Class['ssh_server']
```

## Defining Nodes

Puppet has a **main manifest** that could be a

- site.pp
- file or a directory containing
- .pp

files. For simple infrastructures, we can define the nodes here. For more complex infrastructures, we may prefer to import other files that define the nodes.

Nodes are defined in this way:

```

node 'maria-1.example.com' {
  include common
  include mariadb
}

```

The resource type is

- node
- . Then we specify a hostname that is used to match this node to an existing host. This can also be a list of hostnames, a regular expression that matches multiple nodes, or the
- default
- keyword that matches all hosts. To use a regular expression:

```

node /^(maria|mysql)-[1-3]\.example\.com$/ {
  include common
}

```

## Concepts

The most important Puppet concepts are the following:

- **Target** : A host whose configuration is managed via Puppet.
- **Group** : A logical group of targets. For example there may be a
  - mariadb
  - group, and several targets may be part of this group.
- **Facts** : Information collected from the targets, like the system name or system version. They're collected by a Ruby gem called [Facter](#) . They can be [core facts](#) (collected by default) or [custom facts](#) (defined by the user).
- **Manifest** : A description that can be applied to a target.
- **Catalog** : A compiled manifest.
- **Apply** : Modifying the state of a target so that it reflects its description in a manifest.
- **Module** : A set of manifests.
- **Resource** : A minimal piece of description. A manifest consists of a piece of resources, which describe components of a system, like a file or a service.
- **Resource type** : Determines the class of a resource. For example there is a
  - file
  - resource type, and a manifest can contain any number of resources of this type, which describe different files.
- **Attribute** : It's a characteristic of a resource, like a file owner, or its mode.
- **Class** : A group of resources that can be reused in several manifests.

## Architecture

Depending on how the user decides to deploy changes, Puppet can use two different architectures:

- An **Agent-master** architecture. This is the preferred way to use Puppet.
- A **standalone architecture** , that is similar to [Ansible architecture](#) .

## Agent-master Architecture

A **Puppet master** stores a catalog for each target. There may be more than one Puppet master, for redundancy.

Each target runs a **Puppet agent** in background. Each Puppet agent periodically connects to the Puppet master, sending its facts. The Puppet master compiles the relevant manifest using the facts it receives, and send back a catalog. Note that it is also possible to store the catalogs in PuppetDB instead.

Once the Puppet agent receives the up-to-date catalog, it checks all resources and compares them with its current state. It applies the necessary changes to make sure that its state reflects the resources present in the catalog.

## Standalone Architecture

With this architecture, the targets run **Puppet apply**. This application usually runs as a Linux cron job or a Windows scheduled task, but it can also be manually invoked by the user.

When Puppet apply runs, it compiles the latest versions of manifests using the local facts. Then it checks every resource from the resulting catalogs and compares it to the state of the local system, applying changes where needed.

Newly created or modified manifests are normally deployed to the targets, so Puppet apply can read them from the local host. However it is possible to use PuppetDB instead.

## PuppetDB

PuppetDB is a Puppet node that runs a PostgreSQL database to store information that can be used by other nodes. PuppetDB can be used with both the Agent-master and the standalone architectures, but it is always optional. However it is necessary to use some advanced Puppet features.

PuppetDB stored the following information:

- The latest facts from each target.
- The latest catalogs, compiled by Puppet apply or a Puppet master.
- Optionally, the recent history of each node activities.

## External Node Classifiers

With both architectures, it is possible to have a component called an External Node Classifier (ENC). This is a script or an executable written in any language that Puppet can call to determine the list of classes that should be applied to a certain target.

An ENC received a node name in input, and should return a list of classes, parameters, etc, as a YAML hash.

## Bolt

Bolt can be used in both architectures to run operations against a target or a set of targets. These operations can be commands passed manually to Bolt, scripts, Puppet tasks or plans. Bolt directly connects to targets via ssh and runs system commands.

See [Bolt Examples](#) to get an idea of what you can do with Bolt.

## hiera

hiera is a hierarchical configuration system that allows us to:

- Store configuration in separate files;
- Include the relevant configuration files for every server we automate with Puppet.

See [Puppet hiera Configuration System](#) for more information.

## Puppet Resources

- [Puppet documentation](#).
- [forge.puppet.com](#).
- [Puppet on GitHub](#).
- [Puppet on Wikipedia](#).

More information about the topics discussed in this page can be found in the Ansible documentation:

- [Puppet Glossary](#) in Puppet documentation.
- [Overview of Puppet's architecture](#) in Puppet documentation.
- [PuppetDB documentation](#).
- [Classifying nodes](#) in Puppet documentation.
- [Hiera](#) in Puppet documentation.
- [Bolt documentation](#).

## 2.1.2.14.4.2 Bolt Examples

### Contents

1. [Inventory Files](#)
2. [Running Commands on Targets](#)
3. [Copying Files](#)
4. [Running Scripts on Targets](#)
5. [Running Tasks on Targets](#)
6. [Applying Puppet Code on Targets](#)
7. [Bolt Resources and References](#)

This page shows some examples of what we can do with Bolt to administer a set of MariaDB servers. Bolt is a tool that is part of the [Puppet](#) ecosystem.

For information about installing Bolt, see [Installing Bolt](#) in Bolt documentation.

## Inventory Files

The simplest way to call Bolt and instruct it to do something on some remote targets is the following:

```
bolt ... --nodes 100.100.100.100,200.200.200.200,300,300,300,300
```

However, for non-trivial setups it is usually better to use an inventory file. An example:

```
targets:  
  - uri: maria-1.example.com  
    name: maria_1  
    alias: mariadb_main  
  ...
```

In this way, it will be possible to refer the target by name or alias.

We can also define groups, followed by the group members. For example:

```
groups:  
  - name: mariadb-staging  
    targets:  
      - uri: maria-1.example.com  
        name: maria_1  
      - uri: maria-2.example.com  
        name: maria_2  
  - name: mariadb-production  
    targets:  
      ...  
  ...
```

With an inventory of this type, it will be possible to run Bolt actions against all the targets that are members of a group:

```
bolt ... --nodes mariadb-staging
```

In the examples in the rest of the page, the

```
--targets
```

parameter will be indicated in this way, for simplicity:

```
--targets <targets>
```

## Running Commands on Targets

The simplest way to run a command remotely is the following:

```
bolt command run 'mariadb-admin start-all-slaves' --targets <targets>
```

## Copying Files

To copy a file or a whole directory to targets:

```
bolt file upload /path/to/source /path/to/destination --targets <targets>
```

To copy a file or a whole directory from the targets to the local host:

```
bolt file download /path/to/source /path/to/destination --targets <targets>
```

## Running Scripts on Targets

We can use Bolt to run a local script on remote targets. Bolt will temporarily copy the script to the targets, run it, and delete it from the targets. This is convenient for scripts that are meant to only run once.

```
bolt script run rotate_logs.sh --targets <targets>
```

## Running Tasks on Targets

Puppet tasks are not always as powerful as custom scripts, but they are simpler and many of them are idempotent. The following task stops MariaDB replication:

```
bolt task run mysql::sql --targets <targets> sql="STOP REPLICA"
```

## Applying Puppet Code on Targets

It is also possible to apply whole manifests or portions of Puppet code (resources) on the targets.

To apply a manifest:

```
bolt apply manifests/server.pp --targets <targets>
```

To apply a resource description:

```
bolt apply --execute "file { '/etc/mysql/my.cnf': ensure => present }" --targets <targets>
```

## Bolt Resources and References

- [Bolt documentation](#).
- [Bolt on GitHub](#).

Further information about the concepts explained in this page can be found in Bolt documentation:

- [Inventory Files](#) in Bolt documentation.
- [Applying Puppet code](#) in Bolt documentation.

## 2.1.2.14.4.3 Puppet hiera Configuration System

hiera is part of [Puppet](#). It is a hierarchical configuration system that allows us to:

- Store configuration in separate files;
- Include the relevant configuration files for every server we automate with Puppet.

### Contents

1. [hiera Configuration Files](#)
2. [Configuration files](#)

## hiera Configuration Files

Each hierarchy allows to one choose the proper configuration file for a resource, based on certain criteria. For example criteria may include node names, node groups, operating systems, or datacenters. Hierarchies are defined in a

```
hiera.yaml  
file, which also defines a path for the files in each hierarchy.
```

Puppet facts are commonly used to select the proper files to use. For example, a path may be defined as

```
"os/%{facts.os.name}.yaml"
```

. In this case, each resource will use a file named after the operating system it uses, in the os directory. You may need to use custom facts, for example to check which microservices will use a MariaDB server, or in which datacenter it runs.

We do not have to create a file for each possible value of a certain fact. We can define a default configuration file with settings that are reasonable for most resources. Other files, when included, will override some of the default settings.

A hiera configuration file will look like this:

```
version: 5
defaults:
  datadir: global
  data_hash: yaml_data

hierarchy:
  - name: "Node data"
    path: "nodes/%{trusted.certname}.yaml"

  - name: "OS data"
    path: "os/%{facts.os.family}.yaml"

  - name: "Per-datacenter business group data" # Uses custom facts.
    path: "location/%{facts.whereami}/%{facts.group}.yaml"
```

This file would include the global files, the OS-specific files and the node-specific files. Each hierarchy will override settings from previous hierarchies.

We can actually have several hiera configuration files.

`hiera.yaml`

is the global file. But we will typically have additional hiera configuration files for each environment. So we can include the configuration files that apply to production, staging, etc, plus global configuration files that should be included for every environment.

Importantly, we can also have hiera configuration files for each module. So, for example, a separate

`mariadb/hiera.yaml`

file may defined the hierarchies for MariaDB servers. This allow us to define, for example, different configuration files for MariaDB and for MaxScale, as most of the needed settings are typically different.

## Configuration files

You probably noticed that, in the previous example, we defined

`data_hash: yaml_data`

, which indicates that configuration files are written in YAML. Other allowed formats are JSON and HOCON. The

`data_hash`

setting is defined in

`defaults`

, but it can be overridden by hierarchies.

---

Content initially contributed by [Vettabase Ltd](#).

### 2.1.2.14.4 Deploying Docker Containers with Puppet

Puppet can also be used to manage Docker container upgrades and configuration changes. Docker has more specific tools for this purpose, but sometimes there are reasons to choose alternatives. See [Benefits of Managing Docker Containers with Automation Software](#).

In this page you will find out what managing Docker with Puppet looks like. All the snippets in this page use the

`docker`

resource type, supported by the Puppet company.

#### Contents

1. [How to Install, Upgrade or Uninstall Docker with Puppet](#)
2. [How to Build or Pull Docker Images with Puppet](#)
3. [How to Deploy Containers with Puppet](#)
4. [References](#)

### How to Install, Upgrade or Uninstall Docker with Puppet

Installing or upgrading Docker is simple:

```
class { 'docker':
  use_upstream_package_source => false,
  version => '17.09.0~ce-0~debian',
}
```

In this example we are using our system's repositories instead of Docker official repositories, and we are specifying the desired version. To upgrade

Docker later, all we need to do is to modify the version number. While specifying a version is not mandatory, it is a good idea because it makes our manifest more reproducible.

To uninstall Docker:

```
class { 'docker':
  ensure => absent
}
```

Check the

docker resource type documentation to find out how to use more features: for example you can use Docker Enterprise Edition, or bind the Docker daemon to a TCP port.

## How to Build or Pull Docker Images with Puppet

To pull an image from Dockerhub:

```
docker::image { 'mariadb:10.0': }
```

We specified the

10.0 tag to get the desired MariaDB version. If we don't, the image with the latest tag will be used. Note that this is not desirable in production, because it can lead to unexpected upgrades.

You can also write a Dockerfile yourself, and then build it to create a Docker image. To do so, you need to instruct Puppet to copy the Dockerfile to the target and then build it::

```
file { '/path/to/remote/Dockerfile':
  ensure => file,
  source => 'puppet:///path/to/local/Dockerfile',
}

docker::image { 'image_name':
  docker_file => '/path/to/remote/Dockerfile'
}
```

It is also possible to subscribe to Dockerfile changes, and automatically rebuild the image whenever a new file is found:

```
docker::image { 'image_name':
  docker_file => '/path/to/remote/Dockerfile'
  subscribe => File['/path/to/remote/Dockerfile'],
}
```

To remove an image that was possibly built or pulled:

```
docker::image { 'mariadb':
  ensure => absent
}
```

## How to Deploy Containers with Puppet

To run a container:

```
docker::run { 'mariadb-01':
  image    => 'mariadb:10.5',
  ports    => ['3306:6606']
}
```

mariadb-01 is the contained name. We specified the optional 10.5 tag, and we mapped the guest port 3306 to the host port 6606. In production, you normally don't map ports because you don't need to connect MariaDB clients from the host system to MariaDB servers in the containers. Third-party tools can be installed as separate containers.

Content initially contributed by [Vettabase Ltd](#) .

## 2.1.2.14.4.5 Existing Puppet Modules for MariaDB

This page contains links to Puppet modules that can be used to automate MariaDB deployment and configuration. The list is not meant to be exhaustive. Use it as a starting point, but then please do your own research.

### Contents

1. [Puppet Forge](#)
2. [Acceptance Tests](#)
3. [Supported Modules for MariaDB](#)
4. [Resources and References](#)

## Puppet Forge

Puppet Forge is the website to search for Puppet modules, maintained by the Puppet company. Modules are searched by the technology that needs to be automated, and the target operating system.

Search criteria include whether the modules are supported by Puppet or its partners, and whether a module is approved by Puppet. Approved modules are certified by Puppet based on their quality and maintenance standards.

## Acceptance Tests

Some modules that support the Puppet Development Kit allow some types of acceptance tests.

We can run a static analysis on a module's source code to find certain bad practices that are likely to be a source of bugs:

```
pdk validate
```

If a module's authors wrote unit tests, we can run them in this way:

```
pdk test unit
```

## Supported Modules for MariaDB

At the time of writing, there are no supported or approved modules for MariaDB.

However there is a [mysql module](#) supported by Puppet, that supports the Puppet Development Kit. Though it doesn't support MariaDB-specific features, it works with MariaDB. Its documentation shows how to use the module to install MariaDB on certain operating systems.

Several unsupported and not approved modules exist for MariaDB and MaxScale.

## 2.1.2.14.5 Vagrant and MariaDB

Vagrant is an open source tool to quickly setup machines that can be used for development and testing. These machines can be local virtual machines, Docker containers, AWS EC2 instances, and so on. Vagrant allows one to easily and quickly setup test MariaDB servers.

### Vagrant Overview for MariaDB Users

*Vagrant architecture, general concepts and basic usage.*

### Creating a Vagrantfile

*How to create a new Vagrant box running MariaDB.*

### Vagrant Security Concerns

*Security matters related to Vagrant machines.*

### 2.1.2.14.5.1 Vagrant Overview for MariaDB Users

Vagrant is a tool to create and manage development machines (Vagrant boxes). They are usually virtual machines on the localhost system, but they could also be Docker containers or remote machines. Vagrant is open source software maintained by HashiCorp and released under the MIT license.

Vagrant benefits include simplicity, and a system to create test boxes that is mostly independent from the technology used.

For information about installing Vagrant, see [Installation](#) in Vagrant documentation.

In this page we discuss basic Vagrant concepts.

#### Contents

- 1. [Vagrant Concepts](#)
  - 1. [Example](#)
  - 2. [Vagrantfiles](#)
  - 3. [Providers](#)
  - 4. [Provisioners](#)
  - 5. [Plugins](#)
  - 6. [Changes in Vagrant 3.0](#)
- 2. [Vagrant Commands](#)
- 3. [Vagrant Resources and References](#)

## Vagrant Concepts

A **Vagrant machine** is compiled from a box. It can be a virtual machine, a container or a remote server from a cloud service.

A **box** is a package that can be used to create Vagrant machines. We can download boxes from [app.vagrantup.com](#), or we can build a new box from a Vagrantfile. A box can be used as a base for another box. The base boxes are usually operating system boxes downloaded from [app.vagrantup.com](#).

A **provider** is responsible for providing the virtualization technology that will run our machine.

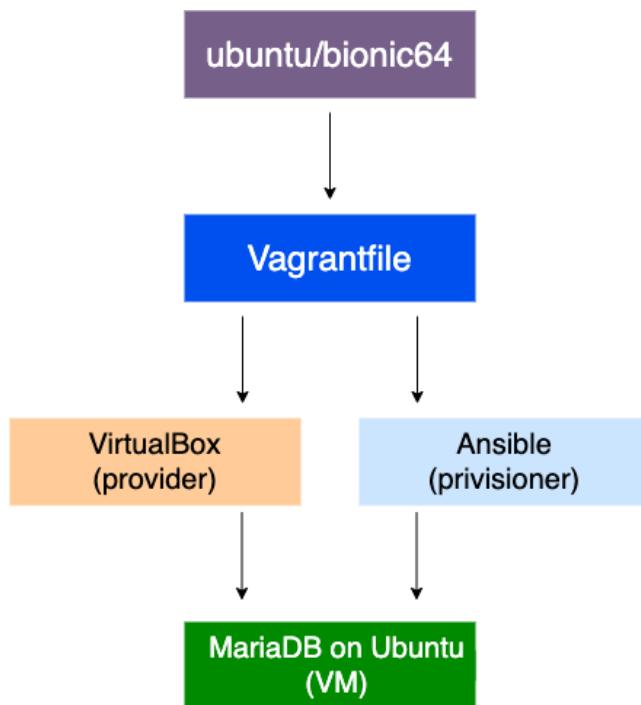

A **provisioner** is responsible for installing and configuring the necessary software on a newly created Vagrant machine.

## Example

The above concepts are probably easier to understand with an example.

We can use an Ubuntu box as a base to build a Vagrant machine with MariaDB. So we write a Vagrantfile for this purpose. In the Vagrantfile we specify VirtualBox as a provider. And we use the Ansible provisioner to install and configure MariaDB. Once we finish this Vagrantfile, we can run a Vagrant command to start a Vagrant machine, which is actually a VirtualBox VM running MariaDB on Ubuntu.

The following diagram should make the example clear:

## Vagrantfiles

A Vagrantfile is a file that describes how to create one or more Vagrant machines. Vagrantfiles use the Ruby language, as well as objects provided by

Vagrant itself.

A Vagrantfile is often based on a box, which is usually an operating system in which we are going to install our software. For example, one can create a MariaDB Vagrantfile based on the

```
ubuntu/trusty64
```

box. A Vagrantfile can describe a box with a single server, like MariaDB, but it can also contain a whole environment, like LAMP. For most practical use cases, having the whole environment in a single box is more convenient.

Boxes can be searched in [Vagrant Cloud](#). Most of their Vagrantfiles are available on GitHub. Searches can be made, among other things, by keyword to find a specific technology, and by provider.

## Providers

A provider adds support for creating a specific type of machines. Vagrant comes with several providers, for example:

- VirtualBox allows one to create virtual machines with VirtualBox.
- Hyper-V allows one to create virtual machines with Microsoft Hyper-V.
- Docker allows one to create Docker containers.

Alternative providers are maintained by third parties or sold by HashiCorp. They allow one to create different types of machines, for example using VMWare.

Some examples of useful providers, recognized by the community:

- [Vagrant AWS Provider](#).
- [Vagrant Google Compute Engine \(GCE\) Provider](#).
- [Vagrant Azure Provider](#).
- [OpenVZ](#).
- [vagrant-lxc](#).

If you need to create machines with different technologies, or deploy them to unsupported cloud platforms, you can develop a custom provider in Ruby language. To find out how, see [Plugin Development: Providers](#) in Vagrant documentation. The [Vagrant AWS Provider](#) was initially written as an example provider.

## Provisioners

A provisioner is a technology used to deploy software to the newly created machines.

The simplest provisioner is

```
shell  
, which runs a shell file inside the Vagrant machine.  
powershell  
is also available.
```

Other providers use automation software to provision the machine. There are provisioners that allow one to use [Ansible](#), [Puppet](#), Chef or Salt. Where relevant, there are different provisioners allowing the use of these technologies in a distributed way (for example, using Puppet apply) or in a centralized way (for example, using a Puppet server).

It is interesting to note that there is both a Docker provider and a Docker provisioner. This means that a Vagrant machine can be a Docker container, thanks to the

```
docker  
provisioner. Or it could be any virtualisation technology with Docker running in it, thanks to the  
docker  
provisioner. In this case, Docker pulls images and starts containers to run the software that should be running in the Vagrant machine.
```

If you need to use an unsupported provisioning method, you can develop a custom provisioner in Ruby language. See [Plugin Development: Provisioners](#) in Vagrant documentation.

## Plugins

It is possible to install a plugin with this command:

```
vagrant plugin install <plugin_name>
```

A Vagrantfile can require that a plugin is installed in this way:

```
require 'plugin_name'
```

A plugin can be a Vagrant plugin or a Ruby gem installable from [rubygems.org](#). It is possible to install a plugin that only exists locally by specifying its path.

## Changes in Vagrant 3.0

HashiCorp published an article that describes its [plans for Vagrant 3.0](#).

Vagrant will switch to a client-server architecture. Most of the logic will be stored in the server, while the development machines will run a thin client that communicates with the server. It will be possible to store the configuration in a central database.

Another notable change is that Vagrant is switching from Ruby to Go. For some time, it will still be possible to use Vagrantfiles and plugins written in Ruby. However, in the future Vagrantfiles and plugins should be written in one of the languages that support [gRPC](#) (not necessarily Go). Vagrantfiles can also be written in [HCL](#), HashiCorp Configuration Language.

## Vagrant Commands

This is a list of the most common Vagrant commands. For a complete list, see [Command-Line Interface](#) in Vagrant documentation.

To list the available machines:

```
vagrant box list
```

To start a machine from a box:

```
cd /box/directory  
vagrant up
```

To connect to a machine:

```
vagrant ssh
```

To see all machines status and their id:

```
vagrant global-status
```

To destroy a machine:

```
vagrant destroy <id>
```

### 2.1.2.14.5.2 Creating a Vagrantfile

In this page we discuss how to create a Vagrantfile, which you can use to create new boxes or machines. This content is specifically written to address the needs of MariaDB users.

6. [References](#)

## A Basic Vagrantfile

A Vagrantfile is a Ruby file that instructs Vagrant to create, depending on how it is executed, new Vagrant machines or boxes. You can see a box as a compiled Vagrantfile. It describes a type of Vagrant machines. From a box, we can create new Vagrant machines. However, while a box is easy to distribute to a team or to a wider public, a Vagrantfile can also directly create one or more Vagrant machines, without generating any box.

Here is a simple Vagrantfile example:

```
Vagrant.configure("2") do |config|
  config.vm.box = "hashicorp/bionic64"
  config.vm.provider "virtualbox"
  config.vm.provision :shell, path: "bootstrap.sh"
end
```

Vagrant.configure("2")  
returns the Vagrant configuration object for the new box. In the block, we'll use the  
config  
alias to refer this object. We are going to use version 2 of Vagrant API.

vm.box

is the base box that we are going to use. It is Ubuntu BionicBeaver (18.04 LTS), 64-bit version, provided by HashiCorp. The schema for box names is simple: the maintainer account in [Vagrant Cloud](#) followed by the box name.

We use

```
vm.provision  
to specify the name of the file that is going to be executed at the machine creation, to provision the machine.  
bootstrap.sh  
is the conventional name used in most cases.
```

To create new Vagrant machines from the Vagrantfile, move to the directory that contains the Vagrant project and run:

```
vagrant up
```

To compile the Vagrantfile into a box:

```
vagrant package
```

These operations can take time. To check if the Vagrantfile contains syntax errors or certain types of bugs:

```
vagrant validate
```

## Providers

A provider allows Vagrant to create a Vagrant machine using a certain technology. Different providers may enable a virtual machine manager ([VirtualBox](#), [VMWare](#), [Hyper-V](#) ...), a container manager ([Docker](#)), or remote cloud hosts ([AWS](#), [Google Compute Engine](#) ...).

Some providers are developed by third parties. [app.vagrant.com](#) supports search for boxes that support the most important third parties providers. To find out how to develop a new provider, see [Plugin Development: Providers](#).

Provider options can be specified. Options affect the type of Vagrant machine that is created, like the number of virtual CPUs. Different providers support different options.

It is possible to specify multiple providers. In this case, Vagrant will try to use them in the order they appear in the Vagrantfile. It will try the first provider; if it is not available it will try the second; and so on.

Here is an example of providers usage:

```
Vagrant.configure("2") do |config|
  config.vm.box = "hashicorp/bionic64"
  config.vm.provider "virtualbox" do |vb|
    vb.customize ["modifyvm", :id, "--memory", 1024 * 4]
  end
  config.vm.provider "vmware_fusion"
end
```

In this example, we try to use VirtualBox to create a virtual machine. We specify that this machine must have 4G of RAM (1024M \* 4). If VirtualBox is not available, Vagrant will try to use VMWare.

This mechanism is useful for at least a couple of reasons:

- Different users may use different systems, and maybe they don't have the same virtualization technologies installed.
- We can gradually move from one provider to another. For a period of time, some users will have the new virtualization technology installed, and they will use it; other users will only have the old technology installed, but they will still be able to create machines with Vagrant.

# Provisioners

We can use different methods for provisioning. The simplest provisioner is

```
shell
```

, that allows one to run a Bash file to provision a machine. Other provisioners allow setting up the machines using automation software, including Ansible, Puppet, Chef and Salt.

To find out how to develop a new provisioner, see [Plugin Development: Provisioners](#).

## The

### shell Provisioner

In the example above, the `shell` provisioner runs `bootstrap.sh` inside the Vagrant machine to provision it. A simple `bootstrap.sh` may look like the following:

```
#!/bin/bash

apt-get update
apt-get install -y
```

To find out the steps to install MariaDB on your system of choice, see the [Getting, Installing, and Upgrading MariaDB](#) section.

You may also want to restore a database backup in the new Vagrant machine. In this way, you can have the database needed by the application you are developing. To find out how to do it, see [Backup and Restore Overview](#). The most flexible type of backup (meaning that it works between different MariaDB versions, and in some cases even between MariaDB and different DBMSs) is a `dump`.

On Linux machines, the

```
shell
```

provisioner uses the default shell. On Windows machines, it uses PowerShell.

## Uploading Files

If we use the

```
shell
```

provisioner, we need a way to upload files to the new machine when it is created. We could use the `file`

provisioner, but it works by connecting the machine via ssh, and the default user doesn't have permissions for any directory except for the synced folders. We could change the target directory owner, or we could add the default user to a group with the necessary privileges, but these are not considered good practices.

Instead, we can just put the file we need to upload somewhere in the synced folder, and then copy it with a shell command:

```
cp ./files/my.cnf /etc/mysql/conf.d/
```

## Provisioning Vagrant with Ansible

Here is an example of how to provision a Vagrant machine or box by running Ansible:

```
Vagrant.configure("2") do |config|
  ...
  config.vm.provision "ansible" do |ansible|
    ansible.playbook = "vagrant.yml"
  end
end
```

With the [Ansible provisioner](#), Ansible runs in the host system. In this example, it runs a playbook called

```
vagrant.yml
```

. The [Ansible Local provisioner](#) runs the playbook in the vagrant machine.

For an introduction to Ansible for MariaDB users, see [Ansible and MariaDB](#).

## Provisioning Vagrant with Puppet

To provision a Vagrant machine or box by running Puppet:

```
Vagrant.configure("2") do |config|
  ...
  config.vm.provision "puppet" do |puppet|
    puppet.manifests_path = "manifests"
    puppet.manifest_file = "default.pp"
  end
end
```

In this example, Puppet Apply runs in the host system and no Puppet Server is needed. Puppet expects to find a

```
manifests
directory in the project directory. It expects it to contain
default.pp
, which will be used as an entry point. Note that
puppet.manifests_path
and
puppet.manifest_file
are set to their default values.
```

Puppet needs to be installed in the guest machine.

To use a Puppet server, the

```
puppet_server
provisioner can be used:
```

```
Vagrant.configure("2") do |config|
  ...
  config.vm.provision "puppet_server" do |puppet|
    puppet.puppet_server = "puppet.example.com"
  end
end
```

See the [Puppet Apply provisioner](#) and the [Puppet Agent Provisioner](#).

For an introduction to Puppet for MariaDB users, see [Puppet and MariaDB](#).

## Sharing Files Between the Host and a Guest System

To restore a backup into MariaDB, in most cases we need to be able to copy it from the host system to the box. We may also want to occasionally copy MariaDB logs from the box to the host system, to be able to investigate problems.

The project directory (the one that contains the Vagrantfile) by default is shared with the virtual machine and mapped to the

```
/vagrant
directory (the synced folder). It is a good practice to put there all files that should be shared with the box when it is started. Those files should normally be versioned.
```

The synced folder can be changed. In the above example, we could simply add one line:

```
config.vm.synced_folder "/host/path", "/guest/path"
```

The synced folder can also be disabled:

```
config.vm.synced_folder '.', '/vagrant', disabled: true
```

Note that multiple Vagrant machines may have synced folders that point to the same directory on the host system. This can be useful in some cases, if you prefer to test some functionalities quickly, rather than replicating production environment as faithfully as possible. For example, to test if you're able to take a backup from one machine and restore it to another, you can store the backup in a common directory.

## Network Communications

It is often desirable for a machine to be able to communicate with "the outside". This can be done in several ways:

- Private networks;
- Public networks;
- Exposing ports to the host.

Remember that Vagrant doesn't create machines, but it asks a provisioner to create machines. Some provisioners support all of these communication methods, others may support some of them, or even none of them. When you create a Vagrantfile that starts machines using one of these features, it is implicit that this can only happen if the provisioner you are using supports the features you need. Check your provisioner documentation to find out which features it supports.

The default provisioner, VirtualBox, supports all these communication methods, including multiple networks.

## Private Networks

A private network is a networks that can only be accessed by machines that run on the same host. Usually this also means that the machines must run on the same provisioner (for example, they all must be VirtualBox virtual machines).

Some provisioners support multiple private networks. This means that every network has a different name and can be accessed by different machines.

The following line shows how to create or join a private network called "example", where this machine's IP is assigned by the provisioner via DHCP:

```
config.vm.network 'private_network', name: 'example', type: 'dhcp'
```

While this is very convenient to avoid IP conflicts, sometimes you prefer to assign some IP's manually, in this way:

```
config.vm.network 'private_network', name: 'example', ip: '111.222.111.222'
```

## Public Networks

As explained above, public networks are networks that can be accessed by machines that don't run on the same host with the same provider.

To let a machine join a public network:

```
# use provisioner DHCP:  
config.vm.network "public_network", use_dhcp_assigned_default_route: true  
  
# assign ip manually:  
config.vm.network "public_network", ip: "111.222.111.222"
```

To improve security, you may want to configure a gateway:

```
config.vm.provision "shell", run: "always", inline: "route add default gw 111.222.111.222"
```

## Exposing Ports

Vagrant allows us to map a TCP or UDP port in a guest system to a TCP or UDP port in the host system. For example, you can map a virtual machine port 3306 to the host port 12345. Then you can connect MariaDB in this way:

```
mariadb -hlocalhost -P12345 -u<user> -p<password>
```

You are not required to map a port to a port with a different number. In the above example, if the port 3306 in your host is not in use, you are free to map the guest port 3306 to the host port 3306.

There are a couple of caveats:

- You can't map a single host port to multiple guest ports. If you want to expose the port 3306 from multiple Vagrant machines, you'll have to map them to different host ports. When running many machines this can be hard to maintain.
- Ports with numbers below 1024 are privileged ports. Mapping privileged ports requires root privileges.

To expose a port:

```
config.vm.network 'forwarded_port', guest: 3306, host: 3306
```

## Use Cases

Suppose you run MariaDB and an application server in two separate Vagrant machines. It's usually best to let them communicate via a private network, because this greatly increases your security. The application server will still need to expose ports to the host, so the application can be tested with a web browser.

Suppose you have multiple environments of the same type, like the one described above. They run different applications that don't communicate with each other. In this case, if your provisioner supports this, you will run multiple private networks. You will need to expose the applications servers ports, mapping them to different host ports.

You may even want to implement different private networks to create an environment that reflects production complexity. Maybe in production you have a cluster of three MariaDB servers, and the application servers communicate with them via a proxy layer (ProxySQL, HAProxy, or MaxScale). So the applications can communicate with the proxies, but have no way to reach MariaDB directly. So there is a private network called "database" that can be accessed by the MariaDB servers and the proxy servers, and another private network called "application" that can be accessed by the proxy servers and the application servers. This requires that your provisioner supports multiple private networks.

Using public networks instead of private one will allow VMs that run on different hosts to be part of your topology. In general this is considered as an insecure practice, so you should probably ask yourself if you really need to do this.

## 2.1.2.14.5.3 Vagrant Security Concerns

Databases typically contain information to which access should be restricted. For this reason, it's worth discussing some security concerns that Vagrant users should be aware of.

### Contents

1. [Access to the Vagrant Machine](#)
2. [Synced Folders](#)
3. [Reporting Security Bugs](#)

## Access to the Vagrant Machine

By default, Vagrant machines are only accessible from the localhost. SSH access uses randomly generated key pairs, and therefore it is secure.

The password for

root  
and  
vagrant  
is "vagrant" by default. Consider changing it.

## Synced Folders

By default, the project folder in the host system is shared with the machine, which sees it as

/vagrant

This means that whoever has access to the project folder also has read and write access to the synced folder. If this is a problem, make sure to properly restrict the access to the synced folder.

If we need to exchange files between the host system and the Vagrant machine, it is not advisable to disable the synced folder. This is because the only alternative is to use the

file

provider, which works by copying files to the machine via ssh. The problem is that the default ssh user does not have permissions to write to any directory by default, and changing this would be less secure than using a synced folder.

When a machine is provisioned, it should read the needed files from the synced folder or copy them to other places. Files in the synced folder should not be accessed by the Vagrant machine during its normal activities. For example, it is fine to load a dump from the synced folder during provisioning; and it is fine to copy configuration files from the synced folder to directories in

/etc

during provisioning. But it is a bad practice to let MariaDB use table files located in the synced folder.

## Reporting Security Bugs

Note that security bugs are not reported as normal bugs. Information about security bugs are not public. See [Security at HashiCorp](#) for details.

## 2.1.2.14.5.4 Running MariaDB ColumnStore Docker containers on Linux, Windows and MacOS

### Contents

1. [Introduction](#)
2. [Windows Linux Subsystem](#)
3. [Docker](#)

# Introduction

Docker allows for a simple and lightweight setup of a MariaDB ColumnStore single server instance for evaluation purposes. The configuration is designed for simplified developer / evaluation setup rather than production use. It allows to evaluate ColumnStore on a Windows or MacOS system, setting up a Linux system in a container. The Docker image uses a base OS of CentOS and currently require separate download of the CentOS RPM install bundle.

## Windows Linux Subsystem

If you have Windows 10 Creators update installed, then you can install the Ubuntu installation into the Bash console. Please follow the Ubuntu instructions in getting started. If you have recently upgraded and had Bash installed previously, ensure you uninstall and reinstall Bash first to have a clean Ubuntu installation. Note that ColumnStore will be terminated should you terminate the Bash console.

## Docker

[Docker](#) manages lightweight containers that allows for creation of lightweight and reproducible containers with a dedicated function. On Windows and MacOS systems, Docker transparently runs on a Linux virtual machine.

Since MariaDB ColumnStore relies on a Syslog daemon, the container must start both ColumnStore and rsyslogd and the runit utility is used to achieve this.

A single node docker image can be found at [MariaDB on docker hub](#).

```
docker run -d --name mcs mariadb/columnstore  
docker exec -it mcs bash
```

A ColumnStore cluster can be brought up using a compose file provided in the ColumnStore github repository:

```
git clone https://github.com/mariadb-corporation/mariadb-columnstore-docker.git  
cd mariadb-columnstore-docker/columnstore  
docker-compose up -d
```

For more information about how to manage Docker containers, see [Installing and Using MariaDB via Docker](#).

To test an application that uses ColumnStore, it is desirable to setup several containers that will communicate with each other. To do this, we can use Docker Compose. See [Setting Up a LAMP Stack with Docker Compose](#) for more information.

### 2.1.2.14.6 Docker and MariaDB

Docker is an open source container manager that can be used to quickly create ephemeral containers running specific software. Docker containers can be used for production, development or testing, though it is not the preferred choice to run MariaDB in production.

### 2.1.2.14.6.1 Benefits of Managing Docker Containers with Orchestration Software

In this page we'll discuss why automating [Docker](#) containers with software like [Ansible](#) or [Puppet](#) may be desirable in some cases. To talk about this, we'll first need to discuss why Docker containers are defined *ephemeral*, and how this applies to containerized database servers (particularly MariaDB).

During the discussion, we should keep in mind that Docker can be used to setup production and/or development environments. These use cases are very different from a database perspective: a production database may be big, and typically contains data that we don't want to lose. Development environments usually contain small sample data that can be rebuilt relatively quickly. This page focuses on the latter case.

## Docker's Ephemeral Nature

Docker images are compiled from Dockerfiles. Containers are created from images. Normally, a container is not modified from the moment it is created. In other words, containers are usually designed to be **ephemeral**, meaning that they can be destroyed and replaced with new containers at any time. Provided that there is proper redundancy (for example, there are several web servers running the same services) destroying one container and starting a new one of the same type won't cause any damage.

We will discuss a bit later how this applies to MariaDB, and more generally to database servers.

When something should change, for example some software version or configuration, normally Dockerfiles are updated and containers are recreated from the latest image versions. For this reason, containers shouldn't contain anything that shouldn't be lost, and recreating them should be an extremely cheap operation. **Docker Compose** or the **Swarm mode** are used to declare which containers form a certain environment, and how they communicate with each other.

On the contrary, Ansible and Puppet are mainly built to manage the configuration of existing servers. It doesn't recreate servers, it changes their configuration. So Docker and Ansible have very different approaches. For this reason, Ansible and Puppet are not frequently used to deploy containers to production. However, using them together can bring some benefits, especially for development environments.

More on this later in the page. First, we need to understand how these concepts apply to database servers.

## Stateful Technologies

Using ephemeral containers works very well for *stateless* technologies, like web servers and proxies. These technologies virtually only need binaries, configuration and small amounts of data (web pages). If some data need to be restored after a container creation, it will be a fast operation.

In the case of a database, the problem is that data can be large and need to be written somewhere. We don't want all databases to disappear when we destroy a container. Even if we had an up-to-date backup, restoring it would take time.

However, Docker has features called **volumes** and **volume containers**. We won't discuss the difference here, let's focus on their purpose. A volume is a directory in the host system mapped to a directory in one or more containers. Volumes are not destroyed when containers are destroyed. They can be used to share data between any number of containers and the host system. Therefore, they are also a good way to persist data.

Suppose a MariaDB container called

```
mariadb-main-01  
uses a volume that is mapped to  
/var/docker/volumes/mariadb-main
```

. At some point we want to use a more recent MariaDB version. As explained earlier, the Docker way to do this is to destroy the container and create a new one that uses a more recent version of the MariaDB image.

So, we will destroy

```
mariadb-main-01  
. The volume is still there. Then we create a new container with the same name, but based on a newer image. We make sure to link the volume  
to the new container too, so it will be able to use  
/var/docker/volumes/mariadb-main  
again. At this point we may want to run mysql\_upgrade, but apart from that, everything should just work.
```

The above described steps are simple, but running them manually is time consuming and error-prone. Automating them with some automation software like Ansible or Puppet is often desirable.

## Ways to Deploy Docker Containers

Docker containers can be deployed in the following ways:

- Manually. See [Installing and Using MariaDB via Docker](#). This is not recommended for production, or for complex environments. However, it can easily be done for the simplest cases. If we want to make changes to our [custom images](#), we'll need to modify the Dockerfiles, destroy the containers and recreate them.
- With Docker Compose. See [Setting Up a LAMP Stack with Docker Compose](#) for a simple example. When we modify a Dockerfile, we'll need to destroy the containers and recreate them, which is usually as simple as running

```
docker-compose down  
followed by  
docker-compose-up  
. After changing  
docker-compose.yml  
(maybe to add a container or a network) we'll simply need to run  
docker-compose-up  
again, because it is idempotent.
```

- Using Ansible, Puppet or other automation software, as mentioned before. We can use Ansible or Puppet to create the containers, and run them again every time we want to apply some change to the containers. This means that the containers are potentially created once and modified any

number of times.

In all these cases, it is entirely possible to add [Vagrant](#) to the picture. Vagrant is a way to deploy or provision several hosts, including virtual machines (the most common case), and containers. It is agnostic in regarding the underlying technology, so it can deploy to a virtual machine, a container, or even a remote server in the same way. Docker can work with Vagrant in two ways:

- As a [provisioner](#). In this case Vagrant will most commonly deploy a virtual machine, and will use Docker to setup the applications that need to run in it, as containers. This guarantees a higher level of isolation, compared to running the containers in the local host. Especially if you have different environments to deploy locally, because you can have them on different virtual machines.
- As a [provider](#). Vagrant will deploy one or more Docker containers locally. Once each container is up, Vagrant can optionally use a provisioner on it, to make sure that the container runs the proper software with proper configuration. In this case, Ansible, Puppet or other automation software can be used as a provisioner. But again, this is optional: it is possible to make changes to the Dockerfiles and recreate the containers every time.

## Benefits of Managing Docker Containers with Automation Software

Docker containers can be entirely managed with Docker Compose or the Swarm mode. This is often a good idea.

However, choosing to use automation software like Ansible or Puppet has some benefits too. Benefits include:

- Docker containers allow working without modifying the host system, and their creation is very fast. Much faster than virtual machines. This makes Docker desirable for development environments.
- As explained, making all containers ephemeral and using volumes to store important data is possible. But this means adding some complexity to adapt an ephemeral philosophy to technologies that are not ephemeral by nature (databases). Also, many database professionals don't like this approach. Using automation software allows easily triggering upgrades and configuration changes in the containers, treating them as non-ephemeral systems.
- Sometimes Docker is only used in development environments. If production databases are managed via Ansible, Puppet, or other automation software, this could lead to some code duplication. Dealing with configuration changes using the same procedures will reduce the cost of maintenance.
- While recreating containers is fast, being able to apply small changes with Ansible or Puppet can be more convenient in some cases: particularly if we write files into the container itself, or if recreating a container bootstrap involves some lengthy procedure.
- Trying to do something non-standard with Dockerfiles can be tricky. For example, running two processes in a container is possible but can be problematic, as Docker is designed to run a process per container. However there are situations when this is desirable. For example PMM containers run several different processes. Launching additional processes with Ansible or Puppet may be easier than doing it with a Dockerfile.

With all this in mind, let's see some examples of cases when managing Docker containers with Ansible, Puppet or other automation software is preferable, rather than destroying containers every time we want to make a change:

- We use Ansible or Puppet in production, and we try to keep development environments as similar as possible to production. By using Ansible/Puppet in development too, we can reuse part of the code.
- We make changes to the containers often, and recreating containers is not as fast as it should be (for example because a MariaDB [dump](#) needs to be restored).
- Creating a container implies some complex logic that does not easily fit a Dockerfile or Docker Compose (including, but not limited to, running multiple processes per container).

That said, every case is different. There are environments where these advantages do not apply, or bring a very small benefit. In those cases, the cost of adding some automation with Ansible, Puppet or similar software is probably not justified.

## How to Deploy to Container from Orchestration Software

Suppose you want to manage containers configuration with Ansible.

**At a first glance**, the simplest way is to run Ansible in the host system. It will need to connect to the containers via SSH, so they need to expose the 22 port. But we have multiple containers, so we'll need to map the 22 port of each container to a different port in the host. This is hard to maintain and potentially insecure: in production you want to avoid exposing any container port to the host.

A better solution is to run Ansible itself in a container. The playbooks will be in a Docker volume, so we can access them from the host system to manage them more easily. The Ansible container will communicate with other containers using a Docker network, using the standard 22 port (or another port of your choice) for all containers.

## See Also

  - 1. Daemonizing the Operating System
  - 2. Installing MariaDB
- 4. [See Also](#)

Sometimes we want to install a specific version of MariaDB, [MariaDB ColumnStore](#), or [MaxScale](#) on a certain system, but no packages are available. Or maybe, we simply want to isolate MariaDB from the rest of the system, to be sure that we won't cause any damage.

A virtual machine would certainly serve the scope. However, this means installing a system on the top of another system. It requires a lot of resources.

In many cases, the best solution is using containers. Docker is a framework that runs containers. A container is meant to run a specific daemon, and the software that is needed for that daemon to properly work. Docker does not virtualize a whole system; a container only includes the packages that are not included in the underlying system.

Docker requires a very small amount of resources. It can run on a virtualized system. It is used both in development and in production environments. Docker is an open source project, released under the Apache License, version 2.

Note that, while your package repositories could have a package called

```
docker  
, it is probably not the Docker we are talking about. The Docker package could be called  
docker.io  
or  
docker-engine
```

For information about installing Docker, see [Get Docker](#) in Docker documentation.

## Installing Docker on Your System with the Universal Installation Script

The script below will install the Docker repositories, required kernel modules and packages on the most common Linux distributions:

```
curl -sSL https://get.docker.com/ | sh
```

## Starting dockerd

On some systems you may have to start the

```
dockerd daemon  
yourself:
```

```
sudo systemctl start docker  
sudo gpasswd -a "${USER}" docker
```

If you don't have

```
dockerd  
running, you will get the following error for most  
docker  
commands:
```

```
Cannot connect to the Docker daemon at unix:///var/run/docker.sock. Is the docker daemon running?
```

## Using MariaDB Images

The easiest way to use MariaDB on Docker is choosing a MariaDB image and creating a container.

## Downloading an Image

You can download a MariaDB image for Docker from the [Official Docker MariaDB](#), or choose another image that better suits your needs. You can search Docker Hub (the official set of repositories) for an image with this command:

```
docker search mariadb
```

Once you have found an image that you want to use, you can download it via Docker. Some layers including necessary dependencies will be downloaded too. Note that, once a layer is downloaded for a certain image, Docker will not need to download it again for another image.

For example, if you want to install the default MariaDB image, you can type:

```
docker pull mariadb:10.4
```

This will install the 10.4 version. Versions 10.2, 10.3, 10.5 are also valid choices.

You will see a list of necessary layers. For each layer, Docker will say if it is already present, or its download progress.

To get a list of installed images:

```
docker images
```

## Creating a Container

An image is not a running process; it is just the software needed to be launched. To run it, we must create a container first. The command needed to create a container can usually be found in the image documentation. For example, to create a container for the official MariaDB image:

```
docker run --name mariadbtest -e MYSQL_ROOT_PASSWORD=mypass -p 3306:3306 -d docker.io/library/mariadb:10.3
```

mariadbtest

is the name we want to assign the container. If we don't specify a name, an id will be automatically generated.

10.2 and 10.5 are also valid target versions:

```
docker run --name mariadbtest -e MYSQL_ROOT_PASSWORD=mypass -p 3306:3306 -d docker.io/library/mariadb:10.2
```

```
docker run --name mariadbtest -e MYSQL_ROOT_PASSWORD=mypass -p 3306:3306 -d docker.io/library/mariadb:10.5
```

Optionally, after the image name, we can specify some [options for mysqld](#). For example:

```
docker run --name mariadbtest -e MYSQL_ROOT_PASSWORD=mypass -p 3306:3306 -d mariadb:10.3 --log-bin --binlog-format=MIXED
```

Docker will respond with the container's id. But, just to be sure that the container has been created and is running, we can get a list of running containers in this way:

```
docker ps
```

We should get an output similar to this one:

CONTAINER ID	IMAGE	COMMAND	CREATED	STATUS	PORTS
819b786a8b48	mariadb	/docker-entrypoint.	4 minutes ago	Up 4 minutes	3306/tcp

## Running and Stopping the Container

Docker allows us to restart a container with a single command:

```
docker restart mariadbtest
```

The container can also be stopped like this:

```
docker stop mariadbtest
```

The container will not be destroyed by this command. The data will still live inside the container, even if MariaDB is not running. To restart the container and see our data, we can issue:

```
docker start mariadbtest
```

With

```
docker stop  
, the container will be gracefully terminated: a  
SIGTERM  
signal will be sent to the  
mysqld  
process, and Docker will wait for the process to shutdown before returning the control to the shell. However, it is also possible to set a timeout,  
after which the process will be immediately killed with a  
SIGKILL  
. Or it is possible to immediately kill the process, with no timeout.
```

```
docker stop --time=30 mariadbtest  
docker kill mariadbtest
```

In case we want to destroy a container, perhaps because the image does not suit our needs, we can stop it and then run:

```
docker rm mariadbtest
```

Note that the command above does not destroy the data volume that Docker has created for /var/lib/mysql. If you want to destroy the volume as well, use:

```
docker rm -v mariadbtest
```

## Automatic Restart

When we start a container, we can use the

```
--restart  
option to set an automatic restart policy. This is useful in production.
```

Allowed values are:

- no  
: No automatic restart.
- on-failure  
: The container restarts if it exits with a non-zero exit code.
- unless-stopped  
: Always restart the container, unless it was explicitly stopped as shown above.
- always  
: Similar to  
unless-stopped  
, but when Docker itself restarts, even containers that were explicitly stopped will restart.

It is possible to change the restart policy of existing, possibly running containers:

```
docker update --restart always mariadb  
# or, to change the restart policy of all containers:  
docker update --restart always $(docker ps -q)
```

A use case for changing the restart policy of existing containers is performing maintenance in production. For example, before upgrading the Docker version, we may want to change all containers restart policy to

```
always  
, so they will restart as soon as the new version is up and running. However, if some containers are stopped and not needed at the moment, we  
can change their restart policy to  
unless-stopped
```

## Pausing Containers

A container can also be frozen with the

```
pause  
command. Docker will freeze the process using cgroups. MariaDB will not know that it is being frozen and, when we  
unpause  
it, MariaDB will resume its work as expected.
```

Both

```
pause  
and  
unpause
```

accept one or more container names. So, if we are running a cluster, we can freeze and resume all nodes simultaneously:

```
docker pause node1 node2 node3
docker unpause node1 node2 node3
```

Pausing a container is very useful when we need to temporarily free our system's resources. If the container is not crucial at this moment (for example, it is performing some batch work), we can free it to allow other programs to run faster.

## Troubleshooting a Container

If the container doesn't start, or is not working properly, we can investigate with the following command:

```
docker logs mariadbtest
```

This command shows what the daemon sent to the stdout since the last attempt of starting - the text that we typically see when we invoke

```
mysqld
from the command line.
```

On some systems, commands such as

```
docker stop mariadbtest
and
docker restart mariadbtest
may fail with a permissions error. This can be caused by AppArmor, and even
sudo
```

won't allow you to execute the command. In this case, you will need to find out which profile is causing the problem and correct it, or disable it.

**Disabling AppArmor altogether is not recommended, especially in production.**

To check which operations were prevented by AppArmor, see [AppArmor Failures](#) in AppArmor documentation.

To disable a profile, create a symlink with the profile name (in this example,

```
mysqld
) to
/etc/apparmor.d/disable
, and then reload profiles:
```

```
ln -s /etc/apparmor.d/usr.sbin.mysql /etc/apparmor.d/disable/
sudo apparmor_parser -R /etc/apparmor.d/usr.sbin.mysql
```

For more information, see [Policy Layout](#) in AppArmor documentation.

After disabling the profile, you may need to run:

```
sudo service docker restart
docker system prune --all --volumes
```

Restarting the system will then allow Docker to operate normally.

## Accessing the Container

To access the container via Bash, we can run this command:

```
docker exec -it mariadbtest bash
```

Now we can use normal Linux commands like `cd`, `ls`, etc. We will have root privileges. We can even install our favorite file editor, for example:

```
apt-get update
apt-get install vim
```

In some images, no repository is configured by default, so we may need to add them.

Note that if we run [mysqladmin shutdown](#) or the [SHUTDOWN](#) command to stop the container, the container will be deactivated, and we will automatically exit to our system.

## Connecting to MariaDB from Outside the Container

If we try to connect to the MariaDB server on

```
localhost
, the client will bypass networking and attempt to connect to the server using a socket file in the local filesystem. However, this doesn't work
when MariaDB is running inside a container because the server's filesystem is isolated from the host. The client can't access the socket file which is inside
the container, so it fails to connect.
```

Therefore connections to the MariaDB server must be made using TCP, even when the client is running on the same machine as the server container.

Find the IP address that has been assigned to the container:

```
docker inspect -f '{{range .NetworkSettings.Networks}}{{.IPAddress}}{{end}}' mariadbtest
```

You can now connect to the MariaDB server using a TCP connection to that IP address.

## Forcing a TCP Connection

After enabling network connections in MariaDB as described above, we will be able to connect to the server from outside the container.

On the host, run the client and set the server address ("h") to the container's IP address that you found in the previous step:

```
mysql -h 172.17.0.2 -u root -p
```

This simple form of the connection should work in most situations. Depending on your configuration, it may also be necessary to specify the port for the server or to force TCP mode:

```
mysql -h 172.17.0.2 -P 3306 --protocol=TCP -u root -p
```

## Port Configuration for Clustered Containers and Replication

Multiple MariaDB servers running in separate Docker containers can connect to each other using TCP. This is useful for forming a Galera cluster or for replication.

When running a cluster or a replication setup via Docker, we will want the containers to use different ports. The fastest way to achieve this is mapping the containers ports to different port on our system. We can do this when creating the containers (

```
docker run  
command), by using the  
-p  
option, several times if necessary. For example, for Galera nodes we will use a mapping similar to this one:
```

```
-p 4306:3306 -p 5567:5567 -p 5444:5444 -p 5568:5568
```

## Installing MariaDB on Another Image

It is possible to download a Linux distribution image, and to install MariaDB on it. This is not much harder than installing MariaDB on a regular operating system (which is easy), but it is still the hardest option. Normally we will try existing images first. However, it is possible that no image is available for the exact version we want, or we want a custom installation, or perhaps we want to use a distribution for which no images are available. In these cases, we will install MariaDB in an operating system image.

## Daemonizing the Operating System

First, we need the system image to run as a daemon. If we skip this step, MariaDB and all databases will be lost when the container stops.

To demonize an image, we need to give it a command that never ends. In the following example, we will create a Debian Jessie daemon that constantly pings the 8.8.8.8 special address:

```
docker run --name debian -p 3306:3306 -d debian /bin/sh -c "while true; do ping 8.8.8.8; done"
```

## Installing MariaDB

At this point, we can enter the shell and issue commands. First we will need to update the repositories, or no packages will be available. We can also update the packages, in case some of them are newer than the image. Then, we will need to install a text editor; we will need it to edit configuration files. For example:

```
# start an interactive Bash session in the container  
docker exec -ti debian bash  
apt-get -y update  
apt-get -y upgrade  
apt-get -y install vim
```

Now we are ready to [install MariaDB](#) in the way we prefer.

## 2.1.2.14.6.3 Running MariaDB ColumnStore Docker containers on Linux, Windows and MacOS

### Contents

1. [Introduction](#)
2. [Windows Linux Subsystem](#)
3. [Docker](#)

## Introduction

Docker allows for a simple and lightweight setup of a MariaDB ColumnStore single server instance for evaluation purposes. The configuration is designed for simplified developer / evaluation setup rather than production use. It allows to evaluate ColumnStore on a Windows or MacOS system, setting up a Linux system in a container. The Docker image uses a base OS of CentOS and currently require separate download of the CentOS RPM install bundle.

## Windows Linux Subsystem

If you have Windows 10 Creators update installed, then you can install the Ubuntu installation into the Bash console. Please follow the Ubuntu instructions in getting started. If you have recently upgraded and had Bash installed previously, ensure you uninstall and reinstall Bash first to have a clean Ubuntu installation. Note that ColumnStore will be terminated should you terminate the Bash console.

## Docker

[Docker](#) manages lightweight containers that allows for creation of lightweight and reproducible containers with a dedicated function. On Windows and MacOS systems, Docker transparently runs on a Linux virtual machine.

Since MariaDB ColumnStore relies on a Syslog daemon, the container must start both ColumnStore and rsyslogd and the runit utility is used to achieve this.

A single node docker image can be found at [MariaDB on docker hub](#) .

```
docker run -d --name mcs mariadb/columnstore
docker exec -it mcs bash
```

A ColumnStore cluster can be brought up using a compose file provided in the ColumnStore github repository:

```
git clone https://github.com/mariadb-corporation/mariadb-columnstore-docker.git
cd mariadb-columnstore-docker/columnstore
docker-compose up -d
```

For more information about how to manage Docker containers, see [Installing and Using MariaDB via Docker](#) .

To test an application that uses ColumnStore, it is desirable to setup several containers that will communicate with each other. To do this, we can use Docker Compose. See [Setting Up a LAMP Stack with Docker Compose](#) for more information.

## 2.1.2.14.6.4 Creating a Custom Docker Image

OCI containers, frequently called Docker containers, are created from OCI images. An image contains software that can be launched, including the underlying system. A container is an instance of that software.

When we want to automate MariaDB, creating an image with MariaDB and the desired configuration, we may want to create an image by ourselves, which fulfills our needs.

## Images Architecture

One "source code" of an image is a Dockerfile. A Dockerfile is written in Docker specific language, and can be compiled into an image by the

```
docker  
binary, using the  
docker build  
command. It can also be compiled by
```

```
buildah
```

```
using  
buildah bud
```

Most images are based on another image. The base image is specified at the beginning of the Dockerfile, with the

```
FROM
```

directive. If the base image is not present in the local system, it is downloaded from the repository specified, or if not specified, from the default repository of the build program. This is often Docker Hub. For example, we can build a

```
mariadb-rocksdb:10.5  
image starting from the  
debian:13
```

image. In this way, we'll have all the software included in a standard Debian image, and we'll add MariaDB and its configuration upon that image.

All the following Dockerfile directives are compiled into a new Docker image, identified by an SHA256 string. Each of these images is based on the image compiled from the previous directive. A physical compiled image can serve as a base for any number of images. This mechanism saves a lot of disk space, download time and build time.

The following diagram shows the relationship between Dockerfiles, images and containers:

## Dockerfile Syntax

Here's a simple Dockerfile example:

```
FROM ubuntu:20.04  
  
RUN apt-get update  
RUN apt-get install -y mariadb-server  
  
EXPOSE 3306  
  
LABEL version="1.0"  
LABEL description="MariaDB Server"  
  
HEALTHCHECK --start-period=5m \  
CMD mariadb -e 'SELECT @@datadir;' || exit 1  
  
CMD ["mysqld"]
```

This example is not very good for practical purposes, but it shows what a Dockerfile looks like.

First, we declare that the base image to use is

```
ubuntu:20.04
```

Then we run some commands to install MariaDB from the Ubuntu default repositories and stop the MariaDB service.

We define some metadata about the image with

```
LABEL  
. Any label is valid.
```

We declare that the port 3306 (MariaDB default port) should be exposed. However, this has no effect if the port is not exposed at container creation.

We also define a healthcheck. This is a command that is run to check if the container is healthy. If the return code is 0 the healthcheck succeeds, if it's 1 it fails. In the MariaDB specific case, we want to check that it's running and able to answer a simple query. This is better than just checking that MariaDB process is running, because MariaDB could be running but unable to respond, for example because `max_connections` was reached or data was corrupted.

We read a system variable, because we should not assume that any user-created table exists. We also specify

```
--start-period
```

to allow some time for MariaDB to start, keeping in mind that restarting it may take some time if some data is corrupted. Note that there can be only one healthcheck: if the command is specified multiple times, only the last occurrence will take effect.

Finally, we start the container command: `mysqld`. This command is run when a container based on this image starts. When the process stops or crashes, the container will immediately stop.

Note that, in a container, we normally run `mysqld` directly, rather than running `mysqld_safe` or running MariaDB as a service. Containers restart can be handled by the container service. See [automatic restart](#).

See the documentation links below to learn the syntax allowed in a Dockerfile.

## Using Variables

It is possible to use variables in a Dockerfile. This allows us, for example, to install different packages, install different versions of a package, or configure software differently depending on how variables are set, without modifying the Dockerfile itself.

To use a variable, we can do something like this:

```
FROM ubuntu:20.04

ARG MARIADB_CONFIG_FILE

...
RUN mysqld --defaults-file=$MARIADB_CONFIG_FILE
```

Here

```
ARG
```

is used after the

```
FROM
```

directive, thus the variable cannot be used in

```
FROM
```

. It is also possible to declare a variable before

```
FROM
```

, so we can use a variable to select the base image to use or its tag, but in this case the variable cannot be used after the

```
FROM
```

directive. Here is an example:

```
ARG UBUNTU_VERSION
FROM ubuntu:$UBUNTU_VERSION

# But this will cause a build error:
RUN echo 'Ubuntu version: $UBUNTU_VERSION' > /var/build_log
```

We'll have to assign variables a value when we build the Dockerfile, in this way:

```
docker build --build-arg UBUNTU_VERSION=20.04 .
```

Note that Dockerfile variables are just placeholders for values. Dockerfiles do not support assignment, conditionals or loops.

## Versioning and Deploying Images

Dockerfiles are normally versioned, as well as the files that are copied to the images.

Once an image is built, it can be pushed to a container registry. Whenever an image is needed on a host to start containers from it, it is pulled from the registry.

## Container registries

A default container registry for OCI images is Docker Hub. It contains images created by both the Docker Library team and the community. Any individual or organization can open an account and push images to Docker Hub. Most Docker images are open source: the Dockerfiles and the needed files to build the images are usually on GitHub.

It is also possible to setup a self-hosted registry. Images can be pushed to that registry and pulled from it, instead of using Docker Hub. If the registry is not publicly accessible, it can be used to store images used by the organization without making them publicly available.

But a self-hosted registry can also be useful for open source images: if an image is available on Docker Hub and also on a self-hosted registry, in case Docker Hub is down or not reachable, it will still be possible to pull images.

## Choosing Image Names and Tags

The names of images developed by the community follow this schema:

```
repository/maintainer/technology
```

It doesn't matter if the maintainer is an individual or an organization. For images available on Docker Hub, the maintainer is the name of a Docker Hub account.

Official images maintained by the Docker Library maintainers don't contain the name of the maintainer. For example, the official MariaDB image is called `mariadb` which is an alias for `docker.io/library/mariadb`.

All images have a tag, which identifies the version or the variant of an image. For example, all MariaDB versions available on Docker are used as image tags. [MariaDB 10.5](#) is called

```
mariadb:10.5
```

By convention, tags form a hierarchy. So for example, there is a

```
10.1.1  
tag whose meaning will not change over time.  
10.5  
will always identify the latest version in the 10.5 branch. For some time it was  
10.5.1  
, then it became  
10.5.2  
, and so on.
```

When we pull an image without specifying a tag (ie,

```
docker pull mariadb  
)  
, we are implicitly requiring the image with the  
latest  
tag. This is even more mutable: at different periods of time, it pointed to the latest  
10.0  
version, to the latest  
10.1  
version, and so on.
```

In production, it is always better to know for sure which version we are installing. Therefore it is better to specify a tag whose meaning won't change over time, like

```
10.5.1
```

## Pushing and Pulling Images

To pull an image from Docker Hub or a self-hosted registry, we use the

```
docker pull  
command. For example:
```

```
docker pull mariadb:10.5
```

This command downloads the specified image if it is not already present in the system, or if the local version is not up to date.

After modifying a Dockerfile, we can build an image in this way:

```
docker build .
```

This step can be automated by services like Docker Hub and GitHub. Check those service's documentation to find out how this feature works.

Once an image is created, it can be pushed to a registry. We can do it in this way:

```
docker push <image_name>:<tag>
```

## Docker Content Trust

Docker has a feature called Docker Content Trust (DCT). It is a system used to digitally sign images, based on PEM keys. For environments where security is a major concern, it is important to sign images before pushing them. This can be done with both Docker Hub and self-hosted registries.

## Good Practices and Caveats

As mentioned, a Dockerfile is built by creating a new image for each directive that follows

- FROM  
 . This leads to some considerations.
- Sometimes it can be a good idea to run several shell commands in a single  
`RUN`  
 directive to avoid creating images that are not useful.
  - Modifying a directive means that all subsequent directives also need to be rebuilt. When possible, directives that are expected to change often should follow directives that will change seldom.
  - Directives like  
`LABEL`  
 or  
`EXPOSE`  
 should be placed close to the end of Dockerfiles. In this way they will be rebuilt often, but this operation is cheap. On the other side, changing a label should not trigger a long rebuild process.
  - Variables should be used to avoid Dockerfiles proliferation. But if a variable is used, changing its value should be tested. So, be sure not to use variables without a good reason.
  - Writing logic into a Dockerfile is impossible or very hard. Call shell scripts instead, and write your logic into them. For example, in a shell script it is easy to perform a certain operation only if a variable is set to a certain value.
  - If you need MariaDB containers with different configurations or different sets of plugins, use the method explained above. Do not create several Dockerfiles, with different tags, for each desired configuration or plugin set. This may lead to undesired code duplication and increased maintenance costs.

## 2.1.2.14.6.5 Setting Up a LAMP Stack with Docker Compose

Docker Compose is a tool that allows one to declare which Docker containers should run, and which relationships should exist between them. It follows the **infrastructure as code** approach, just like most automation software and Docker itself.

For information about installing Docker Compose, see [Install Docker Compose](#) in Docker documentation.

### Contents

1. [The docker-compose.yml File](#)
  1. [About Volumes](#)
  2. [Using Variables](#)
2. [Docker Compose Commands](#)
3. [Docker Compose Resources and References](#)

## The

### docker-compose.yml File

When using Docker Compose, the Docker infrastructure must be described in a YAML file called  
`docker-compose.yml`

Let's see an example:

```

version: "3"

services:
  web:
    image: "apache:${PHP_VERSION}"
    restart: 'always'
    depends_on:
      - mariadb
    restart: 'always'
    ports:
      - '8080:80'
    links:
      - mariadb
  mariadb:
    image: "mariadb:${MARIADB_VERSION}"
    restart: 'always'
    volumes:
      - "/var/lib/mysql/data:${MARIADB_DATA_DIR}"
      - "/var/lib/mysql/logs:${MARIADB_LOG_DIR}"
      - /var/docker/mariadb/conf:/etc/mysql
    environment:
      MYSQL_ROOT_PASSWORD: "${MYSQL_ROOT_PASSWORD}"
      MYSQL_DATABASE: "${MYSQL_DATABASE}"
      MYSQL_USER: "${MYSQL_USER}"
      MYSQL_PASSWORD: "${MYSQL_PASSWORD}"

```

In the first line we declare that we are using version 3 of the Docker compose language.

Then we have the list of services, namely the

- `web`
- and the
- `mariadb`
- services.

Let's see the properties of the services:

- `port`  
maps the 8080 container port to the 80 host system port. This is very useful for a development environment, but not in production, because it allows us to connect our browser to the containerized web server. Normally there is no need to connect to MariaDB from the host system.
- `links`  
declares that this container must be able to connect  
`mariadb`  
. The hostname is the container name.
- `depends_on`  
declares that  
`mariadb`  
needs to start before  
`web`  
. This is because we cannot do anything with our application until MariaDB is ready to accept connections.
- `restart: always`  
declares that the containers must restart if they crash.
- `volumes`  
creates volumes for the container if it is set in a service definition, or a volume that can be used by any container if it is set globally, at the same level as  
`services`  
. Volumes are directories in the host system that can be accessed by any number of containers. This allows destroying a container without losing data.
- `environment`  
sets environment variables inside the container. This is important because in setting these variables we set the MariaDB root credentials for the container.

## About Volumes

It is good practice to create volumes for:

- The [data directory](#), so we don't lose data when a container is created or replaced, perhaps to upgrade MariaDB.
- The directory where we put all the logs, if it is not the datadir.

- The directory containing all configuration files (for development environments), so we can edit those files with the editor installed in the host system. Normally no editor is installed in containers. In production we don't need to do this, because we can copy files from a repository located in the host system to the containers.

Note that Docker Compose variables are just placeholders for values. Compose does not support assignment, conditionals or loops.

## Using Variables

In the above example you can see several variables, like

```
 ${MARIADB_VERSION}
 . Before executing the file, Docker Compose will replace this syntax with the
 MARIADB_VERSION
 variable.
```

Variables allow making Docker Compose files more re-usable: in this case, we can use any MariaDB image version without modifying the Docker Compose file.

The most common way to pass variables is to write them into a file. This has the benefit of allowing us to version the variable file along with the Docker Compose file. It uses the same syntax you would use in BASH:

```
PHP_VERSION=8.0
MARIADB_VERSION=10.5
...
```

For bigger setups, it could make sense to use different environment files for different services. To do so, we need to specify the file to use in the Compose file:

```
services:
  web:
    env_file:
      - web-variables.env
...
```

## Docker Compose Commands

Docker Compose is operated using

```
docker-compose
. Here we'll see the most common commands. For more commands and for more information about the commands mentioned here, see the documentation.
```

Docker Compose assumes that the Composer file is located in the current directory and it's called

```
docker-compose.yml
. To use a different file, the
-f <filename>
parameter must be specified.
```

To pull the necessary images:

```
docker-compose pull
```

Containers described in the Compose file can be created in several ways.

To create them only if they do not exist:

```
docker-compose up --no-recreate
```

To create them if they do not exist and recreate them if their image or configuration have changed:

```
docker-compose up
```

To recreate containers in all cases:

```
docker-compose up --force-recreate
```

Normally

```
docker-compose up
starts the containers. To create them without starting them, add the
--no-start
option.
```

To restart containers without recreating them:

```
docker-compose restart
```

To kill a container by sending it a

```
SIGKILL
```

```
:
```

```
docker-compose kill <service>
```

To instantly remove a running container:

```
docker-compose rm -f <service>
```

To tear down all containers created by the current Compose file:

```
docker-compose down
```

### 2.1.2.14.6.6 Docker Security Concerns

When using Docker containers in production, it is important to be aware of Docker security concerns.

#### Contents

1. [Host System Security](#)
2. [Images Security](#)
3. [References](#)

## Host System Security

All Docker containers are built upon the host system's kernel. If the host system's kernel has security bugs, those bugs are also present in the containers.

In particular, Docker leverages two Linux features:

- Namespaces, to isolate containers from each other and make sure that a container can't establish unauthorized connections to another container.
- cgroups, to limit the resources (CPU, memory, IO) that each container can consume.

The administrators of a system running Docker should be particularly careful to upgrade the kernel whenever security bugs to these features are fixed.

Docker, like most container technologies, uses the runC open source library. runC security bugs are likely to affect Docker.

Finally, Docker's own security bugs potentially affect all containers.

It is important to note that when we upgrade the kernel, runC or Docker itself we cause downtime for all the containers running on the system.

## Images Security

Docker containers are built from images. If security is a major concern, you should make sure that the images you use are secure.

If you want to be sure that you are pulling authentic images, you should only pull images signed with [Docker Content Trust](#).

The images should create and use a system user with less privileges than root. For example, the MariaDB daemon usually runs as a user called

```
mysql  
, who belongs the  
mysql
```

group. There is no need to run it as root (and by default it will refuse to start as root). Containers should not run it as root. Using an unprivileged user will reduce the chances that a bug in Docker or in the kernel will allow the user to gain access to the host system.

Updated images should be used. An image usually downloads packages information at build time. If the image is not recently built, a newly created container will have old packages. Updating the packages on container creation and regularly re-updating them will ensure that the container uses packages with the most recent versions. Rebuilding an image often will reduce the time necessary to update the packages the first time.

Security bugs are usually important for a database server, so you don't want your version of MariaDB to contain known security bugs. But suppose you also have a bug in Docker, in runC, or in the kernel. A bug in a user-facing application may allow an attacker to exploit a bug in those lower level technologies. So, after gaining access to the container, an attacker may gain access to the host system. This is why system administrators should keep both the host system and the software running in the containers updated.

## References

## 2.1.2.14.6.7 MariaDB Container Cheat Sheet

- Get the images  
Images can be found on [MariaDB Docker Hub](#).  
To get the list of images run

```
$ docker images ls
```

- Create the network

```
$ docker network create mynetwork
```

It is good practice to create the Docker network and attach the container to the network.

- Start the container with server options  
To start the container in the background with the MariaDB server image run:

```
$ docker run --rm --detach \
--env MARIADB_ROOT_PASSWORD=sosecret \
--network mynetwork \
--name mariadb-server \
mariadb:latest
```

Additionally [environment variables](#) are also provided.

- Get the list of running containers (specify the flag `-a` in case you want to see all containers)

CONTAINER ID	IMAGE	COMMAND	CREATED	STATUS	PORTS	NAMES
ad374ec8a272	mariadb:latest	"docker-entrypoint.s..."	3 seconds ago	Up 1 second	3306/tcp	mariadb-server

- Start the client from the container

To start the `mariadb` client inside the created container and run specific commands, run the following:

```
$ docker exec -it mariadb-server mariadb -psosecret -e "SHOW PLUGINS"
```

- Inspect logs from the container

```
$ docker logs mariadb-server
```

In the logs you can find status information about the server, plugins, generated passwords, errors and so on.

- Restart the container

```
$ docker restart mariadb-server
```

- Run commands within the container

```
$ docker exec -it mariadb-server bash
```

- Use a volume to specify configuration options

```
$ docker run --detach --env MARIADB_USER=anel \
--env MARIADB_PASSWORD=anel \
--env MARIADB_DATABASE=my_db \
--env MARIADB_RANDOM_ROOT_PASSWORD=1 \
--volume $PWD/my_container_config:/etc/mysql/conf.d:z \
--network mynetwork \
--name mariadb-server1 \
mariadb:latest
```

One can specify custom [configuration files](#) through the `/etc/mysql/conf.d` volume during container startup.

- Use a volume to specify grants during container start

```
$ docker run --detach --env MARIADB_USER=anel \
--env MARIADB_PASSWORD=anel \
--env MARIADB_DATABASE=my_db \
--env MARIADB_RANDOM_ROOT_PASSWORD=1 \
--volume $PWD/my_init_db:/docker-entrypoint-initdb.d \
--network mynetwork \
--name mariadb-server1 \
mariadb:latest
```

User created with the environment variables has full grants only to the `MARIADB_DATABASE`. In order to override those grants, one can specify grants to a user, or execute any SQL statements from host file to `docker-entrypoint-initdb.d`. In the `local_init_dir` directory we can find the file, created like this:

```
$ echo "GRANT ALL PRIVILEGES ON *.* TO anel;" > my_init_db/my_grants.sql
```

### 2.1.2.14.7 Kubernetes and MariaDB

General information and hints on how to deploy MariaDB Kubernetes containers.

Kubernetes is an open source containers orchestration system. It automates deployments, horizontal scaling, configuration and operations. It is often referred to as K8s.

#### Kubernetes Overview for MariaDB Users

[An overview of Kubernetes and how it works with MariaDB.](#)

#### Kubernetes Operators for MariaDB

[An overview of Kubernetes operators that can be used with MariaDB](#)

### 2.1.2.14.8 Kubernetes Overview for MariaDB Users

Kubernetes, or K8s, is software to orchestrate containers. It is released under the terms of an open source license, Apache License 2.0.

Kubernetes was originally developed by Google. Currently it is maintained by the Cloud Native Computing Foundation (CNCF), with the status of Graduated Project.

For information about how to setup a learning environment or a production environment, see [Getting started](#) in Kubernetes documentation.

# Architecture

Kubernetes runs in a **cluster**. A cluster runs a **workload**: a set of servers that are meant to work together (web servers, database servers, etc).

A Kubernetes cluster consists of the following components:

- **Nodes** run containers with the servers needed by our applications.
- **Controllers** constantly check the cluster nodes current state, and compare it with the desired state.
- A **Control Plane** is a set of different components that store the cluster desired state and take decisions about the nodes. The Control Plane provides an API that is used by the controllers.

For more information on Kubernetes architecture, see [Concepts](#) and [Kubernetes Components](#) in Kubernetes documentation.

## Nodes

A node is a system that is responsible to run one or more pods. A pod is a set of containers that run a Kubernetes workload or part of it. All containers that run in the same pod are also located on the same node. Usually identical pods run on different nodes for fault tolerance.

For more details, see [Nodes](#) in the Kubernetes documentation.

Every node must necessarily have the following components:

- **kubelet**
- **kube-proxy**
- A **container runtime**

### kubelet

kubelet has a set of **PodSpecs** which describe the desired state of pods. It checks that the current state of the pods matches the desired state. It especially takes care that containers don't crash.

### kube-proxy

In a typical Kubernetes cluster, several containers located in different pods need to connect to other containers, located in the same pods (for performance and fault tolerance reasons). Therefore, when we develop and deploy an application, we can't know in advance the IPs of the containers to which it will have to connect. For example, an application server may need to connect to MariaDB, but the MariaDB IP will be different for every pod.

The main purpose of kube-proxy is to implement the concept of Kubernetes **services**. When an application needs to connect to MariaDB, it will connect to the MariaDB service. kube-proxy will receive the request and will redirect it to a running MariaDB container in the same pod.

## Container Runtime

Kubernetes manages the containers in a pod via a container runtime, or container manager, that supports the Kubernetes Container Runtime Interface (CRI). Container runtimes that meet this requisite are listed in the [Container runtimes](#) page in the Kubernetes documentation. More information about the Container Runtime Interface can be found [on GitHub](#).

Originally, Kubernetes used Docker as a container runtime. This was later deprecated, but Docker images can still be used using any container runtime.

## Controllers

Controllers constantly check if there are differences between the pod's current state and their desired state. When differences are found, controllers try to fix them. Each node type controls one or more resource types. Several types of controllers are needed to run a cluster.

Most of the actions taken by the controllers user the API server in the Control Plane. However, this is not necessarily true for custom controllers. Also, some actions cannot be performed via the Control Plane. For example, if some nodes crashed, adding new nodes involves taking actions outside of the Kubernetes cluster, and controllers will have to do this themselves.

It is possible to write custom controllers to perform checks that require knowledge about a specific technology. For example, a MariaDB custom controller may want to check if [replication](#) is working by issuing [SHOW REPLICAS STATUS](#) commands. This logic is specific to the way MariaDB works, and can only be implemented in a customer controller. Custom controllers are usually part of operators.

For more information, see [Controllers](#) in the Kubernetes documentation.

## Control Plane

The control plane consists of the following components.

For more information about the control plane, see [Control Plane Components](#) in Kubernetes documentation.

## API Server

An API Server exposes API functions both internally and externally. It is essential to coordinate Kubernetes components so that they react to node's change of state, and it allows the user to send commands.

The default implementation of the API Server is kube-apiserver. It is able to scale horizontally and to balance the load between its instances.

## kube-controller-manager

Most controllers run in this component.

## etcd

etcd contains all data used by a Kubernetes cluster. It is a good idea to take regular backups of etcd data.

## kube-scheduler

When a new pod is created, kube-scheduler decides which node should host it. The decision is made based on several criteria, like the resource requirements for the pod.

## cloud-controller-manager

cloud-controller-manager implements the logic and API of a cloud provider. It receives requests from the API Server and performs specific actions, like creating an instance in AWS. It also runs controllers that are specific to a cloud vendor.

# Clients and Tools

Kubernetes comes with a set of tools that allow us to communicate with the API server and test a cluster.

## kubectl

kubectl allows communication with the API server and run commands on a Kubernetes cluster.

## kubeadm

kubeadm allows creating a Kubernetes cluster that is ready to receive commands from kubectl.

## kind and minikube

These tools are meant to create and manage test clusters on a personal machine. They work on Linux, MacOS and Windows. kind creates a cluster that consists of Docker containers, therefore it requires Docker to be installed. minikube runs a single-node cluster on the local machine.

## 2.1.2.14.9 Kubernetes Operators for MariaDB

Operators basically instruct Kubernetes about how to manage a certain technology. Kubernetes comes with some default operators, but it is possible to create custom operators. Operators created by the community can be found on [OperatorHub.io](#) .

### Contents

1. [Custom Operators](#)
2. [MariaDB Operator](#)
3. [Other Operators](#)

## Custom Operators

Kubernetes provides a declarative API. To support a specific (i.e. MariaDB) technology or implement a desired behavior (i.e. provisioning a [replica](#) ), we extend Kubernetes API. This involves creating two main components:

- A custom resource.
- A custom controller.

A custom resource adds an API endpoint, so the resource can be managed via the API server. It includes functionality to get information about the resource, like a list of the existing servers.

A custom controller implements the checks that must be performed against the resource to check if its state should be corrected using the API. In the case of MariaDB, some reasonable checks would be verifying that it accepts connections, replication is running, and a server is (or is not) read only.

# MariaDB Operator

[OperatorHub.io](#) has a [MariaDB operator](#). At the time of this writing it is in alpha stage, so please check its maturity before using it.

MariaDB operator is open source and is released under the terms of the MIT license. The source code is [available on GitHub](#). The `README.md` file shows usage examples.

It defines the following custom resources:

- MariaDB server.
- MariaDB Backup. [mariabackup](#) is used.
- MariaDB Monitor. Prometheus metrics are exposed on port 9090.

## Other Operators

If you know about other MariaDB operators, feel free to add them to this page (see [Writing and Editing Knowledge Base Articles](#)).

MySQL and Percona Server operators should work as well, though some changes may be necessary to fix [incompatibilities](#) or take advantage of certain [MariaDB features](#).

---

Content initially contributed by [Vettabase Ltd](#).

## 2.1.2.14.10 Automating Upgrades with MariaDB.Org Downloads REST API

The MariaDB Foundation maintains a Downloads REST API. See the [Downloads API documentation](#) to find out all the tasks that you can accomplish with this API. Generally speaking, we can say that it provides information about MariaDB products and available versions. This allows to easily automate upgrades for MariaDB and related products.

The Downloads API exposes HTTPS endpoints that return information in JSON format. HTTP and JSON are extremely common standards that can be easily used with any programming language. All the information provided by the API is public, so no authentication is required.

### How to Use the API with a Unix Shell

Linux shells are great for writing simple scripts. They are compatible to each other to some extent, so simple scripts can be run on almost any Unix/Linux system. In the following examples we'll use Bash.

On Linux, some programs you'll generally need to work with any REST API are:

- `curl`, to call HTTP URLs and get their output.
- `js`, to extract or transform information from a JSON document.

### Example: Check When a New Version Becomes GA

A trivial use case is to write a script that checks the list of MariaDB GA major versions and, when something changes, send us an email. So we can test the newest GA version and eventually install it.

The script in this example will be extremely simple. We'll do it this way:

- Retrieve the JSON object describing all MariaDB versions.
- For each element of the array, only show the
  - `release_id`
  - and
  - `release_status`
  - properties, and concatenate them.
- Apply a filter, so we only select the rows containing 'stable' but not 'old' (so we exclude 'Old Stable').
- From the remaining rows, only show the first column (the version number).
- If the results we obtained are different from the previously written file (see last point) send an email.
- Save the results into a file.

This is something that we can easily do with a Unix shell:

```

#!/bin/bash

current_ga_versions=$(
    curl https://downloads.mariadb.org/rest-api/mariadb/ | \
    jq -r '.major_releases[] | .release_id + " " + .release_status' | \
    grep -i 'stable' | grep -vi 'old' | \
    cut -d ' ' -f 1
)

# create file if it doesn't exist, then compare version lists
touch ga_versions
previous_ga_versions=$( cat ga_versions )

echo "$current_ga_versions" > ga_versions

if [ "$current_ga_versions" != "$previous_ga_versions" ];
then
    mail -s 'NOTE: New MariaDB GA Versions' devops@example.com <<< 'There seems to be a new MariaDB GA version! Yay!'
fi

```

The only non-standard command here is jq. It is a great way to manipulate JSON documents, so if you don't know it you may want to take a look at [jq documentation](#).

## How to use the API with a Python script

To use the API with Python, we need a module that is able to send HTTP requests and parse a JSON output. The

requests  
module has both these features. It can be installed as follows:

```
pip install requests
```

The following script prints stable versions to the standard output:

```

#!/usr/bin/env python

import requests

response = requests.get('https://downloads.mariadb.org/rest-api/mariadb/').json()

for x in response['major_releases']:
    if x['release_status'] == 'Stable':
        print(x['release_id'])

requests.get()
makes an HTTP call of type GET, and
requests.json()
returns a dictionary representing the previously obtained JSON document.

```

Content initially contributed by [Vettabase Ltd](#).

## 2.1.2.14.11 HashiCorp Vault and MariaDB

Vault is open source software for secret management provided by HashiCorp. It is designed to avoid sharing secrets of various types, like passwords and private keys. When building automation, Vault is a good solution to avoid storing secrets in plain text in a repository.

MariaDB and Vault may relate each other in several ways:

- MariaDB secrets can be stored in Vault. Typically this includes user's passwords and private keys for SSH access.
- MariaDB (and MySQL) can be used as a secret engine, a component which stores, generates, or encrypts data.
- MariaDB (and MySQL) can be used as a backend storage, providing durability for Vault data.

For information about how to install Vault, see [Install Vault](#).

### Contents

1. [Vault Features](#)
2. [Vault Architecture](#)
3. [Dev Mode](#)
4. [Vault Resources and References](#)

## Vault Features

Vault is used via an HTTP/HTTPS API.

Vault is identity-based. Users login and Vault sends them a token that is valid for a certain amount of time, or until certain conditions occur. Users with a valid token may request to obtain secrets for which they have proper permissions.

Vault encrypts the secrets it stores.

Vault can optionally audit changes to secrets and secrets requests by the users.

## Vault Architecture

Vault is a server. This allows decoupling the secrets management logic from the clients, which only need to login and keep a token until it expires.

The sever can actually be a cluster of servers, to implement high availability.

The main Vault components are:

- **Storage Backend** : This is where the secrets are stored. Vault only send encrypted data to the backend storage.
- **HTTP API** : This API is used by the clients, and provides an access to Vault server.
- **Barrier** : Similarly to an actual barrier, it protects all inner Vault components. The HTTP API and the storage backend are outside of the barrier and could be accessed by anyone. All communications from and to these components have to pass through the barrier. The barrier verifies data and encrypts it. The barrier can have two states: *sealed* or *unsealed*. Data can only pass through when the barrier is unsealed. All the following components are located inside the barrier.
- **Auth Method** : Handles login attempts from clients. When a login succeeds, the auth method returns a list of security policies to Vault core.
- **Token Store** : Here the tokens generated as a result of a succeeded login are stored.
- **Secrets Engines** : These components manage secrets. They can have different levels of complexity. Some of them simply expect to receive a key, and return the corresponding secret. Others may generate secrets, including one-time-passwords.
- **Audit Devices** : These components log the requests received by Vault and the responses sent back to the clients. There may be multiple devices, in which case an **Audit Broker** sends the request or response to the proper device.

## Dev Mode

It is possible to start Vault in dev mode:

```
vault server -dev
```

Dev mode is useful for learning Vault, or running experiments on some particular features. It is extremely insecure, because dev mode is equivalent to starting Vault with several insecure options. This means that Vault should never run in production in dev mode. However, this also means that all the regular Vault features are available in dev mode.

Dev mode simplifies all operations. Actually, no configuration is necessary to get Vault up and running in dev mode. It makes it possible to communicate with the Vault API from the shell without any authentication. Data is stored in memory by default. Vault is unsealed by default, and if explicitly sealed, it can be unsealed using only one key.

For more details, see "["Dev" Server Mode](#)" in Vault documentation.

Content initially contributed by [Vettabase Ltd](#).

## 2.1.2.14.12 Orchestrator Overview

Orchestrator is a MySQL and MariaDB high availability and replication management tool. It is released by Shlomi Noach under the terms of the Apache License, version 2.0.

Orchestrator provides automation for MariaDB replication in the following ways:

- It can be used to perform certain operations, like repairing broken replication or moving a replica from one master to another. These operations can be requested using CLI commands, or via the GUI provided with Orchestrator. The actual commands sent to MariaDB are automated by Orchestrator, and the user doesn't have to worry about the details.
- Orchestrator can also automatically perform a failover in case a master crashes or is unreachable by its replicas. If that is the case, Orchestrator will promote one of the replicas to a master. The replica to promote is chosen based on several criteria, like the server versions, the [binary log](#) formats in use and the datacenters locations.

Note that, if we don't want to use Orchestrator to automate operations, we can still use it as a dynamic inventory. Other tools can use it to obtain a list of existing MariaDB servers via its REST API or CLI commands.

Orchestrator has several big users, listed in the documentation [Users](#) page. It is also included in the PMM monitoring solution.

To install Orchestrator, see:

- The [install.md](#) for a manual installation;
- The links in [README.md](#), to install Orchestrator using automation tools.

## Contents

1. [Supported Topologies](#)
2. [Architecture](#)
3. [CLI Examples](#)
4. [Orchestrator Resources and References](#)

## Supported Topologies

Currently, Orchestrator fully supports MariaDB [GTID](#), [replication](#), and [semi-synchronous replication](#). While Orchestrator does not support Galera specific logic, it works with Galera clusters. For details, see [Supported Topologies and Versions](#) in Orchestrator documentation.

## Architecture

Orchestrator consists of a single executable called

```
orchestrator
```

. This is a process that periodically connects to the target servers. It will run SQL queries against target servers, so it needs a user with proper permissions. When the process is running, a GUI is available via a web browser, at the URL '<https://localhost:3000>'. It also exposes a REST API (see [Using the web API](#) in the Orchestrator documentation).

Orchestrator expects to find a JSON configuration file called

```
orchestrator.conf.json
, in
/etc
```

A database is used to store the configuration and the state of the target servers. By default, this is done using built-in SQLite. However, it is possible to use an external MariaDB or MySQL server instance.

If a cluster of Orchestrator instances is running, only one central database is used. One Orchestrator node is active, while the others are passive and are only used for failover. If the active node crashes or becomes unreachable, one of the other nodes becomes the active instance. The

```
active_node
table shows which node is active. Nodes communicate between them using the Raft protocol.
```

## CLI Examples

As mentioned, Orchestrator can be used from the command-line. Here you can find some examples.

List clusters:

```
orchestrator -c clusters
```

Discover a specified instance and add it to the known topology:

```
orchestrator -c discover -i <host>:<port>
```

Forget about an instance:

```
orchestrator -c topology -i <host>:<port>
```

Move a replica to a different master:

```
orchestrator -c move-up -i <replica-host>:<replica-port> -d <master-host>:<master-port>
```

Move a replica up, so that it becomes a "sibling" of its master:

```
orchestrator -c move-up -i <replica-host>:<replica-port>
```

Move a replica down, so that it becomes a replica of its "sibling":

```
orchestrator -c move-below -i <replica-host>:<replica-port> -d <master-host>:<master-port>
```

Make a node read-only:

```
orchestrator -c set-read-only -i <host>:<port>
```

Make a node writeable:

```
orchestrator -c set-writeable -i <host>:<port>
```

The

```
--debug  
and  
--stack
```

options can be added to the above commands to make them more verbose.

## Orchestrator Resources and References

- [Orchestrator on GitHub](#) .
- [Documentation](#) .
- [Raft consensus protocol website](#) .

The [README.md](#) file lists some related community projects, including modules to automate Orchestrator with [Puppet](#) and other technologies.

On GitHub you can also find links to projects that allow the use of automation software to deploy and manage Orchestrator.

### 2.1.2.14.13 Rotating Logs on Unix and Linux

#### Contents

1. [Configuring Locations and File Names of Logs](#)
2. [Configuring Authentication for Logrotate](#)
3. [Configuring Logrotate](#)
4. [Testing Log Rotation](#)
5. [Logrotate in Ansible](#)

Unix and Linux distributions offer the

[logrotate](#)

utility, which makes it very easy to rotate log files. This page will describe how to configure log rotation for the [error log](#) , [general query log](#) , and the [slow query log](#) .

## Configuring Locations and File Names of Logs

The first step is to configure the locations and file names of logs. To make the log rotation configuration easier, it can be best to put these logs in a dedicated log directory.

We will need to configure the following:

- The [error log](#) location and file name is configured with the

[log\\_error](#)

system variable.

- The [general query log](#) location and file name is configured with the

[general\\_log\\_file](#)

system variable.

- The [slow query log](#) location and file name is configured with the

[slow\\_query\\_log\\_file](#)

system variable.

If you want to enable the [general query log](#) and [slow query log](#) immediately, then you will also have to configure the following:

- The [general query log](#) is enabled with the

[general\\_log](#)

system variable.

- The [slow query log](#) is enabled with the

[slow\\_query\\_log](#)

system variable.

These options can be set in a server [option group](#) in an [option file](#) prior to starting up the server. For example, if we wanted to put our log files in

/var/log/mysql/

, then we could configure the following:

```
[mariadb]
...
log_error=/var/log/mysql/mariadb.err
general_log
general_log_file=/var/log/mysql/mariadb.log
slow_query_log
slow_query_log_file=/var/log/mysql/mariadb-slow.log
long_query_time=5
```

We will also need to create the relevant directory:

```
sudo mkdir /var/log/mysql/
sudo chown mysql:mysql /var/log/mysql/
sudo chmod 0770 /var/log/mysql/
```

If you are using [SELinux](#), then you may also need to set the SELinux context for the directory. See [SELinux: Setting the File Context for Log Files](#) for more information. For example:

```
sudo semanage fcontext -a -t mysqld_log_t "/var/log/mysql(/.*)?"
sudo restorecon -Rv /var/log/mysql
```

After MariaDB is [restarted](#), it will use the new log locations and file names.

## Configuring Authentication for Logrotate

The

[logrotate](#)

utility needs to be able to authenticate with MariaDB in order to flush the log files.

The easiest way to allow the

[logrotate](#)

utility to authenticate with MariaDB is to configure the

root@localhost

user account to use

[unix\\_socket](#)

authentication.

MariaDB starting with [10.4](#)

In [MariaDB 10.4](#) and later, the

root@localhost

user account is configured to use

[unix\\_socket](#)

authentication by default, so this part can be skipped in those versions.

MariaDB until [10.3](#)

In [MariaDB 10.3](#) and before, a user account is only able to have one authentication method at a time. In these versions, this means that once you enable

[unix\\_socket](#)

authentication for the

root@localhost

user account, you will no longer be able to use a password to log in with that user account. The user account will only be able to use

`unix_socket`

authentication.

In MariaDB 10.3 and before, you need to [install the `unix\_socket` plugin](#) before you can configure the `root@localhost` user account to use it. For example:

```
INSTALL SONAME 'auth_socket';
```

After the plugin is installed, the

`root@localhost` user account can be configured to use

`unix_socket`

authentication. How this is done depends on the version of MariaDB.

MariaDB starting with 10.2

In MariaDB 10.2 and later, the

`root@localhost` user account can be altered to use

`unix_socket`

authentication with the

`ALTER USER`

statement. For example:

```
ALTER USER 'root'@'localhost' IDENTIFIED VIA unix_socket;
```

MariaDB until 10.1

In MariaDB 10.1 and before, the

`root@localhost` user account can be altered to use

`unix_socket`

authentication with the

`GRANT`

statement. For example:

```
GRANT ALL PRIVILEGES ON *.* TO 'root'@'localhost' IDENTIFIED VIA unix_socket WITH GRANT OPTION;
```

## Configuring Logrotate

At this point, we can configure the

`logrotate`

utility to rotate the log files.

On many systems, the primary

`logrotate`

configuration file is located at the following path:

- `/etc/logrotate.conf`

And the

### logrotate

configuration files for individual services are located in the following directory:

- /etc/logrotate.d/

We can create a

### logrotate

configuration file for MariaDB by executing the following command in a shell:

```
$ sudo tee /etc/logrotate.d/mariadb <<EOF
/var/log/mysql/* {
    su mysql mysql
    missingok
    create 660 mysql mysql
    notifempty
    daily
    minsize 1M # only use with logrotate >= 3.7.4
    maxsize 100M # only use with logrotate >= 3.8.1
    rotate 30
    # dateext # only use if your logrotate version is compatible with below dateformat
    # dateformat .%Y-%m-%d-%H-%M-%S # only use with logrotate >= 3.9.2
    compress
    delaycompress
    sharedscripts
    olddir archive/
    createolddir 770 mysql mysql # only use with logrotate >= 3.8.9
postrotate
    # just if mysqld is really running
    if test -x /usr/bin/mysqladmin && \
        /usr/bin/mysqladmin ping &>/dev/null
    then
        /usr/bin/mysqladmin --local flush-error-log \
            flush-engine-log flush-general-log flush-slow-log
    fi
endscript
}
EOF
```

You may have to modify this configuration file to use it on your system, depending on the specific version of the

### logrotate

utility that is installed. See the description of each configuration directive below to determine which

### logrotate

versions support that configuration directive.

Each specific configuration directive does the following:

- **missingok**  
: This directive configures it to ignore missing files, rather than failing with an error.
- **create 660 mysql mysql**  
: This directive configures it to recreate the log files after log rotation with the specified permissions and owner.
- **notifempty**  
: This directive configures it to skip a log file during log rotation if it is empty.
- **daily**  
: This directive configures it to rotate each log file once per day.
- **minsize 1M**  
: This directive configures it to skip a log file during log rotation if it is smaller than 1 MB. This directive is only available with

## `logrotate`

3.7.4 and later.

- `maxsize 100M`

: This directive configures it to rotate a log file more frequently than daily if it grows larger than 100 MB. This directive is only available with

## `logrotate`

3.8.1 and later.

- `rotate 30`

: This directive configures it to keep 30 old copies of each log file.

- `dateext`

: This directive configures it to use the date as an extension, rather than just a number. This directive is only available with

## `logrotate`

3.7.6 and later.

- `dateformat .%Y-%m-%d-%H-%M-%S`

: This directive configures it to use this date format string (as defined by the format specification for

## `strftime`

) for the date extension configured by the

`dateext` directive. This directive is only available with

## `logrotate`

3.7.7 and later. Support for

`%H`

is only available with

## `logrotate`

3.9.0 and later. Support for

`%M`

and

`%S`

is only available with

## `logrotate`

3.9.2 and later.

- `compress`

: This directive configures it to compress the log files with

## `gzip`

- `delaycompress`

: This directive configures it to delay compression of each log file until the next log rotation. If the log file is compressed at the same time that it is rotated, then there may be cases where a log file is being compressed while the MariaDB server is still writing to the log file. Delaying compression of a log file until the next log rotation can prevent race conditions such as these that can happen between the compression operation and the MariaDB server's log flush operation.

- `olddir archive/`

: This directive configures it to archive the rotated log files in  
`/var/log/mysql/archive/`

- `createolddir 770 mysql mysql`

: This directive configures it to create the directory specified by the  
`olddir` directive with the specified permissions and owner, if the directory does not already exist. This directive is only available with

### `logrotate`

3.8.9 and later.

- **sharedscripts**  
: This directive configures it to run the `postrotate` script just once, rather than once for each rotated log file.
- **postrotate**  
: This directive configures it to execute a script after log rotation. This particular script executes the `mysqladmin` utility, which executes the `FLUSH`

statement, which tells the MariaDB server to flush its various log files. When MariaDB server flushes a log file, it closes its existing file handle and reopens a new one. This ensures that MariaDB server does not continue writing to a log file after it has been rotated. This is an important component of the log rotation process.

If our system does not have

### `logrotate`

3.8.9 or later, which is needed to support the `createolddir` directive, then we will also need to create the relevant directory specified by the `olddir` directive:

```
sudo mkdir /var/log/mysql/archive/
sudo chown mysql:mysql /var/log/mysql/archive/
sudo chmod 0770 /var/log/mysql/archive/
```

## Testing Log Rotation

We can test log rotation by executing the

### `logrotate`

utility with the `--force` option. For example:

```
sudo logrotate --force /etc/logrotate.d/mariadb
```

Keep in mind that under normal operation, the

### `logrotate`

utility may skip a log file during log rotation if the utility does not believe that the log file needs to be rotated yet. For example:

- If you set the `notifempty` directive mentioned above, then it will be configured to skip a log file during log rotation if the log file is empty.
- If you set the `daily` directive mentioned above, then it will be configured to only rotate each log file once per day.
- If you set the `minsize 1M` directive mentioned above, then it will be configured to skip a log file during log rotation if the log file size is smaller than 1 MB.

However, when running tests with the

`--force` option, the

### `logrotate`

utility does not take these options into consideration.

After a few tests, we can see that the log rotation is indeed working:

```
$ sudo ls -l /var/log/mysql/archive/
total 48
-rw-rw---- 1 mysql mysql 440 Mar 31 15:31 mariadb.err.1
-rw-rw---- 1 mysql mysql 138 Mar 31 15:30 mariadb.err.2.gz
-rw-rw---- 1 mysql mysql 145 Mar 31 15:28 mariadb.err.3.gz
-rw-rw---- 1 mysql mysql 1007 Mar 31 15:27 mariadb.err.4.gz
-rw-rw---- 1 mysql mysql 1437 Mar 31 15:32 mariadb.log.1
-rw-rw---- 1 mysql mysql 429 Mar 31 15:31 mariadb.log.2.gz
-rw-rw---- 1 mysql mysql 439 Mar 31 15:28 mariadb.log.3.gz
-rw-rw---- 1 mysql mysql 370 Mar 31 15:27 mariadb.log.4.gz
-rw-rw---- 1 mysql mysql 3915 Mar 31 15:32 mariadb-slow.log.1
-rw-rw---- 1 mysql mysql 554 Mar 31 15:31 mariadb-slow.log.2.gz
-rw-rw---- 1 mysql mysql 569 Mar 31 15:28 mariadb-slow.log.3.gz
-rw-rw---- 1 mysql mysql 487 Mar 31 15:27 mariadb-slow.log.4.gz
```

## Logrotate in Ansible

Let's see an example of how to configure logrotate in Ansible.

First, we'll create a couple of tasks in our playbook:

```
- name: Create mariadb_logrotate_old_dir
  file:
    path: "{{ mariadb_logrotate_old_dir }}"
    owner: mysql
    group: mysql
    mode: '770'
    state: directory

- name: Configure logrotate
  template:
    src: "../templates/logrotate.j2"
    dest: "/etc/logrotate.d/mysql"
```

The first task creates a directory to store the old, compressed logs, and set proper permissions.

The second task uploads logrotate configuration file into the proper directory, and calls it

```
mysql
.
As you can see the original name is different, and it ends with the
.j2
extension, because it is a Jinja 2 template.
```

The file will look like the following:

```
{{ mariadb_log_dir }}/* {
  su mysql mysql
  missingok
  create 660 mysql mysql
  notifempty
  daily
  minsize 1M {{ mariadb_logrotate_min_size }}
  maxsize 100M {{ mariadb_logrotate_max_size }}
  rotate {{ mariadb_logrotate_old_dir }}
  dateformat %Y-%m-%d-%H-%M-%S # only use with logrotate >= 3.9.2
  compress
  delaycompress
  sharedscripts
  olddir archive/
  createolddir 770 mysql mysql # only use with logrotate >= 3.8.9
postrotate
  # just if mysqld is really running
  if test -x /usr/bin/mysqladmin && \
    /usr/bin/mysqladmin ping &>/dev/null
  then
    /usr/bin/mysqladmin --local flush-error-log \
      flush-engine-log flush-general-log flush-slow-log
  fi
endscript
}
```

The file is very similar to the file shown above, which is obvious because we're still uploading a logrotate configuration file. Ansible is just a tool we've

chosen to do this.

However, both in the tasks and in the template, we used some variables. This allows to use different paths and rotation parameters for different hosts, or host groups.

If we have a group host called

```
mariadb
that contains the default configuration for all our MariaDB servers, we can define these variables in a file called
group_vars/mariadb.yml
:
```

```
# MariaDB writes its logs here
mariadb_log_dir: /var/lib/mysql/logs

# logrotate configuration

mariadb_logrotate_min_size: 500M
mariadb_logrotate_max_size: 1G
mariadb_logrotate_old_files: 7
mariadb_logrotate_old_dir: /var/mysql/old-logs
```

After setting up logrotate in Ansible, you may want to deploy it to a non-production server and test it manually as explained above. Once you're sure that it works fine on one server, you can be confident in the new Ansible tasks and deploy them on all servers.

For more information on how to use Ansible to automate MariaDB configuration, see [Ansible and MariaDB](#).

## 2.1.2.14.14 Automating MariaDB Tasks with Events

MariaDB has an event scheduler that can be used to automate tasks, making them run at regular intervals of time. This page is about using events for [automation](#). For more information about events themselves, and how to work with them, see [event scheduler](#).

### Pro's and Con's of Using Events for Automation

Events can be compared to Unix cron jobs or Windows scheduled tasks. MariaDB events have at least the following benefits compared to those tools:

- Events are system-independent.
- Events are written in procedural SQL. There is no need for other languages.
- Events run in MariaDB. An implication, for example, is that the results of queries remain in MariaDB itself and are not sent to a client.

Some drawbacks of using events are the following:

- Events can only perform tasks that can be developed in SQL. So, for example, it is not possible to send alerts. Access to files or remote databases is limited.
- The event scheduler is a single thread. While this thread is busy running an event, other events cannot start. They are just skipped, not postponed. This can be a big problem when automating a number of tasks that should run in a limited time range.
- For more events limitations, see [Event Limitations](#).

In many cases you may prefer to develop scripts in an external programming language. However, you should know that simple tasks consisting of a few queries can easily be implemented as events.

## Good Practices

When using events to automate tasks, there are good practices one may want to follow.

Move your SQL code in a stored procedure. All the event will do is to call a stored procedures. Several events may call the same stored procedure, maybe with different parameters. The procedure may also be called manually, if necessary. This will avoid code duplication. This will separate the logic from the schedule, making it possible to change an event without a risk of making changes to the logic, and the other way around.

Just like cron jobs, events should log whether if they succeed or not. Logging debug messages may also be useful for non-trivial events. This information can be logged into a dedicated table. The contents of the table can be monitored by a monitoring tool like Grafana. This allows to visualize in a dashboard the status of events, and send alerts in case of a failure.

## Examples

Some examples of tasks that could easily be automated with events:

- Copying data from a remote table to a local table by night, using the [CONNECT](#) storage engine. This can be a good idea if many rows need be copied, because data won't be sent to an external client.
- Periodically delete historical data. For example, rows that are older than 5 years. Nothing prevents us from doing this with an external script, but probably this wouldn't add any value.
- Periodically delete invalid rows. In an e-commerce, they could be abandoned carts. In a messaging system, they could be messages to users that don't exist anymore.
- Add a new [partition](#) to a table and drop the oldest one.

## 2.1.2.15 MariaDB Package Repository Setup and Usage

If you are looking to set up MariaDB Server, it is often easiest to use a repository. The MariaDB Foundation has a repository configuration tool at <https://downloads.mariadb.org/> and MariaDB Corporation provides a convenient shell script to configure access to their MariaDB Package Repositories. It is available at:

- [https://r.mariadb.com/downloads/mariadb\\_repo\\_setup](https://r.mariadb.com/downloads/mariadb_repo_setup)

The script by default sets up 3 different repositories in a single repository configuration file. The repositories are

- MariaDB Server Repository
- MariaDB MaxScale Repository
- MariaDB Tools Repository

The script can be executed in the following way:

```
curl -LsS https://r.mariadb.com/downloads/mariadb_repo_setup | sudo bash
```

For the script to work, the

curl

and

ca-certificates

packages need to be installed on your system. Additionally on Debian and Ubuntu the

apt-transport-https

package needs to be installed. The script will check if these are installed and let you know before it attempts to create the repository configuration on your system.

  1. [Installing Packages on RHEL and CentOS](#)
  2. [Installing Packages on Debian and Ubuntu](#)
  3. [Installing Packages on SLES](#)
5. [Versions](#)

## Repositories

The script will set up 2 different repositories in a single repository configuration file.

### MariaDB Repository

The **MariaDB Repository** contains software packages related to MariaDB Server, including the server itself, [clients and utilities](#), [client libraries](#), [plugins](#), and [Mariabackup](#).

The binaries in MariaDB Corporation's **MariaDB Repository** are currently identical to the binaries in MariaDB Foundation's MariaDB Repository that is configured with the [MariaDB Repository Configuration Tool](#).

By default, the script will configure your system to install from the repository of the latest GA version of MariaDB. That is currently [MariaDB 10.5](#). If a new major GA release occurs and you would like to upgrade to it, then you will need to either manually edit the repository configuration file to point to the new version, or run the MariaDB Package Repository setup script again.

The script can also configure your system to install from the repository of a different version of MariaDB if you use the

```
--mariadb-server-version
```

option.

If you would not like to configure the **MariaDB Repository** on your system, then you can use the

```
--skip-server
```

option to prevent the MariaDB Package Repository setup script from configuring it.

## MariaDB MaxScale Repository

The **MariaDB MaxScale Repository** contains software packages related to **MariaDB MaxScale**.

By default, the script will configure your system to install from the repository of the *latest* GA version of MariaDB MaxScale. When a new major GA release occurs, the repository will automatically switch to the new version. If instead you would like to stay on a particular version you will need to manually edit the repository configuration file and change '

```
latest
```

' to the version you want (e.g. '

```
6.1
```

') or run the MariaDB Package Repository setup script again, specifying the particular version or series you want.

Older versions of the MariaDB Package Repository setup script would configure a specific MariaDB MaxScale series in the repository (i.e. '

```
2.4
```

'), so if you used the script in the past to set up your repository and want MariaDB MaxScale to automatically use the latest GA version then change '

```
2.4
```

' or '

```
2.3
```

' in the repository configuration to '

```
latest
```

'. Or download the current version of the script and re-run it to set up the repository again.

The script can configure your system to install from the repository of an older version of MariaDB MaxScale if you use the

```
--mariadb-maxscale-version
```

option. For example,

```
--mariadb-maxscale-version=2.4
```

if you want the latest release in the MariaDB MaxScale 2.4.x series.

If you do not want to configure the **MariaDB MaxScale Repository** on your system, then you can use the

```
--skip-maxscale
```

option to prevent the MariaDB Package Repository setup script from configuring it.

MariaDB MaxScale is licensed under the [Business Source License 1.1](#), so it is not entirely free to use for organizations who do not have a subscription with MariaDB Corporation. If you would like more information, see the information at [MariaDB Business Source License \(BSL\)](#): [Frequently Asked Questions](#). If you would like to know how much a subscription to use MariaDB MaxScale would cost, see [MariaDB Corporation's subscription pricing](#).

## Supported Distributions

The script supports Linux distributions that are officially supported by MariaDB Corporation's [MariaDB TX subscription](#). However, a MariaDB TX subscription with MariaDB Corporation is not required to use the MariaDB Package Repository.

The distributions currently supported by the script include:

- Red Hat Enterprise Linux (RHEL) 7 and 8
- CentOS 7
- Debian 9 (Stretch), 10 (Buster), 11 (Bullseye)
- Ubuntu 18.04 LTS (Bionic), and 20.04 LTS (Focal)
- SUSE Linux Enterprise Server (SLES) 12 and 15

To install MariaDB on distributions not supported by the MariaDB Package Repository setup script, please consider using MariaDB Foundation's [MariaDB Repository Configuration Tool](#). Some Linux distributions also include MariaDB [in their own repositories](#).

## Using the MariaDB Package Repository Setup Script

The script can be executed in the following way:

```
curl -LsS https://r.mariadb.com/downloads/mariadb_repo_setup | sudo bash
```

The script will have to set up package repository configuration files, so it will need to be executed as root.

The script will also install the GPG public keys used to verify the signature of MariaDB software packages. If you want to avoid that, then you can use the `--skip-key-import` option.

If the script tries to create the repository configuration file and one with that name already exists, then the script will rename the existing file with an extension in the format ".old\_[0-9]+", which would make the OS's package manager ignore the file. You can safely remove those files after you have confirmed that the updated repository configuration file works..

If you want to see the repository configuration file that would be created without actually doing so, then you can use the

```
--write-to-stdout
```

option. This also prevents the need to run the script as root,

If you want to download the script, rather than executing it, then you can do so in the following way:

```
curl -LO https://r.mariadb.com/downloads/mariadb_repo_setup
```

## Options

To provide options to the script, you must tell bash to expect them by executing bash with the options

```
-s --
```

, for example:

```
curl -LsS https://r.mariadb.com/downloads/mariadb_repo_setup | sudo bash -s -- --help
```

Option	Description
<code>--help</code>	Display a usage message and exit.
<code>--mariadb-server-version=&lt;version&gt;</code>	Override the default MariaDB Server version. By default, the script will use 'mariadb-10.5'.
<code>--mariadb-maxscale-version=&lt;version&gt;</code>	Override the default MariaDB MaxScale version. By default, the script will use 'latest'.
<code>--os-type=&lt;type&gt;</code>	Override detection of OS type. Acceptable values include debian , ubuntu , rhel , and sles .
<code>--os-version=&lt;version&gt;</code>	Override detection of OS version. Acceptable values depend on the OS type you specify.
<code>--skip-key-import</code>	Skip importing GPG signing keys.
<code>--skip-maxscale</code>	Skip the 'MaxScale' repository.
<code>--skip-server</code>	Skip the 'MariaDB Server' repository.
<code>--skip-tools</code>	Skip the 'Tools' repository.

--skip-check-installed	Skip tests for required prerequisites for this script.
--write-to-stdout	Write output to stdout instead of to the OS's repository configuration file. This will also skip importing GPG public keys and updating the package cache on platforms where that behavior exists.

#### --mariadb-server-version

By default, the script will configure your system to install from the repository of the latest GA version of MariaDB. That is currently [MariaDB 10.5](#). If a new major GA release occurs and you would like to upgrade to it, then you will need to either manually edit the repository configuration file to point to the new version, or run the MariaDB Package Repository setup script again.

The script can also configure your system to install from the repository of a different version of MariaDB if you use the

```
--mariadb-server-version  
option.
```

The string

```
mariadb-
```

has to be prepended to the version number. For example, to configure your system to install from the repository of [MariaDB 10.3](#), that would be:

```
curl -LsS https://r.mariadb.com/downloads/mariadb_repo_setup | sudo bash -s -- --mariadb-server-version="mariadb-10.6"
```

The following MariaDB versions are currently supported:

- mariadb-10.2
- mariadb-10.3
- mariadb-10.4
- mariadb-10.5
- mariadb-10.6
- mariadb-10.7

If you want to pin the repository of a specific minor release, such as [MariaDB 10.3.9](#), then you can also specify the minor release. For example,

```
mariadb-10.6.4
```

This may be helpful if you want to avoid upgrades. However, avoiding upgrades is not recommended, since minor releases can contain important bug fixes and fixes for security vulnerabilities.

#### --mariadb-maxscale-version

By default, the script will configure your system to install from the repository of the latest GA version of MariaDB MaxScale.

If you would like to pin the repository to a specific version of MariaDB MaxScale then you will need to either manually edit the repository configuration file to point to the desired version, or use the

```
--mariadb-maxscale-version  
option.
```

For example, to configure your system to install from the repository of MariaDB MaxScale 6.1, that would be:

```
curl -LsS https://r.mariadb.com/downloads/mariadb_repo_setup | sudo bash -s -- --mariadb-maxscale-version="6.1"
```

The following MariaDB MaxScale versions are currently supported:

- MaxScale 1.4
- MaxScale 2.0
- MaxScale 2.1
- MaxScale 2.2

- MaxScale 2.3
- MaxScale 2.4
- MaxScale 2.5
- MaxScale 6.1
- MaxScale 6.2

The special identifiers

```
latest  
(for the latest GA release) and  
beta  
(for the latest beta release) are also supported. By default the  
mariadb_repo_setup  
script uses  
latest  
as the version.
```

```
--os-type  
and  
--os-version
```

If you want to run this script on an unsupported OS that you believe to be package-compatible with an OS that is supported, then you can use the

```
--os-type  
and  
--os-version  
options to override the script's OS detection. If you use either option, then you must use both options.
```

The supported values for

```
--os-type  
are:
```

- rhel
- debian
- ubuntu
- sles

If you use a non-supported value, then the script will fail, just as it would fail if you ran the script on an unsupported OS.

The supported values for

```
--os-version  
are entirely dependent on the OS type.
```

For Red Hat Enterprise Linux (RHEL) and CentOS,

```
7  
and  
8  
are valid options.
```

For Debian and Ubuntu, the version must be specified as the codename of the specific release. For example, Debian 9 must be specified as

```
stretch  
, and Ubuntu 18.04 must be specified as  
bionic
```

These options can be useful if your distribution is a fork of another distribution. As an example, Linux Mint 8.1 is based on and is fully compatible with Ubuntu 16.04 LTS (Xenial). Therefore, If you are using Linux Mint 8.1, then you can configure your system to install from the repository of Ubuntu 16.04 LTS (Xenial). If you would like to do that, then you can do so by specifying

```
--os-type=ubuntu  
and  
--os-version=xenial  
to the MariaDB Package Repository setup script.
```

For example, to manually set the

```
--os-type  
and  
--os-version
```

to RHEL 8 you could do:

```
curl -LsS https://r.mariadb.com/downloads/mariadb_repo_setup | sudo bash -s -- --os-type=rhel --os-version=8
```

--write-to-stdout

The

--write-to-stdout

option will prevent the script from modifying anything on the system. The repository configuration will not be written to the repository configuration file. Instead, it will be printed to standard output. That allows the configuration to be reviewed, redirected elsewhere, consumed by another script, or used in some other way.

The

--write-to-stdout

option automatically enables

--skip-key-import

For example:

```
curl -LsS https://r.mariadb.com/downloads/mariadb_repo_setup | sudo bash -s -- --write-to-stdout
```

## Platform-Specific Behavior

### Platform-Specific Behavior on RHEL and CentOS

On Red Hat Enterprise Linux (RHEL) and CentOS, the MariaDB Package Repository setup script performs the following tasks:

- Creates a repository configuration file at

/etc/yum.repos.d/mariadb.repo

- Imports the GPG public key used to verify the signature of MariaDB software packages with

```
rpm --import  
from  
downloads.mariadb.com
```

### Platform-Specific Behavior on Debian and Ubuntu

On Debian and Ubuntu, the MariaDB Package Repository setup script performs the following tasks:

- Creates a repository configuration file at

/etc/apt/sources.list.d/mariadb.list

- Creates a package preferences file at

/etc/apt/preferences.d/mariadb-enterprise.pref

, which gives packages from MariaDB repositories a higher priority than packages from OS and other repositories, which can help avoid conflicts. It looks like the following:

```
Package: *\nPin: origin downloads.mariadb.com\nPin-Priority: 1000
```

- Imports the GPG public key used to verify the signature of MariaDB software package with

```
apt-key  
from the  
keyserver.ubuntu.com  
key server.
```

- Updates the package cache with package definitions from the MariaDB Package Repository with

apt-get update

### Platform-Specific Behavior on SLES

On SUSE Linux Enterprise Server (SLES), the MariaDB Package Repository setup script performs the following tasks:

- Creates a repository configuration file at

/etc/zypp/repos.d/mariadb.repo

- Imports the GPG public key used to verify the signature of MariaDB software packages with

```
rpm --import  
from  
downloads.mariadb.com
```

.

## Installing Packages with the MariaDB Package Repository

After setting up the MariaDB Package Repository, you can install the software packages in the supported repositories.

### Installing Packages on RHEL and CentOS

To install MariaDB on Red Hat Enterprise Linux (RHEL) and CentOS, see the instructions at [Installing MariaDB Packages with YUM](#). For example:

```
sudo yum install MariaDB-server MariaDB-client MariaDB-backup
```

To install MariaDB MaxScale on Red Hat Enterprise Linux (RHEL) and CentOS, see the instructions at [MariaDB MaxScale Installation Guide](#). For example:

```
sudo yum install maxscale
```

### Installing Packages on Debian and Ubuntu

To install MariaDB on Debian and Ubuntu, see the instructions at [Installing MariaDB Packages with APT](#). For example:

```
sudo apt-get install mariadb-server mariadb-client mariadb-backup
```

To install MariaDB MaxScale on Debian and Ubuntu, see the instructions at [MariaDB MaxScale Installation Guide](#). For example:

```
sudo apt-get install maxscale
```

### Installing Packages on SLES

To install MariaDB on SUSE Linux Enterprise Server (SLES), see the instructions at [Installing MariaDB Packages with ZYpp](#). For example:

```
sudo zypper install MariaDB-server MariaDB-client MariaDB-backup
```

To install MariaDB MaxScale on SUSE Linux Enterprise Server (SLES), see the instructions at [MariaDB MaxScale Installation Guide](#). For example:

```
sudo zypper install maxscale
```

## Versions

6. Downgrading
7. See Also

MariaDB is designed to allow easy upgrades. You should be able to trivially upgrade from ANY earlier MariaDB version to the latest one (for example [MariaDB 5.5 .x](#) to [MariaDB 10.5 .x](#)), usually in a few seconds. This is also mainly true for any MySQL version < 8.0 to [MariaDB 10.4](#) and up.

Upgrades are normally easy because:

- All MariaDB table data files are backward compatible
- The MariaDB connection protocol is backward compatible. You don't normally need to upgrade any of your old clients to be able to connect to a newer MariaDB version.
- The MariaDB slave can be of any newer version than the master.

MariaDB Corporation regularly runs tests to check that one can upgrade from [MariaDB 5.5](#) to the latest MariaDB version without any trouble. All older versions should work too (as long as the storage engines you were using are still around).

Note that if you are using [MariaDB Galera Cluster](#), you have to follow the [Galera upgrading instructions](#) !

## Requirements for Doing an Upgrade Between Major Versions

- Go through the individual version upgrade notes (listed below) to look for any major changes or configuration options that have changed.
- Ensure that the target MariaDB version supports the storage engines you are using. For example, in 10.5 [TokuDB](#) is not supported.
- Backup the database (just in case). At least, take a copy of the

```
mysql
      data directory with mysqldump --add-drop-table mysql as most of the upgrade changes are done there (adding new fields and new system tables etc).
```
- Ensure that the `innodb_fast_shutdown` variable is not 2 (fast crash shutdown) or 3. The default of this variable is 1. The safest option for upgrades is 0, but the shutdown time may be notably larger with 0 than for 1 as there are a lot more cleanups done for 0.
- `innodb_force_recovery` must be less than

```
3
.
.
.
• Cleanly shutdown of the server. This is necessary because even if data files are compatible between versions, recovery logs may not be.
```

Note that rpms don't support upgrading between major versions, only minor like 10.4.1 to 10.4.2. If you are using rpms, you should de-install the old MariaDB rpms and install the new MariaDB rpms before running `mysql_upgrade`. Note that when installing the new rpms, `mysql_upgrade` may be run automatically. There is no problem with running `mysql_upgrade` many times.

## Recommended Steps

- If you have a [master-slave setup](#), first upgrade one slave and when you have verified that the slave works well, upgrade the rest of the slaves (if any). Then [upgrade one slave to master](#), upgrade the master, and change the master to a slave.
- If you don't have a master-slave setup, then [take a backup](#), [shutdown MariaDB](#) and do the upgrade.

## Step by step instructions for upgrades

- Upgrade MariaDB binaries and libraries, preferably without starting MariaDB.
- If the MariaDB server process, `mysqld` or `mariadb` was not started as part of the upgrade, start it by executing

```
mysqld --skip-grant-tables
.
.
.
This may produce some warnings about some system tables not being up to date, but you can ignore these for now as mysql_upgrade will fix that.
```
- Run `mysql_upgrade`
- Restart MariaDB server.

## Work Done by `mysql_upgrade`

The main work done when upgrading is done by running `mysql_upgrade`. The main things it does are:

- Updating the system tables in the

```
mysql
      database to the newest version. This is very quick.
```
- `mysql_upgrade` also runs `mysqlcheck --check-upgrade` to check if there have been any collation changes between the major versions. This recreates indexes in old tables that are using any of the changed collations. This can take a bit of time if there are a lot of tables or there are many

tables which used the changed collation. The last time a collation changed was in MariaDB/MySQL 5.1.23.

## Post Upgrade Work

Check the [MariaDB error log](#) for any problems during upgrade. If there are any warnings in the log files, do you best to get rid of them!

The common warnings/errors are:

- Using obsolete options. If this is the case, remove them from your [my.cnf files](#).
- Check the manual for [new features](#) that have been added since your last MariaDB version.
- Test that your application works as before. The main difference from before is that because of optimizer improvements your application should work better than before, but in some rare cases the optimizer may get something wrong. In this case, you can try to use [explain](#), [optimizer trace](#) or [optimizer\\_switch](#) to fix the queries.

## If Something Goes Wrong

- First, check the [MariaDB error log](#) to see if you are using configure options that are not supported anymore.
- Check the upgrade notices for the MariaDB release that you are upgrading to.
- File an issue in the [MariaDB bug tracker](#) so that we know about the issue and can provide a fix to make upgrades even better.
- Add a comment to this manual entry for how we can improve it.

## Disaster Recovery

In the unlikely event something goes wrong, you can try the following:

- Remove the InnoDB tables from the

```
mysql
      data directory. They are:
      o gtid_slave_pos
      o innodb_table_stats
      o innodb_index_stats
      o transaction_registry
```

- Move the

```
mysql
      data directory to
      mysql-old
      and run mysql\_install\_db to generate a new one.
```

- After the above, you have to add back your old users.
- When done, delete the

```
mysql-old
      data directory.
```

## Downgrading

MariaDB server is not designed for downgrading. That said, in most cases, as long as you haven't run any [ALTER TABLE](#) or [CREATE TABLE](#) statements and you have a [mysqldump](#) of your old

```
mysql
      database , you should be able to downgrade to your previous version by doing the following:
```

- Do a clean shutdown. For this special case you have to set [innodb\\_fast\\_shutdown](#) to 0, before taking down the new MariaDB server, to ensure there are no redo or undo logs that need to be applied on the downgraded server.
- Delete the tables in the

```
mysql
      database (if you didn't use the option
      --add-drop-table
      to mysqldump )
```

- Delete the new MariaDB installation
- Install the old MariaDB version
- Start the server with [mysqld --skip-grant-tables](#)
- Install the old

```
mysql
      database
      FLUSH PRIVILEGES
```

## 2.1.3.2 Upgrading Between Minor Versions on Linux

For Windows, see [Upgrading MariaDB on Windows instead](#).

For MariaDB Galera Cluster, see [Upgrading Between Minor Versions with Galera Cluster instead](#).

Before you upgrade, it would be best to take a backup of your database. This is always a good idea to do before an upgrade. We would recommend [Mariabackup](#).

To upgrade between minor versions of MariaDB on Linux/Unix (for example from [MariaDB 10.3.12](#) to [MariaDB 10.3.13](#)), the following procedure is suggested:

1. [Stop MariaDB](#).
2. Uninstall the old version of MariaDB.
3. Install the new version of MariaDB.
  - On Debian, Ubuntu, and other similar Linux distributions, see [Installing MariaDB Packages with APT](#) for more information.
  - On RHEL, CentOS, Fedora, and other similar Linux distributions, see [Installing MariaDB Packages with YUM](#) for more information.
  - On SLES, OpenSUSE, and other similar Linux distributions, see [Installing MariaDB Packages with ZYpp](#) for more information.
4. Make any desired changes to configuration options in [option files](#), such as  
`my.cnf`

5. [Start MariaDB](#).
6. Run

`mysql_upgrade`

◦

`mysql_upgrade`  
does two things:

1. Ensures that the system tables in the

`mysq`

`1`

database are fully compatible with the new version.

2. Does a very quick check of all tables and marks them as compatible with the new version of MariaDB.

◦ In most cases this should be a fast operation (depending of course on the number of tables).

To upgrade between major versions, see the following:

- [Upgrading from MariaDB 10.4 to MariaDB 10.5](#)
- [Upgrading from MariaDB 10.3 to MariaDB 10.4](#)
- [Upgrading from MariaDB 10.2 to MariaDB 10.3](#)
- [Upgrading from MariaDB 10.1 to MariaDB 10.2](#)
- [Upgrading from MariaDB 10.0 to MariaDB 10.1](#)
- [Upgrading from MariaDB 5.5 to MariaDB 10.0](#)

## 2.1.3.3 Upgrading from MariaDB 10.6 to MariaDB 10.7

### Contents

1. [How to Upgrade](#)
2. [Incompatible Changes Between 10.6 and 10.7](#)
  1. [Compression](#)
  2. [Options That Have Been Removed or Renamed](#)
3. [See Also](#)

## How to Upgrade

For Windows, see [Upgrading MariaDB on Windows](#).

Before you upgrade, it would be best to take a backup of your database. This is always a good idea to do before an upgrade. We would recommend [Mariabackup](#).

The suggested upgrade procedure is:

1. Modify the repository configuration, so the system's package manager installs [MariaDB 10.7](#). For example,
  - On Debian, Ubuntu, and other similar Linux distributions, see [Updating the MariaDB APT repository to a New Major Release](#) for more information.
  - On RHEL, CentOS, Fedora, and other similar Linux distributions, see [Updating the MariaDB YUM repository to a New Major Release](#) for more information.
  - On SLES, OpenSUSE, and other similar Linux distributions, see [Updating the MariaDB ZYpp repository to a New Major Release](#) for more information.
2. [Stop MariaDB](#).
3. Uninstall the old version of MariaDB.
  - On Debian, Ubuntu, and other similar Linux distributions, execute the following:

```
sudo apt-get remove mariadb-server
```
  - On RHEL, CentOS, Fedora, and other similar Linux distributions, execute the following:

```
sudo yum remove MariaDB-server
```
  - On SLES, OpenSUSE, and other similar Linux distributions, execute the following:

```
sudo zypper remove MariaDB-server
```
4. Install the new version of MariaDB.
  - On Debian, Ubuntu, and other similar Linux distributions, see [Installing MariaDB Packages with APT](#) for more information.
  - On RHEL, CentOS, Fedora, and other similar Linux distributions, see [Installing MariaDB Packages with YUM](#) for more information.
  - On SLES, OpenSUSE, and other similar Linux distributions, see [Installing MariaDB Packages with ZYpp](#) for more information.
5. Make any desired changes to configuration options in [option files](#), such as  
`my.cnf`  
. This includes removing any options that are no longer supported.
6. [Start MariaDB](#).
7. Run [mariadb-upgrade](#).
  - `mariadb-upgrade`  
does two things:
    1. Ensures that the system tables in the `mysql` database are fully compatible with the new version.
    2. Does a very quick check of all tables and marks them as compatible with the new version of MariaDB .

## Incompatible Changes Between 10.6 and 10.7

On most servers upgrading from 10.6 should be painless. However, there are some things that have changed which could affect an upgrade:

### Compression

If a non-zlib compression algorithm was used in [InnoDB](#) or [Mroonga](#) before upgrading to 10.7, those tables will be unreadable until the appropriate compression library is installed. See [Compression Plugins#Upgrading](#).

### Options That Have Been Removed or Renamed

The following options should be removed or renamed if you use them in your [option files](#):

Option	Reason
<code>wsrep_replicate_myisam</code>	Use <code>wsrep_mode</code> instead.
<code>wsrep_strict_ddl</code>	Use <code>wsrep_mode</code> instead.

### How to Upgrade

For Windows, see [Upgrading MariaDB on Windows](#).

Before you upgrade, it would be best to take a backup of your database. This is always a good idea to do before an upgrade. We would recommend [Mariabackup](#).

The suggested upgrade procedure is:

1. Modify the repository configuration, so the system's package manager installs [MariaDB 10.6](#). For example,
  - On Debian, Ubuntu, and other similar Linux distributions, see [Updating the MariaDB APT repository to a New Major Release](#) for more information.
  - On RHEL, CentOS, Fedora, and other similar Linux distributions, see [Updating the MariaDB YUM repository to a New Major Release](#) for more information.
  - On SLES, OpenSUSE, and other similar Linux distributions, see [Updating the MariaDB ZYpp repository to a New Major Release](#) for more information.
2. [Stop MariaDB](#).
3. Uninstall the old version of MariaDB.
  - On Debian, Ubuntu, and other similar Linux distributions, execute the following:
 

```
sudo apt-get remove mariadb-server
```
  - On RHEL, CentOS, Fedora, and other similar Linux distributions, execute the following:
 

```
sudo yum remove MariaDB-server
```
  - On SLES, OpenSUSE, and other similar Linux distributions, execute the following:
 

```
sudo zypper remove MariaDB-server
```
4. Install the new version of MariaDB.
  - On Debian, Ubuntu, and other similar Linux distributions, see [Installing MariaDB Packages with APT](#) for more information.
  - On RHEL, CentOS, Fedora, and other similar Linux distributions, see [Installing MariaDB Packages with YUM](#) for more information.
  - On SLES, OpenSUSE, and other similar Linux distributions, see [Installing MariaDB Packages with ZYpp](#) for more information.
5. Make any desired changes to configuration options in [option files](#), such as
  - `my.cnf`
  - . This includes removing any options that are no longer supported.
6. [Start MariaDB](#).
7. Run [mariadb-upgrade](#).
  - ```
mariadb-upgrade
```

 does two things:
    1. Ensures that the system tables in the `mysql` database are fully compatible with the new version.
    2. Does a very quick check of all tables and marks them as compatible with the new version of MariaDB .

### Incompatible Changes Between 10.5 and 10.6

On most servers upgrading from 10.5 should be painless. However, there are some things that have changed which could affect an upgrade:

## Reserved Word

- New reserved word : OFFSET. This can no longer be used as an identifier without being quoted.

## InnoDB COMPRESSED Row Format

From MariaDB 10.6.0 , tables that are of the COMPRESSED row format are read-only by default. This is the first step towards removing write support and deprecating the feature.

Set the innodb\_read\_only\_compressed variable to

OFF

to make the tables writable.

## Character Sets

From MariaDB 10.6 , the

utf8

character set (and related collations) is by default an alias for

utf8mb3

rather than the other way around. It can be set to imply

utf8mb4

by changing the value of the old\_mode system variable.

## Options That Have Changed Default Values

| Option                               | Old default value | New default value |
|--------------------------------------|-------------------|-------------------|
| character_set_client                 | utf8              | utf8mb3           |
| character_set_connection             | utf8              | utf8mb3           |
| character_set_results                | utf8              | utf8mb3           |
| character_set_system                 | utf8              | utf8mb3           |
| innodb_flush_method                  | fsync             | O_DIRECT          |
| [[server-system-variables/#old_mode] | old_mode]         | Empty             |
|                                      |                   | UTF8_IS_UTF8MB3   |

## Options That Have Been Removed or Renamed

The following options should be removed or renamed if you use them in your option files :

| Option                                      | Reason                                                                                                                                          |
|---------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------|
| innodb_adaptive_max_sleep_delay             |                                                                                                                                                 |
| innodb_background_scrub_data_check_interval |                                                                                                                                                 |
| innodb_background_scrub_data_compressed     |                                                                                                                                                 |
| innodb_background_scrub_data_interval       |                                                                                                                                                 |
| innodb_background_scrub_data_uncompressed   |                                                                                                                                                 |
| innodb_buffer_pool_instances                |                                                                                                                                                 |
| innodb_checksum_algorithm                   | The variable is still present, but the *innodb and *none options have been removed as the crc32 algorithm only is supported from MariaDB 10.6 . |
| innodb_commit_concurrency                   |                                                                                                                                                 |
| innodb_concurrency_tickets                  |                                                                                                                                                 |
| innodb_file_format                          |                                                                                                                                                 |
| innodb_large_prefix                         |                                                                                                                                                 |
| innodb_lock_schedule_algorithm              |                                                                                                                                                 |
| innodb_log_checksums                        |                                                                                                                                                 |

|                             |

## 2.1.3.5 Upgrading from MariaDB 10.4 to MariaDB 10.5

### Contents

1. [How to Upgrade](#)
2. [Incompatible Changes Between 10.4 and 10.5](#)
  1. [Binary name changes](#)
  2. [GRANT PRIVILEGE changes](#)
  3. [Options That Have Changed Default Values](#)
  4. [Options That Have Been Removed or Renamed](#)
  5. [Deprecated Options](#)
3. [Major New Features To Consider](#)
4. [See Also](#)

## How to Upgrade

For Windows, see [Upgrading MariaDB on Windows](#) instead.

Before you upgrade, it would be best to take a backup of your database. This is always a good idea to do before an upgrade. We would recommend [Mariabackup](#).

The suggested upgrade procedure is:

1. Modify the repository configuration, so the system's package manager installs [MariaDB 10.5](#). For example,
  - On Debian, Ubuntu, and other similar Linux distributions, see [Updating the MariaDB APT repository to a New Major Release](#) for more information.

- On RHEL, CentOS, Fedora, and other similar Linux distributions, see [Updating the MariaDB YUM repository to a New Major Release](#) for more information.
  - On SLES, OpenSUSE, and other similar Linux distributions, see [Updating the MariaDB ZYpp repository to a New Major Release](#) for more information.
2. [Stop MariaDB](#).
3. Uninstall the old version of MariaDB.
- On Debian, Ubuntu, and other similar Linux distributions, execute the following:
- ```
sudo apt-get remove mariadb-server
```
- On RHEL, CentOS, Fedora, and other similar Linux distributions, execute the following:
- ```
sudo yum remove MariaDB-server
```
- On SLES, OpenSUSE, and other similar Linux distributions, execute the following:
- ```
sudo zypper remove MariaDB-server
```
4. Install the new version of MariaDB.
- On Debian, Ubuntu, and other similar Linux distributions, see [Installing MariaDB Packages with APT](#) for more information.
  - On RHEL, CentOS, Fedora, and other similar Linux distributions, see [Installing MariaDB Packages with YUM](#) for more information.
  - On SLES, OpenSUSE, and other similar Linux distributions, see [Installing MariaDB Packages with ZYpp](#) for more information.
5. Make any desired changes to configuration options in [option files](#), such as
- ```
my.cnf
```
- . This includes removing any options that are no longer supported.
6. [Start MariaDB](#).
7. Run [mysql\\_upgrade](#).
- 

```
mysql_upgrade
does two things:
1. Ensures that the system tables in the# mysql database are fully compatible with the new version.
2. Does a very quick check of all tables and marks them as compatible with the new version of MariaDB .
```

## Incompatible Changes Between 10.4 and 10.5

On most servers upgrading from 10.4 should be painless. However, there are some things that have changed which could affect an upgrade:

### Binary name changes

All binaries previously beginning with mysql now begin with mariadb, with symlinks for the corresponding mysql command.

Usually that shouldn't cause any changed behavior, but when starting the MariaDB server via [systemd](#), or via the [mysqld\\_safe](#) script symlink, the server process will now always be started as

```
mariadb
, not
mysqld
```

So anything looking for the

```
mysqld
name in the system process list, like e.g. monitoring solutions, now needs for
mariadb
instead when the server / service is not started directly, but via
mysqld_safe
or as a system service.
```

### GRANT PRIVILEGE changes

A number of statements changed the privileges that they require. The old privileges were historically inappropriately chosen in the upstream. 10.5.2 fixes this problem. Note, these changes are incompatible to previous versions. A number of GRANT commands might be needed after upgrade.

- SHOW BINLOG EVENTS  
now requires the  
BINLOG MONITOR  
privilege (required  
REPLICATION SLAVE  
prior to 10.5.2).
- SHOW SLAVE HOSTS  
now requires the  
REPLICATION MASTER ADMIN  
privilege (required

REPLICATION SLAVE  
prior to 10.5.2).

- SHOW SLAVE STATUS  
now requires the  
REPLICATION SLAVE ADMIN  
or the  
SUPER  
privilege (required  
REPLICATION CLIENT  
or  
SUPER  
prior to 10.5.2).

- SHOW RELAYLOG EVENTS  
now requires the  
REPLICATION SLAVE ADMIN  
privilege (required  
REPLICATION SLAVE  
prior to 10.5.2).

## Options That Have Changed Default Values

| Option                                | Old default value | New default value |
|---------------------------------------|-------------------|-------------------|
| innodb_adaptive_hash_index            | ON                | OFF               |
| innodb_checksum_algorithm             | crc32             | full_crc32        |
| innodb_log_optimize_ddl               | ON                | OFF               |
| slave_parallel_mode                   | conservative      | optimistic        |
| performance_schema_max_cond_classes   | 80                | 90                |
| performance_schema_max_file_classes   | 50                | 80                |
| performance_schema_max_mutex_classes  | 200               | 210               |
| performance_schema_max_rwlock_classes | 40                | 50                |
| performance_schema_setup_actors_size  | 100               | -1                |
| performance_schema_setup_objects_size | 100               | -1                |

## Options That Have Been Removed or Renamed

The following options should be removed or renamed if you use them in your [option files](#) :

| Option                         | Reason                                                                                                |
|--------------------------------|-------------------------------------------------------------------------------------------------------|
| innodb_checksums               | Deprecated and functionality replaced by <a href="#">innodb_checksum_algorithms</a> in MariaDB 10.0 . |
| idle_flush_pct                 | Has had no effect since merging InnoDB 5.7 from mysql-5.7.9 ( <a href="#">MariaDB 10.2.2</a> ).       |
| innodb_locks_unsafe_for_binlog | Deprecated in MariaDB 10.0 . Use <a href="#">READ COMMITTED</a> transaction isolation level instead.  |
| innodb_rollback_segments       | Deprecated and replaced by <a href="#">innodb_undo_logs</a> in MariaDB 10.0 .                         |
| innodb_stats_sample_pages      | Deprecated in MariaDB 10.0 . Use <a href="#">innodb_stats_transient_sample_pages</a> instead.         |
| max_long_data_size             | Deprecated and replaced by <a href="#">max_allowed_packet</a> in MariaDB 5.5 .                        |
| multi_range_count              | Deprecated and has had no effect since MariaDB 5.3 .                                                  |
| thread_concurrency             | Deprecated and has had no effect since MariaDB 5.5 .                                                  |
| timed_mutexes                  | Deprecated and has had no effect since MariaDB 5.5 .                                                  |

## Deprecated Options

The following options have been deprecated. They have not yet been removed, but will be in a future version, and should ideally no longer be used.

| Option                                      | Reason                                           |
|---------------------------------------------|--------------------------------------------------|
| innodb_adaptive_max_sleep_delay             | No need for thread throttling any more.          |
| innodb_background_scrub_data_check_interval | Problematic ‘background scrubbing’ code removed. |
| innodb_background_scrub_data_interval       | Problematic ‘background scrubbing’ code removed. |

|                                                        |                                                                                                        |
|--------------------------------------------------------|--------------------------------------------------------------------------------------------------------|
| <code>innodb_background_scrub_data_compressed</code>   | Problematic ‘background scrubbing’ code removed.                                                       |
| <code>innodb_background_scrub_data_uncompressed</code> | Problematic ‘background scrubbing’ code removed.                                                       |
| <code>innodb_buffer_pool_instances</code>              | Having more than one buffer pool is no longer necessary.                                               |
| <code>innodb_commit_concurrency</code>                 | No need for thread throttling any more.                                                                |
| <code>innodb_concurrency_tickets</code>                | No need for thread throttling any more.                                                                |
| <code>innodb_log_files_in_group</code>                 | Redo log was unnecessarily split into multiple files. Limited to 1 from <a href="#">MariaDB 10.5</a> . |
| <code>innodb_log_optimize_ddl</code>                   | Prohibited optimizations.                                                                              |
| <code>innodb_page_cleaners</code>                      | Having more than one page cleaner task no longer necessary.                                            |
| <code>innodb_replication_delay</code>                  | No need for thread throttling any more.                                                                |
| <code>innodb_scrub_log</code>                          | Never really worked as intended, redo log format is being redone.                                      |
| <code>innodb_scrub_log_speed</code>                    | Never really worked as intended, redo log format is being redone.                                      |
| <code>innodb_thread_concurrency</code>                 | No need for thread throttling any more.                                                                |
| <code>innodb_thread_sleep_delay</code>                 | No need for thread throttling any more.                                                                |
| <code>innodb_undo_logs</code>                          | It always makes sense to use the maximum number of rollback segments.                                  |
| <code>large_page_size</code>                           | Unused since multiple page size support was added.                                                     |

## Major New Features To Consider

You might consider using the following major new features in [MariaDB 10.5](#):

- The [S3 storage engine](#) allows one to archive MariaDB tables in Amazon S3, or any third-party public or private cloud that implements S3 API.
- [ColumnStore](#) columnar storage engine.
- See also [System Variables Added in MariaDB 10.5](#).

## See Also

- [Upgrading from MariaDB 10.1 to MariaDB 10.2](#)

## 2.1.3.6 Upgrading from MariaDB 10.3 to MariaDB 10.4

### Contents

1. [How to Upgrade](#)
2. [Incompatible Changes Between 10.3 and 10.4](#)
  1. [Options That Have Changed Default Values](#)
  2. [Options That Have Been Removed or Renamed](#)
  3. [Authentication and TLS](#)
3. [Major New Features To Consider](#)
4. [See Also](#)

## How to Upgrade

For Windows, see [Upgrading MariaDB on Windows instead](#).

For MariaDB Galera Cluster, see [Upgrading from MariaDB 10.3 to MariaDB 10.4 with Galera Cluster instead](#).

Before you upgrade, it would be best to take a backup of your database. This is always a good idea to do before an upgrade. We would recommend [Mariabackup](#).

The suggested upgrade procedure is:

1. Modify the repository configuration, so the system’s package manager installs [MariaDB 10.4](#). For example,

- On Debian, Ubuntu, and other similar Linux distributions, see [Updating the MariaDB APT repository to a New Major Release](#) for more information.
  - On RHEL, CentOS, Fedora, and other similar Linux distributions, see [Updating the MariaDB YUM repository to a New Major Release](#) for more information.
  - On SLES, OpenSUSE, and other similar Linux distributions, see [Updating the MariaDB ZYpp repository to a New Major Release](#) for more information.
2. [Stop MariaDB](#).
  3. Uninstall the old version of MariaDB.
    - On Debian, Ubuntu, and other similar Linux distributions, execute the following:

```
sudo apt-get remove mariadb-server
```

    - On RHEL, CentOS, Fedora, and other similar Linux distributions, execute the following:

```
sudo yum remove MariaDB-server
```

    - On SLES, OpenSUSE, and other similar Linux distributions, execute the following:

```
sudo zypper remove MariaDB-server
```
  4. Install the new version of MariaDB.
    - On Debian, Ubuntu, and other similar Linux distributions, see [Installing MariaDB Packages with APT](#) for more information.
    - On RHEL, CentOS, Fedora, and other similar Linux distributions, see [Installing MariaDB Packages with YUM](#) for more information.
    - On SLES, OpenSUSE, and other similar Linux distributions, see [Installing MariaDB Packages with ZYpp](#) for more information.
  5. Make any desired changes to configuration options in [option files](#), such as `my.cnf`
    - . This includes removing any options that are no longer supported.
  6. [Start MariaDB](#).
  7. Run

`mysql_upgrade`

- `mysql_upgrade`  
does two things:
1. Ensures that the system tables in the

```
mysq
1
database are fully compatible with the new version.
```

2. Does a very quick check of all tables and marks them as compatible with the new version of MariaDB .

## Incompatible Changes Between 10.3 and 10.4

On most servers upgrading from 10.3 should be painless. However, there are some things that have changed which could affect an upgrade:

### Options That Have Changed Default Values

| Option                                      | Old default value | New default value                             |
|---------------------------------------------|-------------------|-----------------------------------------------|
| <code>slave_transaction_retry_errors</code> | 1213,1205         | 1158,1159,1160,1161,1205,1213,1429,2013,12701 |
| <code>wsrep_debug</code>                    | OFF               | NONE                                          |
| <code>wsrep_load_data_splitting</code>      | ON                | OFF                                           |

### Options That Have Been Removed or Renamed

The following options should be removed or renamed if you use them in your [option files](#):

| Option | Reason |
|--------|--------|
|--------|--------|

### Authentication and TLS

- See [Authentication from MariaDB 10.4](#) for an overview of the changes.
- The [unix\\_socket authentication plugin](#) is now default on Unix-like systems.
- TLSv1.0 is disabled by default in [MariaDB 10.4](#) . See [tls\\_version](#) and [TLS Protocol Versions](#) .

## Major New Features To Consider

You might consider using the following major new features in MariaDB 10.4 :

- Galera has been upgraded from Galera 3 to Galera 4.
- System-versioning extended with support for application-time periods .
- User password expiry
- Account Locking
- See also [System Variables Added in MariaDB 10.4](#) .

## See Also

- [Upgrading from MariaDB 10.2 to MariaDB 10.3](#)
- [Upgrading from MariaDB 10.1 to MariaDB 10.2](#)
- [Upgrading from MariaDB 10.0 to MariaDB 10.1](#)

## 2.1.3.7 Upgrading from MariaDB 10.2 to MariaDB 10.3

### Contents

1. [How to Upgrade](#)
2. [Incompatible Changes Between 10.2 and 10.3](#)
  1. [Options That Have Changed Default Values](#)
  2. [Options That Have Been Removed or Renamed](#)
  3. [Reserved Words](#)
  4. [SQL\\_MODE=ORACLE](#)
  5. [Functions](#)
  6. [mysqldump](#)
  7. [MariaDB Backup and Percona XtraBackup](#)
  8. [Privileges](#)
3. [Major New Features To Consider](#)
4. [See Also](#)

## How to Upgrade

For Windows, see [Upgrading MariaDB on Windows instead](#).

For MariaDB Galera Cluster, see [Upgrading from MariaDB 10.2 to MariaDB 10.3 with Galera Cluster instead](#).

Before you upgrade, it would be best to take a backup of your database. This is always a good idea to do before an upgrade. We would recommend [Mariabackup](#) .

The suggested upgrade procedure is:

1. Modify the repository configuration, so the system's package manager installs MariaDB 10.3 . For example,
  - On Debian, Ubuntu, and other similar Linux distributions, see [Updating the MariaDB APT repository to a New Major Release](#) for more information.
  - On RHEL, CentOS, Fedora, and other similar Linux distributions, see [Updating the MariaDB YUM repository to a New Major Release](#) for more information.
  - On SLES, OpenSUSE, and other similar Linux distributions, see [Updating the MariaDB ZYpp repository to a New Major Release](#) for more information.
2. Stop MariaDB . The server should be cleanly shut down, with no incomplete transactions remaining. `innodb_fast_shutdown` must be set to
  - 0
  - or
  - 1
  - and `innodb_force_recovery` must be less than
  - 3
3. Uninstall the old version of MariaDB.
  - On Debian, Ubuntu, and other similar Linux distributions, execute the following:

```
sudo apt-get remove mariadb-server
```
  - On RHEL, CentOS, Fedora, and other similar Linux distributions, execute the following:

```
sudo yum remove MariaDB-server
```

- On SLES, OpenSUSE, and other similar Linux distributions, execute the following:

```
sudo zypper remove MariaDB-server
```

#### 4. Install the new version of MariaDB.

- On Debian, Ubuntu, and other similar Linux distributions, see [Installing MariaDB Packages with APT](#) for more information.
- On RHEL, CentOS, Fedora, and other similar Linux distributions, see [Installing MariaDB Packages with YUM](#) for more information.
- On SLES, OpenSUSE, and other similar Linux distributions, see [Installing MariaDB Packages with ZYpp](#) for more information.

#### 5. Make any desired changes to configuration options in [option files](#), such as

```
my.cnf
```

. This includes removing any options that are no longer supported.

#### 6. [Start MariaDB](#).

#### 7. Run

```
mysql_upgrade
```

◦

```
mysql_upgrade
```

does two things:

1. Ensures that the system tables in the

```
mysq
```

```
l
```

database are fully compatible with the new version.

2. Does a very quick check of all tables and marks them as compatible with the new version of MariaDB .

## Incompatible Changes Between 10.2 and 10.3

On most servers upgrading from 10.2 should be painless. However, there are some things that have changed which could affect an upgrade:

### Options That Have Changed Default Values

| Option                               | Old default value | New default value                 |
|--------------------------------------|-------------------|-----------------------------------|
| innodb_flush_method                  | (empty)           | fsync                             |
| innodb_spin_wait_delay               | 6                 | 4                                 |
| performance_schema_max_stage_classes | 150               | 160                               |
| plugin_maturity                      | unknown           | One less than the server maturity |

### Options That Have Been Removed or Renamed

The following options should be removed or renamed if you use them in your [option files](#) :

| Option                           | Reason                                                                                                                                                                        |
|----------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| innodb_buffer_pool_populate      | Used in XtraDB-only                                                                                                                                                           |
| innodb_cleaner_lsn_age_factor    | Used in XtraDB-only                                                                                                                                                           |
| innodb_corrupt_table_action      | Used in XtraDB-only                                                                                                                                                           |
| innodb_empty_free_list_algorithm | Used in XtraDB-only                                                                                                                                                           |
| innodb_fake_changes              | Used in XtraDB-only                                                                                                                                                           |
| innodb_file_format               | The <a href="#">InnoDB file format</a> is now Barracuda, and the old Antelope file format is no longer supported.                                                             |
| innodb_file_format_check         | No longer necessary as the Antelope <a href="#">InnoDB file format</a> is no longer supported.                                                                                |
| innodb_file_format_max           | No longer necessary as the Antelope <a href="#">InnoDB file format</a> is no longer supported.                                                                                |
| innodb_foreground_preflush       | Used in XtraDB-only                                                                                                                                                           |
| innodb_instrument_semaphores     |                                                                                                                                                                               |
| innodb_kill_idle_transaction     | Used in XtraDB-only                                                                                                                                                           |
| innodb_large_prefix              | Large index key prefixes were made default from <a href="#">MariaDB 10.2</a> , and limiting tables to small prefixes is no longer permitted in <a href="#">MariaDB 10.3</a> . |

|                                                        |                                                                                                                                                          |
|--------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>innodb_locking_fake_changes</code>               | Used in XtraDB-only                                                                                                                                      |
| <code>innodb_log_arch_dir</code>                       | Used in XtraDB-only                                                                                                                                      |
| <code>innodb_log_arch_expire_sec</code>                | Used in XtraDB-only                                                                                                                                      |
| <code>innodb_log_archive</code>                        | Used in XtraDB-only                                                                                                                                      |
| <code>innodb_log_block_size</code>                     | Used in XtraDB-only                                                                                                                                      |
| <code>innodb_log_checksum_algorithm</code>             | Translated to <code>innodb_log_checksums</code> (NONE to OFF, everything else to ON); only existed to allow easier upgrade from earlier XtraDB versions. |
| <code>innodb_mtflush_threads</code>                    | Replaced by the <code>innodb_page_cleaners</code> system variable.                                                                                       |
| <code>innodb_sched_priority_cleaner</code>             | Used in XtraDB-only                                                                                                                                      |
| <code>innodb_show_locks_held</code>                    | Used in XtraDB-only                                                                                                                                      |
| <code>innodb_show_verbose_locks</code>                 | Used in XtraDB-only                                                                                                                                      |
| <code>innodb_support_xa</code>                         | XA transactions are always supported.                                                                                                                    |
| <code>innodb_use_fallocate</code>                      |                                                                                                                                                          |
| <code>innodb_use_global_flush_log_at_trx_commit</code> | Used in XtraDB-only                                                                                                                                      |
| <code>innodb_use_mtflush</code>                        | Replaced by the <code>innodb_page_cleaners</code> system variable.                                                                                       |
| <code>innodb_use_stacktrace</code>                     | Used in XtraDB-only                                                                                                                                      |
| <code>innodb_use_trim</code>                           |                                                                                                                                                          |

## Reserved Words

- New `reserved words` : EXCEPT and INTERSECT. These can no longer be used as `identifiers` without being quoted.

## SQL\_MODE=ORACLE

- `MariaDB 10.3` has introduced major new Oracle compatibility features. If you upgrade and are using this setting, please check the [changes carefully](#).

## Functions

- As a result of implementing Table Value Constructors, the `VALUES function` has been renamed to `VALUE()`.
- Functions that used to only return 64-bit now can return 32-bit results ( [MDEV-12619](#) ). This could cause incompatibilities with strongly-typed clients.

## mysqldump

- `mysqldump` in `MariaDB 10.3` includes logic to cater for the `mysql.transaction_registry table`.  
`mysqldump` from an earlier MariaDB release cannot be used on `MariaDB 10.3` and beyond.

## MariaDB Backup and Percona XtraBackup

- `Percona XtraBackup` is not compatible with `MariaDB 10.3` . Installations currently using XtraBackup should upgrade to `MariaDB Backup` before upgrading to `MariaDB 10.3` .

## Privileges

- If a user has the `SUPER privilege` but not the `DELETE HISTORY` privilege, running `mysql_upgrade` will grant `DELETE HISTORY` as well.

## Major New Features To Consider

You might consider using the following major new features in `MariaDB 10.3` :

- `System-versioned tables`
- `Sequences`
- See also [System Variables Added in MariaDB 10.3](#) .

## See Also

### How to Upgrade

For Windows, see [Upgrading MariaDB on Windows instead](#).

For MariaDB Galera Cluster, see [Upgrading from MariaDB 10.1 to MariaDB 10.2 with Galera Cluster instead](#).

Before you upgrade, it would be best to take a backup of your database. This is always a good idea to do before an upgrade. We would recommend [Mariabackup](#).

The suggested upgrade procedure is:

1. Modify the repository configuration, so the system's package manager installs [MariaDB 10.2](#). For example,
  - On Debian, Ubuntu, and other similar Linux distributions, see [Updating the MariaDB APT repository to a New Major Release](#) for more information.
  - On RHEL, CentOS, Fedora, and other similar Linux distributions, see [Updating the MariaDB YUM repository to a New Major Release](#) for more information.
  - On SLES, OpenSUSE, and other similar Linux distributions, see [Updating the MariaDB ZYpp repository to a New Major Release](#) for more information.
2. Set

```
innodb_fast_shutdown
to
0
. It can be changed dynamically with
```

```
SET GLOBAL
```

```
. For example:
```

```
SET GLOBAL innodb_fast_shutdown=0;
```

- This step is not necessary when upgrading to [MariaDB 10.2.5](#) or later. Omitting it can make the upgrade process far faster. See [MDEV-12289](#) for more information.

3. [Stop MariaDB](#).

4. Uninstall the old version of MariaDB.

- On Debian, Ubuntu, and other similar Linux distributions, execute the following:

```
sudo apt-get remove mariadb-server
```

- On RHEL, CentOS, Fedora, and other similar Linux distributions, execute the following:

```
sudo yum remove MariaDB-server
```

- On SLES, OpenSUSE, and other similar Linux distributions, execute the following:

```
sudo zypper remove MariaDB-server
```

5. Install the new version of MariaDB.

- On Debian, Ubuntu, and other similar Linux distributions, see [Installing MariaDB Packages with APT](#) for more information.
- On RHEL, CentOS, Fedora, and other similar Linux distributions, see [Installing MariaDB Packages with YUM](#) for more information.
- On SLES, OpenSUSE, and other similar Linux distributions, see [Installing MariaDB Packages with ZYpp](#) for more information.

6. Make any desired changes to configuration options in [option files](#), such as

```
my.cnf
```

. This includes removing any options that are no longer supported.

7. [Start MariaDB](#).

8. Run

```
mysql_upgrade
```

◦

```
mysql_upgrade  
does two things:
```

1. Ensures that the system tables in the

```
mysq
```

```
1
```

database are fully compatible with the new version.

2. Does a very quick check of all tables and marks them as compatible with the new version of MariaDB .

## Incompatible Changes Between 10.1 and 10.2

On most servers upgrading from 10.1 should be painless. However, there are some things that have changed which could affect an upgrade:

### InnoDB Instead of XtraDB

MariaDB 10.2 uses [InnoDB](#) as the default storage engine, rather than XtraDB, used in [MariaDB 10.1](#) and before. See [Why does MariaDB 10.2 use InnoDB instead of XtraDB?](#) In most cases this should have minimal effect as the latest InnoDB has incorporated most of the improvements made in earlier versions of XtraDB. Note that certain [XtraDB system variables](#) are now ignored (although they still exist so as to permit easy upgrading).

### Options That Have Changed Default Values

In particular, take note of the changes to [innodb\\_strict\\_mode](#), [sql\\_mode](#), [binlog\\_format](#), [binlog\\_checksum](#) and [innodb\\_checksum\\_algorithm](#).

| Option                                              | Old default value | New default value |
|-----------------------------------------------------|-------------------|-------------------|
| <a href="#">aria_recover(_options)</a>              | NORMAL            | BACKUP, QUICK     |
| <a href="#">binlog_annotation_row_events</a>        | OFF               | ON                |
| <a href="#">binlog_checksum</a>                     | NONE              | CRC32             |
| <a href="#">binlog_format</a>                       | STATEMENT         | MIXED             |
| <a href="#">group_concat_max_len</a>                | 1024              | 1048576           |
| <a href="#">innodb_autoinc_lock_mode</a>            | 1                 | 2                 |
| <a href="#">innodb_buffer_pool_dump_at_shutdown</a> | OFF               | ON                |
| <a href="#">innodb_buffer_pool_dump_pct</a>         | 100               | 25                |
| <a href="#">innodb_buffer_pool_instances</a>        | 8                 | Varies            |
| <a href="#">innodb_buffer_pool_load_at_startup</a>  | OFF               | ON                |
| <a href="#">innodb_checksum_algorithm</a>           | innodb            | crc32             |
| <a href="#">innodb_file_format</a>                  | Antelope          | Barracuda         |
| <a href="#">innodb_large_prefix</a>                 | OFF               | ON                |
| <a href="#">innodb_lock_schedule_algorithm</a>      | VATS              | FCFS              |

## Options That Have Been Removed or Renamed

The following options should be removed or renamed if you use them in your [option files](#) :

| Option                          | Reason                                                                                            |
|---------------------------------|---------------------------------------------------------------------------------------------------|
| aria_recover                    | Renamed to <a href="#">aria_recover_options</a> to match <a href="#">myisam_recover_options</a> . |
| innodb_additional_mem_pool_size | Deprecated in <a href="#">MariaDB 10.0</a> .                                                      |
| innodb_api_bk_commit_interval   | Memcache never implemented in MariaDB.                                                            |
| innodb_api_disable_rowlock      | Memcache never implemented in MariaDB.                                                            |
| innodb_api_enable_binlog        | Memcache never implemented in MariaDB.                                                            |
| innodb_api_enable_mdl           | Memcache never implemented in MariaDB.                                                            |
| innodb_api_trx_level            | Memcache never implemented in MariaDB.                                                            |
| innodb_use_sys_malloc           | Deprecated in <a href="#">MariaDB 10.0</a> .                                                      |

## Reserved Words

New [reserved words](#) : OVER, RECURSIVE and ROWS. These can no longer be used as [identifiers](#) without being quoted.

## TokuDB

[TokuDB](#) has been split into a separate package, mariadb-plugin-tokudb.

## Replication

[Replication](#) from legacy MySQL servers may require setting [binlog\\_checksum](#) to NONE.

## SQL Mode

[SQL\\_MODE](#) has been changed; in particular, NOT NULL fields with no default will no longer fall back to a dummy value for inserts which do not specify a value for that field.

## Auto\_increment

[Auto\\_increment](#) columns are no longer permitted in [CHECK constraints](#), [DEFAULT value expressions](#) and [virtual columns](#). They were permitted in earlier versions, but did not work correctly.

## TLS

Starting with [MariaDB 10.2](#), when the user specifies the

--ssl

option with a [client or utility](#), the [client or utility](#) will not verify the server certificate by default. In order to verify the server certificate, the user must specify the

--ssl-verify-server-cert

option to the [client or utility](#). For more information, see the [list of options](#) for the

`mysql`

client.

## Major New Features To Consider

You might consider using the following major new features in [MariaDB 10.2](#):

- [Window Functions](#)
- [mysqlbinlog](#) now supports continuous binary log backups
- [Recursive Common Table Expressions](#)
- [JSON functions](#)
- See also [System Variables Added in MariaDB 10.2](#).

## See Also

- [The features in MariaDB 10.2](#)
- [Upgrading from MariaDB 10.1 to MariaDB 10.2 with Galera Cluster](#)
- [Upgrading from MariaDB 10.0 to MariaDB 10.1](#)
- [Upgrading from MariaDB 5.5 to MariaDB 10.0](#)

## 2.1.3.9 Upgrading MariaDB on Windows

### Contents

1. [Minor upgrades](#)
2. [General information on upgrade and version coexistence](#)
3. [General recommendations](#)
4. [Upgrade Wizard](#)
5. [mysql\\_upgrade\\_service](#)
6. [Migration to 64 bit MariaDB from 32 bit](#)
7. [Upgrading ZIP-based installations.](#)

## Minor upgrades

To install a minor upgrade, e.g 10.1.27 on top of existing 10.1.26, with MSI, just download the 10.1.27 MSI and start it. It will do everything that needs to be done for minor upgrade automatically - shutdown MariaDB service(s), replace executables and DLLs, and start service(s) again.

The rest of the article is dedicated to \*major\* upgrades, e.g 10.1.x to 10.2.y.

## General information on upgrade and version coexistence

This section assumes MSI installations.

First, check everything listed in the Incompatibilities section of the article relating to the version you are upgrading, for example, [Upgrading from MariaDB 10.1 to MariaDB 10.2](#), to make sure you are prepared for the upgrade.

MariaDB (and also MySQL) allows different versions of the product to co-exist on the same machine, as long as these versions are different either in major or minor version numbers. For example, it is possible to have say [MariaDB 5.1.51](#) and 5.2.6 to be installed on the same machine.

However only a single instance of 5.2 can exist. If for example 5.2.7 is installed on a machine where 5.2.6 is already installed, the installer will just replace 5.2.6 executables with 5.2.7 ones.

Now imagine, that both 5.1 and 5.2 are installed on the same machine and we want to upgrade the database instance running on 5.1 to the new version. In this case special tools are required. Traditionally,

`mysql_upgrade`

is used to accomplish this. On Windows, the [MySQL upgrade](#) is a complicated multiple-step manual process.

Since [MariaDB 5.2.6](#), the Windows distribution includes tools that simplify migration between different versions and also allow migration between MySQL and MariaDB.

**Note**. Automatic upgrades are only possible for DB instances that run as a Windows service.

## General recommendations

**Important:** Ignore any statement that tells you to "*just uninstall MySQL and install MariaDB*". This does not work on Windows, never has, and never will. Keep your MySQL installed until after the database had been converted.

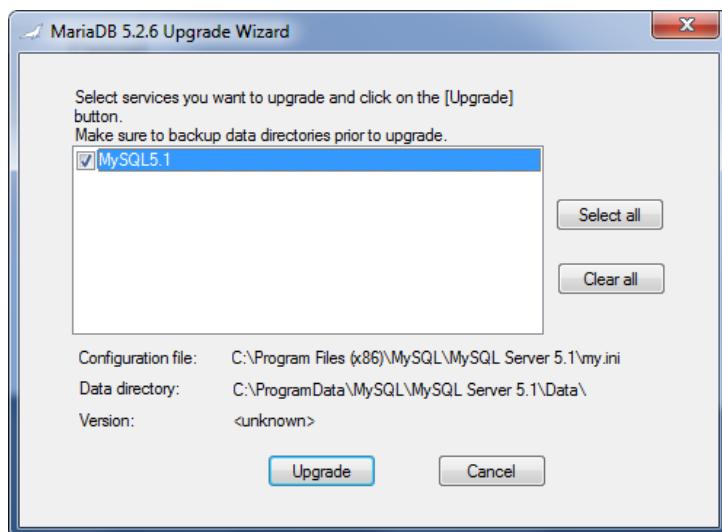

The following install/upgrade sequence is recommended in case of "major" upgrades, like going from 5.3 to 5.5

- Install new version, while still retaining the old one
- Upgrade services one by one, like described later in the document (e.g with `mysql_upgrade_service`). It is recommended to have services cleanly shut down before the upgrade.
- Uninstall old version when previous step is done.

**Note**. This recommendation differs from the procedure on Unixes, where the upgrade sequence is "uninstall old version, install new version"

## Upgrade Wizard

This is a GUI tool that is typically invoked at the end of a MariaDB installation if upgradable services are found. The UI allows you to select instances you want to upgrade.

## mysql\_upgrade\_service

This is a command line tool that performs upgrades. The tool requires full administrative privileges (it has to start and stop services).

Example usage:

```
mysql_upgrade_service --service=MySQL
```

`mysql_upgrade_service` accepts a single parameter — the name of the MySQL or MariaDB service. It performs all the steps to convert a MariaDB/MySQL instance running as the service to the current version.

## Migration to 64 bit MariaDB from 32 bit

Earlier we said that only single instance of "MariaDB <major>.<minor>" version can be installed on the same machine. This was almost correct, because MariaDB MSI installations allow 32 and 64-bit versions to be installed on the same machine, and in this case it is possible to have two instances of say 5.2 installed at the same time, an x86 one and an x64 one. One can use the x64 Upgrade wizard to upgrade an instance running as a 32-bit process to run as 64-bit.

## Upgrading ZIP-based installations.

Both UpgradeWizard and mysql\_upgrade\_service can also be used to upgrade database instances that were installed with the [ZIP installation](#).

## 2.1.3.10 Upgrading Galera Cluster

### 2.1.3.10.1 Upgrading Between Minor Versions with Galera Cluster

#### Performing a Rolling Upgrade

The following steps can be used to perform a rolling upgrade between minor versions of MariaDB (for example from [MariaDB 10.3.12](#) to [MariaDB 10.3.13](#)) when Galera Cluster is being used. In a rolling upgrade, each node is upgraded individually, so the cluster is always operational. There is no downtime from the application's perspective.

Before you upgrade, it would be best to take a backup of your database. This is always a good idea to do before an upgrade. We would recommend [Mariabackup](#).

For each node, perform the following steps:

1. [Stop MariaDB](#).
2. Install the new version of MariaDB and the Galera wsrep provider.
  - On Debian, Ubuntu, and other similar Linux distributions, see [Installing MariaDB Packages with APT](#) for more information.
  - On RHEL, CentOS, Fedora, and other similar Linux distributions, see [Installing MariaDB Packages with YUM](#) for more information.
  - On SLES, OpenSUSE, and other similar Linux distributions, see [Installing MariaDB Packages with ZYpp](#) for more information.
3. Make any desired changes to configuration options in [option files](#), such as  
`my.cnf`  
. This includes removing any system variables or options that are no longer supported.
4. [Start MariaDB](#).
5. Run

`mysql_upgrade`

with the  
`--skip-write-binlog`  
option.

◦

`mysql_upgrade`  
does two things:  
1. Ensures that the system tables in the

`mysq`

1  
database are fully compatible with the new version.

2. Does a very quick check of all tables and marks them as compatible with the new version of MariaDB.

When this process is done for one node, move onto the next node.

Note that when upgrading the Galera wsrep provider, sometimes the Galera protocol version can change. The Galera wsrep provider should not start using the new protocol version until all cluster nodes have been upgraded to the new version, so this is not generally an issue during a rolling upgrade. However, this can cause issues if you restart a non-upgraded node in a cluster where the rest of the nodes have been upgraded.

### 2.1.3.10.2 Upgrading from MariaDB 10.3 to MariaDB 10.4 with Galera Cluster

MariaDB starting with [10.1](#)

Since [MariaDB 10.1](#), the [MySQL-wsrep](#) patch has been merged into MariaDB Server. Therefore, in [MariaDB 10.1](#) and above, the functionality of MariaDB Galera Cluster can be obtained by installing the standard MariaDB Server packages and the Galera wsrep provider library package.

Beginning in [MariaDB 10.1](#), [Galera Cluster](#) ships with the MariaDB Server. Upgrading a Galera Cluster node is very similar to upgrading a server from [MariaDB 10.3](#) to [MariaDB 10.4](#). For more information on that process as well as incompatibilities between versions, see the [Upgrade Guide](#).

#### Performing a Rolling Upgrade

The following steps can be used to perform a rolling upgrade from [MariaDB 10.3](#) to [MariaDB 10.4](#) when using Galera Cluster. In a rolling upgrade, each

node is upgraded individually, so the cluster is always operational. There is no downtime from the application's perspective.

First, before you get started:

1. First, take a look at [Upgrading from MariaDB 10.3 to MariaDB 10.4](#) to see what has changed between the major versions.
  1. Check whether any system variables or options have been changed or removed. Make sure that your server's configuration is compatible with the new MariaDB version before upgrading.
  2. Check whether replication has changed in the new MariaDB version in any way that could cause issues while the cluster contains upgraded and non-upgraded nodes.
  3. Check whether any new features have been added to the new MariaDB version. If a new feature in the new MariaDB version cannot be replicated to the old MariaDB version, then do not use that feature until all cluster nodes have been upgraded to the new MariaDB version.
2. Next, make sure that the Galera version numbers are compatible.
  1. If you are upgrading from the most recent [MariaDB 10.3](#) release to [MariaDB 10.4](#), then the versions will be compatible. [MariaDB 10.3](#) uses Galera 3 (i.e. Galera wsrep provider versions 25.3.x), and [MariaDB 10.4](#) uses Galera 4 (i.e. Galera wsrep provider versions 26.4.x). This means that upgrading to [MariaDB 10.4](#) also upgrades the system to Galera 4. However, Galera 3 and Galera 4 should be compatible for the purposes of a rolling upgrade, as long as you are using Galera 26.4.2 or later.
  2. See [What is MariaDB Galera Cluster?: Galera wsrep provider Versions](#) for information on which MariaDB releases uses which Galera wsrep provider versions.
3. Ideally, you want to have a large enough gcache to avoid a [State Snapshot Transfer \(SST\)](#) during the rolling upgrade. The gcache size can be configured by setting

```
gcache.size
```

For example:

```
wsrep_provider_options="gcache.size=2G"
```

Before you upgrade, it would be best to take a backup of your database. This is always a good idea to do before an upgrade. We would recommend [Mariabackup](#).

Then, for each node, perform the following steps:

1. Modify the repository configuration, so the system's package manager installs [MariaDB 10.4](#). For example,
  - On Debian, Ubuntu, and other similar Linux distributions, see [Updating the MariaDB APT repository to a New Major Release](#) for more information.
  - On RHEL, CentOS, Fedora, and other similar Linux distributions, see [Updating the MariaDB YUM repository to a New Major Release](#) for more information.
  - On SLES, OpenSUSE, and other similar Linux distributions, see [Updating the MariaDB ZYpp repository to a New Major Release](#) for more information.
2. If you use a load balancing proxy such as MaxScale or HAProxy, make sure to drain the server from the pool so it does not receive any new connections.
3. [Stop MariaDB](#).
4. Uninstall the old version of MariaDB and the Galera wsrep provider.
  - On Debian, Ubuntu, and other similar Linux distributions, execute the following:

```
sudo apt-get remove mariadb-server galera
```
  - On RHEL, CentOS, Fedora, and other similar Linux distributions, execute the following:

```
sudo yum remove MariaDB-server galera
```
  - On SLES, OpenSUSE, and other similar Linux distributions, execute the following:

```
sudo zypper remove MariaDB-server galera
```

5. Install the new version of MariaDB and the Galera wsrep provider.
  - On Debian, Ubuntu, and other similar Linux distributions, see [Installing MariaDB Packages with APT](#) for more information.
  - On RHEL, CentOS, Fedora, and other similar Linux distributions, see [Installing MariaDB Packages with YUM](#) for more information.
  - On SLES, OpenSUSE, and other similar Linux distributions, see [Installing MariaDB Packages with ZYpp](#) for more information.

6. Make any desired changes to configuration options in [option files](#), such as

```
my.cnf
. This includes removing any system variables or options that are no longer supported.
```

7. On Linux distributions that use

```
systemd
you may need to increase the service startup timeout as the default timeout of 90 seconds may not be sufficient. See Systemd: Configuring the Systemd Service Timeout for more information.
```

8. [Start MariaDB](#).

9. Run

```
mysql_upgrade
```

with the

```
--skip-write-binlog  
option.  
◦  
mysql_upgrade  
does two things:  
1. Ensures that the system tables in the
```

```
mysql
```

```
1  
database are fully compatible with the new version.
```

```
2. Does a very quick check of all tables and marks them as compatible with the new version of MariaDB .
```

When this process is done for one node, move onto the next node.

Note that when upgrading the Galera wsrep provider, sometimes the Galera protocol version can change. The Galera wsrep provider should not start using the new protocol version until all cluster nodes have been upgraded to the new version, so this is not generally an issue during a rolling upgrade. However, this can cause issues if you restart a non-upgraded node in a cluster where the rest of the nodes have been upgraded.

## 2.1.3.10.3 Upgrading from MariaDB 10.2 to MariaDB 10.3 with Galera Cluster

MariaDB starting with [10.1](#)

Since [MariaDB 10.1](#), the MySQL-wsrep patch has been merged into MariaDB Server. Therefore, in [MariaDB 10.1](#) and above, the functionality of MariaDB Galera Cluster can be obtained by installing the standard MariaDB Server packages and the Galera wsrep provider library package.

Beginning in [MariaDB 10.1](#), Galera Cluster ships with the MariaDB Server. Upgrading a Galera Cluster node is very similar to upgrading a server from [MariaDB 10.2](#) to [MariaDB 10.3](#). For more information on that process as well as incompatibilities between versions, see the [Upgrade Guide](#).

## Performing a Rolling Upgrade

The following steps can be used to perform a rolling upgrade from [MariaDB 10.2](#) to [MariaDB 10.3](#) when using Galera Cluster. In a rolling upgrade, each node is upgraded individually, so the cluster is always operational. There is no downtime from the application's perspective.

First, before you get started:

1. First, take a look at [Upgrading from MariaDB 10.2 to MariaDB 10.3](#) to see what has changed between the major versions.
  1. Check whether any system variables or options have been changed or removed. Make sure that your server's configuration is compatible with the new MariaDB version before upgrading.
  2. Check whether replication has changed in the new MariaDB version in any way that could cause issues while the cluster contains upgraded and non-upgraded nodes.
  3. Check whether any new features have been added to the new MariaDB version. If a new feature in the new MariaDB version cannot be replicated to the old MariaDB version, then do not use that feature until all cluster nodes have been upgraded to the new MariaDB version.
2. Next, make sure that the Galera version numbers are compatible.
  1. If you are upgrading from the most recent [MariaDB 10.2](#) release to [MariaDB 10.3](#), then the versions will be compatible. Both [MariaDB 10.2](#) and [MariaDB 10.3](#) use Galera 3 (i.e. Galera wsrep provider versions 25.3.x), so they should be compatible.
  2. See [What is MariaDB Galera Cluster?: Galera wsrep provider Versions](#) for information on which MariaDB releases uses which Galera wsrep provider versions.
3. Ideally, you want to have a large enough gcache to avoid a [State Snapshot Transfer \(SST\)](#) during the rolling upgrade. The gcache size can be configured by setting

```
gcache.size
```

For example:

```
wsrep_provider_options="gcache.size=2G"
```

Before you upgrade, it would be best to take a backup of your database. This is always a good idea to do before an upgrade. We would recommend [Mariabackup](#).

Then, for each node, perform the following steps:

1. Modify the repository configuration, so the system's package manager installs [MariaDB 10.3](#). For example,
  - On Debian, Ubuntu, and other similar Linux distributions, see [Updating the MariaDB APT repository to a New Major Release](#) for more information.
  - On RHEL, CentOS, Fedora, and other similar Linux distributions, see [Updating the MariaDB YUM repository to a New Major Release](#) for more information.

- On SLES, OpenSUSE, and other similar Linux distributions, see [Updating the MariaDB ZYpp repository to a New Major Release](#) for more information.
- If you use a load balancing proxy such as MaxScale or HAProxy, make sure to drain the server from the pool so it does not receive any new connections.
  - [Stop MariaDB](#).
  - Uninstall the old version of MariaDB and the Galera wsrep provider.
    - On Debian, Ubuntu, and other similar Linux distributions, execute the following:

```
sudo apt-get remove mariadb-server galera
```

- On RHEL, CentOS, Fedora, and other similar Linux distributions, execute the following:

```
sudo yum remove MariaDB-server galera
```

- On SLES, OpenSUSE, and other similar Linux distributions, execute the following:

```
sudo zypper remove MariaDB-server galera
```

- Install the new version of MariaDB and the Galera wsrep provider.

- On Debian, Ubuntu, and other similar Linux distributions, see [Installing MariaDB Packages with APT](#) for more information.
- On RHEL, CentOS, Fedora, and other similar Linux distributions, see [Installing MariaDB Packages with YUM](#) for more information.
- On SLES, OpenSUSE, and other similar Linux distributions, see [Installing MariaDB Packages with ZYpp](#) for more information.

- Make any desired changes to configuration options in [option files](#), such as

`my.cnf`

. This includes removing any system variables or options that are no longer supported.

- On Linux distributions that use

`systemd`

you may need to increase the service startup timeout as the default timeout of 90 seconds may not be sufficient. See [Systemd: Configuring the Systemd Service Timeout](#) for more information.

- [Start MariaDB](#).

- Run

`mysql_upgrade`

with the

`--skip-write-binlog`  
option.

- 

`mysql_upgrade`  
does two things:

- Ensures that the system tables in the

`mysq`

`l`

database are fully compatible with the new version.

- Does a very quick check of all tables and marks them as compatible with the new version of MariaDB .

When this process is done for one node, move onto the next node.

Note that when upgrading the Galera wsrep provider, sometimes the Galera protocol version can change. The Galera wsrep provider should not start using the new protocol version until all cluster nodes have been upgraded to the new version, so this is not generally an issue during a rolling upgrade. However, this can cause issues if you restart a non-upgraded node in a cluster where the rest of the nodes have been upgraded.

## 2.1.3.10.4 Upgrading from MariaDB 10.1 to MariaDB 10.2 with Galera Cluster

MariaDB starting with [10.1](#)

Since [MariaDB 10.1](#), the [MySQL-wsrep](#) patch has been merged into MariaDB Server. Therefore, in [MariaDB 10.1](#) and above, the functionality of MariaDB Galera Cluster can be obtained by installing the standard MariaDB Server packages and the Galera wsrep provider library package.

## Contents

1. Performing a Rolling Upgrade
  1. Additional details
    1. Checking Status of the State Transfer
    1. State Transfers that Provide Access to the Server
    2. State Transfers that Require the Server to be Down

Beginning in MariaDB 10.1 , Galera Cluster ships with the MariaDB Server. Upgrading a Galera Cluster node is very similar to upgrading a server from MariaDB 10.1 to MariaDB 10.2 . For more information on that process as well as incompatibilities between versions, see the [Upgrade Guide](#) .

## Performing a Rolling Upgrade

The following steps can be used to perform a rolling upgrade from MariaDB 10.1 to MariaDB 10.2 when using Galera Cluster. In a rolling upgrade, each node is upgraded individually, so the cluster is always operational. There is no downtime from the application's perspective.

First, before you get started:

1. First, take a look at [Upgrading from MariaDB 10.1 to MariaDB 10.2](#) to see what has changed between the major versions.
  1. Check whether any system variables or options have been changed or removed. Make sure that your server's configuration is compatible with the new MariaDB version before upgrading.
  2. Check whether replication has changed in the new MariaDB version in any way that could cause issues while the cluster contains upgraded and non-upgraded nodes.
  3. Check whether any new features have been added to the new MariaDB version. If a new feature in the new MariaDB version cannot be replicated to the old MariaDB version, then do not use that feature until all cluster nodes have been upgraded to the new MariaDB version.
2. Next, make sure that the Galera version numbers are compatible.
  1. If you are upgrading from the most recent MariaDB 10.1 release to MariaDB 10.2 , then the versions will be compatible. Both MariaDB 10.1 and MariaDB 10.2 use Galera 3 (i.e. Galera wsrep provider versions 25.3.x), so they should be compatible.
  2. See [What is MariaDB Galera Cluster?: Galera wsrep provider Versions](#) for information on which MariaDB releases uses which Galera wsrep provider versions.
3. Ideally, you want to have a large enough gcache to avoid a [State Snapshot Transfer \(SST\)](#) during the rolling upgrade. The gcache size can be configured by setting

`gcache.size`

For example:

```
wsrep_provider_options="gcache.size=2G"
```

Before you upgrade, it would be best to take a backup of your database. This is always a good idea to do before an upgrade. We would recommend [Mariabackup](#) .

Then, for each node, perform the following steps:

1. Modify the repository configuration, so the system's package manager installs MariaDB 10.2 . For example,
  - On Debian, Ubuntu, and other similar Linux distributions, see [Updating the MariaDB APT repository to a New Major Release](#) for more information.
  - On RHEL, CentOS, Fedora, and other similar Linux distributions, see [Updating the MariaDB YUM repository to a New Major Release](#) for more information.
  - On SLES, OpenSUSE, and other similar Linux distributions, see [Updating the MariaDB ZYpp repository to a New Major Release](#) for more information.
2. If you use a load balancing proxy such as MaxScale or HAProxy, make sure to drain the server from the pool so it does not receive any new connections.
3. Set

`innodb_fast_shutdown`

```
to  
0  
. It can be changed dynamically with
```

`SET GLOBAL`

. For example:

```
SET GLOBAL innodb_fast_shutdown=0;
```

◦ This step is not necessary when upgrading to MariaDB 10.2.5 or later. Omitting it can make the upgrade process far faster. See [MDEV-1025](#).

[12289](#) for more information.

4. [Stop MariaDB](#) .

5. Uninstall the old version of MariaDB and the Galera wsrep provider.

- On Debian, Ubuntu, and other similar Linux distributions, execute the following:

```
sudo apt-get remove mariadb-server galera
```

- On RHEL, CentOS, Fedora, and other similar Linux distributions, execute the following:

```
sudo yum remove MariaDB-server galera
```

- On SLES, OpenSUSE, and other similar Linux distributions, execute the following:

```
sudo zypper remove MariaDB-server galera
```

6. Install the new version of MariaDB and the Galera wsrep provider.

- On Debian, Ubuntu, and other similar Linux distributions, see [Installing MariaDB Packages with APT](#) for more information.
- On RHEL, CentOS, Fedora, and other similar Linux distributions, see [Installing MariaDB Packages with YUM](#) for more information.
- On SLES, OpenSUSE, and other similar Linux distributions, see [Installing MariaDB Packages with ZYpp](#) for more information.

7. Make any desired changes to configuration options in [option files](#) , such as

`my.cnf`

. This includes removing any system variables or options that are no longer supported.

- In order to use Galera Cluster without problems in [MariaDB 10.2](#) , the

`innodb_lock_schedule_algorithm`

system variable must be set to

`FCFS`

. In [MariaDB 10.2.12](#) and later, this system variable is automatically set to this value when Galera Cluster is enabled. In [MariaDB 10.2.11](#) and before, this system variable must be set to this value manually. See [MDEV-12837](#) for more information.

8. On Linux distributions that use

`systemd`

you may need to increase the service startup timeout as the default timeout of 90 seconds may not be sufficient. See [Systemd: Configuring the Systemd Service Timeout](#) for more information.

9. [Start MariaDB](#) .

10. Run

`mysql_upgrade`

with the

`--skip-write-binlog`  
option.

- 

`mysql_upgrade`  
does two things:

1. Ensures that the system tables in the

`mysq`

`1`

database are fully compatible with the new version.

2. Does a very quick check of all tables and marks them as compatible with the new version of MariaDB .

When this process is done for one node, move onto the next node.

Note that when upgrading the Galera wsrep provider, sometimes the Galera protocol version can change. The Galera wsrep provider should not start using the new protocol version until all cluster nodes have been upgraded to the new version, so this is not generally an issue during a rolling upgrade. However, this can cause issues if you restart a non-upgraded node in a cluster where the rest of the nodes have been upgraded.

## Additional details

### Checking Status of the State Transfer

When a node rejoins the cluster after being upgraded, it may have to perform a state transfer, such as an [Incremental State Transfer \(IST\)](#) or a [State Snapshot Transfer\(SST\)](#) . It is recommended to ensure that the node's state transfer is complete before upgrading the next node in the cluster.

### State Transfers that Provide Access to the Server

If the node is synchronizing with the cluster by performing a state transfer that allows access to the server, such as an [Incremental State Transfer \(IST\)](#) or a [State Snapshot Transfer\(SST\)](#) that uses the

```
mysqldump
```

SST method, then you can check the status of the state transfer by connecting to the server through the

```
mysql
```

client, then checking the

```
wsrep_local_state_uuid
```

and

```
wsrep_cluster_state_uuid
```

status variables. When they equal each other, the node is in sync with the cluster.

```
select if((SELECT VARIABLE_VALUE AS "uuid"
FROM information_schema.GLOBAL_STATUS
WHERE VARIABLE_NAME = "wsrep_cluster_state_uuid")=(SELECT VARIABLE_VALUE AS "uuid"
FROM information_schema.GLOBAL_STATUS
WHERE VARIABLE_NAME = "wsrep_local_state_uuid"), "Synced", "Not Synced") as "Cluster Status";
+-----+
| Cluster Status |
+-----+
| Synced         |
+-----+
```

When the local and cluster UUID's come into sync, the node is again online and functioning as a part of the cluster.

#### State Transfers that Require the Server to be Down

Some state transfers require the server to be unavailable, such as all [State Snapshot Transfer\(SST\)](#) methods other than

```
mysqldump
```

, so

```
mysql
```

client access is unavailable while the state transfer is happening. In those cases, you may have to monitor the progress of the state transfer in the [error log](#). You'll know when the SST is complete when the joiner node changes its state to

```
SYNCED
```

. For example:

```
2018-08-30 14:44:15 140694729484032 [Note] WSREP: Shifting JOINED -> SYNCED (TO: 210248566)
```

## 2.1.3.11 Upgrading from MySQL to MariaDB

### 2.1.3.11.1 Upgrading from MySQL to MariaDB

#### Contents

1. [Upgrading on Windows](#)
2. [Upgrading my.cnf](#)
3. [Other Things to Think About](#)
4. [See Also](#)

For [all practical purposes](#), you can view MariaDB as an upgrade of MySQL:

- Before upgrading, please [check if there are any known incompatibilities](#) between your MySQL release and the MariaDB release you want to move to.
- In particular, note that the [JSON type](#) in MariaDB is a LONGTEXT, while in MySQL it's a binary type. See [Making MariaDB understand MySQL JSON](#).
- If you are using MySQL 8.0 or above, you have to use [mysqldump](#) to move your database to MariaDB.
- For upgrading from very old MySQL versions, see [Upgrading to MariaDB from MySQL 5.0 \(or older version\)](#).
- Within the same base version (for example MySQL 5.5 -> [MariaDB 5.5](#), MySQL 5.6 -> [MariaDB 10.0](#) and MySQL 5.7 -> [MariaDB 10.2](#)) you can in most cases just uninstall MySQL and install MariaDB and you are good to go. There is no need to dump and restore databases. As with any upgrade, we recommend making a backup of your data beforehand.
- You should run

```
mysql_upgrade
```

(just as you would with MySQL) to finish the upgrade. This is needed to ensure that your mysql privilege and event tables are updated with the new fields MariaDB uses. Note that if you use a MariaDB package,

```
mysql_upgrade
```

is usually run automatically.

- All your old clients and connectors (PHP, Perl, Python, Java, etc.) will work unchanged (no need to recompile). This works because MariaDB and MySQL use the same client protocol and the client libraries are binary compatible. You can also use your old MySQL connector packages with MariaDB if you want.

## Upgrading on Windows

On Windows, you should not uninstall MySQL and install MariaDB, this would not work, the existing database will not be found.

Thus On Windows, just install MariaDB and use the upgrade wizard which is part of installer package and is launched by MSI installer. Or, in case you prefer command line, use

```
mysql_upgrade_service <service_name>
on the command line.
```

## Upgrading my.cnf

All the options in your original MySQL

```
my.cnf
file should work fine for MariaDB.
```

However as MariaDB has more features than MySQL, there is a few things that you should consider changing in your

```
my.cnf
file.
```

- MariaDB uses by default the [Aria storage engine](#) for internal temporary files instead of MyISAM. If you have a lot of temporary files, you should add and set

```
aria-pagecache-buffer-size
```

to the same value as you have for

```
key-buffer-size
```

- If you don't use MyISAM tables, you can set

```
key-buffer-size
```

to a very low value, like 64K.

- If using [MariaDB 10.1](#) or earlier, and your applications often connect and disconnect to MariaDB, you should set up

```
thread-cache-size
```

to the number of concurrent queries threads you are typically running. This is important in MariaDB as we are using the [jemalloc](#) memory allocator. [jemalloc](#) usually has better performance when running many threads compared to other memory allocators, except if you create and destroy a lot of threads, in which case it will spend a lot of resources trying to manage thread specific storage. Having a thread cache will fix this problem.

- If you have a LOT of connections (> 100) that mostly run short running queries, you should consider using the [thread pool](#). For example using :

```
thread_handling=pool-of-threads
```

and

```
thread_pool_size=128
```

could give a notable performance boost in this case. Where the

```
thread_pool_size
```

should be about

```
2 * number of cores on your machine
```

## Other Things to Think About

- Views with definition

```
ALGORITHM=MERGE
```

or

```
ALGORITHM=TEMPTABLE
```

got accidentally swapped between MariaDB and MySQL. You have to re-create views created with either of these definitions (see [MDEV-6916](#)).

- MariaDB has LGPL versions of the [C connector](#) and [Java Client](#). If you are shipping an application that supports MariaDB or MySQL, you should consider using these!

- You should consider trying out the [MyRocks storage engine](#) or some of the other [new storage engines](#) that MariaDB provides.

## See Also

## 2.1.3.11.2 Moving from MySQL to MariaDB in Debian 9

MariaDB 10.1 is now the default mysql server in Debian 9 "Stretch". This page provides information on this change and instructions to help with upgrading your Debian 8 "Jessie" version of MySQL or MariaDB to [MariaDB 10.1](#) in Debian 9 "Stretch".

### Contents

1. [Background information](#)
2. [Before you upgrade](#)
  1. [Backup before you begin](#)
  2. [Changed, renamed, and removed options](#)
    1. [Options with changed default values](#)
    2. [Options that have been removed or renamed](#)
  3. [Suggested upgrade procedure for replication](#)
  4. [Other resources to consult before beginning your upgrade](#)
3. [Upgrading to MariaDB 10.1 from MySQL 5.5](#)
4. [Upgrading to MariaDB 10.1 from an older version of MariaDB](#)
5. [MariaDB Galera Cluster](#)
6. [Configuration options for advanced database users](#)
7. [Secure passwordless root accounts only on new installs](#)
8. [See also](#)
9. [Comments and suggestions](#)
10. [Notes](#)

## Background information

The version of MySQL in Debian 8 "Jessie" is 5.5. When installing, most users will install the

```
mysql-server
package, which depends on the
mysql-server-5.5 package
. In Debian 9 "Stretch" the
mysql-server
package depends on a new package called
default-mysql-server
. This package in turn depends on
mariadb-server-10.1
. There is no
default-mysql-server
package in Jessie.
```

In both Jessie and Stretch there is also a

```
mariadb-server
package which is a MariaDB-specific analog to the
mysql-server
package. In Jessie this package depends on
mariadb-server-10.0
and in Stretch this package depends on
mariadb-server-10.1
(the same as the
default-mysql-server
package).
```

So, the main repository difference in Debian 9 "Stretch" is that when you install the

```
mysql-server
package on Stretch you will get MariaDB 10.1 instead of MySQL, like you would with previous versions of Debian. Note that
```

```
mysql-server  
is just an empty transitional meta-package and users are encouraged to install MariaDB using the actual package  
mariadb-server
```

All apps and tools, such as the popular LAMP stack, in the repositories that depend on the mysql-server package will continue to work using MariaDB as the database. For new installs there is nothing different that needs to be done when installing the mysql-server or mariadb-server packages.

## Before you upgrade

If you are currently running MySQL 5.5 on Debian 8 "Jessie" and are planning an upgrade to [MariaDB 10.1](#) on Debian 9 "Stretch", there are some things to keep in mind:

### Backup before you begin

This is a major upgrade, and so complete database backups are strongly suggested before you begin. [MariaDB 10.1](#) is compatible on disk and wire with MySQL 5.5, and the MariaDB developer team has done extensive development and testing to make upgrades as painless and trouble-free as possible. Even so, it's always a good idea to do regular backups, especially before an upgrade. As the database has to shutdown anyway for the upgrade, this is a good opportunity to do a backup!

### Changed, renamed, and removed options

Some default values have been changed, some have been renamed, and others have been removed between MySQL 5.5 and [MariaDB 10.1](#). The following sections detail them.

#### Options with changed default values

Most of the following options have increased a bit in value to give better performance. They should not use much additional memory, but some of them do use a bit more disk space.

| Option                                   | Old default value | New default value |
|------------------------------------------|-------------------|-------------------|
| <code>aria-sort-buffer-size</code>       | 128M              | 256M              |
| <code>back_log</code>                    | 50                | 150               |
| <code>innodb-concurrency-tickets</code>  | 500               | 5000              |
| <code>innodb-log-file-size</code>        | 5M                | 48M               |
| <code>innodb_log_compressed_pages</code> | ON                | OFF               |
| <code>innodb-old-blocks-time</code>      | 0                 | 1000              |

|                         |      |                                            |
|-------------------------|------|--------------------------------------------|
| innodb-open-files       | 300  | 400<br>[2]                                 |
| innodb-purge-batch-size | 20   | 300                                        |
| innodb-undo-logs        | ON   | 20                                         |
| join_buffer_size        | 128K | 256K                                       |
| max_allowed_packet      | 1M   | 4M                                         |
| max-connect-errors      | 10   | 100                                        |
| max-relay-log-size      | 0    | 1024M                                      |
| myisam-sort-buffer-size | 8M   | 128M                                       |
| optimizer-switch        | ...  | Added<br>extended_keys=on, exists_to_in=on |
| query_alloc_block_size  | 8192 | 16384                                      |
| query_cache_size        | 0    | 1M                                         |
| query_cache_type        | ON   | OFF                                        |

|                                      |       |                                                              |
|--------------------------------------|-------|--------------------------------------------------------------|
| <code>query_prealloc_size</code>     | 8192  | 24576                                                        |
| <code>secure_auth</code>             | OFF   | ON                                                           |
| <code>sql_log_bin</code>             |       | No longer affects replication of events in a Galera cluster. |
| <code>sql_mode</code>                | empty | <code>NO_AUTO_CREATE_USER, NO_ENGINE_SUBSTITUTION</code>     |
| <code>sync_master_info</code>        | 0     | 10000                                                        |
| <code>sync_relay_log</code>          | 0     | 10000                                                        |
| <code>sync_relay_log_info</code>     | 0     | 10000                                                        |
| <code>table_open_cache</code>        | 400   | 2000                                                         |
| <code>thread_pool_max_threads</code> | 500   | 1000                                                         |

### Options that have been removed or renamed

The following options should be removed or renamed if you use them in your config files:

| Option                                       | Reason                                                                                |
|----------------------------------------------|---------------------------------------------------------------------------------------|
| <code>engine-condition-pushdown</code>       | Replaced with<br><br><code>set optimizer_switch='engine_condition_pushdown=on'</code> |
| <code>innodb-adaptive-flushing-method</code> | Removed by <a href="#">XtraDB</a>                                                     |
| <code>innodb-autoextend-increment</code>     | Removed by <a href="#">XtraDB</a>                                                     |

|                                       |                                                      |
|---------------------------------------|------------------------------------------------------|
| innodb-blocking-buffer-pool-restore   | Removed by <a href="#">XtraDB</a>                    |
| innodb-buffer-pool-pages              | Removed by <a href="#">XtraDB</a>                    |
| innodb-buffer-pool-pages-blob         | Removed by <a href="#">XtraDB</a>                    |
| innodb-buffer-pool-pages-index        | Removed by <a href="#">XtraDB</a>                    |
| innodb-buffer-pool-restore-at-startup | Removed by <a href="#">XtraDB</a>                    |
| innodb-buffer-pool-shm-checksum       | Removed by <a href="#">XtraDB</a>                    |
| innodb-buffer-pool-shm-key            | Removed by <a href="#">XtraDB</a>                    |
| innodb-checkpoint-age-target          | Removed by <a href="#">XtraDB</a>                    |
| innodb-dict-size-limit                | Removed by <a href="#">XtraDB</a>                    |
| innodb-doublewrite-file               | Removed by <a href="#">XtraDB</a>                    |
| innodb-fast-checksum                  | Renamed to <a href="#">innodb-checksum-algorithm</a> |
| innodb-flush-neighbor-pages           | Renamed to <a href="#">innodb-flush-neighbors</a>    |
| innodb-ibuf-accel-rate                | Removed by <a href="#">XtraDB</a>                    |
| innodb-ibuf-active-contract           | Removed by <a href="#">XtraDB</a>                    |
| innodb-ibuf-max-size                  | Removed by <a href="#">XtraDB</a>                    |
| innodb-import-table-from-xtrabackup   | Removed by <a href="#">XtraDB</a>                    |
| innodb-index-stats                    | Removed by <a href="#">XtraDB</a>                    |
| innodb-lazy-drop-table                | Removed by <a href="#">XtraDB</a>                    |
| innodb-merge-sort-block-size          | Removed by <a href="#">XtraDB</a>                    |

|                                       |                                        |
|---------------------------------------|----------------------------------------|
| innodb-persistent-stats-root-page     | Removed by <a href="#">XtraDB</a>      |
| innodb-read-ahead                     | Removed by <a href="#">XtraDB</a>      |
| innodb-recovery-stats                 | Removed by <a href="#">XtraDB</a>      |
| innodb-recovery-update-relay-log      | Removed by <a href="#">XtraDB</a>      |
| innodb-stats-auto-update              | Renamed to<br>innodb-stats-auto-recalc |
| innodb-stats-update-need-lock         | Removed by <a href="#">XtraDB</a>      |
| innodb-sys-stats                      | Removed by <a href="#">XtraDB</a>      |
| innodb-table-stats                    | Removed by <a href="#">XtraDB</a>      |
| innodb-thread-concurrency-timer-based | Removed by <a href="#">XtraDB</a>      |
| innodb-use-sys-stats-table            | Removed by <a href="#">XtraDB</a>      |
| rpl_recovery_rank                     | Unused in 10.0+                        |
| xtradb-admin-command                  | Removed by <a href="#">XtraDB</a>      |

## Suggested upgrade procedure for replication

If you have a [master-slave setup](#), the normal procedure is to first upgrade your slaves to MariaDB, then move one of your slaves to be the master and then upgrade your original master. In this scenario you can upgrade from MySQL to MariaDB or upgrade later to a new version of MariaDB without any downtime.

## Other resources to consult before beginning your upgrade

It may also be useful to check out the [Upgrading MariaDB](#) section. It contains several articles on upgrading from MySQL to MariaDB and from one version of MariaDB to another. For upgrade purposes, MySQL 5.5 and [MariaDB 5.5](#) are very similar. In particular, see the [Upgrading from MariaDB 5.5 to MariaDB 10.0](#) and [Upgrading from MariaDB 10.0 to MariaDB 10.1](#) articles.

If you need help with upgrading or setting up replication, you can always [contact the MariaDB corporation](#) to find experts to help you with this.

## Upgrading to MariaDB 10.1 from MySQL 5.5

The suggested upgrade procedure is:

1. Set `innodb_fast_shutdown` to
  - 0
  - . This is to ensure that if you make a backup as part of the upgrade, all data is written to the InnoDB data files, which simplifies any restore in the future.
2. Shutdown MySQL 5.5
3. Take a [backup](#)
  - when the server is shut down is the perfect time to take a backup of your databases

- store a copy of the backup on external media or a different machine for safety
4. Perform the upgrade from Debian 8 to Debian 9
  5. During the upgrade, the [mysql\\_upgrade](#) script will be run automatically; this script does two things:
    1. Upgrades the permission tables in the
 

```
mysql
database with some new fields
```
    2. Does a very quick check of all tables and marks them as compatible with [MariaDB 10.1](#)
      - In most cases this should be a fast operation (depending of course on the number of tables)
  6. Add new options to [my.cnf](#) to enable features
    - If you change
 

```
my.cnf
then you need to restart
mysqld
with e.g.
sudo service mysql restart
or
sudo service mariadb restart
```
    -

## Upgrading to [MariaDB 10.1](#) from an older version of MariaDB

If you have installed [MariaDB 5.5](#) or [MariaDB 10.0](#) on your Debian 8 "Jessie" machine from the MariaDB repositories you will need to upgrade to [MariaDB 10.1](#) when upgrading to Debian 9 "Stretch". You can choose to continue using the MariaDB repositories or move to using the Debian repositories.

If you want to continue using the MariaDB repositories edit the MariaDB entry in your sources.list and change every instance of 5.5 or 10.0 to 10.1. Then upgrade as suggested [above](#).

If you want to move to using [MariaDB 10.1](#) from the Debian repositories, delete or comment out the MariaDB entries in your sources.list file. Then upgrade as suggested [above](#).

If you are already using [MariaDB 10.1](#) on your Debian 8 "Jessie" machine, you can choose to continue to use the MariaDB repositories or move to using the Debian repositories as with [MariaDB 5.5](#) and 10.0. In either case, the upgrade will at most be just a minor upgrade from one version of [MariaDB 10.1](#) to a newer version. In the case that you are already on the current version of MariaDB that exists in the Debian repositories or a newer one) MariaDB will not be upgraded during the system upgrade but will be upgraded when future versions of MariaDB are released.

You should always perform a compete backup of your data prior to performing any major system upgrade, even if MariaDB itself is not being upgraded!

## MariaDB Galera Cluster

If you have been using MariaDB Galera Cluster 5.5 or 10.0 on Debian 8 "Jessie" it is worth mentioning that [Galera Cluster](#) is included by default in [MariaDB 10.1](#), there is no longer a need to install a separate

```
mariadb-galera-server
package.
```

## Configuration options for advanced database users

To get better performance from MariaDB used in production environments, here are some suggested additions to [your configuration file](#) which in Debian is at

```
/etc/mysql/mariadb.d/my.cnf
:
```

```
[[mysqld]]
# Cache for disk based temporary files
aria_pagecache_buffer_size=128M
# If you are not using MyISAM tables directly (most people are using InnoDB)
key_buffer_size=64K
```

The reason for the above change is that MariaDB is using the newer [Aria](#) storage engine for disk based temporary files instead of MyISAM. The main benefit of Aria is that it can cache both indexes and rows and thus gives better performance than MyISAM for large queries.

## Secure passwordless root accounts only on new installs

Unlike the old MySQL packages in Debian, [MariaDB 10.0](#) onwards in Debian uses unix socket authentication on new installs to avoid root password management issues and thus be more secure and easier to use with provision systems of the cloud age.

This only affects new installs. Upgrades from old versions will continue to use whatever authentication and user accounts already existed. This is however good to know, because it can affect upgrades of dependant systems, typically e.g. require users to rewrite their Ansible scripts and similar tasks. The new feature is much easier than the old, so adjusting for it requires little work.

## Comments and suggestions

If you have comments or suggestions on things we can add or change to improve this page. Please add them as comments below.

## Notes

1. ↑ The

```
innodb-open-files  
variable defaults to the value of  
table-open-cache  
(  
400  
is the default) if it is set to any value less than  
10  
so long as  
innodb-file-per-table  
is set to  
1  
or  
TRUE  
(the default). If  
innodb_file_per_table  
is set to  
0  
or  
FALSE  
and  
innodb-open-files  
is set to a value less than  
10  
, the default is  
300
```

### 2.1.3.11.3 Screencast for Upgrading MySQL to MariaDB

There is a [screencast](#) for upgrading from MySQL 5.1.55 to MariaDB. Watch this example to see how easy this process is. It really is just a "drop in replacement" to MySQL.

## 2.1.4 Downgrading between Major Versions of MariaDB

Downgrading MariaDB is not supported. The only reliable way to downgrade is to [restore from a full backup](#) made before upgrading, and start the old version of MariaDB.

Some people have reported successfully downgrading, but there are many possible things that can go wrong, and downgrading is not tested in any way by the MariaDB developers.

Between major releases, there are often substantial changes, even if none of the new features are used. For example, both [MariaDB 10.2](#) and [MariaDB 10.3](#) introduce new versions of the redo log.

Even within minor releases, there may be problems, for example [MariaDB 10.1.21](#) fixed a file format incompatibility bug that prevents a downgrade to earlier [MariaDB 10.1](#) releases.

## 2.1.5 Compiling MariaDB From Source

### 2.1.6

#### 2.1.6.1 Starting and Stopping MariaDB

## Contents

- 1. Service Managers
  - 1. [Systemd](#)
  - 2. [SysVinit](#)
  - 3. [launchd](#)
  - 4. [Upstart](#)
- 2. Starting the Server Process Manually
  - 1. [mysqld](#)
  - 2. [mysqld\\_safe](#)
  - 3. [mysqld\\_multi](#)
  - 4. [mysql.server](#)

There are several different methods to start or stop the MariaDB Server process. There are two primary categories that most of these methods fall into: starting the process with the help of a service manager, and starting the process manually.

## Service Managers

[sysVinit](#) and [systemd](#) are the most common Linux service managers. [launchd](#) is used in MacOS X. [Upstart](#) is a less common service manager.

### Systemd

RHEL/CentOS 7 and above, Debian 8 Jessie and above, and Ubuntu 15.04 and above use [systemd](#) by default.

For information on how to start and stop MariaDB with this service manager, see [systemd: Interacting with the MariaDB Server Process](#).

### SysVinit

RHEL/CentOS 6 and below, and Debian 7 Wheezy and below use [sysVinit](#) by default.

For information on how to start and stop MariaDB with this service manager, see [sysVinit: Interacting with the MariaDB Server Process](#).

### launchd

[launchd](#) is used in MacOS X.

### Upstart

Ubuntu 14.10 and below use Upstart by default.

## Starting the Server Process Manually

### mysqld

[mysqld](#) is the actual MariaDB Server binary. It can be started manually on its own.

### mysqld\_safe

[mysqld\\_safe](#) is a wrapper that can be used to start the [mysqld](#) server process. The script has some built-in safeguards, such as automatically restarting the server process if it dies. See [mysqld\\_safe](#) for more information.

### mysqld\_multi

[mysqld\\_multi](#) is a wrapper that can be used to start the [mysqld](#) server process if you plan to run multiple server processes on the same host. See [mysqld\\_multi](#) for more information.

### mysql.server

[mysql.server](#) is a wrapper that works as a standard [sysVinit](#) script. However, it can be used independently of [sysVinit](#) as a regular `sh` script. The script starts the [mysqld](#) server process by first changing its current working directory to the MariaDB install directory and then starting [mysqld\\_safe](#). The script requires the standard [sysVinit](#) arguments, such as  
`start`  
`,`  
`stop`  
`, and`  
`status`  
. See [mysql.server](#) for more information.

## 2.1.6.2 Configuring MariaDB with Option Files

### Contents

1. [Global Options Related to Option Files](#)
2. [Default Option File Locations](#)
  1. Default Option File Locations on Linux, Unix, Mac
  2. Default Option File Locations on Windows
  3. Default Option File Hierarchy
3. [Custom Option File Locations](#)
4. [Option File Syntax](#)
5. [Option Groups](#)
  1. Server Option Groups
  2. Client Option Groups
  3. Tool-Specific Option Groups
  4. Custom Option Group Suffixes
6. [Including Option Files](#)
7. [Including Option File Directories](#)
8. [Checking Program Options](#)
9. [MySQL 5.6 Obfuscated Authentication Credential Option File](#)
10. [Option Prefixes](#)
11. [Options](#)
  1. MariaDB Server Options
  2. MariaDB Client Options
12. [Example Option Files](#)
  1. [Example Minimal Option File](#)
  2. [Example Hybrid Option File](#)
13. [See Also](#)

You can configure MariaDB to run the way you want by configuring the server with MariaDB's option files. The default MariaDB option file is called

`my.cnf`

on Unix-like operating systems and

`my.ini`

on Windows. Depending on how you've [installed](#) MariaDB, the default option file may be in a number of places, or it may not exist at all.

## Global Options Related to Option Files

The following options relate to how MariaDB handles option files. These options can be used with most of MariaDB's command-line tools, not just `mysqld`. They must be given as the first argument on the command-line:

| Option                                                   | Description                                                                         |
|----------------------------------------------------------|-------------------------------------------------------------------------------------|
| <code>--print-defaults</code>                            | Read options from option files, print all option values, and then exit the program. |
| <code>--no-defaults</code>                               | Don't read options from any option file.                                            |
| <code>--defaults-file</code><br><code>=path</code>       | Only read options from the given option file.                                       |
| <code>--defaults-extra-file</code><br><code>=path</code> | Read this extra option file after all other option files are read.                  |

|                                            |                                                                                                 |
|--------------------------------------------|-------------------------------------------------------------------------------------------------|
| <pre>--defaults-group-suffix =suffix</pre> | <p>In addition to the default option groups, also read option groups with the given suffix.</p> |
|--------------------------------------------|-------------------------------------------------------------------------------------------------|

## Default Option File Locations

MariaDB reads option files from many different directories by default. See the sections below to find out which directories are checked for which system.

For an exact list of option files read on your system by a specific program, you can execute:

```
$program --help --verbose
```

For example:

```
$ mysqld --help --verbose
mysqld Ver 10.3.13-MariaDB-log for Linux on x86_64 (MariaDB Server)
Copyright (c) 2000, 2018, Oracle, MariaDB Corporation Ab and others.

Starts the MariaDB database server.

Usage: mysqld [OPTIONS]

Default options are read from the following files in the given order:
/etc/my.cnf ~/.my.cnf
The following groups are read: mysqld server mysqld-10.3 mariadb mariadb-10.3 client-server galera
....
```

The option files are each scanned once, in the order given by

- `--help` --verbose
- . The effect of the configuration options are as if they would have been given as command line options in the order they are found.

## Default Option File Locations on Linux, Unix, Mac

On Linux, Unix, or Mac OS X, the default option file is called

- `my.cnf`
- . MariaDB looks for the MariaDB option file in the locations and orders listed below.

The locations are dependent on whether the

`DEFAULT_SYSCONFDIR`

`cmake`

option was defined when MariaDB was built. This option is usually defined as  
`/etc`  
when building [RPM packages](#), but it is usually not defined when building [DEB packages](#) or [binary tarballs](#).

- When the

`DEFAULT_SYSCONFDIR`

`cmake`

option was **not** defined, MariaDB looks for the MariaDB option file in the following locations in the following order:

| Location                           | Scope  |
|------------------------------------|--------|
| <code>/etc/my.cnf</code>           | Global |
| <code>/etc/mysql/my.cnf</code>     | Global |
| <code>\$MARIADB_HOME/my.cnf</code> | Server |

|                     |                                                          |
|---------------------|----------------------------------------------------------|
| \$MYSQL_HOME/my.cnf | Server                                                   |
| defaults-extra-file | File specified with<br>--defaults-extra-file<br>, if any |
| ~/.my.cnf           | User                                                     |

- When the

DEFAULT\_SYSConFDIR

cmake

option was defined, MariaDB looks for the MariaDB option file in the following locations in the following order:

| Location                  | Scope                                                    |
|---------------------------|----------------------------------------------------------|
| DEFAULT_SYSConFDIR/my.cnf | Global                                                   |
| \$MARIADB_HOME/my.cnf     | Server (from <a href="#">MariaDB 10.6</a> )              |
| \$MYSQL_HOME/my.cnf       | Server                                                   |
| defaults-extra-file       | File specified with<br>--defaults-extra-file<br>, if any |
| ~/.my.cnf                 | User                                                     |

- MARIADB\_HOME  
(from [MariaDB 10.6](#)) or  
MYSQL\_HOME  
is the [environment variable](#) containing the path to the directory holding the server-specific  
my.cnf  
file. If  
MYSQL\_HOME  
is not set, and the server is started with [mysqld\\_safe](#) ,  
MYSQL\_HOME  
is set as follows:
  - If there is a  
my.cnf  
file in the MariaDB data directory, but not in the MariaDB base directory,  
MYSQL\_HOME  
is set to the MariaDB data directory.
  - Else,  
MYSQL\_HOME  
is set to the MariaDB base directory.
- Note that if  
MARIADB\_HOME  
is set (from [MariaDB 10.6](#) ),  
MYSQL\_HOME  
will not be used, even if set.

## Default Option File Locations on Windows

On Windows, the option file can be called either

my.ini

or

my.cnf

. MariaDB looks for the MariaDB option file in the following locations in the following order:

| Location                        | Scope                                                            |
|---------------------------------|------------------------------------------------------------------|
| System Windows Directory\my.ini | Global                                                           |
| System Windows Directory\my.cnf | Global                                                           |
| Windows Directory\my.ini        | Global                                                           |
| Windows Directory\my.cnf        | Global                                                           |
| C:\my.ini                       | Global                                                           |
| C:\my.cnf                       | Global                                                           |
| INSTALLDIR\my.ini               | Server                                                           |
| INSTALLDIR\my.cnf               | Server                                                           |
| INSTALLDIR\data\my.ini          | Server                                                           |
| INSTALLDIR\data\my.cnf          | Server                                                           |
| %MARIADB_HOME%\my.ini           | Server (from <a href="#">MariaDB 10.6</a> )                      |
| %MARIADB_HOME%\my.cnf           | Server (from <a href="#">MariaDB 10.6</a> )                      |
| %MYSQL_HOME%\my.ini             | Server                                                           |
| %MYSQL_HOME%\my.cnf             | Server                                                           |
| defaults-extra-file             | File specified with<br><br>--defaults-extra-file<br><br>, if any |

- The

System Windows Directory  
is the directory returned by the

[GetSystemWindowsDirectory](#)

function. The value is usually

C:\Windows

. To find its specific value on your system, open

`cmd.exe`

and execute:

```
echo %WINDIR%
```

- The

Windows Directory  
is the directory returned by the

`GetWindowsDirectory`

function. The value may be a private  
Windows Directory  
for the application, or it may be the same as the  
System Windows Directory  
returned by the

`GetSystemWindowsDirectory`

function.

- `INSTALLDIR`  
is the parent directory of the directory where  
`mysqld.exe`  
is located. For example, if  
`mysqld.exe`  
is in  
`C:\Program Files\`

`MariaDB 10.3`

`\bin`  
, then  
`INSTALLDIR`  
would be  
`C:\Program Files\`

`MariaDB 10.3`

- `MARIADB_HOME`  
(from [MariaDB 10.6](#)) or  
`MYSQL_HOME`  
is the [environment variable](#) containing the path to the directory holding the server-specific  
`my.cnf`  
file.

- Note that if

`MARIADB_HOME`  
is set (from [MariaDB 10.6](#)),  
`MYSQL_HOME`  
will not be used, even if set.

## Default Option File Hierarchy

MariaDB will look in all of the above locations, in order, even if it has already found an option file, and it's possible for more than one option file to exist. For example, you could have an option file in

`/etc/my.cnf`  
with global settings for all servers, and then you could another option file in  
`~/.my.cnf`  
(i.e. your user account's home directory) which will specify additional settings (or override previously specified setting) that are specific only to that user.

Option files are usually optional. However, if the

`--defaults-file`

option is set, and if the file does not exist, then MariaDB will raise an error. If the

`--defaults-file`

option is set, then MariaDB will *only* read the option file referred to by this option.

If an option or system variable is not explicitly set, then it will be set to its default value. See [Server System Variables](#) for a full list of all server system variables and their default values.

## Custom Option File Locations

MariaDB can be configured to read options from custom options files with the following command-line arguments. These command-line arguments can be used with most of MariaDB's command-line tools, not just

`mysqld`

. They must be given as the first argument on the command-line:

| Option                                                   | Description                                                        |
|----------------------------------------------------------|--------------------------------------------------------------------|
| <code>--defaults-file</code><br><code>=path</code>       | Only read options from the given option file.                      |
| <code>--defaults-extra-file</code><br><code>=path</code> | Read this extra option file after all other option files are read. |

## Option File Syntax

The syntax of the MariaDB option files are:

- Lines starting with # are comments.
- Empty lines are ignored.
- Option groups use the syntax
  - [group-name]
  - . See the [Option Groups](#) section below for more information on available option groups.
- The same option group can appear multiple times.
- The
  - `!include`  
directive can be used to include other option files. See the [Including Option Files](#) section below for more information on this syntax.
  - The
    - `!includedir`  
directive can be used to include all  
.cnf  
files (and potentially  
.ini  
files) in a given directory. The option files within the directory are read in alphabetical order. See the [Including Option File Directories](#) section below for more information on this syntax.
- Dashes (-)
  - 
  - ) and underscores (\_)
  - 
  - ) in options are interchangeable.
- Double quotes can be used to quote values
- - `\n`
  - ,
  - `\r`
  - ,
  - `\t`
  - ,
  - `\b`
  - ,
  - `\s`
  - ,
  - `\"`
  - ,

\',  
, and  
\\\\'  
are recognized as character escapes for new line, carriage return, tab, backspace, space, double quote, single quote, and backslash respectively.

- Certain option prefixes are supported. See the [Option Prefixes](#) section below for information about available option prefixes.
- See the [Options](#) section below for information about available options.

## Option Groups

A MariaDB program can read options from one or many option groups. For an exact list of option groups read on your system by a specific program, you can execute:

```
$program --help --verbose
```

For example:

```
$ mysqld --help --verbose
mysqld Ver 10.3.13-MariaDB-log for Linux on x86_64 (MariaDB Server)
Copyright (c) 2000, 2018, Oracle, MariaDB Corporation Ab and others.

Starts the MariaDB database server.

Usage: mysqld [OPTIONS]

Default options are read from the following files in the given order:
/etc/my.cnf ~/.my.cnf
The following groups are read: mysqld server mysqld-10.3 mariadb mariadb-10.3 client-server galera
...
```

## Server Option Groups

MariaDB programs reads server options from the following server option groups:

| Group           | Description                                                                                                                                                                              |
|-----------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| [client-server] | Options read by all MariaDB <a href="#">client programs</a> and the MariaDB Server. This is useful for options like socket and port, which is common between the server and the clients. |
| [server]        | Options read by MariaDB Server.                                                                                                                                                          |
| [mysqld]        | Options read by<br>mysqld<br>, which includes both MariaDB Server and MySQL Server.                                                                                                      |
| [mysqld-X.Y]    | Options read by a specific version of<br>mysqld<br>, which includes both MariaDB Server and MySQL Server. For example,<br>[mysqld-10.4]<br>.                                             |
| [mariadb]       | Options read by MariaDB Server.                                                                                                                                                          |
| [mariadb-X.Y]   | Options read by a specific version of MariaDB Server. For example,<br>[mariadb-10.4]<br>.                                                                                                |
| [mariadb-ndb]   | Options read by MariaDB Server. Available starting with <a href="#">MariaDB 10.4.6</a> .                                                                                                 |

|               |                                                                                                                                                                                                                                                                                                                                                                                   |
|---------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| [mariadb-X.Y] | Options read by a specific version of MariaDB Server. For example,<br>[mariadb-10.4]<br>. Available starting with <a href="#">MariaDB 10.4.6</a> .                                                                                                                                                                                                                                |
| [galera]      | Options read by MariaDB Server, but only if it is compiled with <a href="#">Galera Cluster</a> support. In <a href="#">MariaDB 10.1</a> and later, all builds on Linux are compiled with <a href="#">Galera Cluster</a> support. When using one of these builds, options from this option group are read even if the <a href="#">Galera Cluster</a> functionality is not enabled. |

X.Y in the examples above refer to the base (major.minor) version of the server. For example, [MariaDB 10.3.10](#) would read from

[mariadb-10.3]  
. By using the  
mariadb-X.Y

syntax, one can create option files that have MariaDB-only options in the MariaDB-specific option groups. That would allow the option file to work for both MariaDB and MySQL.

## Client Option Groups

MariaDB programs reads client options from the following option groups:

| Group            | Description                                                                                                                                                                              |
|------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| [client]         | Options read by all MariaDB and MySQL <a href="#">client programs</a> , which includes both MariaDB and MySQL clients. For example,<br>mysqldump                                         |
| [client-server]  | Options read by all MariaDB <a href="#">client programs</a> and the MariaDB Server. This is useful for options like socket and port, which is common between the server and the clients. |
| [client-mariadb] | Options read by all MariaDB <a href="#">client programs</a> .                                                                                                                            |

## Tool-Specific Option Groups

Many MariaDB tools reads options from their own option groups as well. Many of them are listed below:

| Group          | Description                                                                                                                                 |
|----------------|---------------------------------------------------------------------------------------------------------------------------------------------|
| [mysqld_safe]  | Options read by<br><a href="#">mysqld_safe</a><br>, which includes both MariaDB Server and MySQL Server.                                    |
| [safe_mysqld]  | Options read by<br><a href="#">mysqld_safe</a><br>, which includes both MariaDB Server and MySQL Server.                                    |
| [mariadb_safe] | Options read by<br><a href="#">mysqld_safe</a><br>from MariaDB Server.                                                                      |
| [mariadb-safe] | Options read by<br><a href="#">mysqld_safe</a><br>from MariaDB Server. Available starting with <a href="#">MariaDB 10.4.6</a> .             |
| [mariabackup]  | Options read by <a href="#">Mariabackup</a> . Available starting with <a href="#">MariaDB 10.1.31</a> and <a href="#">MariaDB 10.2.13</a> . |
| [xtrabackup]   | Options read by <a href="#">Mariabackup</a> and <a href="#">Percona XtraBackup</a> .                                                        |

|                   |                                                                                                                        |
|-------------------|------------------------------------------------------------------------------------------------------------------------|
| [mysql_upgrade]   | Options read by<br><br>mysql_upgrade<br><br>, which includes both MariaDB Server and MySQL Server.                     |
| [mariadb-upgrade] | Options read by<br><br>mysql_upgrade<br><br>. Available starting with <a href="#">MariaDB 10.4.6</a> .                 |
| [sst]             | Specific options read by the <a href="#">mariabackup SST method</a> and the <a href="#">xtrabackup-v2 SST method</a> . |
| [mysql]           | Options read by<br><br>mysql<br><br>, which includes both MariaDB Server and MySQL Server.                             |
| [mariadb-client]  | Options read by<br><br>mysql<br><br>. Available starting with <a href="#">MariaDB 10.4.6</a> .                         |
| [mysqldump]       | Options read by<br><br>mysqldump<br><br>, which includes both MariaDB Server and MySQL Server.                         |
| [mariadb-dump]    | Options read by<br><br>mysqldump<br><br>. Available starting with <a href="#">MariaDB 10.4.6</a> .                     |
| [mysqlimport]     | Options read by<br><br>mysqlimport<br><br>, which includes both MariaDB Server and MySQL Server.                       |
| [mariadb-import]  | Options read by<br><br>mysqlimport<br><br>. Available starting with <a href="#">MariaDB 10.4.6</a> .                   |
| [mysqlbinlog]     | Options read by<br><br>mysqlbinlog<br><br>, which includes both MariaDB Server and MySQL Server.                       |
| [mariadb-binlog]  | Options read by<br><br>mysqlbinlog<br><br>. Available starting with <a href="#">MariaDB 10.4.6</a> .                   |
| [mysqladmin]      | Options read by<br><br>mysqladmin<br><br>, which includes both MariaDB Server and MySQL Server.                        |
| [mariadb-admin]   | Options read by<br><br>mysqladmin<br><br>. Available starting with <a href="#">MariaDB 10.4.6</a> .                    |

|                 |                                                                                                                         |
|-----------------|-------------------------------------------------------------------------------------------------------------------------|
| [mysqlshow]     | Options read by<br><br>mysqlshow<br><br>, which includes both MariaDB Server and MySQL Server.                          |
| [mariadb-show]  | Options read by<br><br>mysqlshow<br><br>. Available starting with <a href="#">MariaDB 10.4.6</a> .                      |
| [mysqlcheck]    | Options read by<br><br>mysqlcheck<br><br>, which includes both MariaDB Server and MySQL Server.                         |
| [mariadb-check] | Options read by<br><br>mysqlcheck<br><br>. Available starting with <a href="#">MariaDB 10.4.6</a> .                     |
| [mysqlslap]     | Options read by<br><br>mysqlslap<br><br>, which includes both MariaDB Server and MySQL Server.                          |
| [mariadb-slap]  | Options read by<br><br>mysqlslap<br><br>. Available starting with <a href="#">MariaDB 10.4.6</a> .                      |
| [odbc]          | Options read by <a href="#">MariaDB Connector/ODBC</a> , but only if the<br><br>USE_MCNF<br><br>parameter has been set. |

## Custom Option Group Suffixes

MariaDB can be configured to read options from option groups with a custom suffix by providing the following command-line argument. This command-line argument can be used with most of MariaDB's command-line tools, not just

`mysqld`

. It must be given as the first argument on the command-line:

| Option                                 | Description                                                                              |
|----------------------------------------|------------------------------------------------------------------------------------------|
| --defaults-group-suffix<br><br>=suffix | In addition to the default option groups, also read option groups with the given suffix. |

The default group suffix can also be specified via the

`MYSQL_GROUP_SUFFIX`  
[environment variable](#).

## Including Option Files

It is possible to include additional option files from another option file. For example, to include  
`/etc/mysql/dbserver1.cnf`  
, an option file could contain:

```
[mariadb]
...
!include /etc/mysql/dbserver1.cnf
```

## Including Option File Directories

It is also possible to include all option files in a directory from another option file. For example, to include all option files in

```
/etc/my.cnf.d/
, an option file could contain:
```

```
[mariadb]
...
!includedir /etc/my.cnf.d/
```

The option files within the directory are read in alphabetical order.

All option file names must end in

```
.cnf
on Unix-like operating systems. On Windows, all option file names must end in
.cnf
or
.ini
.
```

## Checking Program Options

You can check which options a given program is going to use by using the

```
--print-defaults
```

command-line argument:

| Option           | Description                                                                         |
|------------------|-------------------------------------------------------------------------------------|
| --print-defaults | Read options from option files, print all option values, and then exit the program. |

This command-line argument can be used with most of MariaDB's command-line tools, not just

```
mysqld
```

. It must be given as the first argument on the command-line. For example:

```
$ mysqldump --print-defaults
mysqldump would have been started with the following arguments:
--ssl_cert=/etc/my.cnf.d/certificates/client-cert.pem --ssl_key=/etc/my.cnf.d/certificates/client-key.pem --ssl_ca=/etc/my.cnf.d/certificates/ca.pem
```

You can also check which options a given program is going to use by using the

```
my_print_defaults
```

utility and providing the names of the option groups that the program reads. For example:

```
$ my_print_defaults mysqldump client client-server client-mariadb
--ssl_cert=/etc/my.cnf.d/certificates/client-cert.pem
--ssl_key=/etc/my.cnf.d/certificates/client-key.pem
--ssl_ca=/etc/my.cnf.d/certificates/ca.pem
--ssl-verify-server-cert
--max_allowed_packet=1GB
```

The

```
my_print_defaults
```

utility's

```
--mysqld  
command-line option provides a shortcut to refer to all of the server option groups :
```

```
$ my_print_defaults --mysqld  
--log_bin=mariadb-bin  
--log_slave_updates=ON  
--ssl_cert=/etc/my.cnf.d/certificates/server-cert.pem  
--ssl_key=/etc/my.cnf.d/certificates/server-key.pem  
--ssl_ca=/etc/my.cnf.d/certificates/ca.pem
```

## MySQL 5.6 Obfuscated Authentication Credential Option File

MySQL 5.6 and above support an obfuscated authentication credential option file called

.mylogin.cnf

that is created with

[mysql\\_config\\_editor](#)

MariaDB does not support this. The passwords in MySQL's

.mylogin.cnf

are only obfuscated, rather than encrypted, so the feature does not really add much from a security perspective. It is more likely to give users a false sense of security, rather than to seriously protect them.

## Option Prefixes

MariaDB supports certain prefixes that can be used with options. The supported option prefixes are:

| Option Prefix                      | Description                                                                                                                     |
|------------------------------------|---------------------------------------------------------------------------------------------------------------------------------|
| <code>auto</code> <code>set</code> | Sets the option value automatically. Only supported for certain options. Available in <a href="#">MariaDB 10.1.7</a> and later. |
| <code>dis</code> <code>able</code> | For all boolean options, disables the setting (equivalent to setting it to<br>0<br>). Same as<br><code>skip</code>              |
| <code>en</code> <code>able</code>  | For all boolean options, enables the setting (equivalent to setting it to<br>1<br>).                                            |
| <code>lo</code> <code>ose</code>   | Don't produce an error if the option doesn't exist.                                                                             |
| <code>ma</code> <code>ximum</code> | Sets the maximum value for the option.                                                                                          |
| <code>sk</code> <code>ip</code>    | For all boolean options, disables the setting (equivalent to setting it to<br>0<br>). Same as<br><code>disable</code>           |

For example:

```
[mariadb]
...
# determine a good value for open_files_limit automatically
auto_set_open_files_limit

# disable the unix socket plugin
disable_unix_socket

# enable the slow query log
enable_slow_query_log

# don't produce an error if these options don't exist
loose_file_key_management_filename = /etc/mysql/encryption/keyfile.enc
loose_file_key_management_filekey = FILE:/etc/mysql/encryption/keyfile.key
loose_file_key_management_encryption_algorithm = AES_CTR

# set max_allowed_packet to maximum value
maximum_max_allowed_packet

# disable external locking for MyISAM
skip_external_locking
```

## Options

Dashes (-

) and underscores (\_

\_ ) in options are interchangeable.

If an option is not explicitly set, then the server or client will simply use the default value for that option.

## MariaDB Server Options

MariaDB Server options can be set in [server option groups](#).

For a list of options that can be set for MariaDB Server, see the list of options available for

`mysqld`

Most of the [server system variables](#) can also be set in MariaDB's option file.

## MariaDB Client Options

MariaDB client options can be set in [client option groups](#).

See the specific page for each [client program](#) to determine what options are available for that program.

## Example Option Files

Most MariaDB installations include a sample MariaDB option file called

`my-default.cnf`

. On older releases, you would have also found the following option files:

- `my-small.cnf`
- `my-medium.cnf`
- `my-large.cnf`
- `my-huge.cnf`

However, these option files are now very dated for modern servers, so they were removed in [MariaDB 10.3.1](#).

In source distributions, the sample option files are usually found in the  
`support-files`

directory, and in other distributions, the option files are usually found in the share/mysql directory that is relative to the MariaDB base installation directory.

You can copy one of these sample MariaDB option files and use it as the basis for building your server's primary MariaDB option file.

## Example Minimal Option File

The following is a minimal my.cnf file that you can use to test MariaDB.

```
[client-server]
# Uncomment these if you want to use a nonstandard connection to MariaDB
#socket=/tmp/mysql.sock
#port=3306

# This will be passed to all MariaDB clients
[client]
#password=my_password

# The MariaDB server
[mysqld]
# Directory where you want to put your data
data=/usr/local/mysql/var
# Directory for the errmsg.sys file in the language you want to use
language=/usr/local/share/mysql/english

# This is the prefix name to be used for all log, error and replication files
log basename=mysqld

# Enable logging by default to help find problems
general-log
log-slow-queries
```

## Example Hybrid Option File

The following is an extract of an option file that one can use if one wants to work with both MySQL and MariaDB.

```

# Example mysql config file.

[client-server]
socket=/tmp/mysql-dbug.sock
port=3307

# This will be passed to all mysql clients
[client]
password=my_password

# Here are entries for some specific programs
# The following values assume you have at least 32M ram

# The MySQL server
[mysqld]
temp-pool
key_buffer_size=16M
datadir=/my/mysqldata
loose-innodb_file_per_table

[mariadb]
datadir=/my/data
default-storage-engine=aria
loose-mutex-deadlock-detector
max-connections=20

[mariadb-5.5]
language=/my/maria-5.5/sql/share/english/
socket=/tmp/mysql-dbug.sock
port=3307

[mariadb-10.1]
language=/my/maria-10.1/sql/share/english/
socket=/tmp/mysql2-dbug.sock

[mysqldump]
quick
max_allowed_packet=16M

[mysql]
no-auto-rehash
loose-abort-source-on-error

```

  7. Information Schema Plugin - user\_variables
    1. user\_variables
  8. Information Schema Plugin - WSREP\_MEMBERSHIP
    1. wsrep\_membership
  9. Information Schema Plugin - WSREP\_STATUS
    1. wsrep\_status
20. Replication Plugins - Options and System Variables
1. Replication Plugin - rpl\_semi\_sync\_master
    1. rpl\_semi\_sync\_master
    2. rpl-semi-sync-master-enabled
    3. rpl-semi-sync-master-timeout
    4. rpl-semi-sync-master-trace-level
    5. rpl-semi-sync-master-wait-no-slave
    6. rpl-semi-sync-master-wait-point
  2. Replication Plugin - rpl\_semi\_sync\_slave
    1. rpl\_semi\_sync\_slave
    2. rpl-semi-sync-slave-delay-master
    3. rpl-semi-sync-slave-kill-conn-timeout
    4. rpl-semi-sync-slave-enabled
    5. rpl-semi-sync-slave-trace-level
21. Default Values

This page lists all of the options for

```
mysqld
/
mariadb
```

, ordered by topic. For a full alphabetical list of all mysqld options, as well as server and status variables, see [Full list of MariaDB options, system and status variables](#).

In many cases, the entry here is a summary, and links to the full description.

By convention, [server variables](#) have usually been specified with an underscore in the configuration files, and a dash on the command line. You can however specify underscores as dashes - they are interchangeable.

See [mysqld startup options](#) for which files and groups mysqld reads for it's default options.

## Option Prefixes

--auto-set--\*

- **Description:** Sets the option value automatically. Only supported for certain options. Available in [MariaDB 10.1.7](#) and later.

--disable--\*

- **Description:** For all boolean options, disables the setting (equivalent to setting it to

0  
). Same as  
--skip

--enable--\*

- **Description:** For all boolean options, enables the setting (equivalent to setting it to

1  
).

--loose--\*

- **Description:** Don't produce an error if the option doesn't exist.

--maximum--\*

- **Description:** Sets the maximum value for the option.

--skip--\*

- **Description:** For all boolean options, disables the setting (equivalent to setting it to

0  
). Same as  
--disable

## Option File Options

--defaults-extra-file

- **Commandline:**

--defaults-extra-file=name

- **Description:** Read this extra option file after all other option files are read.

◦ See [Configuring MariaDB with Option Files](#).

---

--defaults-file

- **Commandline:**

--defaults-file=name

- **Description:** Only read options from the given option file.

◦ See [Configuring MariaDB with Option Files](#).

---

```
--defaults-group-suffix
```

- **Commandline:**

```
--defaults-group-suffix=name
```

- **Description:** In addition to the default option groups, also read option groups with the given suffix.

- See [Configuring MariaDB with Option Files](#) .

---

```
--no-defaults
```

- **Commandline:**

```
--no-defaults
```

- **Description:** Don't read options from any option file.

- See [Configuring MariaDB with Option Files](#) .

---

```
--print-defaults
```

- **Commandline:**

```
--print-defaults
```

- **Description:** Read options from option files, print all option values, and then exit the program.

- See [Configuring MariaDB with Option Files](#) .

## Compatibility Options

The following options have been added to MariaDB to make it more compliant with other MariaDB and MySQL versions:

```
-a, --ansi
```

- **Description:** Use ANSI SQL syntax instead of MySQL syntax. This mode will also set [transaction isolation level serializable](#) .

---

```
--new
```

- **Description:** Use new functionality that will exist in next version of MariaDB. This function exists to make it easier to prepare for an upgrade. For version 5.1 this functions enables the LIST and RANGE partitions functions for ndbcluster.

---

```
--old-style-user-limits
```

- **Description:** Enable old-style user limits (before MySQL 5.0.3, user resources were counted per each user+host vs. per account).

---

```
--safe-mode
```

- **Description:** Disable some potential unsafe optimizations. For 5.2, [INSERT DELAYED](#) is disabled, [myisam\\_recover\\_options](#) is set to DEFAULT (automatically recover crashed MyISAM files) and the [query cache](#) is disabled. For [Aria](#) tables, disable bulk insert optimization to enable one to use [aria\\_read\\_log](#) to recover tables even if tables are deleted (good for testing recovery).

---

```
--skip-new
```

- **Description:** Disables `--new` in 5.2. In 5.1 used to disable some new potentially unsafe functions.
- 

## Compatibility Options and System Variables

- `--old`
- `--old-alter-table`
- `--old-mode`
- `--old-passwords`
- `--show-old-temporals`

## Locale Options

`--character-set-client-handshake`

- **Commandline:**

`--character-set-client-handshake`

- **Description:** Don't ignore client side character set value sent during handshake.
- 

`--default-character-set`

- **Commandline:**

`--default-character-set=name`

- **Description:** Still available as an option for setting the default character set for clients and their connections, it was deprecated and removed in MariaDB 10.2 as a server option. Use [character-set-server](#) instead.
- 

`--language`

- **Description:** This option can be used to set the server's language for error messages. This option can be specified either as a language name or as the path to the directory storing the language's [error message file](#). See [Server Locales](#) for a list of supported locales and their associated languages.

- This option is deprecated. Use the

`lc_messages`

and

`lc_messages_dir`

system variables instead.

- See [Setting the Language for Error Messages](#) for more information.
- 

## Locale Options and System Variables

- [character-set-filesystem](#)
- [character-set-client](#)
- [character-set-connection](#)
- [character-set-database](#)
- [character-set-filesystem](#)
- [character-set-results](#)
- [character-set-server](#)
- [character-set-system](#)
- [character-sets-dir](#)
- [collation-connection](#)
- [collation-database](#)
- [collation-server](#)
- [default-week-format](#)
- [default-time-zone](#)
- [lc-messages](#)

- [lc-messages-dir](#)
- [lc-time-names](#)

## Windows Options

`--console`

- **Description:** Windows-only option that keeps the console window open and for writing log messages to stderr and stdout. If specified together with [--log-error](#), the last option will take precedence.
- 

`--install`

- **Description:** Windows-only option that installs the

`mysqld`  
process as a Windows service.

- The Windows service created with this option [auto-starts](#). If you want a service that is [started on demand](#), then use the

`--install-manual`

option.

- This option takes a service name as an argument. If this option is provided without a service name, then the service name defaults to "MySQL".
  - This option is deprecated and may be removed in a future version. See [MDEV-19358](#) for more information.
- 

`--install-manual`

- **Description:** Windows-only option that installs the

`mysqld`  
process as a Windows service.

- The Windows service created with this option is [started on demand](#). If you want a service that [auto-starts](#), use the

`--install`

option.

- This option takes a service name as an argument. If this option is provided without a service name, then the service name defaults to "MySQL".
  - This option is deprecated and may be removed in a future version. See [MDEV-19358](#) for more information.
- 

`--remove`

- **Description:** Windows-only option that removes the Windows service created by the

`--install`

or

`--install-manual`

options.

- This option takes a service name as an argument. If this option is provided without a service name, then the service name defaults to "MySQL".
  - This option is deprecated and may be removed in a future version. See [MDEV-19358](#) for more information.
- 

`--slow-start-timeout`

- **Description:** Windows-only option that defines the maximum number of milliseconds that the service control manager should wait before trying to

kill the Windows service during startup. Defaults to  
15000

---

--standalone

- **Description:** Windows-only option that has no effect. Kept for compatibility reasons.
- 

## Windows Options and System Variables

The following options and system variables are related to using MariaDB on Windows:

- --named-pipe

## Replication and Binary Logging Options

The following options are related to [replication](#) and the [binary log](#) :

--abort-slave-event-count

- **Commandline:**  
--abort-slave-event-count=#
  - **Description:** Option used by mysql-test for debugging and testing of replication.
- 

--binlog-do-db

- **Commandline:**  
--binlog-do-db=name
  - **Description:** This option allows you to configure a [replication master](#) to write statements and transactions affecting databases that match a specified name into its [binary log](#). Since the filtered statements or transactions will not be present in the [binary log](#), its replication slaves will not be able to replicate them.
    - This option will **not** work with cross-database updates with [statement-based logging](#). See the [Statement-Based Logging](#) section for more information.
    - This option can **not** be set dynamically.
    - When setting it on the command-line or in a server [option group](#) in an [option file](#), the option does not accept a comma-separated list. If you would like to specify multiple filters, then you need to specify the option multiple times.
    - See [Replication Filters](#) for more information.
- 

--binlog-ignore-db

- **Commandline:**  
--binlog-ignore-db=name
- **Description:** This option allows you to configure a [replication master](#) to **not** write statements and transactions affecting databases that match a specified name into its [binary log](#). Since the filtered statements or transactions will not be present in the [binary log](#), its replication slaves will not be able to replicate them.
  - This option will **not** work with cross-database updates with [statement-based logging](#). See the [Statement-Based Logging](#) section for more information.
  - This option can **not** be set dynamically.
  - When setting it on the command-line or in a server [option group](#) in an [option file](#), the option does not accept a comma-separated list. If you would like to specify multiple filters, then you need to specify the option multiple times.
  - See [Replication Filters](#) for more information.

```
--binlog-row-event-max-size
```

- **Commandline:**

```
--binlog-row-event-max-size=#
```

- **Description:** The maximum size of a row-based [binary log](#) event in bytes. Rows will be grouped into events smaller than this size if possible. The value has to be a multiple of 256.

- **Default value**

◦

8192  
(>= [MariaDB 10.2.4](#))

◦

1024  
(<= [MariaDB 10.2.3](#))

---

```
--disconnect-slave-event-count
```

- **Commandline:**

```
--disconnect-slave-event-count=#
```

- **Description:** Option used by mysql-test for debugging and testing of replication.
- 

```
--flashback
```

- **Commandline:**

```
--flashback
```

- **Description:** Setup the server to use flashback. This enables the [binary log](#) and sets  
`binlog_format=ROW`

- **Introduced:** [MariaDB 10.2.4](#)
- 

```
--init-rpl-role
```

- **Commandline:**

```
--init-rpl-role=name
```

- **Description:** Set the replication role.
- 

```
--log-basename
```

- **Commandline:**

```
--log-basename=name
```

- **Description:** Basename for all log files and the .pid file. This sets all log file names at once (in 'datadir') and is normally the only option you need for specifying log files. This is especially recommended to be set if you are using [replication](#) as it ensures that your log file names are not dependent on your host name. Sets names for [log-bin](#) , [log-bin-index](#) , [relay-log](#) , [relay-log-index](#) , [general-log-file](#) ,

```
--log-slow-query-log-file
```

,

```
--log-error-file
```

, and [pid-file](#) .

- **Introduced:** [MariaDB 5.2](#)
- 

```
--log-bin-trust-routine-creators
```

- **Commandline:**

```
--log-bin-trust-routine-creators
```

- **Description:** Deprecated, use [log-bin-trust-function-creators](#) .
- 

```
--master-host
```

- **Commandline:**

```
--master-host=name
```

- **Description:** Master hostname or IP address for replication. If not set, the slave thread will not be started. Note that the setting of master-host will be ignored if there exists a valid master.info file.
- 

```
--master-info-file
```

- **Commandline:**

```
--master-info-file=name
```

- **Description:** Name and location of the file where the

MASTER\_LOG\_FILE

and

MASTER\_LOG\_POS

options (i.e. the [binary log](#) position on the master) and most other

[CHANGE MASTER](#)

options are written. The [slave's I/O thread](#) keeps this [binary log](#) position updated as it downloads events.

- See [CHANGE MASTER TO: Option Persistence](#) for more information.
- 

```
--master-password
```

- **Commandline:**

```
--master-password=name
```

- **Description:** The password the slave thread will authenticate with when connecting to the master. If not set, an empty password is assumed. The value in master.info will take precedence if it can be read.
- 

```
--master-port
```

- **Commandline:**

```
--master-port=#
```

- **Description:** The port the master is listening on. If not set, the compiled setting of MYSQL\_PORT is assumed. If you have not tinkered with configure options, this should be 3306. The value in master.info will take precedence if it can be read.
- 

```
--master-retry-count
```

- **Commandline:**

```
--master-retry-count=#
```

- **Description:** Number of times a slave will attempt to connect to a master before giving up. The retry interval is determined by the MASTER\_CONNECT\_RETRY option for the CHANGE MASTER statement. A value of 0 means the slave will not stop attempting to reconnect. Reconnects are triggered when a slave has timed out. See [slave\\_net\\_timeout](#) .

- **Default Value:**

86400

- **Range - 32 bit:**  
0 to 4294967295

- **Range - 64 bit:**  
0 to 18446744073709551615
- 

--master-ssl

- **Commandline:**  
--master-ssl
  - **Description:** Enable the slave to [connect to the master using TLS](#).
- 

--master-ssl-ca

- **Commandline:**  
--master-ssl-ca[=name]
  - **Description:** Master TLS CA file. Only applies if you have enabled [master-ssl](#).
- 

--master-ssl-capath

- **Commandline:**  
--master-ssl-capath[=name]
  - **Description:** Master TLS CA path. Only applies if you have enabled [master-ssl](#).
- 

--master-ssl-cert

- **Commandline:**  
--master-ssl-cert[=name]
  - **Description:** Master TLS certificate file name. Only applies if you have enabled [master-ssl](#).
- 

--master-ssl-cipher

- **Commandline:**  
--master-ssl-cipher[=name]
  - **Description:** Master TLS cipher. Only applies if you have enabled [master-ssl](#).
- 

--master-ssl-key

- **Commandline:**  
--master-ssl-key[=name]
  - **Description:** Master TLS keyfile name. Only applies if you have enabled [master-ssl](#).
- 

--master-user

- **Commandline:**

```
--master-user=name
```

- **Description:** The username the slave thread will use for authentication when connecting to the master. The user must have FILE privilege. If the master user is not set, user test is assumed. The value in master.info will take precedence if it can be read.
- 

```
--max-binlog-dump-events
```

- **Commandline:**

```
--max-binlog-dump-events=#
```

- **Description:** Option used by mysql-test for debugging and testing of replication.
- 

```
--replicate-rewrite-db
```

- **Commandline:**

```
--replicate-rewrite-db=master_database->slave_database
```

- **Description:** This option allows you to configure a [replication slave](#) to rewrite database names. It uses the format

```
master_database->slave_database
```

. If a slave encounters a [binary log](#) event in which the default database (i.e. the one selected by the

```
USE
```

statement) is

```
master_database
```

, then the slave will apply the event in

```
slave_database
```

instead.

- This option will **not** work with cross-database updates with [statement-based logging](#) . See the [Statement-Based Logging](#) section for more information.
- This option only affects statements that involve tables. This option does not affect statements involving the database itself, such as

```
CREATE DATABASE
```

```
,
```

```
ALTER DATABASE
```

, and

```
DROP DATABASE
```

- This option can **not** be set dynamically.
  - When setting it on the command-line or in a server [option group](#) in an [option file](#) , the option does not accept a comma-separated list. If you would like to specify multiple filters, then you need to specify the option multiple times.
  - See [Replication Filters](#) for more information.
- 

```
--replicate-same-server-id
```

- **Commandline:**

```
--replicate-same-server-id
```

- **Description:** In replication, if set to 1, do not skip events having our server id. Default value is 0 (to break infinite loops in circular replication). Can't be set to 1 if [log-slave-updates](#) is used.
- 

```
--sporadic-binlog-dump-fail
```

- **Commandline:**

```
--sporadic-binlog-dump-fail
```

- **Description:** Option used by mysql-test for debugging and testing of replication.
- 

```
--sysdate-is-now
```

- **Commandline:**

```
--sysdate-is-now
```

- **Description:** Non-default option to alias [SYSDATE\(\)](#) to [NOW\(\)](#) to make it safe for replication . Since 5.0, SYSDATE() has returned a 'dynamic' value different for different invocations, even within the same statement.
- 

## Replication and Binary Logging Options and System Variables

The following options and system variables are related to [replication](#) and the [binary log](#) :

- [auto-increment-increment](#)
- [auto-increment-offset](#)
- [binlog-annotate-row-events](#)
- [binlog-cache-size](#)
- [binlog-checksum](#)
- [binlog-commit-wait-count](#)
- [binlog-commit-wait-usec](#)
- [binlog-direct-non-transactional-updates](#)
- [binlog-expire-logs-seconds](#)
- [binlog-file-cache-size](#)
- [binlog-format](#)
- [binlog-optimize-thread-scheduling](#)
- [binlog-row-image](#)
- [binlog-row-metadata](#)
- [binlog-stmt-cache-size](#)
- [default-master-connection](#)
- [gtid-cleanup-batch-size](#)
- [gtid-domain-id](#)
- [gtid-ignore-duplicates](#)
- [gtid-strict-mode](#)
- [init-slave](#)
- [log-bin](#)
- [log-bin-compress](#)
- [log-bin-compress-min-len](#)
- [log-bin-index](#)
- [log-bin-trust-function-creators](#)
- [log-slave-updates](#)
- [master-verify-checksum](#)
- [max-binlog-cache-size](#)
- [max-binlog-size](#)
- [max-binlog-stmt-cache-size](#)
- [max-relay-log-size](#)
- [read-binlog-speed-limit](#)
- [relay-log](#)
- [relay-log-index](#)
- [relay-log-info-file](#)
- [relay-log-purge](#)
- [relay-log-recovery](#)
- [relay-log-space-limit](#)

- [slave\\_transaction\\_retry\\_interval](#)
- [slave-type-conversions](#)
- [sync-binlog](#)
- [sync-master-info](#)
- [sync-relay-log](#)
- [sync-relay-log-info](#)

## Semisynchronous Replication Options and System Variables

The options and system variables related to [Semisynchronous Replication](#) are described [here](#).

## Optimizer Options

--record-buffer

- **Commandline:**  
--record-buffer=#
- **Description:** Old alias for [read\\_buffer\\_size](#).
- **Removed:** [MariaDB 5.5](#)

---

--table-cache

- **Commandline:**  
--table-open-cache=#
- **Description:** Removed; use [--table-open-cache](#) instead.
- **Removed:** [MariaDB 5.1.3](#)

---

## Optimizer Options and System Variables

- [alter-algorithm](#)
- [analyze-sample-percentage](#)
- [big-tables](#)
- [bulk-insert-buffer-size](#)
- [expensive-subquery-limit](#)
- [join-buffer-size](#)
- [join-buffer-space-limit](#)
- [join-cache-level](#)
- [max-heap-table-size](#)
- [max-join-size](#)
- [max-seeks-for-key](#)
- [max-sort-length](#)
- [mrr-buffer-size](#)
- [optimizer-maxsel-arg-weight](#)
- [optimizer-prune-level](#)

- [optimizer-search-depth](#)
- [optimizer-selectivity-sampling-limit](#)
- [optimizer-switch](#)
- [optimizer-trace](#)
- [optimizer-trace-max-mem-size](#)
- [optimizer-use-condition-selectivity](#)
- [query-alloc-block-size](#)
- [query-prealloc-size](#)
- [range-alloc-block-size](#)
- [read-buffer-size](#)
- [rowid-merge-buff-size](#)
- [table-definition-cache](#)
- [table-open-cache](#)
- [table-open-cache-instances](#)
- [tmp-disk-table-size](#)
- [tmp-memory-table-size](#)
- [tmp-table-size](#)
- [use-stat-tables](#)

## Storage Engine Options

--skip-bdb

- **Commandline:**

----skip-bdb

- **Description:** Deprecated option; Exists only for compatibility with very old my.cnf files.
- **Removed:** [MariaDB 10.5.1](#)

---

## MyISAM Storage Engine Options

The options related to the [MyISAM](#) storage engine are described below.

--external-locking

- **Commandline:**

--external-locking

- **Description:** Use system (external) locking (disabled by default). With this option enabled you can run [myisamchk](#) to test (not repair) tables while the server is running. Disable with [--skip-external-locking](#).

--log-isam

- **Commandline:**

--log-isam[=file\_name]

- **Description:** Enable the [MyISAM log](#), which logs all MyISAM changes to file. If no filename is provided, the default, *myisam.log* is used.

---

## MyISAM Storage Engine Options and System Variables

Some options and system variables related to the [MyISAM](#) storage engine can be found [here](#). Direct links to many of them can be found below.

- [concurrent-insert](#)
- [delayed-insert-limit](#)
- [delayed-insert-timeout](#)
- [delayed-queue-size](#)
- [keep-files-on-create](#)
- [key-buffer-size](#)
- [key-cache-age-threshold](#)
- [key-cache-block-size](#)
- [key-cache-division-limit](#)
- [key-cache-file-hash-size](#)

- [key-cache-segments](#)
- [myisam-block-size](#)
- [myisam-data-pointer-size](#)
- [myisam-max-sort-file-size](#)
- [myisam-mmap-size](#)
- [myisam-recover-options](#)
- [myisam-repair-threads](#)
- [myisam-sort-buffer-size](#)
- [myisam-stats-method](#)
- [myisam-use-mmap](#)

## InnoDB Storage Engine Options

The options related to the [InnoDB](#) storage engine are described below.

--innodb

- **Commandline:**

```
--innodb=value  
,  
--skip-innodb
```

- **Description:** This variable controls whether or not to load the InnoDB storage engine. Possible values are

```
ON  
,  
OFF  
,  
FORCE  
or  
FORCE_PLUS_PERMANENT
```

(from [MariaDB 5.5](#) ). If set to

OFF

(the same as --skip-innodb), since InnoDB is the default storage engine, the server will not start unless another storage engine has been chosen with [--default-storage-engine](#) .

FORCE

means that the storage engine must be successfully loaded, or else the server won't start.

FORCE\_PLUS\_PERMANENT

enables the plugin, but if plugin cannot initialize, the server will not start. In addition, the plugin cannot be uninstalled while the server is running.

---

--innodb-cmp

- **Commandline:**

```
--innodb-cmp
```

- **Description:**

- **Default:**

ON

---

--innodb-cmp-reset

- **Commandline:**

```
--innodb-cmp-reset
```

- **Description:**

- **Default:**

ON

---

--innodb-cmpmem

- **Commandline:**  
--innodb-cmpmem

- **Description:**
- **Default:**  
ON

---

```
--innodb-cmpmem-reset
```

- **Commandline:**  
--innodb-cmpmem-reset

- **Description:**
- **Default:**  
ON

---

```
--innodb-file-io-threads
```

- **Commandline:**  
--innodb-file-io-threads

- **Description:**
- **Default:**  
4

- **Removed:** [MariaDB 10.3.0](#)
- 

```
--innodb-index-stats
```

- **Commandline:**  
--innodb-index-stats

- **Description:**
- **Default:**  
ON

- **Removed:** [MariaDB 10.0.0](#)
- 

```
--innodb-lock-waits
```

- **Commandline:**  
--innodb-lock-waits

- **Description:**
- **Default:**  
ON

---

```
--innodb-locks
```

- **Commandline:**  
--innodb-locks

- **Description:**

- **Default:**

ON

---

--innodb-rseg

- **Commandline:**

--innodb-rseg

- **Description:**

- **Default:**

ON

- **Removed:** [MariaDB 10.0.0](#)
- 

--innodb-status-file

- **Commandline:**

--innodb-status-file

- **Description:**

- **Default:**

FALSE

---

--innodb-sys-indexes

- **Commandline:**

--innodb-sys-indexes

- **Description:**

- **Default:**

ON

---

--innodb-sys-stats

- **Commandline:**

--innodb-sys-stats

- **Description:**

- **Default:**

ON

- **Removed:** [MariaDB 10.0.0](#)
- 

--innodb-sys-tables

- **Commandline:**

--innodb-sys-tables

- **Description:**

- **Default:**

ON

---

```
--innodb-table-stats
```

- **Commandline:**

```
--innodb-table-stats
```

- **Description:**

- **Default:**

```
ON
```

- **Removed:** MariaDB 10.0.0

---

```
--innodb-trx
```

- **Commandline:**

```
--innodb-trx
```

- **Description:**

- **Default:**

```
ON
```

---

## InnoDB Storage Engine Options and System Variables

## Aria Storage Engine Options

The options related to the [Aria](#) storage engine are described below.

`--aria-log-dir-path`

- **Commandline:**

`--aria-log-dir-path=value`

- **Description:** Path to the directory where transactional log should be stored

- **Default:**

SAME AS DATADIR

Some options and system variables related to the [Aria](#) storage engine can be found [here](#). Direct links to many of them can be found below.

- [aria-block-size](#)
- [aria-checkpoint-interval](#)
- [aria-checkpoint-log-activity](#)
- [aria-encrypt-tables](#)
- [aria-force-start-after-recovery-failures](#)
- [aria-group-commit](#)
- [aria-group-commit-interval](#)
- [aria-log-file-size](#)
- [aria-log-purge-type](#)
- [aria-max-sort-file-size](#)
- [aria-page-checksum](#)
- [aria-pagecache-age-threshold](#)
- [aria-pagecache-buffer-size](#)
- [aria-pagecache-division-limit](#)
- [aria-pagecache-file-hash-size](#)
- [aria-recover](#)
- [aria-recover-options](#)
- [aria-repair-threads](#)
- [aria-sort-buffer-size](#)
- [aria-stats-method](#)

- [connect-force\\_bson](#)
- [connect-idx-map](#)
- [connect-java-wrapper](#)
- [connect-json-all-path](#)
- [connect-json-grp-size](#)
- [connect-json-null](#)
- [connect-jvm-path](#)
- [connect-type-conv](#)
- [connect-use-tempfile](#)
- [connect-work-size](#)
- [connect-xtrace](#)

## Spider Storage Engine Options

The options and system variables related to the [Spider](#) storage engine can be found [here](#).

## Mroonga Storage Engine Options

The options and system variables related to the [Mroonga](#) storage engine can be found [here](#).

# TokuDB Storage Engine Options

The options and system variables related to the [TokuDB](#) storage engine can be found [here](#).

## Performance Schema Options

The options related to the [Performance Schema](#) are described below.

--performance-schema-consumer-events-stages-current

- **Commandline:**

--performance-schema-consumer-events-stages-current

- **Description:** Enable the [events-stages-current](#) consumer.

- **Default:**

OFF

---

--performance-schema-consumer-events-stages-history

- **Commandline:**

--performance-schema-consumer-events-stages-history

- **Description:** Enable the [events-stages-history](#) consumer.

- **Default:**

OFF

---

--performance-schema-consumer-events-stages-history-long

- **Commandline:**

--performance-schema-consumer-events-stages-history-long

- **Description:** Enable the [events-stages-history-long](#) consumer.

- **Default:**

OFF

---

--performance-schema-consumer-events-statements-current

- **Commandline:**

--performance-schema-consumer-events-statements-current

- **Description:** Enable the [events-statements-current](#) consumer. Use

--skip-performance-schema-consumer-events-statements-current  
to disable.

- **Default:**

ON

---

--performance-schema-consumer-events-statements-history

- **Commandline:**

--performance-schema-consumer-events-statements-history

- **Description:** Enable the [events-statements-history](#) consumer.

- **Default:**

OFF

---

--performance-schema-consumer-events-statements-history-long

- **Commandline:**

--performance-schema-consumer-events-statements-history-long

- **Description:** Enable the [events-statements-history-long](#) consumer.

- **Default:**

OFF

---

--performance-schema-consumer-events-waits-current

- **Commandline:**

--performance-schema-consumer-events-waits-current

- **Description:** Enable the [events-waits-current](#) consumer.

- **Default:**

OFF

---

--performance-schema-consumer-events-waits-history

- **Commandline:**

--performance-schema-consumer-events-waits-history

- **Description:** Enable the [events-waits-history](#) consumer.

- **Default:**

OFF

---

--performance-schema-consumer-events-waits-history-long

- **Commandline:**

--performance-schema-consumer-events-waits-history-long

- **Description:** Enable the [events-waits-history-long](#) consumer.

- **Default:**

OFF

---

--performance-schema-consumer-global-instrumentation

- **Commandline:**

--performance-schema-consumer-global-instrumentation

- **Description:** Enable the global-instrumentation consumer. Use

--skip-performance-schema-consumer-global-instrumentation  
to disable.

- **Default:**

ON

---

```
--performance-schema-consumer-statements-digest
```

- **Commandline:**

```
--performance-schema-consumer-statements-digest
```

- **Description:** Enable the statements-digest consumer. Use

```
--skip-performance-schema-consumer-statements-digest  
to disable.
```

- **Default:**

```
ON
```

```
--performance-schema-consumer-thread-instrumentation
```

- **Commandline:**

```
--performance-schema-consumer-thread-instrumentation
```

- **Description:** Enable the statements-thread-instrumentation. Use

```
--skip-performance-schema-thread-instrumentation  
to disable.
```

- **Default:**

```
ON
```

## Performance Schema Options and System Variables

Some options and system variables related to the [Performance Schema](#) can be found [here](#). Direct links to many of them can be found below.

## Galera Cluster Options

The options related to [Galera Cluster](#) are described below.

```
--wsrep-new-cluster
```

- **Commandline:**

```
--wsrep-new-cluster
```

- **Description:** Bootstrap a cluster. It works by overriding the current value of wsrep\_cluster\_address. It is recommended not to add this option to the config file as this will trigger bootstrap on every server start.
- 

## Galera Cluster Options and System Variables

Some options and system variables related to [Galera Cluster](#) can be found [here](#). Direct links to many of them can be found below.

- [wsrep-auto-increment-control](#)

## Options When Debugging mysqld

```
--debug-assert-if-crashed-table
```

- **Description:** Do an assert in handler::print\_error() if we get a crashed table.

```
--debug-binlog-fsync-sleep
```

- **Description:**

```
--debug-binlog-fsync-sleep=#
```

If not set to zero, sets the number of micro-seconds to sleep after running `fsync()` on the [binary log](#) to flush transactions to disk. This can thus be used to artificially increase the perceived cost of such an `fsync()`.

---

```
--debug-crc-break
```

- **Description:**

```
--debug-crc-break=#
```

Call `my_debug_put_break_here()` if crc matches this number (for debug).

---

```
--debug-flush
```

- **Description:** Default debug log with flush after write.

---

```
--debug-no-sync
```

- **Description:**

```
debug-no-sync[=#]
```

Disables system sync calls. Only for running tests or debugging!

---

```
--debug-sync-timeout
```

- **Description:**

```
debug-sync-timeout[=#]
```

Enable the debug sync facility and optionally specify a default wait timeout in seconds. A zero value keeps the facility disabled.

---

```
--gdb
```

- **Description:** Set up signals usable for debugging.

---

```
--silent-startup
```

- **Description:** Don't print Notes to the [error log](#) during startup.

- **Introduced:** [MariaDB 10.1.8](#)

---

```
--sync-sys
```

- **Description:** Enable/disable system sync calls. Syncs should only be turned off (

```
--disable-sync-sys
```

) when running tests or debugging! Replaced by [debug-no-sync](#) from [MariaDB 5.5](#).

- **Removed:** [MariaDB 5.5](#)

---

```
--thread-alarm
```

- **Description:** Enable/disable system thread alarm calls. Should only be turned off (  
    --disable-thread-alarm  
    ) when running tests or debugging!
- 

## Debugging Options and System Variables

- [core-file](#)
- [debug](#)
- [debug-no-thread-alarm](#)

## Other Options

```
--allow-suspicious-udfs
```

- **Commandline:**

```
--allow-suspicious-udfs
```

- **Description:** Allows use of [user-defined functions](#) consisting of only one symbol

```
x()  
without corresponding  
x_init()  
or  
x_deinit()  
. That also means that one can load any function from any library, for example  
exit()  
from  
libc.so  
. Not recommended unless you require old UDF's with one symbol that cannot be recompiled
```

---

```
--bootstrap
```

- **Commandline:**

```
--bootstrap
```

- **Description:** Used by mysql installation scripts, such as [mysql\\_install\\_db](#) to execute SQL scripts before any privilege or system tables exist. Do no use while an existing MariaDB instance is running.
- 

```
--chroot
```

- **Commandline:**

```
--chroot=name
```

- **Description:** Chroot mysqld daemon during startup.
- 

```
--des-key-file
```

- **Commandline:**

```
--des-key-file=name
```

- **Description:** Load keys for [des\\_encrypt\(\)](#) and des\_encrypt from given file.
- 

```
--exit-info
```

- **Commandline:**

```
--exit-info[=#]
```

- **Description:** Used for debugging. Use at your own risk.
- 

```
--getopt-prefix-matching
```

- **Commandline:**

```
--getopt-prefix-matching={0|1}
```

- **Description:** Makes it possible to disable historical "unambiguous prefix" matching in the command-line option parsing.

- **Default:** TRUE

- **Introduced:** MariaDB 10.1.3
- 

```
--help
```

- **Commandline:**

```
--help
```

- **Description:** Displays help with many commandline options described, and exits.
- 

```
--log-ddl-recovery
```

- **Commandline:**

```
--log-ddl-recovery=name
```

- **Description:** Path to file used for recovery of DDL statements after a crash.

- **Default Value:**

```
ddl-recover.log
```

- **Introduced:** MariaDB 10.6.1
- 

```
--log-short-format
```

- **Commandline:**

```
--log-short-format
```

- **Description:** Don't log extra information to update and slow-query logs.
- 

```
--log-slow-file
```

- **Commandline:**

```
--log-slow-file=name
```

- **Description:** Log slow queries to given log file. Defaults logging to hostname-slow.log
- 

```
--log-slow-time
```

- **Commandline:**

```
--log-slow-time=#
```

- **Description:** Log all queries that have taken more than long-query-time seconds to execute to the slow query log, if active. The argument will be treated as a decimal value with microsecond precision.
-

--log-tc

- **Commandline:**

--log-tc=name

- **Description:** Defines the path to the memory-mapped file-based transaction coordinator log, which is only used if the [binary log](#) is disabled. If you have two or more XA-capable storage engines enabled, then a transaction coordinator log must be available. See [Transaction Coordinator Log](#) for more information. Also see the the

[log\\_tc\\_size](#)

system variable and the

[--tc-heuristic-recover](#)

option.

- **Default Value:**

tc.log

---

--master-connect-retry

- **Commandline:**

--master-connect-retry=#

- **Description:** Deprecated in 5.1.17 and removed in 5.5. The number of seconds the slave thread will sleep before retrying to connect to the master, in case the master goes down or the connection is lost.
- 

--memlock

- **Commandline:**

--memlock

- **Description:** Lock mysqld in memory.
- 

--ndb-use-copying-alter-table

- **Commandline:**

--ndb-use-copying-alter-table

- **Description:** Force ndbcluster to always copy tables at alter table (should only be used if on-line alter table fails).
- 

--one-thread

- **Commandline:**

--one-thread

- **Description:** (Deprecated): Only use one thread (for debugging under Linux). Use [thread-handling=no-threads](#) instead.
  - **Removed:** [MariaDB 10.0.4](#)
- 

--plugin-load

- **Commandline:**

--plugin-load=name

- **Description:** This option can be used to configure the server to load specific [plugins](#). This option uses the following format:

- Plugins can be specified in the format

```
name=library
, where
name
is the plugin name and
library
is the plugin library. This format installs a single plugin from the given plugin library.
```

- Plugins can also be specified in the format

```
library
, where
library
is the plugin library. This format installs all plugins from the given plugin library.
```

- Multiple plugins can be specified by separating them with semicolons.

- Special care must be taken when specifying the

[--plugin-load](#)

option multiple times, or when specifying both the

[--plugin-load](#)

option and the

[--plugin-load-add](#)

option together. The

[--plugin-load](#)

option resets the plugin load list, and this can cause unexpected problems if you are not aware. The

[--plugin-load-add](#)

option does **not** reset the plugin load list, so it is much safer to use. See [Plugin Overview: Specifying Multiple Plugin Load Options](#) for more information.

- See [Plugin Overview: Installing a Plugin with Plugin Load Options](#) for more information.

[--plugin-load-add](#)

- **Commandline:**

[--plugin-load-add=name](#)

- **Description:** This option can be used to configure the server to load specific [plugins](#). This option uses the following format:

- Plugins can be specified in the format

```
name=library
, where
name
is the plugin name and
library
is the plugin library. This format installs a single plugin from the given plugin library.
```

- Plugins can also be specified in the format

```
library
, where
library
is the plugin library. This format installs all plugins from the given plugin library.
```

- Multiple plugins can be specified by separating them with semicolons.

- Special care must be taken when specifying both the

[--plugin-load](#)

option and the

[--plugin-load-add](#)

option together. The

[--plugin-load](#)

option resets the plugin load list, and this can cause unexpected problems if you are not aware. The

```
--plugin-load-add
```

option does **not** reset the plugin load list, so it is much safer to use. See [Plugin Overview: Specifying Multiple Plugin Load Options](#) for more information.

- See [Plugin Overview: Installing a Plugin with Plugin Load Options](#) for more information.
  - **Introduced:** MariaDB 10.0.1
- 

```
--port-open-timeout
```

- **Commandline:**

```
--port-open-timeout=#
```

- **Description:** Maximum time in seconds to wait for the port to become free. (Default: No wait).
- 

```
--safe-user-create
```

- **Commandline:**

```
--safe-user-create
```

- **Description:** Don't allow new user creation by the user who has no write privileges to the `mysql.user` table.
- 

```
--safemalloc-mem-limit
```

- **Commandline:**

```
--safemalloc-mem-limit=#
```

- **Description:** Simulate memory shortage when compiled with the

```
--
```

```
with-debug=full  
option.
```

```
--show-slave-auth-info
```

- **Commandline:**

```
--show-slave-auth-info
```

- **Description:** Show user and password in SHOW SLAVE HOSTS on this master.
- 

```
--skip-grant-tables
```

- **Commandline:**

```
--skip-grant-tables
```

- **Description:** Start without grant tables. This gives all users FULL ACCESS to all tables, which is useful in case of a lost root password. Use `mysqladmin flush-privileges` , `mysqladmin reload` or `FLUSH PRIVILEGES` to resume using the grant tables.
- 

```
--skip-host-cache
```

- **Commandline:**

```
--skip-host-cache
```

- **Description:** Don't cache host names.
- 

```
--skip-partition
```

- **Commandline:**

```
--skip-partition  
,  
--disable-partition
```

- **Description:** Disables user-defined [partitioning](#). Previously partitioned tables cannot be accessed or modified. Tables can still be seen with [SHOW TABLES](#) or by viewing the [INFORMATION\\_SCHEMA.TABLES](#) table. Tables can be dropped with [DROP TABLE](#), but this only removes .frm files, not the associated .par files, which will need to be removed manually.
- 

```
--skip-slave-start
```

- **Commandline:**

```
--skip-slave-start
```

- **Description:** If set, slave is not autostarted.
- 

```
--skip-ssl
```

- **Commandline:**

```
--skip-ssl
```

- **Description:** Disable [TLS connections](#).
- 

```
--skip-symlink
```

- **Commandline:**

```
--skip-symlink
```

- **Description:** Don't allow symlinking of tables. Deprecated and removed in [MariaDB 5.5](#). Use [symbolic-links](#) with the skip option prefix instead.

- **Removed:** [MariaDB 5.5](#)
- 

```
--skip-thread-priority
```

- **Commandline:**

```
--skip-thread-priority
```

- **Description:** Don't give threads different priorities. Deprecated and removed in [MariaDB 10.0](#).
  - **Removed:** [MariaDB 10.0](#)
- 

```
--sql-bin-update-same
```

- **Commandline:**

```
--sql-bin-update-same=#
```

- **Description:** The update log was deprecated in version 5.0 and replaced by the [binary log](#), so this option did nothing since then. Deprecated and removed in [MariaDB 5.5](#).
  - **Removed:** [MariaDB 5.5](#)
- 

--ssl

- **Commandline:**

--ssl

- **Description:** Enable [TLS for connection](#) (automatically enabled with other flags). Disable with '

--

skip-ssl

'

---

--stack-trace

- **Commandline:**

--stack-trace

,

--skip-stack-trace

- **Description:** Print a stack trace on failure. Enabled by default, disable with

-skip-stack-trace

---

--symbolic-links

- **Commandline:**

--symbolic-links

- **Description:** Enables symbolic link support. When set, the [have\\_symlink](#) system variable shows as

YES

. Silently ignored in Windows. Use

--skip-symbolic-links

to disable.

---

--tc-heuristic-recover

- **Commandline:**

--tc-heuristic-recover=name

- **Description:** If [manual heuristic recovery](#) is needed, this option defines the decision to use in the heuristic recovery process. Manual heuristic recovery may be needed if the [transaction coordination log](#) is missing or if it doesn't contain all prepared transactions. This option can be set to

OFF

,

COMMIT

, or

ROLLBACK

. The default is

OFF

. See also the

--log-tc

server option and the

[log\\_tc\\_size](#)

system variable.

---

--temp-pool

- **Commandline:**

--temp-pool

- **Description:** Using this option will cause most temporary files created to use a small set of names, rather than a unique name for each new file. Defaults to

1  
until [MariaDB 10.5.6](#) , use  
--skip-temp-pool  
to disable. Deprecated and defaults to  
0  
from [MariaDB 10.5.7](#) , as benchmarking shows it causes a heavy mutex contention.

---

--test-expect-abort

- **Commandline:**

--test-expect-abort

- **Description:** Expect that server aborts with 'abort'; Don't write out server variables on 'abort'. Useful only for test scripts.
- 

--test-ignore-wrong-options

- **Commandline:**

--test-ignore-wrong-options

- **Description:** Ignore wrong enums values in command line arguments. Useful only for test scripts.
- 

--user

- **Commandline:**

--user=name

- **Description:** Run mysqld daemon as user.
- 

--verbose

- **Commandline:**

-v  
,  
--verbose

- **Description:** Used with [help](#) option for detailed help.
-

[rpl\\_semi\\_sync\\_slave](#)

replication plugin can be found [here](#).

## Default Values

You can verify the default values for an option by doing:

```
mysqld --no-defaults --help --verbose
```

## 2.1.6.5 What to Do if MariaDB Doesn't Start

### Contents

1. [The Error Log and the Data Directory](#)
2. [Option Files](#)
  1. [Invalid Option or Option Value](#)
3. [Can't Open Privilege Tables](#)
4. [Can't Create Test File](#)
5. [InnoDB](#)
  1. [Cannot Allocate Memory for the InnoDB Buffer Pool](#)
  2. [InnoDB Table Corruption](#)
6. [MyISAM](#)
7. [systemd](#)
8. [SELinux](#)

There could be many reasons that MariaDB fails to start. This page will help troubleshoot some of the more common reasons and provide solutions.

If you have tried everything here, and still need help, you can ask for help on IRC or on the forums - see [Where to find other MariaDB users and developers](#) - or ask a question at the [Starting and Stopping MariaDB](#) page.

## The Error Log and the Data Directory

The reason for the failure will almost certainly be written in the [error log](#) and, if you are starting MariaDB manually, to the console. By default, the error log is named *host-name*.err and is written to the data directory.

Common Locations:

- /var/log/
- /var/log/mysql
- C:\Program Files\MariaDB x.y\data (x.y refers to the version number)
- C:\Program Files (x86)\MariaDB x.y\data (32bit version on 64bit Windows)

It's also possible that the error log has been explicitly written to another location. This is often done by changing the

[datadir](#)

or

## log\_error

system variables in an [option file](#). See [Option Files](#) below for more information about that.

A quick way to get the values of these system variables is to execute the following commands:

```
mysqld --help --verbose | grep 'log-error' | tail -1  
mysqld --help --verbose | grep 'datadir' | tail -1
```

## Option Files

Another kind of file to consider when troubleshooting is [option files](#). The default option file is called

`my.cnf`

. Option files contain configuration options, such as the location of the data directory mentioned above. If you're unsure where the option file is located, see [Configuring MariaDB with Option Files: Default Option File Locations](#) for information on the default locations.

You can check which configuration options MariaDB server will use from its option files by executing the following command:

```
mysqld --print-defaults
```

You can also check by executing the following command:

```
my_print_defaults --mysqld
```

See [Configuring MariaDB with Option Files: Checking Program Options](#) for more information on checking configuration options.

## Invalid Option or Option Value

Another potential reason for a startup failure is that an [option file](#) contains an invalid option or an invalid option value. In those cases, the [error log](#) should contain an error similar to this:

```
140514 12:19:37 [ERROR] /usr/local/mysql/bin/mysqld: unknown variable 'option=value'
```

This is more likely to happen when you upgrade to a new version of MariaDB. In most cases the [option file](#) from the old version of MariaDB will work just fine with the new version. However, occasionally, options are removed in new versions of MariaDB, or the valid values for options are changed in new versions of MariaDB. Therefore, it's possible for an [option file](#) to stop working after an upgrade.

Also remember that option names are case sensitive.

Examine the specifics of the error. Possible fixes are usually one of the following:

- If the option is completely invalid, then remove it from the [option file](#).
- If the option's name has changed, then fix the name.
- If the option's valid values have changed, then change the option's value to a valid one.
- If the problem is caused by a simple typo, then fix the typo.

## Can't Open Privilege Tables

It is possible to see errors similar to the following:

```
System error 1067 has occurred.  
Fatal error: Can't open privilege tables: Table 'mysql.host' doesn't exist
```

If errors like this occur, then critical [system tables](#) are either missing or are in the wrong location. The above error is quite common after an upgrade if the [option files](#) set the

`basedir`

or

`datadir`

to a non-standard location, but the new server is using the default location. Therefore, make sure that the

`basedir`

and

`datadir`

variables are correctly set.

If you're unsure where the option file is located, see [Configuring MariaDB with Option Files: Default Option File Locations](#) for information on the default locations.

If the `system tables` really do not exist, then you may need to create them with

```
mysql_install_db
```

. See [Installing System Tables \(mysql\\_install\\_db\)](#) for more information.

## Can't Create Test File

One of the first tests on startup is to check whether MariaDB can write to the data directory. When this fails, it will log an error like this:

```
May 13 10:24:28 mariadb3 mysqld[19221]: 2019-05-13 10:24:28 0 [Warning] Can't create test file /usr/local/data/mariadb/mariadb3.  
May 13 10:24:28 mariadb3 mysqld[19221]: 2019-05-13 10:24:28 0 [ERROR] Aborting
```

This is usually a permission error on the directory in which this file is being written. Ensure that the entire

```
datadir
```

is owned by the user running

```
mysqld
```

, usually

```
mysql
```

. Ensure that directories have the "x" (execute) directory permissions for the owner. Ensure that all the parent directories of the

```
datadir
```

upwards have "x" (execute) permissions for all (

user

,

group

, and

other

).

Once this is checked look at the [systemd](#) and [selinux](#) documentation below, or [apparmor](#).

## InnoDB

[InnoDB](#) is probably the MariaDB component that most frequently causes a crash. In the error log, lines containing InnoDB messages generally start with "InnoDB:".

### Cannot Allocate Memory for the InnoDB Buffer Pool

In a typical installation on a dedicated server, at least 70% of your memory should be assigned to [InnoDB buffer pool](#); sometimes it can even reach 85%. But be very careful: don't assign to the buffer pool more memory than it can allocate. If it cannot allocate memory, InnoDB will use the disk's swap area, which is very bad for performance. If swapping is disabled or the swap area is not big enough, InnoDB will crash. In this case, MariaDB will probably try to restart several times, and each time it will log a message like this:

```
140124 17:29:01 InnoDB: Fatal error: cannot allocate memory for the buffer pool
```

In that case, you will need to add more memory to your server/VM or decrease the value of the `innodb_buffer_pool_size` variables.

Remember that the buffer pool will slightly exceed that limit. Also, remember that MariaDB also needs allocate memory for other storage engines and several per-connection buffers. The operating system also needs memory.

### InnoDB Table Corruption

By default, InnoDB deliberately crashes the server when it detects table corruption. The reason for this behavior is preventing corruption propagation. However, in some situations, server availability is more important than data integrity. For this reason, we can avoid these crashes by changing the value of `innodb_corrupt_table_action` to 'warn'.

If InnoDB crashes the server after detecting data corruption, it writes a detailed message in the error log. The first lines are similar to the following:

```
InnoDB: Database page corruption on disk or a failed  
InnoDB: file read of page 7.  
InnoDB: You may have to recover from a backup.
```

Generally, it is still possible to recover most of the corrupted data. To do so, restart the server in [InnoDB recovery mode](#) and try to extract the data that you want to backup. You can save them in a CSV file or in a non-InnoDB table. Then, restart the server in normal mode and restore the data.

## MyISAM

Most tables in the `mysql` database are MyISAM tables. These tables are necessary for MariaDB to properly work, or even start.

A MariaDB crash could cause system tables corruption. With the default settings, MariaDB will simply not start if the system tables are corrupted. With `myisam_recover_options`, we can force MyISAM to repair damaged tables.

## systemd

If you are using

```
systemd
```

, then there are a few relevant notes about startup failures:

- If MariaDB is configured to access files under

```
/home  
,  
/root  
, or  
/run/user
```

, then the default systemd unit file will prevent access to these directories with a `Permission Denied` error. This happens because the unit file set

```
ProtectHome=true
```

. See [Systemd: Configuring Access to Home Directories](#) for information on how to work around this.

- The default systemd unit file also sets `ProtectSystem=full`, which places restrictions on writing to a few other directories. Overwriting this with `ProtectSystem=off` in the same way as above will restore access to these directories.
- If MariaDB takes longer than 90 seconds to start, then the default systemd unit file will cause it to fail with an error. This happens because the default value for the

```
TimeoutStartSec
```

option is 90 seconds. See [Systemd: Configuring the Systemd Service Timeout](#) for information on how to work around this.

- The systemd journal may also contain useful information about startup failures. See [Systemd: Systemd Journal](#) for more information.

See [systemd](#) documentation for further information on systemd configuration.

## SELinux

[Security-Enhanced Linux \(SELinux\)](#) is a Linux kernel module that provides a framework for configuring [mandatory access control \(MAC\)](#) system for many resources on the system. It is enabled by default on some Linux distributions, including RHEL, CentOS, Fedora, and other similar Linux distribution. SELinux prevents programs from accessing files, directories or ports unless it is configured to access those resources.

You might need to troubleshoot SELinux-related issues in cases, such as:

- MariaDB is using a non-default port.
- MariaDB is reading from or writing to some files (datadir, log files, option files, etc.) located at non-default paths.
- MariaDB is using a plugin that requires access to resources that default installations do not use.

Setting SELinux state to

```
permissive
```

is a common way to investigate what is going wrong while allowing MariaDB to function normally.

```
permissive
```

is supposed to produce a log entry every time it should block a resource access, without actually blocking it. However, [there are situations](#) when SELinux blocks resource accesses even in

```
permissive
```

mode.

See [SELinux](#) for more information.

## 2.1.6.6 Running MariaDB from the Build Directory

You can run mysqld directly from the build directory (without doing

```
make install  
).
```

### Starting mariadb After Build on Windows

On Windows, the data directory is produced during the build.

The simplest way to start database from the command line is:

1. Go to the directory where mariadb.exe is located (subdirectory sql\Debug or sql\Relwithdebinfo of the build directory)
2. From here, execute, if you are using [MariaDB 10.5](#) or newer,

```
mariadb.exe --console
```

```
else
```

```
mysqld.exe --console
```

As usual, you can pass other server parameters on the command line, or store them in a my.ini configuration file and pass

```
--defaults-file=path\to\my.ini
```

The default search path on Windows for the my.ini file is:

- GetSystemWindowsDirectory()
- GetWindowsDirectory()
- C:\
- Directory where the executable is located

### Starting mysqld After Build on Unix

Copy the following to your '

```
~/my.cnf  
' file.
```

There are two lines you have to edit: '

```
datadir=  
' and '  
language=  
'.
```

Be sure to change them to match your environment.

```

# Example Mariadb config file.
# You can copy this to one of:
# /etc/my.cnf to set global options,
# /mysql-data-dir/my.cnf to get server specific options or
# ~/my.cnf for user specific options.
#
# One can use all long options that the program supports.
# Run the program with --help to get a list of available options

# This will be passed to all MariaDB clients
[client]
#password=my_password
#port=3306
#socket=/tmp/mysql.sock

# Here is entries for some specific programs
# The following values assume you have at Least 32M ram

# The mariadb server (both [mysqld] and [mariadb] works here)
[mariadb]
#port=3306
#socket=/tmp/mysql.sock

# The following three entries caused mysqld 10.0.1-MariaDB (and possibly other versions) to abort...
# skip-locking
# set-variable = key_buffer=16M

loose-innodb_data_file_path = ibdata1:1000M
loose-mutex-deadlock-detector
gdb

##### Fix the two following paths

# Where you want to have your database
datadir=/path/to/data/dir

# Where you have your mysql/MariaDB source + sql/share/english
language=/path/to/src/dir/sql/share/english

##### One can also have a different path for different versions, to simplify development.

[mariadb-10.1]
lc-messages-dir=/my/maria-10.1/sql/share

[mariadb-10.2]
lc-messages-dir=/my/maria-10.2/sql/share

[mysqldump]
quick
set-variable = max_allowed_packet=16M

[mysql]
no-auto-rehash

[myisamchk]
set-variable= key_buffer=128M

```

With the above file in place, go to your MariaDB source directory and execute:

```
./scripts/mysql_install_db --srcdir=$PWD --datadir=/path/to/data/dir --user=$LOGNAME
```

Above '\$PWD' is the environment variable that points to your current directory. If you added

```
datadir
to your
my.cnf
, you don't have to give this option above. Also above, --user=$LOGNAME is necessary when using msqyld 10.0.1-MariaDB (and possibly other
versions)
```

Now you can start

```
mariadb
(or
```

```
mysqld
if you are using a version older than MariaDB 10.5 ) in the debugger:
```

```
cd sql  
ddd ./mariadb &
```

Or start mysqld on its own:

```
cd sql  
.mariadb &
```

After starting up

```
mariadb  
using one of the above methods (with the debugger or without), launch the client (as root if you don't have any users setup yet).
```

```
./client/mysql
```

## Using a Storage Engine Plugin

The simplest case is to compile the storage engine into MariaDB:

```
cmake -DWITH_PLUGIN_<plugin_name>=1` .
```

Another option is to point

```
mariadb  
to the storage engine directory:
```

```
./mariadb --plugin-dir={build-dir-path}/storage/connect/.libs
```

## 2.1.6.7 mysql.server

### Contents

- 1. [Using mysql.server](#)
  - 1. [Options](#)
  - 2. [Option Files](#)
    - 1. [Option Groups](#)
    - 3. [Customizing mysql.server](#)
- 2. [Installed Locations](#)
  - 1. [Installed SysVinit Locations](#)
    - 1. [Manually Installing with SysVinit](#)

The

[mysql.server](#)

startup script is in MariaDB distributions on Linux and Unix. It is a wrapper that works as a standard [sysVinit](#) script. However, it can be used independently of [sysVinit](#) as a regular

```
sh  
script. The script starts the
```

[mysqld](#)

server process by first changing its current working directory to the MariaDB install directory and then starting

[mysqld\\_safe](#)

. The script requires the standard [sysVinit](#) arguments, such as

```
start  
,  
stop  
,  
restart  
, and  
status  
. For example:
```

```
mysql.server start  
mysql.server restart  
mysql.server stop  
mysql.server status
```

It can be used on systems such as Linux, Solaris, and Mac OS X.

The

```
mysql.server  
script starts
```

[mysqld](#)

by first changing to the MariaDB install directory and then calling

[mysqld\\_safe](#)

## Using mysql.server

The command to use

```
mysql.server
```

and the general syntax is:

```
mysql.server [ start | stop | restart | status ] <options> <mysqld_options>
```

## Options

If an unknown option is provided to

[mysqld\\_safe](#)

on the command-line, then it is passed to

[mysqld\\_safe](#)

[mysql.server](#)

supports the following options:

| Option                              | Description                                                                                                                                                                                                                                                                                   |
|-------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| --basedir=path                      | The path to the MariaDB installation directory.                                                                                                                                                                                                                                               |
| --datadir=path                      | The path to the MariaDB data directory.                                                                                                                                                                                                                                                       |
| --pid-file=file_name                | The path name of the file in which the server should write its process ID. If not provided, the default, <code>host_name.pid</code> is used.                                                                                                                                                  |
| --service-startup-timeout=file_name | How long in seconds to wait for confirmation of server startup. If the server does not start within this time, <code>mysql.server</code> exits with an error. The default value is 900. A value of 0 means not to wait at all for startup. Negative values mean to wait forever (no timeout). |
| --use-mysqld_safe                   | Use <a href="#">mysqld_safe</a> to start the server. This is the default.                                                                                                                                                                                                                     |
| --use-manager                       | Use Instance Manager to start the server.                                                                                                                                                                                                                                                     |

|                      |                                                               |
|----------------------|---------------------------------------------------------------|
| --<br>user=user_name | The login user name to use for running<br><code>mysqld</code> |
|----------------------|---------------------------------------------------------------|

## Option Files

In addition to reading options from the command-line,

`mysql.server`  
can also read options from [option files](#).

The following options relate to how MariaDB command-line tools handles option files. They must be given as the first argument on the command-line:

| Option                               | Description                                      |
|--------------------------------------|--------------------------------------------------|
| <code>--print-defaults</code>        | Print the program argument list and exit.        |
| <code>--no-defaults</code>           | Don't read default options from any option file. |
| <code>--defaults-file=#</code>       | Only read default options from the given file #. |
| <code>--defaults-extra-file=#</code> | Read this file after the global files are read.  |

## Option Groups

`mysql.server`

reads options from the following [option groups](#) from [option files](#):

| Group                       | Description                                                                                         |
|-----------------------------|-----------------------------------------------------------------------------------------------------|
| <code>[mysql.server]</code> | Options read by<br><code>mysql.server</code> , which includes both MariaDB Server and MySQL Server. |

`mysql.server`

also reads options from the following server [option groups](#) from [option files](#):

| Group                      | Description                                                                                                                                                   |
|----------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>[mysqld]</code>      | Options read by<br><code>mysqld</code> , which includes both MariaDB Server and MySQL Server.                                                                 |
| <code>[server]</code>      | Options read by MariaDB Server.                                                                                                                               |
| <code>[mysqld-X.Y]</code>  | Options read by a specific version of<br><code>mysqld</code> , which includes both MariaDB Server and MySQL Server. For example,<br><code>[mysqld-5.5]</code> |
| <code>[mariadb]</code>     | Options read by MariaDB Server.                                                                                                                               |
| <code>[mariadb-X.Y]</code> | Options read by a specific version of MariaDB Server.                                                                                                         |

|                 |                                                                                                                                                                                          |
|-----------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| [client-server] | Options read by all MariaDB <a href="#">client programs</a> and the MariaDB Server. This is useful for options like socket and port, which is common between the server and the clients. |
| [galera]        | Options read by a galera-capable MariaDB Server. Available on systems compiled with Galera support.                                                                                      |

## Customizing mysql.server

If you have installed MariaDB to a non-standard location, then you may need to edit the

`mysql.server`  
script to get it to work right.

If you do not want to edit the

`mysql.server`  
script itself, then  
`mysql.server`  
also sources a few other  
`sh`

scripts. These files can be used to set any variables that might be needed to make the script work in your specific environment. The files are:

- `/etc/default/mysql`
- `/etc/sysconfig/mysql`
- `/etc/conf.d/mysql`

## Installed Locations

`mysql.server`  
can be found in the  
`support-files`  
directory under your MariaDB installation directory or in a MariaDB source distribution.

## Installed SysVinit Locations

On systems that use [sysVinit](#),

`mysql.server`  
may also be installed in other locations and with other names.

If you installed MariaDB on Linux using [RPMs](#), then the

`mysql.server`  
script will be installed into the  
`/etc/init.d`  
directory with the name  
`mysql`  
. You need not install it manually.

## Manually Installing with SysVinit

If you install MariaDB from [source](#) or from a [binary tarball](#) that does not install

`mysql.server`

automatically, and if you are on a system that uses [sysVinit](#), then you can manually install  
`mysql.server`  
with [sysVinit](#). This is usually done by copying it to  
`/etc/init.d/`  
and then creating specially named symlinks in the appropriate  
`/etc/rcX.d/`  
directories (where 'X' is a number between 0 and 6).

In the examples below we will follow the historical convention of renaming the

`mysql.server`  
script to '  
`mysql`'  
'when we copy it to  
`/etc/init.d/`  
'

The first step for most Linux distributions is to copy the

```
mysql.server  
script to  
/etc/init.d/  
and make it executable:
```

```
cd /path/to/your/mariadb-version/support-files/  
cp mysql.server /etc/init.d/mysql  
chmod +x /etc/init.d/mysql
```

Now all that is needed is to create the specially-named symlinks. On both RPM and Debian-based Linux distributions there are tools which do this for you. Consult your distribution's documentation if neither of these work for you and follow their instructions for generating the symlinks or creating them manually.

On RPM-based distributions (like Fedora and CentOS), you use

```
chkconfig  
:  
:
```

```
chkconfig --add mysql  
chkconfig --level 345 mysql on
```

On Debian-based distributions you use

```
update-rc.d  
:  
:
```

```
update-rc.d mysql defaults
```

On FreeBSD, the location for startup scripts is

```
/usr/local/etc/rc.d/  
and when you copy the  
mysql.server  
script there you should rename it so that it matches the  
*.sh  
pattern, like so:
```

```
cd /path/to/your/mariadb/support-files/  
cp mysql.server /usr/local/etc/rc.d/mysql.server.sh
```

As stated above, consult your distribution's documentation for more information on starting services like MariaDB at system startup.

See [mysqld startup options](#) for information on configuration options for

```
mysqld
```

## 2.1.6.8 mysqld\_safe

MariaDB starting with 10.4.6

From [MariaDB 10.4.6](#) ,  
mariadb-safe  
is a symlink to  
mysqld\_safe  
.

MariaDB starting with 10.5.2

From [MariaDB 10.5.2](#) ,  
mariadb-safe  
is the name of the server, with  
mysqld\_safe  
a symlink .

7. [See Also](#)

The

`mysqld_safe`

startup script is in MariaDB distributions on Linux and Unix. It is a wrapper that starts

`mysqld`

with some extra safety features. For example, if

`mysqld_safe`

notices that

`mysqld`

has crashed, then

`mysqld_safe`

will automatically restart

`mysqld`

.

`mysqld_safe`

is the recommended way to start

`mysqld`

on Linux and Unix distributions that do not support

`systemd`

. Additionally, the

`mysql.server`

init script used by

`sysVinit`

starts

`mysqld`

with

`mysqld_safe`

by default.

## Using mysqld\_safe

The command to use

`mysqld_safe`

and the general syntax is:

```
mysqld_safe [ --no-defaults | --defaults-file | --defaults-extra-file | --defaults-group-suffix | --print-defaults ] <options> <
```

## Options

Many of the options supported by

`mysqld_safe`

are identical to options supported by

## `mysqld`

. If an unknown option is provided to  
`mysqld_safe`  
on the command-line, then it is passed to  
`mysqld`

`mysqld_safe`  
supports the following options:

| Option                                  | Description                                                                                                                                                                                                                                                                                                                                                                                                                                    |
|-----------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>--help</code>                     | Display a help message and exit.                                                                                                                                                                                                                                                                                                                                                                                                               |
| <code>--autoclose</code>                | (NetWare only) On NetWare,<br><code>mysqld_safe</code><br>provides a screen presence. When you unload (shut down) the<br><code>mysqld_safe</code><br>NLM, the screen does not by default go away. Instead, it prompts for user input:<br>NLM has terminated; Press any key to close the screen<br>. If you want NetWare to close the screen automatically instead, use the<br><code>--autoclose</code><br>option to <code>mysqld_safe</code> . |
| <code>--basedir=path</code>             | The path to the MariaDB installation directory.                                                                                                                                                                                                                                                                                                                                                                                                |
| <code>--core-file-size=size</code>      | The size of the core file that <code>mysqld</code> should be able to create. The option value is passed to ulimit -c.                                                                                                                                                                                                                                                                                                                          |
| <code>--crash-script=file</code>        | Script to call in the event of <code>mysqld</code> crashing.                                                                                                                                                                                                                                                                                                                                                                                   |
| <code>--datadir=path</code>             | The path to the data directory.                                                                                                                                                                                                                                                                                                                                                                                                                |
| <code>--defaults-extra-file=path</code> | The name of an option file to be read in addition to the usual option files. This must be the first option on the command line if it is used. If the file does not exist or is otherwise inaccessible, the server will exit with an error.                                                                                                                                                                                                     |
| <code>--defaults-file=file_name</code>  | The name of an option file to be read instead of the usual option files. This must be the first option on the command line if it is used.                                                                                                                                                                                                                                                                                                      |
| <code>--defaults-group-suffix=#</code>  | In addition to the default option groups, also read option groups with this suffix.                                                                                                                                                                                                                                                                                                                                                            |
| <code>--flush-caches</code>             | Flush and purge buffers/caches before starting the server.                                                                                                                                                                                                                                                                                                                                                                                     |
| <code>--ledir=path</code>               | If <code>mysqld_safe</code> cannot find the server, use this option to indicate the path name to the directory where the server is located.                                                                                                                                                                                                                                                                                                    |

|                          |                                                                                                                                                                                                                                                                                                                                                                            |
|--------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| --log-error=file_name    | Write the error log to the given file.                                                                                                                                                                                                                                                                                                                                     |
| --malloc-lib=lib         | Preload shared library <i>lib</i> if available. See <a href="#">debugging MariaDB</a> for an example.                                                                                                                                                                                                                                                                      |
| --mysqld=prog_name       | The name of the server program (in the ledir directory) that you want to start. This option is needed if you use the MariaDB binary distribution but have the data directory outside of the binary distribution. If mysqld_safe cannot find the server, use the --ledir option to indicate the path name to the directory where the server is located.                     |
| --mysqld-version=suffix  | This option is similar to the --mysqld option, but you specify only the suffix for the server program name. The basename is assumed to be mysqld. For example, if you use<br>--mysqld-version=debug<br>, mysqld_safe starts the mysqld-debug program in the ledir directory. If the argument to --mysqld-version is empty, mysqld_safe uses mysqld in the ledir directory. |
| --nice=priority          | Use the nice program to set the server's scheduling priority to the given value.                                                                                                                                                                                                                                                                                           |
| --no-auto-restart        | Exit after starting mysqld.                                                                                                                                                                                                                                                                                                                                                |
| --no-defaults            | Do not read any option files. This must be the first option on the command line if it is used.                                                                                                                                                                                                                                                                             |
| --no-watch               | Exit after starting mysqld.                                                                                                                                                                                                                                                                                                                                                |
| --numa-interleave        | Run mysqld with its memory interleaved on all NUMA nodes.                                                                                                                                                                                                                                                                                                                  |
| --open-files-limit-count | The number of files that mysqld should be able to open. The option value is passed to ulimit -n. Note that you need to start mysqld_safe as root for this to work properly.                                                                                                                                                                                                |
| --pid-file=file_name     | The path name of the process ID file.                                                                                                                                                                                                                                                                                                                                      |
| --plugin-dir=dir_name,   | Directory for client-side plugins.                                                                                                                                                                                                                                                                                                                                         |
| --port=port_num          | The port number that the server should use when listening for TCP/IP connections. The port number must be 1024 or higher unless the server is started by the root system user.                                                                                                                                                                                             |
| --print-defaults         | Print the program argument list and exit.                                                                                                                                                                                                                                                                                                                                  |

|                               |                                                                                                                                                                                                                                                                                                                                                      |
|-------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| --skip-kill-mysqld            | Do not try to kill stray mysqld processes at startup. This option works only on Linux.                                                                                                                                                                                                                                                               |
| --socket=path                 | The Unix socket file that the server should use when listening for local connections.                                                                                                                                                                                                                                                                |
| --syslog,<br>--skip-syslog    | --syslog<br>causes error messages to be sent to syslog on systems that support the logger program.<br>--skip-syslog<br>suppresses the use of syslog; messages are written to an error log file.                                                                                                                                                      |
| --syslog-tag=tag              | For logging to syslog, messages from<br><code>mysqld_safe</code><br>and <code>mysqld</code> are written with a tag of <code>mysqld_safe</code> and <code>mysqld</code> , respectively. To specify a suffix for the tag, use<br>--syslog-tag=tag<br>, which modifies the tags to be<br><code>mysqld_safe-tag</code><br>and<br><code>mysqld-tag</code> |
| --timezone=timezone           | Set the TZ time zone <a href="#">environment variable</a> to the given option value. Consult your operating system documentation for legal time zone specification formats. Also see <a href="#">Time Zones</a> .                                                                                                                                    |
| --user={user_name or user_id} | Run the mysqld server as the user having the name <code>user_name</code> or the numeric user ID <code>user_id</code> . ("User" in this context refers to a system login account, not a MariaDB user listed in the grant tables.)                                                                                                                     |

## Option Files

In addition to reading options from the command-line,

```
mysqld_safe
can also read options from option files. If an unknown option is provided to
mysqld_safe
in an option file, then it is ignored.
```

The following options relate to how MariaDB command-line tools handles option files. They must be given as the **first argument** on the command-line:

| Option                    | Description                                                                         |
|---------------------------|-------------------------------------------------------------------------------------|
| --print-defaults          | Print the program argument list and exit.                                           |
| --no-defaults             | Don't read default options from any option file.                                    |
| --defaults-file=#         | Only read default options from the given file #.                                    |
| --defaults-extra-file=#   | Read this file after the global files are read.                                     |
| --defaults-group-suffix=# | In addition to the default option groups, also read option groups with this suffix. |

## Option Groups

`mysqld_safe`  
reads options from the following [option groups](#) from [option files](#):

| Group          | Description                                                                                                     |
|----------------|-----------------------------------------------------------------------------------------------------------------|
| [mysqld_safe]  | Options read by<br>mysqld_safe<br>, which includes both MariaDB Server and MySQL Server.                        |
| [safe_mysqld]  | Options read by<br>mysqld_safe<br>, which includes both MariaDB Server and MySQL Server.                        |
| [mariadb_safe] | Options read by<br>mysqld_safe<br>from MariaDB Server.                                                          |
| [mariadb-safe] | Options read by<br>mysqld_safe<br>from MariaDB Server. Available starting with <a href="#">MariaDB 10.4.6</a> . |

The

[safe\_mysqld]  
option group is primarily supported for backward compatibility. You should rename such option groups to [mysqld\_safe] in MariaDB installations to prevent breakage in the future if this compatibility is removed.

mysqld\_safe  
also reads options from the following server [option groups](#) from [option files](#):

| Group           | Description                                                                                                                                                                              |
|-----------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| [mysqld]        | Options read by<br>mysqld<br>, which includes both MariaDB Server and MySQL Server.                                                                                                      |
| [server]        | Options read by MariaDB Server.                                                                                                                                                          |
| [mysqld-X.Y]    | Options read by a specific version of<br>mysqld<br>, which includes both MariaDB Server and MySQL Server. For example,<br>[mysqld-5.5]                                                   |
| [mariadb]       | Options read by MariaDB Server.                                                                                                                                                          |
| [mariadb-X.Y]   | Options read by a specific version of MariaDB Server.                                                                                                                                    |
| [client-server] | Options read by all MariaDB <a href="#">client programs</a> and the MariaDB Server. This is useful for options like socket and port, which is common between the server and the clients. |
| [galera]        | Options read by a galera-capable MariaDB Server. Available on systems compiled with Galera support.                                                                                      |

For example, if you specify the

`log_error`

option in a server option group in an option file, like this:

```
[mariadb]
log_error=error.log
```

Then

mysqld\_safe  
will also use this value for its own  
--log-error

option:

## Configuring the Open Files Limit

When using

`mysqld_safe`  
, the system's open files limit can be changed by providing the  
`--open-files-limit`  
option either on the command-line or in an option file. For example:

```
[mysqld_safe]  
open_files_limit=4294967295
```

The option value is passed to

`ulimit -n`  
. Note that you need to start  
`mysqld_safe`  
as root for this to work properly. However, you can't currently set this to  
unlimited  
. See [MDEV-18410](#) about that.

When

`mysqld_safe`  
starts  
`mysqld`  
, it also uses this option to set the value of the

`open_files_limit`

system variable for  
`mysqld`

## Configuring the Core File Size

When using

`mysqld_safe`  
, if you would like to [enable core dumps](#), the system's core file size limit can be changed by providing the  
`--core-file-size`  
option either on the command-line or in an option file. For example:

```
[mysqld_safe]  
core_file_size=unlimited
```

The option value is passed to

`ulimit -c`  
. Note that you need to start  
`mysqld_safe`  
as root for this to work properly.

## Configuring MariaDB to Write the Error Log to Syslog

When using

`mysqld_safe`  
, if you would like to redirect the error log to the [syslog](#), then that can easily be done by using the  
`--syslog`  
option.  
`mysqld_safe`  
redirects two types of log messages to the syslog--its own log messages, and log messages for  
`mysqld`

- - `mysqld_safe`  
configures its own log messages to go to the  
daemon  
syslog facility. The log level for these messages is either  
`notice`  
or  
`error`

, depending on the specific type of log message. The default tag is  
`mysqld_safe`

- `mysqld_safe`  
also configures the log messages for  
`mysqld`  
to go to the  
daemon  
syslog facility. The log level for these messages is  
error  
. The default tag is  
`mysqld`

Sometimes it can be helpful to add a suffix to the syslog tag, such as if you are running multiple instances of MariaDB on the same host. To add a suffix to each syslog tag, use the

`--syslog-tag`  
option.

## Specifying mysqld

By default,

`mysqld_safe`  
tries to start an executable named  
`mysqld`

You can also specify another executable for

`mysqld_safe`  
to start instead of  
`mysqld`  
by providing the  
`--mysqld`  
or  
`--mysqld-version`  
options either on the command-line or in an option file.

By default, it will look for

`mysqld`  
in the following locations in the following order:

- `$BASEDIR/libexec/mysqld`
- `$BASEDIR/sbin/mysqld`
- `$BASEDIR/bin/mysqld`
- `$PWD/bin/mysqld`
- `$PWD/libexec/mysqld`
- `$PWD/sbin/mysqld`
- `@libexecdir@/mysql`

Where

`$BASEDIR`  
is set by the  
`--basedir`  
option,  
`$PWD`  
is the current working directory where  
`mysqld_safe`

was invoked, and  
@libexecdir@  
is set at compile-time by the  
INSTALL\_BINDIR  
option for

`cmake`

You can also specify where the executable is located by providing the  
--ledir  
option either on the command-line or in an option file.

## Specifying datadir

By default,

`mysqld_safe`  
will look for the  
datadir  
in the following locations in the following order:

- \$BASEDIR/data/mysql
- \$BASEDIR/data
- \$BASEDIR/var/mysql
- \$BASEDIR/var
- @localstatedir@

Where

\$BASEDIR  
is set by the  
--basedir  
option, and  
@localstatedir@  
is set at compile-time by the  
INSTALL\_MYSQLDATADIR  
option for

`cmake`

You can also specify where the  
datadir  
is located by providing the  
--datadir  
option either on the command-line or in an option file.

## Logging

When you use

`mysqld_safe`  
to start  
`mysqld`  
,

`mysqld_safe`  
logs to the same destination as  
`mysqld`

`mysqld_safe`

has several log-related options:

- - - syslog
      - : Write error messages to syslog on systems that support the logger program.
    - - skip-syslog
        - : Do not write error messages to syslog. Messages are written to the default error log file (host\_name.err in the data directory), or to a named file if the
        - log-error
          - option is given.
      - - log-error=file\_name
          - : Write error messages to the named error file.

If none of these options is provided, then the default is

--skip-syslog

If

--syslog  
and  
--log-error  
are both provided, then a warning is issued and  
--log-error  
takes precedence.

mysqld\_safe  
also writes notices to  
stdout  
and errors to  
stderr

## Editing mysqld\_safe

mysqld\_safe  
is a  
sh

script, so if you need to change its behavior, then it can easily be edited. However, you should not normally edit the script. A lot of behavior can be changed by providing options either on the command-line or in an option file.

If you do edit

mysqld\_safe

, then you should be aware of the fact that a package upgrade can overwrite your changes. If you would like to preserve your changes, be sure to have a backup.

## NetWare

On NetWare, mysqld\_safe is a NetWare Loadable Module (NLM) that is ported from the original Unix shell script. It starts the server as follows:

1. Runs a number of system and option checks.
2. Runs a check on MyISAM tables.
3. Provides a screen presence for the MariaDB server.
4. Starts mysqld, monitors it, and restarts it if it terminates in error.
5. Sends error messages from mysqld to the host\_name.err file in the data directory.
6. Sends mysqld\_safe screen output to the host\_name.safe file in the data directory.

  5. [See Also](#)

`mysqladmin`  
is an administration program for the mysqld daemon. It can be used to:

- Monitor what the MariaDB clients are doing (processlist)
- Get usage statistics and variables from the MariaDB server
- Create/drop databases
- Flush (reset) logs, statistics and tables
- Kill running queries.
- Stop the server (shutdown)
- Start/stop replicas
- Check if the server is alive (ping)

## Using mysqladmin

The command to use

`mysqladmin`  
and the general syntax is:

```
mysqladmin [options] command [command-arg] [command [command-arg]] ...
```

## Options

`mysqladmin`  
supports the following options:

| Option                    | Description                                                                                  | Added |
|---------------------------|----------------------------------------------------------------------------------------------|-------|
| --character-sets-dir=name | Directory where the <a href="#">character set</a> files are located.                         |       |
| -C<br>'<br>--compress     | Compress all information sent between the client and the server if both support compression. |       |

|                                                     |                                                                                                                                                                                                                                                                                                                                                                                      |                                  |
|-----------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------------------------|
| --connect_timeout=val                               | Maximum time in seconds before connection timeout. The default value is 43200 (12 hours).                                                                                                                                                                                                                                                                                            |                                  |
| -c val<br>,--count=val                              | Number of iterations to make. This works with<br>-i<br>(<br>--sleep<br>) only.                                                                                                                                                                                                                                                                                                       |                                  |
| --debug[=debug_options]<br>,--#[br/>[debug_options] | Write a debugging log. A typical debug_options string is<br>d:t:o,file_name<br>. The default is<br>d:t:o,/tmp/mysqladmin.trace                                                                                                                                                                                                                                                       |                                  |
| --debug-check                                       | Check memory and open file usage at exit.                                                                                                                                                                                                                                                                                                                                            |                                  |
| --debug-info                                        | Print debugging information and memory and CPU usage statistics when the program exits.                                                                                                                                                                                                                                                                                              |                                  |
| --default-auth=plugin                               | Default authentication client-side plugin to use.                                                                                                                                                                                                                                                                                                                                    |                                  |
| --default-character-set=name                        | Set the default character set.                                                                                                                                                                                                                                                                                                                                                       |                                  |
| -f<br>,--force                                      | Don't ask for confirmation on drop database; with multiple commands, continue even if an error occurs.                                                                                                                                                                                                                                                                               |                                  |
| -?<br>,--help                                       | Display this help and exit.                                                                                                                                                                                                                                                                                                                                                          |                                  |
| -h name<br>,--host=name                             | Hostname to connect to.                                                                                                                                                                                                                                                                                                                                                              |                                  |
| -l<br>,--local                                      | Suppress the SQL command(s) from being written to the <a href="#">binary log</a> by enabling <code>sql_log_bin=0</code> for the session, or, from <a href="#">MariaDB 10.2.7</a> and <a href="#">MariaDB 10.1.24</a> , for flush commands only, using<br>FLUSH LOCAL<br>rather than<br>SET <code>sql_log_bin=0</code><br>, so the privilege requirement is RELOAD rather than SUPER. | MariaDB 10.2.5 , MariaDB 10.1.22 |
| -b<br>,--no-beep                                    | Turn off beep on error.                                                                                                                                                                                                                                                                                                                                                              |                                  |

|                            |                                                                                                                                                                                                                                                                                                                                                                                         |  |
|----------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--|
| -<br>p[password]<br>,      | password to use when connecting to server. If password is not given it's asked from the terminal.                                                                                                                                                                                                                                                                                       |  |
| --pipe<br>,                | On Windows, connect to the server via a named pipe. This option applies only if the server supports named-pipe connections.                                                                                                                                                                                                                                                             |  |
| -P<br>portnum<br>,         | Port number to use for connection, or 0 for default to, in order of preference, my.cnf, \$MYSQL_TCP_PORT, /etc/services, built-in default (3306).                                                                                                                                                                                                                                       |  |
| --<br>protocol=name        | The protocol to use for connection (tcp, socket, pipe, memory).                                                                                                                                                                                                                                                                                                                         |  |
| -r<br>,                    | Show difference between current and previous values when used with<br>-i<br>. Currently only works with extended-status.                                                                                                                                                                                                                                                                |  |
| -O value<br>,              | Change the value of a variable. Please note that this option is deprecated; you can set variables directly with<br>--variable-name=value                                                                                                                                                                                                                                                |  |
| --<br>variable=value       |                                                                                                                                                                                                                                                                                                                                                                                         |  |
| --<br>shutdown_timeout=val | Maximum number of seconds to wait for server shutdown. The default value is 3600 (1 hour).                                                                                                                                                                                                                                                                                              |  |
| -s<br>,                    | Silently exit if one can't connect to server.                                                                                                                                                                                                                                                                                                                                           |  |
| --silent                   |                                                                                                                                                                                                                                                                                                                                                                                         |  |
| -i delay<br>,              | Execute commands repeatedly, sleeping for <i>delay</i> seconds in between. The<br>--count<br>option determines the number of iterations. If<br>--count<br>is not given, <i>mysqladmin</i> executes commands indefinitely until interrupted.                                                                                                                                             |  |
| -S name<br>,               | For connections to localhost, the Unix socket file to use, or, on Windows, the name of the named pipe to use.                                                                                                                                                                                                                                                                           |  |
| --socket=name              |                                                                                                                                                                                                                                                                                                                                                                                         |  |
| --ssl                      | Enables <a href="#">TLS</a> . TLS is also enabled even without setting this option when certain other TLS options are set. Starting with <a href="#">MariaDB 10.2</a> , the<br>--ssl<br>option will not enable <a href="#">verifying the server certificate</a> by default. In order to verify the server certificate, the user must specify the<br>--ssl-verify-server-cert<br>option. |  |

|                              |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |                |
|------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------|
| ca=name<br>--ssl-            | Defines a path to a PEM file that should contain one or more X509 certificates for trusted Certificate Authorities (CAs) to use for <a href="#">TLS</a> . This option requires that you use the absolute path, not a relative path. See <a href="#">Secure Connections Overview: Certificate Authorities (CAs)</a> for more information. This option implies the<br><br>--ssl<br>option.                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |                |
| capath=name<br>--ssl-        | Defines a path to a directory that contains one or more PEM files that should each contain one X509 certificate for a trusted Certificate Authority (CA) to use for <a href="#">TLS</a> . This option requires that you use the absolute path, not a relative path. The directory specified by this option needs to be run through the<br><br><code>openssl rehash</code><br><br>command. See <a href="#">Secure Connections Overview: Certificate Authorities (CAs)</a> for more information. This option is only supported if the client was built with OpenSSL or yaSSL. If the client was built with GnuTLS or Schannel, then this option is not supported. See <a href="#">TLS and Cryptography Libraries Used by MariaDB</a> for more information about which libraries are used on which platforms. This option implies the<br><br>--ssl<br>option. |                |
| cert=name<br>--ssl-          | Defines a path to the X509 certificate file to use for <a href="#">TLS</a> . This option requires that you use the absolute path, not a relative path. This option implies the<br><br>--ssl<br>option.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |                |
| cipher=name<br>--ssl-        | List of permitted ciphers or cipher suites to use for <a href="#">TLS</a> . This option implies the<br><br>--ssl<br>option.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |                |
| crl=name<br>--ssl-           | Defines a path to a PEM file that should contain one or more revoked X509 certificates to use for <a href="#">TLS</a> . This option requires that you use the absolute path, not a relative path. See <a href="#">Secure Connections Overview: Certificate Revocation Lists (CRLs)</a> for more information. This option is only supported if the client was built with OpenSSL or Schannel. If the client was built with yaSSL or GnuTLS, then this option is not supported. See <a href="#">TLS and Cryptography Libraries Used by MariaDB</a> for more information about which libraries are used on which platforms.                                                                                                                                                                                                                                   |                |
| crlpath=name<br>--ssl-       | Defines a path to a directory that contains one or more PEM files that should each contain one revoked X509 certificate to use for <a href="#">TLS</a> . This option requires that you use the absolute path, not a relative path. The directory specified by this option needs to be run through the<br><br><code>openssl rehash</code><br><br>command. See <a href="#">Secure Connections Overview: Certificate Revocation Lists (CRLs)</a> for more information. This option is only supported if the client was built with OpenSSL. If the client was built with yaSSL, GnuTLS, or Schannel, then this option is not supported. See <a href="#">TLS and Cryptography Libraries Used by MariaDB</a> for more information about which libraries are used on which platforms.                                                                             |                |
| key=name<br>--ssl-           | Defines a path to a private key file to use for <a href="#">TLS</a> . This option requires that you use the absolute path, not a relative path. This option implies the<br><br>--ssl<br>option.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |                |
| verify-server-cert<br>--ssl- | Enables <a href="#">server certificate verification</a> . This option is disabled by default.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |                |
| version=name<br>--tls-       | This option accepts a comma-separated list of TLS protocol versions. A TLS protocol version will only be enabled if it is present in this list. All other TLS protocol versions will not be permitted. See <a href="#">Secure Connections Overview: TLS Protocol Versions</a> for more information.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        | MariaDB 10.4.6 |
| user=name<br>-u<br>,         | User for login if not current user.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |                |
| -v<br>,                      | Write more information.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |                |
| --verbose                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |                |

|  |                                                             |                                                                                                                                                                                    |                   |
|--|-------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------------|
|  | <code>-V</code><br>,<br><code>--version</code>              | Output version information and exit.                                                                                                                                               |                   |
|  | <code>-E</code><br>,<br><code>--vertical</code>             | Print output vertically. Is similar to '<br><code>--relative</code><br>', but prints output vertically.                                                                            |                   |
|  | <code>-w[ count]</code><br>,<br><code>--wait[=count]</code> | If the connection cannot be established, wait and retry instead of aborting. If a <i>count</i> value is given, it indicates the number of times to retry. The default is one time. |                   |
|  | <code>--wait-for-all-slaves</code>                          | Wait for the last binlog event to be sent to all connected replicas before shutting down. This option is off by default.                                                           | MariaDB<br>10.4.4 |

## Option Files

In addition to reading options from the command-line,

```
mysqladmin
can also read options from option files. If an unknown option is provided to
mysqladmin
in an option file, then it is ignored.
```

The following options relate to how MariaDB command-line tools handles option files. They must be given as the first argument on the command-line:

| Option                                 | Description                                                                         |
|----------------------------------------|-------------------------------------------------------------------------------------|
| <code>--print-defaults</code>          | Print the program argument list and exit.                                           |
| <code>--no-defaults</code>             | Don't read default options from any option file.                                    |
| <code>--defaults-file=#</code>         | Only read default options from the given file #.                                    |
| <code>--defaults-extra-file=#</code>   | Read this file after the global files are read.                                     |
| <code>--defaults-group-suffix=#</code> | In addition to the default option groups, also read option groups with this suffix. |

In [MariaDB 10.2](#) and later,

```
mysqladmin
is linked with MariaDB Connector/C. However, MariaDB Connector/C does not yet handle the parsing of option files for this client. That is still
performed by the server option file parsing code. See MDEV-19035 for more information.
```

## Option Groups

```
mysqladmin
reads options from the following option groups from option files:
```

| Group        | Description                                                                             |
|--------------|-----------------------------------------------------------------------------------------|
| [mysqladmin] | Options read by<br>mysqladmin<br>, which includes both MariaDB Server and MySQL Server. |

|                  |                                                                                                                                                                                          |
|------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| [mariadb-admin]  | Options read by<br>mysqladmin<br>. Available starting with <a href="#">MariaDB 10.4.6</a> .                                                                                              |
| [client]         | Options read by all MariaDB and MySQL <a href="#">client programs</a> , which includes both MariaDB and MySQL clients. For example,<br>mysqldump                                         |
| [client-server]  | Options read by all MariaDB <a href="#">client programs</a> and the MariaDB Server. This is useful for options like socket and port, which is common between the server and the clients. |
| [client-mariadb] | Options read by all MariaDB <a href="#">client programs</a> .                                                                                                                            |

## mysqladmin Variables

Variables can be set with

--variable-name=value

| Variables and boolean options | Value                       |
|-------------------------------|-----------------------------|
| count                         | 0                           |
| debug-check                   | FALSE                       |
| debug-info                    | FALSE                       |
| force                         | FALSE                       |
| compress                      | FALSE                       |
| character-sets-dir            | (No default value)          |
| default-character-set         | (No default value)          |
| host                          | (No default value)          |
| no-beep                       | FALSE                       |
| port                          | 3306                        |
| relative                      | FALSE                       |
| socket                        | /var/run/mysqld/mysqld.sock |

|                        |                    |
|------------------------|--------------------|
| sleep                  | 0                  |
| ssl                    | FALSE              |
| ssl-ca                 | (No default value) |
| ssl-capath             | (No default value) |
| ssl-cert               | (No default value) |
| ssl-cipher             | (No default value) |
| ssl-key                | (No default value) |
| ssl-verify-server-cert | FALSE              |
| user                   | (No default value) |
| verbose                | FALSE              |
| vertical               | FALSE              |
| connect_timeout        | 43200              |
| shutdown_timeout       | 3600               |

## mysqladmin Commands

```
mysqladmin [options] command [command-arg] [command [command-arg]] ...
```

Command is one or more of the following. Commands may be shortened to a unique prefix.

| Command                | Description                                        | Added |
|------------------------|----------------------------------------------------|-------|
| create<br>databasename | Create a new database.                             |       |
| debug                  | Instruct server to write debug information to log. |       |
| drop<br>databasename   | Delete a database and all its tables.              |       |

|                         |                                                               |                                  |
|-------------------------|---------------------------------------------------------------|----------------------------------|
| extended-status         | Return all <a href="#">status variables</a> and their values. |                                  |
| flush-all-statistics    | Flush all statistics tables                                   |                                  |
| flush-all-status        | Flush status and statistics.                                  |                                  |
| flush-binary-log        | Flush <a href="#">binary log</a> .                            | MariaDB 10.1.25 , MariaDB 10.2.5 |
| flush-client-statistics | Flush client statistics.                                      |                                  |
| flush-engine-log        | Flush engine log.                                             | MariaDB 10.1.25 , MariaDB 10.2.5 |
| flush-error-log         | Flush <a href="#">error log</a> .                             | MariaDB 10.1.25 , MariaDB 10.2.5 |
| flush-general-log       | Flush <a href="#">general query log</a> .                     | MariaDB 10.1.25 , MariaDB 10.2.5 |
| flush-hosts             | Flush all cached hosts.                                       |                                  |
| flush-index-statistics  | Flush index statistics.                                       |                                  |
| flush-logs              | Flush all logs.                                               |                                  |
| flush-privileges        | Reload grant tables (same as reload).                         |                                  |
| flush-relay-log         | Flush <a href="#">relay log</a> .                             | MariaDB 10.1.25 , MariaDB 10.2.5 |

|                           |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |                                                                     |
|---------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------------------------------------------------------------|
| flush-slow-log            | Flush slow query log.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |                                                                     |
| flush-ssl                 | Flush SSL certificates.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       | (unreleased)                                                        |
| flush-status              | Clear <a href="#">status variables</a> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |                                                                     |
| flush-table-statistics    | Clear table statistics.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |                                                                     |
| flush-tables              | Flush all tables.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |                                                                     |

| kill id,id,...            | Kill mysql threads.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |                                                                     |
| password new-password     | Change old password to new-password. The new password can be passed on the commandline as the next argument (for example,<br><code>mysqladmin password "new_password"</code><br>, or can be omitted (as long as no other command follows), in which case the user will be prompted for a password. If the password contains special characters, it needs to be enclosed in quotation marks. In Windows, the quotes can only be double quotes, as single quotes are assumed to be part of the password. If the server was started with the <a href="#">--skip-grant-tables</a> option, changing the password in this way will have no effect.) |                                                                     |
| old-password new-password | Change old password to new-password using the old pre-MySQL 4.1 format.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |                                                                     |
| ping                      | Check if mysqld is alive. Return status is 0 if the server is running (even in the case of an error such as access denied), 1 if it is not.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |                                                                     |
| processlist               | Show list of active threads in server, equivalent to <a href="#">SHOW PROCESSLIST</a> . With<br><code>--verbose</code><br>, equivalent to <a href="#">SHOW FULL PROCESSLIST</a> .                                                                                                                                                                                                                                                                                                                                                                                                                                                             |                                                                     |

|                  |                                                                                                                                                                                                                                                                                                                  |  |
|------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--|
| reload           | Reload grant tables.                                                                                                                                                                                                                                                                                             |  |
| refresh          | Flush all tables and close and open log files.                                                                                                                                                                                                                                                                   |  |
| shutdown         | Take server down by executing the <a href="#">SHUTDOWN</a> command on the server. If connected to a local server using a Unix socket file, mysqladmin waits until the server's process ID file has been removed to ensure that the server has stopped properly. See also the<br>--wait-for-all-slaves<br>option. |  |
| status           | Gives a short status message from the server.                                                                                                                                                                                                                                                                    |  |
| start-all-slaves | Start all replicas.                                                                                                                                                                                                                                                                                              |  |
| start-slave      | Start replication on a replica server.                                                                                                                                                                                                                                                                           |  |
| stop-all-slaves  | Stop all replicas.                                                                                                                                                                                                                                                                                               |  |
| stop-slave       | Stop replication on a replica server.                                                                                                                                                                                                                                                                            |  |
| variables        | Prints variables available.                                                                                                                                                                                                                                                                                      |  |
| version          | Returns version as well as status info from the server.                                                                                                                                                                                                                                                          |  |

## The shutdown Command and the --wait-for-all-slaves Option

MariaDB starting with [10.4.4](#)

The

--wait-for-all-slaves  
option was first added in [MariaDB 10.4.4](#).

When a master server is shutdown and it goes through the normal shutdown process, the master kills client threads in random order. By default, the master also considers its binary log dump threads to be regular client threads. As a consequence, the binary log dump threads can be killed while client threads still exist, and this means that data can be written on the master during a normal shutdown that won't be replicated. This is true even if [semi-synchronous replication](#) is being used.

In [MariaDB 10.4](#) and later, this problem can be solved by shutting down the server with the

`mysqladmin`

utility and by providing the  
--wait-for-all-slaves  
option to the utility and by executing the  
shutdown

command with the utility. For example:

```
mysqladmin --wait-for-all-slaves shutdown
```

When the

--wait-for-all-slaves

option is provided, the server only kills its binary log dump threads after all client threads have been killed, and it only completes the shutdown after the last [binary log](#) has been sent to all connected replicas.

See [Replication Threads: Binary Log Dump Threads and the Shutdown Process](#) for more information.

## Examples

Quick check of what the server is doing:

```
shell> mysqladmin status
Uptime: 8023 Threads: 1 Questions: 14 Slow queries: 0 Opens: 15 Flush tables: 1 Open tables: 8 Queries per second avg: 0.1
shell> mysqladmin processlist
+-----+-----+-----+-----+-----+
| Id | User | Host | db | Command | Time | State | Info |
+-----+-----+-----+-----+-----+
.....
+-----+-----+-----+-----+-----+
```

More extensive information of what is happening 'just now' changing (great for troubleshooting a slow server):

```
shell> mysqladmin --relative --sleep=1 extended-status | grep -v " 0 "
```

Check the variables for a running server:

```
shell> mysqladmin variables | grep datadir
| datadir | /my/data/ |
```

Using a shortened prefix for the

version

command:

```
shell> mysqladmin ver
mysqladmin Ver 9.1 Distrib 10.1.6-MariaDB, for debian-linux-gnu on x86_64
Copyright (c) 2000, 2015, Oracle, MariaDB Corporation Ab and others.

Server version 10.1.6-MariaDB-1~trusty-log
Protocol version 10
Connection Localhost via UNIX socket
UNIX socket /var/run/mysqld/mysqld.sock
Uptime: 1 hour 33 min 33 sec

Threads: 1 Questions: 281 Slow queries: 0 Opens: 64 Flush tables: 1 Open tables: 76 Queries per second avg: 0.050
```

## Other Ways To Stop mysqld (Unix)

If you get the error:

```
mysqladmin: shutdown failed; error: 'Access denied; you need (at least one of) the SHUTDOWN privilege(s) for this operation'
```

It means that you didn't use

mysqladmin

with a user that has the SUPER or SHUTDOWN privilege.

If you don't know the user password, you can still take the mysqld process down with a system

kill

command:

```
kill -SIGTERM pid-of-mysqld-process
```

The above is identical to

```
mysqladmin shutdown
```

On windows you should use:

You can use the [SHUTDOWN](#) command from any client.

- [SHUTDOWN command](#)
- [mytop](#), a 'top' like program for MariaDB/MySQL that allows you to see what the server is doing. A mytop optimized for MariaDB is included in [MariaDB 5.3](#)

## 2.1.6.10 Switching Between Different Installed MariaDB Versions

### Contents

1. [Stopping a pre-installed MySQL/MariaDB from interfering with your tests](#)
2. [How to create a binary distribution \(tar file\)](#)
3. [Creating a directory structure for the different installations](#)
4. [Setting up the data directory](#)
  1. [Setting up a common data directory](#)
  2. [Setting up different data directories](#)
5. [Running a MariaDB server](#)
6. [Setting up a .my.cnf file for running multiple MariaDB main versions](#)

This article is about managing many different installed MariaDB versions and running them one at a time. This is useful when doing benchmarking, testing, or for when developing different MariaDB versions.

This is most easily done using the tar files from [downloads.askmonty.org](#).

## Stopping a pre-installed MySQL/MariaDB from interfering with your tests

If MySQL/MariaDB is already installed and running, you have two options:

1. Use test MariaDB servers with a different port & socket.
  - In this case you are probably best off creating a specific section for MariaDB in your  
`~/.my.cnf`  
 file.
2. Stop mysqld with
 

```
/etc/rc.d/mysql stop
```

 or
 

```
mysqladmin shutdown
```

Note that you don't have to uninstall or otherwise remove MySQL!

## How to create a binary distribution (tar file)

Here is a short description of how to generate a tar file from a source distribution. If you have [downloaded](#) a binary tar file, you can skip this section.

The steps to create a binary tar file are:

- Decide where to put the source. A good place is under  
`/usr/local/src/mariadb-5.#`
- [Get the source](#)
- [Compile the source](#)
- [Create the binary tar ball](#)

You will then be left with a tar file named something like:

```
mariadb-5.3.2-MariaDB-beta-linux-x86_64.tar.gz
```

## Creating a directory structure for the different installations

Install the binary tar files under

```
/usr/local/  
with the following directory names (one for each MariaDB version you want to use):
```

- mariadb-5.1
- mariadb-5.2
- mariadb-5.3
- mariadb-5.5
- mariadb-10.0

The above assumes you are just testing major versions of MariaDB. If you are testing specific versions, use directory names like  
`mariadb-5.3.2`

With the directories in place, create a sym-link named

```
mariadb  
which points at the  
mariadb-XXX  
directory you are currently testing. When you want to switch to testing a different version, just update the sym-link.
```

Example:

```
cd /usr/local  
tar xfz /tmp/mariadb-5.3.2-MariaDB-beta-linux-x86_64.tar.gz  
mv -vi mariadb-5.3.2-MariaDB-beta-linux-x86_64 mariadb-5.3  
ln -vs mariadb-5.3 mariadb
```

## Setting up the data directory

When setting up the data directory, you have the option of either using a shared database directory or creating a unique database directory for each server version. For testing, a common directory is probably easiest. Note that you can only have one

```
mysqld  
server running against one data directory.
```

### Setting up a common data directory

The steps are:

1. Create the

```
mysql  
system user if you don't have it already! (On Linux you do it with the  
useradd  
command).
```

2. Create the directory (we call it

```
mariadb-data  
in the example below) or add a symlink to a directory which is in some other place.
```

3. Create the

```
mysql  
permission tables with  
mysql_install_db
```

```
cd /usr/local/  
mkdir mariadb-data  
cd mariadb  
.bin/mysql_install_db --no-defaults --datadir=/usr/local/mariadb-data  
chown -R mysql mariadb-data mariadb-data/*
```

The reason to use

```
--no-defaults  
is to ensure that we don't inherit incorrect options from some old my.cnf.
```

### Setting up different data directories

To create a different

data  
directories for each installation:

```
cd mariadb  
.scripts/mysql_install_db --no-defaults  
chown -R mysql mariadb-data mariadb-data/*
```

This will create a directory

data  
inside the current directory.

If you want to use another disk you should do:

```
cd mariadb  
ln -s path-to-empty-directory-for-data data  
.scripts/mysql_install_db --no-defaults --datadir=./data  
chown -R mysql mariadb-data mariadb-data/*
```

## Running a MariaDB server

The normal steps are:

```
rm mariadb  
ln -s mariadb-5.# mariadb  
cd mariadb  
.bin/mysqld_safe --no-defaults --datadir=/usr/local/mariadb-data &
```

## Setting up a .my.cnf file for running multiple MariaDB main versions

If you are going to start/stop MariaDB a lot of times, you should create a

~/.my.cnf  
file for the common options you are using.

The following example shows how to use a non-standard TCP-port and socket (to not interfere with a main MySQL/MariaDB server) and how to setup different options for each main server:

```
[client-server]  
socket=/tmp/mysql.sock  
port=3306  
[mysqld]  
datadir=/usr/local/mariadb-data  
  
[mariadb-5.2]  
# Options for MariaDB 5.2  
[mariadb-5.3]  
# Options for MariaDB 5.3
```

If you create an

~/.my.cnf  
file, you should start  
mysqld  
with  
--defaults-file=~/.my.cnf  
instead of  
--no-defaults  
in the examples above.

## 2.1.6.11 Specifying Permissions for Schema (Data) Directories and Tables

### Default File Permissions

By default MariaDB uses the following permissions for files and directories:

| Object Type | Default Mode | Default Permissions |
|-------------|--------------|---------------------|
|-------------|--------------|---------------------|

|             |      |            |
|-------------|------|------------|
| Files       | 0660 | -rw-rw---- |
| Directories | 0700 | drwx-----  |

## Configuring File Permissions with Environment Variables

You can configure MariaDB to use different permissions for files and directories by setting the following [environment variables](#) before you start the server:

| Object Type | Environment Variable |
|-------------|----------------------|
| Files       | UMASK                |
| Directories | UMASK_DIR            |

In other words, if you would run the following in a shell:

```
export UMASK=0640
export UMASK_DIR=0750
```

These environment variables do not set the umask. They set the default file system permissions. See [MDEV-23058](#) for more information.

## Configuring File Permissions with systemd

If your server is started by

`systemd`

, then there is a specific way to configure the umask. See [Systemd: Configuring the umask](#) for more information.

### 2.1.6.12 mysqld\_multi

MariaDB starting with [10.4.6](#)

From [MariaDB 10.4.6](#) ,  
`mariadb-multi`  
 is a symlink to  
`mysqld_multi`  
 .

MariaDB starting with [10.5.2](#)

From [MariaDB 10.5.2](#) ,  
`mariadb-multi`  
 is the name of the server, with  
`mysqld_multi`  
 a symlink .

Before using `mysqld_multi` be sure that you understand the meanings of the options that are passed to the `mysqld` servers and why you would want to have separate `mysqld` processes. Beware of the dangers of using multiple `mysqld` servers with the same data directory. Use separate data directories, unless you know what you are doing. Starting multiple servers with the same data directory does not give you extra performance in a threaded system.

## Contents

1. [Using mysqld\\_multi](#)
  1. [Options](#)
  2. [Option Files](#)
    1. [Option Groups](#)
  3. [Authentication and Privileges](#)
2. [User Account](#)
3. [Example](#)

The

```
mysqld_multi
```

startup script is in MariaDB distributions on Linux and Unix. It is a wrapper that is designed to manage several  
mysqld  
processes running on the same host. In order for multiple  
mysqld  
processes to work on the same host, these processes must:

- Use different Unix socket files for local connections.
- Use different TCP/IP ports for network connections.
- Use different data directories.
- Use different process ID files (specified by the  
--pid-file  
option) if using

```
mysqld_safe
```

to start

```
mysqld
```

.

```
mysqld_multi
```

can start or stop servers, or report their current status.

## Using mysqld\_multi

The command to use

```
mysqld_multi
```

and the general syntax is:

```
mysqld_multi [options] {start|stop|report} [GNR[,GNR] ...]
```

```
start  
,  
stop  
, and  
report  
indicate which operation to perform.
```

You can specify which servers to perform the operation on by providing one or more

```
GNR  
values.
```

GNR  
refers to an option group number, and it is explained more in the [option groups](#) section below. If there is no  
GNR  
list, then  
mysqld\_multi  
performs the operation for all  
GNR  
values found in its option files.

Multiple

```
GNR  
values can be specified as a comma-separated list.  
GNR  
values can also be specified as a range by separating the numbers by a dash. There must not be any whitespace characters in the  
GNR  
list.
```

For example:

This command starts a single server using option group

```
[mysqld17]
```

```
:
```

```
mysqld_multi start 17
```

This command stops several servers, using option groups

```
[mysqld8]
```

```
and
```

```
[mysqld10]
```

```
through
```

```
[mysqld13]
```

```
:
```

```
mysqld_multi stop 8,10-13
```

## Options

`mysqld_multi`

supports the following options:

| Option                 | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
|------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| --example              | Give an example of a config file with extra information.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| --help                 | Display help and exit.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| --log=filename         | Specify the path and name of the log file. If the file exists, log output is appended to it.                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| --mysqladmin=prog_name | The <code>mysqladmin</code> binary to be used to stop servers. Can be given within groups<br>[mysqld#]<br>.                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| --mysqld=prog_name     | The mysqld binary to be used. Note that you can also specify <code>mysqld_safe</code> as the value for this option. If you use <code>mysqld_safe</code> to start the server, you can include the<br>mysqld<br>or<br>ledir<br>options in the corresponding<br>[mysqldN]<br>option group. These options indicate the name of the server that <code>mysqld_safe</code> should start and the path name of the directory where the server is located. Example:<br>[mysqld38]<br><br>mysqld = mysqld-debug<br><br>ledir = /opt/local/mysql/libexec<br>. |
| --no-log               | Print to stdout instead of the log file. By default the log file is turned on.                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| --password=password    | The password of the MariaDB account to use when invoking <code>mysqladmin</code> . Note that the password value is not optional for this option, unlike for other MariaDB programs.                                                                                                                                                                                                                                                                                                                                                               |

|                     |                                                                                                                                                                                                                                                                                                                                      |
|---------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| --silent            | Silent mode; disable warnings.                                                                                                                                                                                                                                                                                                       |
| --tcp-ip            | Connect to the MariaDB server(s) via the TCP/IP port instead of the UNIX socket. This affects stopping and reporting. If a socket file is missing, the server may still be running, but can be accessed only via the TCP/IP port. By default connecting is done via the UNIX socket. This option affects stop and report operations. |
| --user=username     | The user name of the MariaDB account to use when invoking <a href="#">mysqladmin</a> .                                                                                                                                                                                                                                               |
| --verbose           | Be more verbose.                                                                                                                                                                                                                                                                                                                     |
| --version           | Display version information and exit.                                                                                                                                                                                                                                                                                                |
| --wsrep-new-cluster | Bootstrap a cluster. Added in <a href="#">MariaDB 10.1.15</a> .                                                                                                                                                                                                                                                                      |

## Option Files

In addition to reading options from the command-line,

```
mysqld_multi
can also read options from option files. If an unknown option is provided to
mysqld_multi
in an option file, then it is ignored.
```

The following options relate to how MariaDB command-line tools handles option files. They must be given as the first argument on the command-line:

| Option                    | Description                                                                         |
|---------------------------|-------------------------------------------------------------------------------------|
| --print-defaults          | Print the program argument list and exit.                                           |
| --no-defaults             | Don't read default options from any option file.                                    |
| --defaults-file=#         | Only read default options from the given file #.                                    |
| --defaults-extra-file=#   | Read this file after the global files are read.                                     |
| --defaults-group-suffix=# | In addition to the default option groups, also read option groups with this suffix. |

## Option Groups

`mysqld_safe`  
reads options from the following [option groups](#) from [option files](#):

| Group          | Description                                                                                         |
|----------------|-----------------------------------------------------------------------------------------------------|
| [mysqld_multi] | Options read by<br><code>mysqld_multi</code> , which includes both MariaDB Server and MySQL Server. |

`mysqld_multi`  
also searches [option files](#) for [option groups](#) with names like

[mysqldN]  
, where  
N  
can be any positive integer. This number is referred to in the following discussion as the option group number, or  
GNR  
:

| Group     | Description                                                                                                                                                                   |
|-----------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| [mysqldN] | Options read by a<br>mysqld<br>instance managed by<br>mysqld_multi<br>, which includes both MariaDB Server and MySQL Server. The<br>N<br>refers to the instance's<br>GNR<br>. |

GNR  
values distinguish option groups from one another and are used as arguments to  
mysqld\_multi  
to specify which servers you want to start, stop, or obtain a status report for. The  
GNR  
value should be the number at the end of the option group name in the option file. For example, the  
GNR  
for an option group named  
[mysqld17]  
is  
17  
.

Options listed in these option groups are the same that you would use in the regular server option groups used for configuring  
mysqld  
. However, when using multiple servers, it is necessary that each one use its own value for options such as the Unix socket file and TCP/IP port number.

The

[mysqld\_multi]  
option group can be used for options that are needed for  
mysqld\_multi  
itself.  
[mysqldN]  
option groups can be used for options passed to specific  
mysqld  
instances.

The regular server [option groups](#) can also be used for common options that are read by all instances:

| Group        | Description                                                                                                                                 |
|--------------|---------------------------------------------------------------------------------------------------------------------------------------------|
| [mysqld]     | Options read by<br>mysqld<br>, which includes both MariaDB Server and MySQL Server.                                                         |
| [server]     | Options read by MariaDB Server.                                                                                                             |
| [mysqld-X.Y] | Options read by a specific version of<br>mysqld<br>, which includes both MariaDB Server and MySQL Server. For example,<br>[mysqld-5.5]<br>. |
| [mariadb]    | Options read by MariaDB Server.                                                                                                             |

|                 |                                                                                                                                                                                          |
|-----------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| [mariadb-X.Y]   | Options read by a specific version of MariaDB Server.                                                                                                                                    |
| [client-server] | Options read by all MariaDB <a href="#">client programs</a> and the MariaDB Server. This is useful for options like socket and port, which is common between the server and the clients. |
| [galera]        | Options read by a galera-capable MariaDB Server. Available on systems compiled with Galera support.                                                                                      |

For an example of how you might set up an option file, use this command:

```
mysqld_multi --example
```

## Authentication and Privileges

Make sure that the MariaDB account used for stopping the

`mysqld`  
processes (with the

`mysqladmin`

utility) has the same user name and password for each server. Also, make sure that the account has the SHUTDOWN privilege. If the servers that you want to manage have different user names or passwords for the administrative accounts, you might want to create an account on each server that has the same user name and password. For example, you might set up a common `multi_admin` account by executing the following commands for each server:

```
shell> mysql -u root -S /tmp/mysql.sock -p
Enter password:
mysql> GRANT SHUTDOWN ON *.* TO 'multi_admin'@'localhost' IDENTIFIED BY 'multipass';
```

Change the connection parameters appropriately when connecting to each one. Note that the host name part of the account name must allow you to connect as

`multi_admin`  
from the host where you want to run  
`mysqld_multi`

## User Account

Make sure that the data directory for each server is fully accessible to the Unix account that the specific

`mysqld`  
process is started as. If you run the  
`mysqld_multi`  
script as the Unix  
root  
account, and if you want the  
`mysqld`  
process to be started with another Unix account, then you can use the  
--user  
option with  
`mysqld`  
. If you specify the  
--user  
option in an option file, and if you did not run the  
`mysqld_multi`  
script as the Unix  
root  
account, then it will just log a warning and the  
`mysqld`  
processes are started under the original Unix account.

Do not run the

```
mysqld  
process as the Unix  
root  
account, unless you know what you are doing.
```

## Example

The following example shows how you might set up an option file for use with mysqld\_multi. The order in which the mysqld programs are started or stopped depends on the order in which they appear in the option file. Group numbers need not form an unbroken sequence. The first and fifth [mysqldN] groups were intentionally omitted from the example to illustrate that you can have "gaps" in the option file. This gives you more flexibility.

```
# This file should probably be in your home dir (~/.my.cnf)  
# or /etc/my.cnf  
# Version 2.1 by Jani Tolonen  
[mysqld_multi]  
mysqld      = /usr/local/bin/mysqld_safe  
mysqladmin  = /usr/local/bin/mysqladmin  
user        = multi_admin  
password    = multipass  
[mysqld2]  
socket      = /tmp/mysql.sock2  
port        = 3307  
pid-file   = /usr/local/mysql/var2/hostname.pid2  
datadir    = /usr/local/mysql/var2  
language   = /usr/local/share/mysql/english  
user        = john  
[mysqld3]  
socket      = /tmp/mysql.sock3  
port        = 3308  
pid-file   = /usr/local/mysql/var3/hostname.pid3  
datadir    = /usr/local/mysql/var3  
language   = /usr/local/share/mysql/swedish  
user        = monty  
[mysqld4]  
socket      = /tmp/mysql.sock4  
port        = 3309  
pid-file   = /usr/local/mysql/var4/hostname.pid4  
datadir    = /usr/local/mysql/var4  
language   = /usr/local/share/mysql/estonia  
user        = tonu  
[mysqld6]  
socket      = /tmp/mysql.sock6  
port        = 3311  
pid-file   = /usr/local/mysql/var6/hostname.pid6  
datadir    = /usr/local/mysql/var6  
language   = /usr/local/share/mysql/japanese  
user        = jani
```

## 2.1.6.13 launchd

In Mac OS, create a file called /Library/LaunchDaemons/com.mariadb.server.plist with the following contents (edit to suit):

```

<?xml version="1.0" encoding="UTF-8"?>
<!DOCTYPE plist PUBLIC "-//Apple Computer//DTD PLIST 1.0//EN" "http://www.apple.com/DTDs/PropertyList-1.0.dtd">
<plist version="1.0">
<dict>
    <key>Label</key> <string>com.mariadb.server</string>
    <key>KeepAlive</key><true/>
    <key>RunAtLoad</key><true/>
    <key>LaunchOnlyOnce</key><false/>
    <key>ExitTimeOut</key><integer>600</integer>
        <key>WorkingDirectory</key><string>/usr/local/var</string>
        <key>Program</key><string>/usr/local/bin/mysqld</string>
        <key>ProgramArguments</key>
        <array>
            <string>/usr/local/bin/mysqld</string>
            <string>--user=_mysql</string>
            <string>--basedir=/usr/local/opt/mariadb</string>
            <string>--plugin-dir=/usr/local/opt/mariadb/lib/plugin</string>
            <string>--datadir=/usr/local/var/mysql</string>
            <string>--log-error=/usr/local/var/mysql/Data-Server.local.err</string>
            <string>--pid-file=/usr/local/var/mysql/Data-Server.local.pid</string>
            <string>--sql-mode=ERROR_FOR_DIVISION_BY_ZERO,NO_AUTO_CREATE_USER,NO_ENGINE_SUBSTITUTION</string>
        </array>
    </dict>
</plist>

```

Then from a shell, run

```

launchctl load /Library/LaunchDaemons/com.mariadb.server.plist
and MariaDB will run immediately, and also upon reboot.

```

## 2.1.6.14 systemd

MariaDB starting with [10.1.8](#)

The MariaDB

```

systemd
service was first released in MariaDB 10.1.8 on supported Linux distributions.

```

systemd  
is a

[sysVinit](#)

replacement that is the default service manager on the following Linux distributions:

- RHEL 7 and above
- CentOS 7 and above
- Fedora 15 and above
- Debian 8 and above
- Ubuntu 15.04 and above
- SLES 12 and above
- OpenSUSE 12.2 and above

MariaDB's

```

systemd
unit file is included in the server packages for RPMs and DEBs. It is also included in certain binary tarballs.

```

The service name is

```

mariadb.service
. Aliases to
mysql.service
and
mysqld.service
are also installed for convenience.

```

When MariaDB is started with the

systemd

unit file, it directly starts the

`mysqld`

process as the

`mysql`

user. Unlike with

`sysVinit`

, the

`mysqld`

process is not started with

`mysqld_safe`

. As a consequence, options will not be read from the

`[mysqld_safe]`

option group from option files .

## Locating the MariaDB Service's Unit File

By default, the unit file for the service will be installed in a directory defined at build time by the

`INSTALL_SYSTEMD_UNITDIR`  
option provided to

`cmake`

For example, on RHEL, CentOS, Fedora, and other similar Linux distributions,

`INSTALL_SYSTEMD_UNITDIR`  
is defined as  
`/usr/lib/systemd/system/`  
, so it will be installed to:

- `/usr/lib/systemd/system/mariadb.service`

And on Debian, Ubuntu, and other similar Linux distributions,

`INSTALL_SYSTEMD_UNITDIR`  
is defined as  
`/lib/systemd/system/`  
, so it will be installed to:

- `/lib/systemd/system/mariadb.service`

## Interacting with the MariaDB Server Process

The service can be interacted with by using the

`systemctl`

command.

### Starting the MariaDB Server Process on Boot

MariaDB's

`systemd`  
service can be configured to start at boot by executing the following:

```
sudo systemctl enable mariadb.service
```

### Starting the MariaDB Server Process

MariaDB's

`systemd`  
service can be started by executing the following:

```
sudo systemctl start mariadb.service
```

MariaDB's

`systemd`  
unit file has a default startup timeout of about 90 seconds on most systems. If certain startup tasks, such as crash recovery, take longer than this default startup timeout, then

`systemd`  
will assume that  
`mysqld`  
has failed to startup, which causes  
`systemd`  
to kill the  
`mysqld`  
process. To work around this, you can reconfigure the MariaDB  
`systemd`  
unit to have an [infinite timeout](#).

Note that [systemd 236 added the](#)

`EXTEND_TIMEOUT_USEC`  
[environment variable](#) that allows services to extend the startup timeout during long-running processes. Starting with [MariaDB 10.1.33](#), [MariaDB 10.2.15](#), and [MariaDB 10.3.6](#), on systems with `systemd` versions that support it, MariaDB uses this feature to extend the startup timeout during certain startup processes that can run long. Therefore, if you are using

`systemd`  
236 or later, then you should not need to manually override  
`TimeoutStartSec`

, even if your startup tasks, such as crash recovery, run for longer than the configured value. See [MDEV-14705](#) for more information.

## Stopping the MariaDB Server Process

MariaDB's

systemd  
service can be stopped by executing the following:

```
sudo systemctl stop mariadb.service
```

## Restarting the MariaDB Server Process

MariaDB's

systemd  
service can be restarted by executing the following:

```
sudo systemctl restart mariadb.service
```

## Checking the Status of the MariaDB Server Process

The status of MariaDB's

systemd  
service can be obtained by executing the following:

```
sudo systemctl status mariadb.service
```

## Interacting with Multiple MariaDB Server Processes

A

systemd  
template unit file with the name  
mariadb@.service  
is installed in  
INSTALL\_SYSTEMD\_UNITDIR  
on some systems. See [Locating the MariaDB Service's Unit File](#) to see what directory that refers to on each distribution.

This template unit file allows you to interact with multiple MariaDB instances on the same system using the same template unit file. When you interact with a MariaDB instance using this template unit file, you have to provide an instance name as a suffix. For example, the following command tries to start a MariaDB instance with the name

```
node1
```

```
:
```

```
sudo systemctl start mariadb@node1.service
```

MariaDB's build system cannot include the

mariadb@.service  
template unit file in [RPM](#) packages on platforms that have

[cmake](#)

versions older than 3.3.0, because these

[cmake](#)

versions have a [bug](#) that causes it to encounter errors when packaging a file in RPMs if the file name contains the  
@  
character. MariaDB's RHEL 7 and CentOS 7 RPM build hosts only got a new enough

[cmake](#)

version starting with [MariaDB 10.1.39](#) , [MariaDB 10.2.23](#) , and [MariaDB 10.3.14](#) . To use this functionality on a MariaDB version that does not have the file, you can copy the file from a package that does have the file.

## Default configuration of Multiple Instances in 10.4 and Later

```
systemd  
will also look for an option file for a specific MariaDB instance based on the instance name.
```

It will use the

```
.%I  
as the custom option group suffix that is appended to any server option group, in any configuration file included by default.
```

In all distributions, the

```
%I  
is the MariaDB instance name. In the above  
node1  
case, it would use the option file at the path  
/etc/mynode1.cnf
```

When using multiple instances, each instance will of course also need their own

```
datadir  
,  
socket  
and,  
port  
(unless  
skip\_networking  
is specified). As
```

```
mysql\_install\_db#option-groups
```

```
reads the same sections as the server, and  
ExecStartPre=  
run
```

```
mysql\_install\_db
```

```
within the service, the instances are autocreated if there is sufficient priviledges.
```

To use a 10.3 configuration in 10.4 or later and the following customisation in the editor after running

```
sudo systemctl edit mariadb@.service  
:
```

```
[Unit]  
ConditionPathExists=  
  
[Service]  
Environment='MYSQLD_MULTI_INSTANCE=--defaults-file=/etc/my%I.cnf'
```

## Custom configuration of Multiple Instances in 10.4 and Later

Because users may want to do many various things with their multiple instances, we've provided a way to let the user define how they wish their multiple instances to run. The systemd environment variable

```
MYSQLD_MULTI_INSTANCE  
can be set to anything that mysqld and mysql\_install\_db will recognise.
```

A hosting environment where each user has their own instance may look like (with

```
sudo systemctl edit mariadb@.service  
):
```

```
[Service]  
ProtectHome=false  
Environment='MYSQLD_MULTI_INSTANCE=--defaults-file=/home/%I/my.cnf \  
--user=%I \  
--socket=/home/%I.sock \  
--datadir=/home/%I/mariadb_data \  
--skip-networking'
```

Here the instance name is the unix user of the service.

## Configuring Multiple Instances in 10.3 and Earlier

systemd  
will also look for an [option file](#) for a specific MariaDB instance based on the instance name. By default, it will look for the option file in a directory defined at build time by the  
`INSTALL_SYSCONF2DIR`  
option provided to

`cmake`

For example, on RHEL, CentOS, Fedora, and other similar Linux distributions,

`INSTALL_SYSCONF2DIR`

is defined as

`/etc/my.cnf.d/`

, so it will look for an option file that matches the format:

- `/etc/my.cnf.d/my%I.cnf`

And on Debian, Ubuntu, and other similar Linux distributions,

`INSTALL_SYSCONF2DIR`

is defined as

`/etc/mysql/conf.d//`

, so it will look for an option file that matches the format:

- `/etc/mysql/conf.d/my%I.cnf`

In all distributions, the

`%I`

is the MariaDB instance name. In the above

`node1`

case, it would use the [option file](#) at the path

`/etc/my.cnf.d/mynode1.cnf`

for RHEL-like distributions and

`/etc/mysql/conf.d/mynode1.cnf`

for Debian-like distributions.

When using multiple instances, each instance will of course also need their own

`datadir`

. See [mysql\\_install\\_db](#) for information on how to initialize the

`datadir`

for additional MariaDB instances.

## Systemd and Galera Cluster

### Bootstrapping a New Cluster

When using [Galera Cluster](#) with systemd, the first node in a cluster has to be started with

`galera_new_cluster`

. See [Getting Started with MariaDB Galera Cluster: Bootstrapping a New Cluster](#) for more information.

### Recovering a Node's Cluster Position

When using [Galera Cluster](#) with systemd, a node's position in the cluster can be recovered with

`galera_recovery`

. See [Getting Started with MariaDB Galera Cluster: Determining the Most Advanced Node](#) for more information.

### SSTs and Systemd

MariaDB's

```
systemd
unit file has a default startup timeout of about 90 seconds on most systems. If an SST takes longer than this default startup timeout on a joiner
node, then
systemd
will assume that
mysqld
has failed to startup, which causes
systemd
to kill the
mysqld
process on the joiner node. To work around this, you can reconfigure the MariaDB
systemd
unit to have an infinite timeout. See Introduction to State Snapshot Transfers \(SSTs\): SSTs and Systemd for more information.
```

Note that [systemd 236 added the](#)

```
EXTEND_TIMEOUT_USEC
environment variable that allows services to extend the startup timeout during long-running processes. Starting with MariaDB 10.1.35, MariaDB 10.2.17, and MariaDB 10.3.8, on systems with systemd versions that support it, MariaDB uses this feature to extend the startup timeout during long
SSTs. Therefore, if you are using
systemd
236 or later, then you should not need to manually override
TimeoutStartSec
, even if your SSTs run for longer than the configured value. See MDEV-15607 for more information.
```

## Configuring the Systemd Service

You can configure MariaDB's

```
systemd
service by creating a "drop-in" configuration file for the
systemd
service. On most systems, the
systemd
service's directory for "drop-in" configuration files is
/etc/systemd/system/mariadb.service.d/
. You can confirm the directory and see what "drop-in" configuration files are currently loaded by executing:
```

```
$ sudo systemctl status mariadb.service
● mariadb.service - MariaDB 10.1.37 database server
   Loaded: loaded (/usr/lib/systemd/system/mariadb.service; enabled; vendor preset: disabled)
   Drop-In: /etc/systemd/system/mariadb.service.d
             └─migrated-from-my.cnf-settings.conf, timeoutstartsec.conf
...
...
```

If you want to configure the

```
systemd
service, then you can create a file with the
.conf
extension in that directory. The configuration option(s) that you would like to change would need to be placed in an appropriate section within the
file, usually
[Service]
. If a
systemd
option is a list, then you may need to set the option to empty before you set the replacement values. For example:
```

```
[Service]
ExecStart=
ExecStart=/usr/bin/numactl --interleave=all /usr/sbin/mysqld ${MYSQLD_OPTS} ${_WSREP_NEW_CLUSTER} ${_WSREP_START_POSITION}
```

After any configuration change, you will need to execute the following for the change to go into effect:

```
sudo systemctl daemon-reload
```

## Useful Systemd Options

Useful

```
systemd
options are listed below. If an option is equivalent to a common
```

## `mysqld_safe`

option, then that is also listed.

| <code>mysqld_safe</code><br>option         | systemd option                                     | Comments                                                                                                                        |
|--------------------------------------------|----------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------|
| no option                                  | <code>ProtectHome=false</code>                     | If any MariaDB files are in /home/                                                                                              |
| no option                                  | <code>PrivateDevices=false</code>                  | If any MariaDB storage references raw block devices                                                                             |
| no option                                  | <code>ProtectSystem=</code>                        | If any MariaDB write any files to anywhere under /boot, /usr or /etc                                                            |
| no option                                  | <code>TimeoutStartSec={time}</code>                | Service startup timeout. See <a href="#">Configuring the Systemd Service Timeout</a> .                                          |
| no option (see <a href="#">MDEV-9264</a> ) | <code>OOMScoreAdjust={priority}</code>             | e.g. -600 to lower priority of OOM killer for mysqld                                                                            |
| <code>open-files-limit</code>              | <code>LimitNOFILE={limit}</code>                   | Limit on number of open files. See <a href="#">Configuring the Open Files Limit</a> .                                           |
| <code>core-file-size</code>                | <code>LimitCORE={size}</code>                      | Limit on core file size. Useful when <a href="#">enabling core dumps</a> . See <a href="#">Configuring the Core File Size</a> . |
|                                            | <code>LimitMEMLOCK={size}</code><br>or<br>infinity | Limit on how much can be locked in memory.<br>Useful when <a href="#">large-pages</a> or <a href="#">memlock</a> is used        |
| <code>nice</code>                          | <code>Nice={nice value}</code>                     |                                                                                                                                 |
| <code>syslog</code>                        | <code>StandardOutput=syslog</code>                 | See <a href="#">Configuring MariaDB to Write the Error Log to Syslog</a> .                                                      |

|                              |                                                                                                                                                   |                                                                                                                            |
|------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------|
|                              | <code>StandardError=syslog</code>                                                                                                                 |                                                                                                                            |
|                              | <code>SyslogFacility=daemon</code>                                                                                                                |                                                                                                                            |
|                              | <code>SyslogLevel=err</code>                                                                                                                      |                                                                                                                            |
| <code>syslog-tag</code>      | <code>SyslogIdentifier</code>                                                                                                                     |                                                                                                                            |
| <code>flush-caches</code>    | <code>ExecStartPre=/usr/bin/sync</code>                                                                                                           |                                                                                                                            |
|                              | <code>ExecStartPre=/usr/sbin/sysctl -q -w vm.drop_caches=3</code>                                                                                 |                                                                                                                            |
| <code>malloc-lib</code>      | <code>Environment=LD_PRELOAD=/path/to/library</code>                                                                                              |                                                                                                                            |
| <code>numa-interleave</code> | <code>NUMAPolicy=interleave</code>                                                                                                                | from systemd v243 onwards                                                                                                  |

Note: the

`systemd`

manual contains the official meanings for these options. The manual also lists considerably more options than the ones listed above.

There are other options and the

`mariadb-service-convert`

script will attempt to convert these as accurately as possible.

## Configuring the Systemd Service Timeout

MariaDB's

## systemd

unit file has a default startup timeout of about 90 seconds on most systems. If a service startup takes longer than this default startup timeout, then

systemd  
will assume that  
mysqld  
has failed to startup, which causes  
systemd  
to kill the  
mysqld  
process. To work around this, it can be changed by configuring the

### TimeoutStartSec

option for the  
systemd  
service.

A similar problem can happen when stopping the MariaDB service. Therefore, it may also be a good idea to set

### TimeoutStopSec

For example, you can reconfigure the MariaDB

systemd  
service to have an infinite timeout by executing one of the following commands:

If you are using  
systemd  
228 or older, then you can execute the following to set an infinite timeout:

```
sudo tee /etc/systemd/system/mariadb.service.d/timeoutsec.conf <<EOF
[Service]
TimeoutStartSec=0
TimeoutStopSec=0
EOF
sudo systemctl daemon-reload
```

Systemd 229 added the infinity option , so if you are using

systemd  
229 or later, then you can execute the following to set an infinite timeout:

```
sudo tee /etc/systemd/system/mariadb.service.d/timeoutsec.conf <<EOF
[Service]
TimeoutStartSec=infinity
TimeoutStopSec=infinity
EOF
sudo systemctl daemon-reload
```

Note that [systemd 236 added the EXTEND\\_TIMEOUT\\_USEC environment variable](#) that allows services to extend the startup timeout during long-running processes. On systems with systemd versions that support it, MariaDB uses this feature to extend the startup timeout during certain startup processes that can run long.

## Configuring the Open Files Limit

When using

systemd  
, rather than setting the open files limit by setting the

### open-files-limit

option for  
mysqld\_safe  
or the

### open\_files\_limit

system variable, the limit can be changed by configuring the

#### `LimitNOFILE`

option for the MariaDB  
systemd  
service. The default is set to  
`LimitNOFILE=16364`  
in  
`mariadb.service`  
.

For example, you can reconfigure the MariaDB

systemd  
service to have a larger limit for open files by executing the following commands:

```
sudo tee /etc/systemd/system/mariadb.service.d/limitnofile.conf <<EOF
[Service]
LimitNOFILE=infinity
EOF
sudo systemctl daemon-reload
```

An important note is that setting

`LimitNOFILE=infinity`  
doesn't actually set the open file limit to *infinity*.

In

systemd  
234 and later, setting  
`LimitNOFILE=infinity`  
actually sets the open file limit to the value of the kernel's  
`fs.nr_open`  
parameter. Therefore, in these  
systemd  
versions, you may have to change this parameter's value.

The value of the

`fs.nr_open`  
parameter can be changed permanently by setting the value in

#### `/etc/sysctl.conf`

and restarting the server.

The value of the

`fs.nr_open`  
parameter can be changed temporarily by executing the

#### `sysctl`

utility. For example:

```
sudo sysctl -w fs.nr_open=1048576
```

In

systemd  
233 and before, setting  
`LimitNOFILE=infinity`  
actually sets the open file limit to  
65536  
. See [systemd issue #6559](#) for more information. Therefore, in these  
systemd  
versions, it is not generally recommended to set  
`LimitNOFILE=infinity`  
. Instead, it is generally better to set  
`LimitNOFILE`  
to a very large integer. For example:

```
sudo tee /etc/systemd/system/mariadb.service.d/limitnofile.conf <<EOF
[Service]

LimitNOFILE=1048576
EOF
sudo systemctl daemon-reload
```

## Configuring the Core File Size

When using

systemd  
, if you would like to [enable core dumps](#) , rather than setting the

[core-file-size](#)

option for  
mysqld\_safe  
, the limit can be changed by configuring the

[LimitCORE](#)

option for the MariaDB  
systemd  
service. For example, you can reconfigure the MariaDB  
systemd  
service to have an infinite size for core files by executing the following commands:

```
sudo tee /etc/systemd/system/mariadb.service.d/limitcore.conf <<EOF
[Service]

LimitCORE=infinity
EOF
sudo systemctl daemon-reload
```

## Configuring MariaDB to Write the Error Log to Syslog

When using

systemd  
, if you would like to redirect the [error log](#) to the [syslog](#) , then that can easily be done by doing the following:

- Ensure that

[log\\_error](#)

system variable is **not** set.

- Set

[StandardOutput=syslog](#)

- Set

[StandardError=syslog](#)

- Set

[SyslogFacility=daemon](#)

- Set

[SysLogLevel=err](#)

For example:

```

sudo tee /etc/systemd/system/mariadb.service.d/syslog.conf <<EOF
[Service]

StandardOutput=syslog
StandardError=syslog
SyslogFacility=daemon
SysLogLevel=err
EOF
sudo systemctl daemon-reload

```

If you have multiple instances of MariaDB, then you may also want to set

#### [SyslogIdentifier](#)

with a different tag for each instance.

## Configuring LimitMEMLOCK

If using [--memlock](#) or the iouring in InnoDB in [MariaDB 10.6](#), you will need to raise the LimitMEMLOCK limit.

```

sudo tee /etc/systemd/system/mariadb.service.d/limitcore.conf <<EOF
[Service]

LimitMEMLOCK=2M
EOF
sudo systemctl daemon-reload

```

Note: Prior to [MariaDB 10.1.10](#), the [--memlock](#) option could not be used with the MariaDB

systemd  
service.

## Configuring Access to Home Directories

MariaDB's [systemd](#) unit file restricts access to

/home  
,  
/root  
, and  
/run/user  
by default. This restriction can be overridden by setting the [ProtectHome](#) option to  
false  
for the MariaDB  
systemd  
service. This is done by creating a "drop-in" directory  
[/etc/systemd/system/mariadb.service.d/](#)  
and in it a file with a  
.conf  
suffix that contains the  
ProtectHome=false  
directive.

You can reconfigure the MariaDB

systemd  
service to allow access to  
/home  
by executing the following commands:

```

sudo mkdir /etc/systemd/system/mariadb.service.d
sudo tee /etc/systemd/system/mariadb.service.d/dontprotecthome.conf <<EOF
[Service]

ProtectHome=false
EOF
sudo systemctl daemon-reload

```

## Configuring the umask

When using

systemd  
, the default file permissions of

`mysqld`  
can be set by setting the  
`UMASK`  
and  
`UMASK_DIR`  
environment variables for the  
`systemd`  
service. For example, you can configure the MariaDB  
`systemd`  
service's umask by executing the following commands:

```
sudo tee /etc/systemd/system/mariadb.service.d/umask.conf <<EOF
[Service]

Environment="UMASK=0750"
Environment="UMASK_DIR=0750"
EOF
sudo systemctl daemon-reload
```

These environment variables do not set the umask. They set the default file system permissions. See [MDEV-23058](#) for more information.

Keep in mind that configuring the umask this way will only affect the permissions of files created by the

```
mysqld
process that is managed by
systemd
. The permissions of files created by components that are not managed by
systemd
, such as

mysql_install_db

, will not be effected.
```

See [Specifying Permissions for Schema \(Data\) Directories and Tables](#) for more information.

## Configuring the data directory

When doing a standard binary tarball install the datadir will be under `/usr/local/data`. The `systemd` service file makes the whole `/usr` directory tree write protected via

```
# Prevent writes to /usr, /boot, and /etc
ProtectSystem=full
```

though. So when just copying the distributed service file a tarball install will not start up, complaining e.g. about

```
[Warning] Can't create test file /usr/local/.../data/ubuntu-focal.lower-test
[ERROR] mariadbd: File '/usr/local/.../data/aria_log_control' not found (Errcode: 30 "Read-only file system")
[ERROR] mariadbd: Got error 'Can't open file' when trying to use aria control file '/usr/local/.../data/aria_log_control'
```

So when using a data directory under `/usr/local` that specific directory needs to be made writable for the service using the `ReadWritePaths` setting:

```
sudo tee /etc/systemd/system/mariadb.service.d/datadir.conf <<EOF
[Service]
ReadWritePaths=/usr/local/mysql/data
EOF
sudo systemctl daemon-reload
```

## Systemd Socket Activation

MariaDB starting with [10.6.0](#)

MariaDB can use `systemd`'s socket activation.

This is an on-demand service for MariaDB that will activate when required.

Systemd socket activation uses a

`mariadb.socket`  
definition file to define a set of UNIX and TCP sockets. Systemd will listen on these sockets, and when they are connected to, systemd will start the

`mariadb.service`  
and hand over the socket file descriptors for MariaDB to process the connection.

MariaDB remains running at this point and will have all sockets available and process connections exactly like it did before 10.6.

When MariaDB is shut down, the systemd

`mariadb.socket`  
remains active, and a new connection will restart the  
`mariadb.service`

## Using Systemd Socket Activation

To use MariaDB systemd socket activation, instead of enabling/starting

`mariadb.service`

,

`mariadb.socket`  
is used instead.

So the following commands work exactly like the

`mariadb.service`  
equivalents.

```
systemctl start mariadb.socket
systemctl enable mariadb.socket
```

These files alone only contain the UNIX and TCP sockets and basic network connection information to which will be listening for connections.

`@mariadb`

is a UNIX abstract socket, which means it doesn't appear on the filesystem. Connectors based on MariaDB Connector/C will be able to connect with these by using the socket name directly, provided the higher level implementation doesn't try to test for the file's existence first. Some connectors like PHP use mysqlnd that is a pure PHP implementation and as such will only be able to connect to on filesystem UNIX sockets.

With systemd activated sockets there is only a file descriptor limit on the number of listening sockets that can be created.

## When to Use Systemd Socket Activation

A common use case for systemd socket activated MariaDB is when there needs to be a quick boot up time. MariaDB needs to be ready to run, but it doesn't need to be running.

The ideal use case for systemd socket activation for MariaDB is for infrastructure providers running many multiple instances of MariaDB, where each instance is dedicated for a user.

## Downsides to Using Systemd Socket Activation

From the time the connection occurs, the client is going to be waiting until MariaDB has fully initialized before MariaDB can process the awaiting connection. If MariaDB was previously hard shutdown and needs to perform an extensive InnoDB rollback, then the activation time may be larger than the desired wait time of the client connection.

## Configuring Systemd Socket Activation

When MariaDB is run under systemd socket activation, the usual `socket`, `port`, and `backlog` system variables are ignored, as these settings are contained within the systemd socket definition file.

There is no configuration required in MariaDB to use MariaDB under socket activation.

The systemd options available are from the

[systemd documentation](#)

, however

[ListenStream](#)

and

[BackLog](#)

would be the most common configuration options.

As MariaDB isn't creating these sockets, the sockets don't need to be created with a

```
mysql
user. The sockets MariaDB may end up listening to under systemd socket activation, it may have not had the privileges to create itself.
```

Changes to the default

```
mariadb.socket
can be made in the same way as services,
systemctl edit mariadb.socket
, or using
/etc/systemd/system/mariadb.socket.d/someconfig.conf
files.
```

## Extra Port

A systemd socket can be configured as an

```
extra_port
, by using the
FileDescriptorName=extra
in the
.socket
file.
```

The

```
mariadb-extra.socket
is already packaged and ready for use.
```

## Multi-instance socket activation

```
mariadb@.socket
is MariaDB's packaged multi-instance definition. It creates multiple UNIX sockets based on the socket file started.
```

Starting

```
mariadb@bob.socket
will use the
mariadb@.socket
definition with
%I
within the definition replaced with "bob".
```

When something connects to a socket defined there, the

```
mariadb@bob.service
will be started.
```

## Systemd Socket Activation for Hosting Service Providers

A systemd socket activation service with multi-instance can provide an on-demand per user access to a hosting service provider's dedicated database. "User", in this case, refers to the customer of the hosting service provider.

## End User Benefits

This provides the following benefits for the user:

- Each user has their own dedicated instance with the following benefits:
  - The instance is free from the database contention of neighbors on MariaDB shared resources (table cache, connections, etc)
  - The user is free to change their own configuration of MariaDB, within the limits and permissions of the service provider.
  - Database service level backups, like mariabackup, are now directly available.
  - A user can install their own plugins.
  - The user can run a different database version to their neighbors.
  - If a user's neighbor triggers a fault in the server, the user's instance isn't affected.
- The database runs as their unix user in the server facilitating:
  - User can directly migrate their MariaDB data directory to a different provider.
  - The user's data is protected from other users on a kernel level.

## Hosting Service Provider Benefits

In addition to providing user benefits as a sales item, the following are additional benefits for the hosting service provider compared to a monolith service:

- Without passwords for the database, while still having security, support may be easier.

- When a user's database isn't active, there is no resource usage, only listening file descriptors by systemd.
- The socket activation transparently, with a minor startup time, starts the service as required.
- When the user's database hasn't had any activity after a time, it will deactivate ( [MDEV-25282](#) ).
- Planned enhancements in InnoDB provide:
  - an on-demand consumption of memory ( [MDEV-25340](#) ).
  - a proactive reduction in memory ( [MDEV-25341](#) ).
  - a memory resource pressure reduction in memory use ( [MDEV-24670](#) ).
- The service provider can still cap the user's database memory usage in a ulimit way that a user cannot override in settings.
- The service provider may choose a CPU/memory/IO based billing to the user on Linux cgroup accounting rather than the available compared to the rather limited options in

#### [CREATE USER](#)

- Because a user's database will shutdown when inactive, a database upgrade on the server will not take effect for the user until it passively shuts down, restarts, and then gets reactivated hence reducing user downtime..

## Downsides to the Hosting Service Provider

The extra memory used by more instances. This is mitigated by the on-demand activation. The deactivation when idle, and improved InnoDB memory management.

With plenty of medium size database servers running, the Linux OOM kill has the opportunity to kill off only a small number of database servers running rather than everyone.

## Example on configuration Items for a per user, systemd socket activitated multi-instance service

From a server perspective the operation would be as follows;

To make the socket ready to connect and systemd will be listening to the socket:

```
# systemctl start mariadb@username.socket
# systemctl start mariadb-extra@username.socket
```

To enable this on reboot (the same way as a systemd service):

```
# systemctl enable mariadb@username.socket
# systemctl enable mariadb-extra@username.socket
```

## A MariaDB Template File

A global template file. Once installed as a user's

\$HOME/.my.cnf  
file, it will become the default for many applications, and the MariaDB server itself.

```
# cat /etc/my.cnf.templ
[client]
socket=/home/USER/mariadb.sock

[client-server]
user=USER

[mariadb]
datadir=/home/USER/mariadb-database
```

## Custom Configuration for the Multiinstance Service

This extends/modifies the MariaDB multi-instance service.

The features of this extension are:

- that it will auto-create configuration file for user applications
- It will install the database on first service start
- auth-root-\*
  - in [mariadb-install-db](#) means that the user is their own privileged user with unix socket authentication active. This means non-that user cannot access another user's service, even with access to the unix socket(s). For more information see # [unix socket authentication security](#)
- If the MariaDB version was upgraded, the upgrade changes are made automatically
-

`LimitData`  
places a hard upper limit so the user doesn't exceed a portion of the server resources

```
# cat /etc/systemd/system/mariadb@.service.d/user.conf
[Service]
User=%I
ProtectHome=false

Environment=MYSQLD_MULTI_INSTANCE="--defaults-file=/home/%I/.my.cnf"

ExecStartPre=
ExecStartPre=/bin/sh -c "[ -f /home/%I/.my.cnf ] || sed -e \"s/USER/%I/g\" /etc/my.cnf.templ > /home/%I/.my.cnf"
ExecStartPre=mkdir -p /home/%I/mariadb-datarir
ExecStartPre=/usr/bin/mariadb-install-db $MYSQLD_MULTI_INSTANCE --rpm \
    --auth-root-authentication-method=socket --auth-root-socket-user=%I
ExecStartPost=/usr/bin/mariadb-upgrade $MYSQLD_MULTI_INSTANCE

# To limit user based tuning
LimitData=768M
# For io_uring use by innodb on < 5.12 kernels
LimitMEMLOCK=1M
```

## Custom Configuration for the Multi-instance Socket

This extends/modifies the MariaDB socket definition to be per user.

Create sockets based on the user of the instance (

`%I`

). Permissions are only necessary in the sense that the user can connect to them. It won't matter to the server. Access control is enforced within the server, however if the user web services are run as the user,

`Mode=777`

can be reduced.

`@mariadb-%I`

is an abstract unix socket not on the filesystem. It may help if a user is in a chroot. Not all applications can connect to abstract sockets.

```
# cat /etc/systemd/system/mariadb@.socket.d/user.conf
[Socket]
SocketUser=%I
SocketMode=777
ListenStream=
ListenStream=@mariadb-%I
ListenStream=/home/%I/mariadb.sock
```

The extra socket provides the user the ability to access the server when all max-connections are used:

```
# cat /etc/systemd/system/mariadb-extra@.socket.d/user.conf
[Socket]
SocketUser=%I
SocketMode=777
ListenStream=
ListenStream=@mariadb-extra-%I
ListenStream=/home/%I/mariadb-extra.sock
```

## Systemd Journal

systemd  
has its own logging system called the  
systemd  
journal. The  
systemd  
journal contains information about the service startup process. It is a good place to look when a failure has occurred.

The MariaDB

systemd  
service's journal can be queried by using the

`journalctl`

command. For example:

```
$ sudo journalctl n 20 -u mariadb.service
-- Logs begin at Fri 2019-01-25 13:49:04 EST, end at Fri 2019-01-25 18:07:02 EST. --
Jan 25 13:49:15 ip-172-30-0-249.us-west-2.compute.internal systemd[1]: Starting MariaDB 10.1.37 database server...
Jan 25 13:49:16 ip-172-30-0-249.us-west-2.compute.internal mysqld[2364]: 2019-01-25 13:49:16 140547528317120 [Note] /usr/sbin/my
Jan 25 13:49:17 ip-172-30-0-249.us-west-2.compute.internal systemd[1]: Started MariaDB 10.1.37 database server.
Jan 25 18:06:42 ip-172-30-0-249.us-west-2.compute.internal systemd[1]: Stopping MariaDB 10.1.37 database server...
Jan 25 18:06:44 ip-172-30-0-249.us-west-2.compute.internal systemd[1]: Stopped MariaDB 10.1.37 database server.
Jan 25 18:06:57 ip-172-30-0-249.us-west-2.compute.internal systemd[1]: Starting MariaDB 10.1.37 database server...
Jan 25 18:08:32 ip-172-30-0-249.us-west-2.compute.internal systemd[1]: mariadb.service start-pre operation timed out. Terminatin
Jan 25 18:08:32 ip-172-30-0-249.us-west-2.compute.internal systemd[1]: Failed to start MariaDB 10.1.37 database server.
Jan 25 18:08:32 ip-172-30-0-249.us-west-2.compute.internal systemd[1]: Unit mariadb.service entered failed state.
Jan 25 18:08:32 ip-172-30-0-249.us-west-2.compute.internal systemd[1]: mariadb.service failed.
```

## Converting mysqld\_safe Options to Systemd Options

`mariadb-service-convert`

is a script included in many MariaDB packages that is used by the package manager to convert

`mysqld_safe`

options to

systemd

options. It reads any explicit settings in the

[mysqld\_safe]

option group from option files , and its output is directed to

/etc/systemd/system/mariadb.service.d/migrated-from-my.cnf-settings.conf

. This helps to keep the configuration the same when upgrading from a version of MariaDB that does not use

systemd

to one that does.

Implicitly high defaults of

`open-files-limit`

may be missed by the conversion script and require explicit configuration. See [Configuring the Open Files Limit](#) .

## Known Issues

### 2.1.6.15 sysVinit

#### Contents

- 1. [Interacting with the MariaDB Server Process](#)
- 1. [Starting the MariaDB Server Process on Boot](#)
- 2. [Starting the MariaDB Server Process](#)
- 3. [Stopping the MariaDB Server Process](#)
- 4. [Restarting the MariaDB Server Process](#)
- 5. [Checking the Status of the MariaDB Server Process](#)
- 2. [Manually Installing mysql.server with SysVinit](#)
- 3. [SysVinit and Galera Cluster](#)
  - 1. [Bootstrapping a New Cluster](#)

`sysVinit` is one of the most common service managers. On systems that use `sysVinit` , the

`mysql.server`

script is normally installed to

/etc/init.d/mysql

## Interacting with the MariaDB Server Process

The service can be interacted with by using the

```
service
```

command.

## Starting the MariaDB Server Process on Boot

On RHEL/CentOS and other similar distributions, the

```
chkconfig
```

command can be used to enable the MariaDB Server process at boot:

```
chkconfig --add mysql  
chkconfig --level 345 mysql on
```

On Debian and Ubuntu and other similar distributions, the

```
update-rc.d
```

command can be used:

```
update-rc.d mysql defaults
```

## Starting the MariaDB Server Process

```
service mysql start
```

## Stopping the MariaDB Server Process

```
service mysql stop
```

## Restarting the MariaDB Server Process

```
service mysql restart
```

## Checking the Status of the MariaDB Server Process

```
service mysql status
```

## Manually Installing mysql.server with SysVinit

If you install MariaDB from [source](#) or from a [binary tarball](#) that does not install

```
mysql.server
```

automatically, and if you are on a system that uses [sysVinit](#), then you can manually install `mysql.server` with [sysVinit](#). See [mysql.server: Manually Installing with SysVinit](#) for more information.

## SysVinit and Galera Cluster

### Bootstrapping a New Cluster

When using [Galera Cluster](#) with sysVinit, the first node in a cluster has to be started with

```
service mysql bootstrap
```

. See [Getting Started with MariaDB Galera Cluster: Bootstrapping a New Cluster](#) for more information.

## 2.1.6.16 mariadb-admin

MariaDB starting with 10.4.6

From [MariaDB 10.4.6](#) ,  
mariadb-admin  
is a symlink to  
mysqladmin  
, the administration program for the mysqld daemon.

MariaDB starting with [10.5.2](#)

From [MariaDB 10.5.2](#) ,  
mariadb-admin  
is the name of the administration program for the mysqld daemon, with  
mysqladmin  
a symlink .

See [mysqladmin](#) for details.

## 2.1.6.17 mariadb

MariaDB starting with [10.4.6](#)

From [MariaDB 10.4.6](#) ,  
mariadb  
is a symlink to [mysql](#) , the MariaDB server.

MariaDB starting with [10.5.2](#)

From [MariaDB 10.5.2](#) ,  
mariadb  
is the name of the server, with  
mysqld  
a symlink .

See [mysqld](#) for details.

## 2.1.6.18 mariadb-multi

MariaDB starting with [10.4.6](#)

From [MariaDB 10.4.6](#) ,  
mariadb-multi  
is a symlink to  
mysqld\_multi  
, the wrapper designed to manage several mysqld processes running on the same host.

MariaDB starting with [10.5.2](#)

From [MariaDB 10.5.2](#) ,  
mariadb-multi  
is the name of the server, with  
mysqld\_multi  
a symlink .

See [mysqld\\_multi](#) for details.

## 2.1.6.19 mariadb-safe

MariaDB starting with [10.4.6](#)

From [MariaDB 10.4.6](#) ,  
mariadb-safe  
is a symlink to  
mysqld\_safe  
, the tool for starting mysqld on Linux and Unix distributions that do not support [systemd](#) .

MariaDB starting with [10.5.2](#)

From [MariaDB 10.5.2](#) ,

`mariadb-safe`  
is the name of the binary, with  
`mysqld_safe`  
a symlink .

See [mysqld\\_safe](#) for details.

3. [Future Suggested Development](#)
4. [Settings For Best Performance](#)
5. [Example Configuration](#)
6. [Card Models](#)
7. [Additional Software](#)
8. [See Also](#)

Fusion-io develops PCIe based NAND flash memory cards and related software that can be used to speed up MariaDB databases.

The ioDrive branded products can be used as block devices (super-fast disks) or to extend basic DRAM memory. ioDrive is deployed by installing it on an x86 server and then installing the card driver under the operating system. All main line 64-bit operating systems and hypervisors are supported: RHEL, CentOS, SuSe, Debian, OEL etc. and VMWare, Microsoft Windows/Server etc. Drivers and their features are constantly developed further.

ioDrive cards support software RAID and you can combine two or more physical cards into one logical drive. Through ioMemory SDK and its APIs, one can integrate and enable more thorough interworking between your own software and the cards - and cut latency.

The key differentiator between a Fusion-io and a legacy SSD/HDD is the following: **A Fusion-io card is connected directly on the system bus (PCIe)**, this enables high data transfer throughput (1.5 GB/s, 3.0 GB/s or 6GB/s) and the fast direct memory access (DMA) method can be used to transfer data.

The ATA/SATA protocol stack is omitted and therefore [latency is cut short](#). Fusion-io performance is dependent on server speed: the faster processors and the newer PCIe-bus version you have, the better is the ioDrive performance. [Fusion-io memory is non-volatile](#)., in other words, data remains on the card even when the server is powered off.

## Use Cases

1. You can start by using ioDrive for database files that need heavy random access.
2. Whole database on ioDrive.
3. In some cases, Fusion-io devices allow for atomic writes, which allows the server to safely disable the [doublewrite buffer](#).
4. Use ioDrive as a write-through read cache. This is possible on server level with Fusion-io directCache software or in VMware environments using ioTurbine software or the ioCache bundle product. Reads happen from ioDrive and all writes go directly to your SAN or disk.
5. Highly Available shared storage with ION. Have two different hosts, Fusion-io cards in them and share/replicate data with Fusion-io's ION software.
6. The luxurious Platinum setup: [MariaDB Galera Cluster](#) running on Fusion-io SLC cards on several hosts.

## Atomic Writes

Starting with [MariaDB 5.5.31](#), MariaDB Server supports atomic writes on Fusion-io devices that use the NVMFS (formerly called DirectFS) file system. Unfortunately, NVMFS was never offered under 'General Availability', and SanDisk declared that NVMFS would reach end-of-life in December 2015. Therefore, NVMFS support is no longer offered by SanDisk.

MariaDB Server does not currently support atomic writes on Fusion-io devices with any other file systems.

See [atomic write support](#) for more information about MariaDB Server's atomic write support.

## Future Suggested Development

- Extend InnoDB disk cache to be stored on Fusion-io acting as extended memory.

## Settings For Best Performance

Fusion-io memory can be formatted with different sector size of either 512 or 4096 bytes. Bigger sectors are expected to be faster, but only if I/O is done in blocks of 4KB or multiples of that. Speaking of MariaDB: if only InnoDB data files are stored in Fusion-io memory, all I/O is done in blocks of 16K and thus 4K sector size can be used. If the InnoDB redo log (I/O block size: 512 bytes) goes to the same Fusion-io memory, then short sectors should be used.

Note: XtraDB has the experimental feature of an increased InnoDB log block size of 4K. If this is enabled, then both redo log I/O and page I/O in InnoDB will match a sector size of 4K.

As of file systems: currently XFS is expected to yield the best performance with MariaDB. However depending on the exact kernel version and version of XFS code in use, one might be affected by [a bug that severely limits XFS performance in concurrent environments](#). This has been fixed in kernel versions above 3.5 or RHEL6 kernels kernel-2.6.32-358 or later (because of [bug 807503 being fixed](#)).

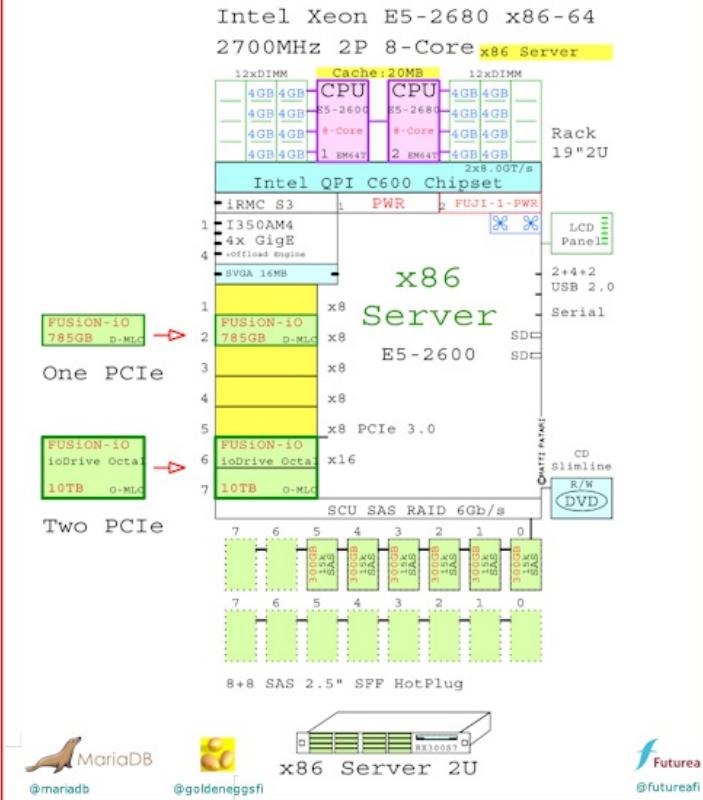

For the pitbull machine where I have run such tests, ext4 was faster than xfs for 32 or more threads:

- up to 8 threads xfs was few percent faster (10% on average).
- at 16 threads it was a draw (2036 tps vs. 2070 tps).
- at 32 threads ext4 was 28% faster (2345 tps vs. 1829 tps).
- at 64 threads ext4 was even 47% faster (2362 tps vs. 1601 tps).
- at higher concurrency ext4 lost its bite, but was still constantly better than xfs.

Those numbers are for spinning disks. I guess for Fusion-io memory the XFS numbers will be even worse.

## Example Configuration

Example configuration of MariaDB with Fusion-io cards, courtesy of [www.goldeneeggs.fi](http://www.goldeneeggs.fi)

## Card Models

There are several card models. ioDrive is older generation, ioDrive2 is newer. SLC sustains more writes. MLC is good enough for normal use.

1. ioDrive2, capacities per card 365GB, 785GB, 1.2TB with MLC. 400GB and 600GB with SLC, performance up to 535000 IOPS & 1.5GB/s bandwidth
2. ioDrive2 Duo, capacities per card 2.4TB MLC and 1.2TB SLC, performance up to 935000 IOPS & 3.0GB/s bandwidth
3. ioDrive, capacities per card 320GB, 640GB MLC and 160GB, 320GB SLC, performance up to 145000 IOPS & 790MB/s bandwidth
4. ioDrive Duo, capacities per card 640GB, 1.28TB MLC and 320GB, 640GB SLC, performance up to 285000 IOPS & 1.5GB/s bandwidth
5. ioDrive Octal, capacities per card 5TB and 10TB MLC, performance up to 1350000 IOPS & 6.7GB/s bandwidth
6. ioFX, a 420GB QDP MLC workstation product, 1.4GB/s bandwidth
7. ioCache, a 600GB MLC card with ioTurbine software bundle that can be used to speed up VMware based virtual hosts.
8. ioScale, 3.2TB card, building block to enable all-flash data center build out in hyperscale web and cloud environments. Product has been developed in co-operation with Facebook.

## Additional Software

- directCache - transforms ioDrive to work as a read cache in your server. Writes go directly to your SAN
- ioTurbine - read cache software for VMware
- ION - transforms ioDrive into a shareable storage
- ioSphere - software to manage and monitor several ioDrives

### 2.1.7.1.2 Atomic Write Support

## Contents

1. Partial Write Operations
2. innodb\_doublewrite - an Imperfect Solution
3. Atomic Write - a Faster Alternative to innodb\_doublewrite
4. Enabling Atomic Writes from MariaDB 10.2
5. Enabling Atomic Writes in MariaDB 5.5 to MariaDB 10.1
  1. About innodb\_use\_atomic\_writes (in MariaDB 5.5 to MariaDB 10.1)
6. Devices that Support Atomic Writes with MariaDB

## Partial Write Operations

When Innodb writes to the filesystem, there is generally no guarantee that a given write operation will be complete (not partial) in cases of a poweroff event, or if the operating system crashes at the exact moment a write is being done.

Without detection or prevention of partial writes, the integrity of the database can be compromised after recovery.

## innodb\_doublewrite - an Imperfect Solution

Since its inception, Innodb has had a mechanism to detect and ignore partial writes via the [InnoDB Doublewrite Buffer](#) (also innodb\_checksum can be used to detect a partial write).

Doublewrites, controlled by the [innodb\\_doublewrite](#) system variable, comes with its own set of problems. Especially on SSD, writing each page twice can have detrimental effects (write leveling).

## Atomic Write - a Faster Alternative to innodb\_doublewrite

A better solution is to directly ask the filesystem to provide an atomic (all or nothing) write guarantee. Currently this is only available on [a few SSD cards](#).

## Enabling Atomic Writes from MariaDB 10.2

When starting, [MariaDB 10.2](#) and beyond automatically detects if any of the supported SSD cards are used.

When opening an InnoDB table, there is a check if the tablespace for the table is [on a device that supports atomic writes](#) and if yes, it will automatically enable atomic writes for the table. If atomic writes support is not detected, the doublewrite buffer will be used.

One can disable atomic write support for all cards by setting the variable [innodb-use-atomic-writes](#) to

OFF  
in your my.cnf file. It's  
ON  
by default.

## Enabling Atomic Writes in MariaDB 5.5 to MariaDB 10.1

To use atomic writes instead of the doublewrite buffer, add:

```
innodb_use_atomic_writes = 1
```

to the my.cnf config file.

Note that atomic writes are only supported on [Fusion-io devices that use the NVMe file system](#) in these versions of MariaDB.

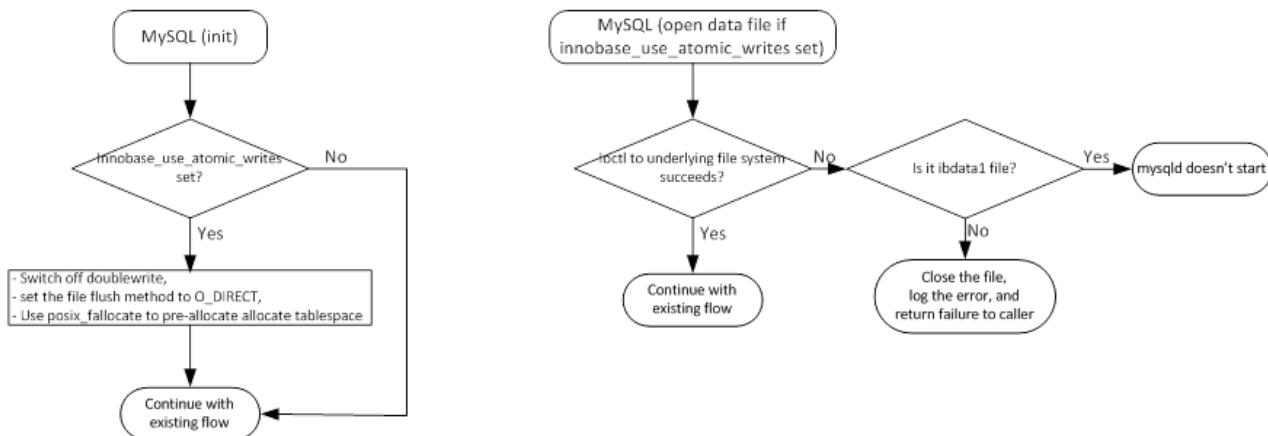

## About innodb\_use\_atomic\_writes (in MariaDB 5.5 to MariaDB 10.1 )

The following happens when atomic writes are enabled

- if [innodb\\_flush\\_method](#) is neither
  - O\_DIRECT
  - ,
  - ALL\_O\_DIRECT
  - , or
  - O\_DIRECT\_NO\_FSYNC
  - , it is switched to
  - O\_DIRECT

- `innodb_use_fallocate` is switched ON  
(files are extended using `posix_fallocate` rather than writing zeros behind the end of file)
- Whenever an InnoDB datafile is opened, a special `ioctl()` is issued to switch on atomic writes. If the call fails, an error is logged and returned to the caller. This means that if the system tablespace is not located on an atomic write capable device or filesystem, InnoDB/XtraDB will refuse to start.
- if `innodb_doublewrite` is set to ON,  
, `innodb_doublewrite` will be switched OFF  
and a message written to the error log.

Here is a flowchart showing how atomic writes work inside InnoDB:

## Devices that Support Atomic Writes with MariaDB

MariaDB currently supports atomic writes on the following devices:

- Fusion-io devices with the NVMS file system . MariaDB 5.5 and above.
- Shannon SSD . MariaDB 10.2 and above.

### 2.1.7.1.3 InnoDB Page Flushing

### 2.1.7.3 Configuring Linux for MariaDB

#### Contents

1. [Linux kernel settings](#)
  1. [IO scheduler](#)
2. [Resource Limits](#)
  - [Configuring the Open Files Limit](#)
  - [Configuring the Core File Size](#)
3. [Swappiness](#)

## Linux kernel settings

### IO scheduler

For optimal IO performance running a database we are using the `noop` scheduler. Recommended schedulers are `noop` and `deadline` . You can check your scheduler setting with:

```
cat /sys/block/${DEVICE}/queue/scheduler
```

For instance, it should look like this output:

```
cat /sys/block/sda/queue/scheduler
[noop] deadline cfq
```

## Resource Limits

### Configuring the Open Files Limit

By default, the system limits how many open file descriptors a process can have open at one time. It has both a soft and hard limit. On many systems, both the soft and hard limit default to 1024. On an active database server, it is very easy to exceed 1024 open file descriptors. Therefore, you may need to increase the soft and hard limits. There are a few ways to do so.

If you are using

```
mysqld_safe  
to start  
mysqld  
, then see the instructions at mysqld\_safe: Configuring the Open Files Limit .
```

If you are using

```
systemd  
to start  
mysqld  
, then see the instructions at systemd: Configuring the Open Files Limit .
```

Otherwise, you can set the soft and hard limits for the

```
mysql  
user account by adding the following lines to
```

```
/etc/security/limits.conf
```

```
:
```

```
mysql soft nofile 65535  
mysql hard nofile 65535
```

After the system is rebooted, the

```
mysql  
user should use the new limits, and the user's  
ulimit  
output should look like the following:
```

```
$ ulimit -Sn  
65535  
$ ulimit -Hn  
65535
```

### Configuring the Core File Size

By default, the system limits the size of core files that could be created. It has both a soft and hard limit. On many systems, the soft limit defaults to 0. If you want to [enable core dumps](#) , then you may need to increase this. Therefore, you may need to increase the soft and hard limits. There are a few ways to do so.

If you are using

```
mysqld_safe  
to start  
mysqld  
, then see the instructions at mysqld\_safe: Configuring the Core File Size .
```

If you are using

```
systemd  
to start  
mysqld  
, then see the instructions at systemd: Configuring the Core File Size .
```

Otherwise, you can set the soft and hard limits for the

```
mysql
user account by adding the following lines to
```

```
/etc/security/limits.conf
```

```
:
```

```
mysql soft core unlimited
mysql hard core unlimited
```

After the system is rebooted, the

```
mysql
user should use the new limits, and the user's
ulimit
output should look like the following:
```

```
$ ulimit -Sc
unlimited
$ ulimit -Hc
unlimited
```

## Swappiness

See [configuring swappiness](#).

### 2.1.7.4 Configuring MariaDB for Optimal Performance

#### Contents

1. [my.cnf Files](#)
2. [InnoDB & XtraDB Storage Engine](#)
3. [Aria Storage Engine](#)
4. [MyISAM](#)
5. [Lots of Connections](#)
  1. [A Lot of Fast Connections + Small Set of Queries + Disconnects](#)
  2. [Connecting From a Lot of Different Machines](#)
6. [See Also](#)
7. [External Links](#)

This article is to help you configure MariaDB for optimal performance.

Note that by default MariaDB is configured to work on a desktop system and should because of this not take a lot of resources. To get things to work for a dedicated server, you have to do a few minutes of work.

For this article we assume that you are going to run MariaDB on a dedicated server.

Feel free to update this article if you have more ideas!

## my.cnf Files

MariaDB is normally configured by editing the [my.cnf](#) file.

The following my.cnf example files were included with MariaDB until [MariaDB 10.3.0](#). If present, you can examine them to see more complete examples of some of the many ways to configure MariaDB and use the one that fits you best as a base. Note that these files are now quite outdated, so what was huge a few years ago may no longer be seen as such.

- my-small.cnf
- my-medium.cnf
- my-large.cnf
- my-huge.cnf

## InnoDB & XtraDB Storage Engine

InnoDB or XtraDB is normally the default storage engine with MariaDB.

- You should set [innodb\\_buffer\\_pool\\_size](#) to about 80% of your memory. The goal is to ensure that 80 % of your working set is in memory!

The other most important InnoDB variables are:

- [innodb\\_log\\_file\\_size](#)
- [innodb\\_flush\\_method](#)

- [innodb\\_thread\\_sleep\\_delay](#)

Some other important InnoDB variables:

- [innodb\\_adaptive\\_max\\_sleep\\_delay](#)
- [innodb\\_buffer\\_pool\\_instances](#)
- [innodb\\_buffer\\_pool\\_size](#)
- [innodb\\_max\\_dirty\\_pages\\_pct\\_lwm](#)
- [innodb\\_read\\_ahead\\_threshold](#)
- [innodb\\_thread\\_concurrency](#)

## Aria Storage Engine

- MariaDB uses by default the Aria storage engine for internal temporary files. If you have many temporary files, you should set [aria\\_pagecache\\_buffer\\_size](#) to a reasonably large value so that temporary overflow data is not flushed to disk. The default is 128M.

## MyISAM

- If you don't use MyISAM tables explicitly (true for most MariaDB 10.4+ users), you can set [key\\_buffer\\_size](#) to a very low value, like 64K.

## Lots of Connections

### A Lot of Fast Connections + Small Set of Queries + Disconnects

- If you are doing a lot of fast connections / disconnects, you should increase [back\\_log](#) and if you are running MariaDB 10.1 or below [thread\\_cache\\_size](#).
- If you have a lot (> 128) of simultaneous running fast queries, you should consider setting [thread\\_handling](#) to [pool\\_of\\_threads](#)

## Connecting From a Lot of Different Machines

- If you are connecting from a lot of different machines you should increase [host\\_cache\\_size](#) to the max number of machines (default 128) to cache the resolving of hostnames. If you don't connect from a lot of machines, you can set this to a very low value!

## See Also

- [MariaDB Memory Allocation](#)

## 2.1.7.5 Configuring Swappiness

### Contents

1. [Why to Avoid Swapping](#)
2. [Setting Swappiness on Linux](#)
3. [Disabling Swap Altogether](#)

## Why to Avoid Swapping

Obviously, accessing swap memory from disk is far slower than accessing RAM directly. This is particularly bad on a database server because:

- MariaDB's internal algorithms assume that memory is not swap, and are highly inefficient if it is. Some algorithms are intended to avoid or delay disk IO, and use memory where possible - performing this with swap can be worse than just doing it on disk in the first place.
- Swap increases IO over just using disk in the first place as pages are actively swapped in and out of swap. Even something like removing a dirty page that is no longer going to be stored in memory, while designed to improve efficiency, will under a swap situation cost more IO.
- Database locks are particularly inefficient in swap. They are designed to be obtained and released often and quickly, and pausing to perform disk IO will have a serious impact on their usability.

The main way to avoid swapping is to make sure you have enough RAM for all processes that need to run on the machine. Setting the [system variables](#) too high can mean that under load the server runs short of memory, and needs to use swap. So understanding what settings to use and how these impact your server's memory usage is critical.

## Setting Swappiness on Linux

Linux has a swappiness setting which determines the balance between swapping out pages (chunks of memory) from RAM to a preconfigured swap space on the hard drive.

The setting is from 0 to 100, with lower values meaning a lower likelihood of swapping. The default is usually 60 - you can check this by running:

```
sysctl vm.swappiness
```

The default setting encourages the server to use swap. Since there probably won't be much else on the database server besides MariaDB processes to put into swap, you'll probably want to reduce this to zero to avoid swapping as much as possible. You can change the default by adding a line to the

```
sysctl.conf  
file (usually found in  
/etc/sysctl.conf  
).
```

To set the swappiness to zero, add the line:

```
vm.swappiness = 0
```

This normally takes effect after a reboot, but you can change the value without rebooting as follows:

```
sysctl -w vm.swappiness=0
```

Since RHEL 6.4, setting swappiness=0 more aggressively avoids swapping out, which increases the risk of OOM killing under strong memory and I/O pressure.

A low swappiness setting is recommended for database workloads. For MariaDB databases, it is recommended to set swappiness to a value of 1.

```
vm.swappiness = 1
```

## Disabling Swap Altogether

While some disable swap altogether, and you certainly want to avoid any database processes from using it, it can be prudent to leave some swap space to at least allow the kernel to fall over gracefully should a spike occur. Having emergency swap available at least allows you some scope to kill any runaway processes.

### 2.1.8 Troubleshooting Installation Issues

4. [Unable to Connect to a Running Server / Lost root Password](#)
  5. [localhost and %](#)
4. [See Also](#)

If you are completely new to MariaDB and relational databases, you may want to start with the [MariaDB Primer](#). Also, make sure you understand the connection parameters discussed in the [Connecting to MariaDB](#) article.

There are a number of common problems that can occur when connecting to MariaDB.

#### Server Not Running in Specified Location

If the error you get is something like:

```
mysql -uname -p
ERROR 2002 (HY000): Can't connect to local MySQL server through
socket '/var/run/mysqld/mysqld.sock' (2 "No such file or directory")
```

or

```
mysql -uname -p --port=3307 --protocol=tcp
ERROR 2003 (HY000): Can't connect to MySQL server on 'localhost'
(111 "Connection refused")
```

the server is either not running, or not running on the specified port, socket or pipe. Make sure you are using the correct [host](#), [port](#), [pipe](#), [socket](#) and [protocol](#) options, or alternatively, see [Getting, Installing and Upgrading MariaDB](#), [Starting and Stopping MariaDB](#) or [Troubleshooting Installation Issues](#).

The socket file can be in a non-standard path. In this case, the

socket

option is probably written in the my.cnf file. Check that its value is identical in the [mysqld] and [client] sections; if not, the client will look for a socket in a wrong place.

If unsure where the Unix socket file is running, it's possible to find this out, for example:

```
netstat -ln | grep mysqld
unix 2 [ ACC ] STREAM LISTENING 33209505 /var/run/mysqld/mysqld.sock
```

#### Unable to Connect from a Remote Location

Usually, the MariaDB server does not by default accept connections from a remote client or connecting with tcp and a hostname and has to be configured to permit these.

```
(/my/maria-10.4) ./client/mysql --host=myhost --protocol=tcp --port=3306 test
ERROR 2002 (HY000): Can't connect to MySQL server on 'myhost' (115)
(/my/maria-10.4) telnet myhost 3306
Trying 192.168.0.11...
telnet: connect to address 192.168.0.11: Connection refused
(/my/maria-10.4) perror 115
OS error code 115: Operation now in progress
```

To solve this, see [Configuring MariaDB for Remote Client Access](#)

## Authentication Problems

Note that from [MariaDB 10.4.3](#), the [unix\\_socket authentication plugin](#) is enabled by default on Unix-like systems. This uses operating system credentials when connecting to MariaDB via the local Unix socket file. See [unix\\_socket authentication plugin](#) for instructions on connecting and on switching to password-based authentication as well as [Authentication from MariaDB 10.4](#) for an overview of the [MariaDB 10.4](#) changes..

Authentication is granted to a particular username/host combination.

```
user1'@'localhost'
, for example, is not the same as
user1'@'166.78.144.191'
```

. See the [GRANT](#) article for details on granting permissions.

Passwords are hashed with [PASSWORD](#) function. If you have set a password with the [SET PASSWORD](#) statement, or used [INSERT](#) or [UPDATE](#) to update the [permissions table](#) directly, the [PASSWORD](#) function must be used at the same time. For example,

```
SET PASSWORD FOR 'bob'@'%.loc.gov' = PASSWORD('newpass')
rather than just
SET PASSWORD FOR 'bob'@'%.loc.gov' = 'newpass'
;
```

If grant tables have been changed directly, the new passwords or authentication data will not immediately be active. A [FLUSH PRIVILEGES](#) statement, or the [flush-privileges mysqladmin](#) option must be run in order for the changes to take effect.

## Problems Exporting Query Results

If you can run regular queries, but get an authentication error when running the [SELECT ... INTO OUTFILE](#), [SELECT ... INTO DUMPFILE](#) or [LOAD DATA INFILE](#) statements, you do not have permission to write files to the server. This requires the FILE privilege. See the [GRANT](#) article.

## Access to the Server, but not to a Database

If you can connect to the server, but not to a database, for example:

```
USE test;
ERROR 1044 (42000): Access denied for user 'ian'@'localhost' to database 'test'
```

or can connect to a particular database, but not another, for example

```
mysql -u name db1
works but not
mysql -u name db2
, you have not been granted permission for the particular database. See the GRANT article.
```

## Option Files and Environment Variables

It's possible that option files or environment variables may be providing incorrect connection parameters. Check the values provided in any option files read by the client you are using (see [mysqld Configuration Files and Groups](#) and the documentation for the particular client you're using - see [Clients and Utilities](#) ).

Option files can usually be suppressed with

```
no-defaults
option, for example:
```

```
mysqlimport --no-defaults ...
```

## Unable to Connect to a Running Server / Lost root Password

If you are unable to connect to a server, for example because you have lost the root password, you can start the server without using the privilege tables by running the

```
--skip-grant-tables
```

option, which gives users full access to all tables. You can then run [FLUSH PRIVILEGES](#) to resume using the grant tables, followed by [SET PASSWORD](#) to change the password for an account.

localhost and %

You may have created a user with something like:

```
CREATE USER melisa identified by 'password';
```

This creates a user with the '%' wildcard host.

```
select user,host from mysql.user where user='melisa';
+-----+-----+
| user | host |
+-----+-----+
| melisa | %   |
+-----+-----+
```

However, you may still be failing to login from localhost. Some setups create anonymous users, including localhost. So the following records exist in the user table:

```
select user,host from mysql.user where user='melisa' or user='';
+-----+-----+
| user | host |
+-----+-----+
| melisa | %   |
|          | localhost |
+-----+-----+
```

Since you are connecting from localhost, the anonymous credentials, rather than those for the 'melisa' user, are used. The solution is either to add a new user specific to localhost, or to remove the anonymous localhost user.

## 2.1.8.2 Installation issues on Windows

### Contents

1. [MariaDB 10.4.13](#)
2. [Unsupported Versions of Windows](#)
3. [MariaDB 5.2.5 and earlier](#)
  1. [On Windows Vista/7 , changes to database or my.ini are not persistent, when mysqld.exe is run from the command line.](#)
  4. [Systems with User Account Control](#)

## MariaDB 10.4.13

[MariaDB 10.4.13](#) may not start on Windows. See [MDEV-22555](#).

To resolve this, download, click and install [https://aka.ms/vs/16/release/vc\\_redist.x64.exe](https://aka.ms/vs/16/release/vc_redist.x64.exe) and then install 10.4.13.

## Unsupported Versions of Windows

Recent versions of MariaDB may not install on unsupported Windows versions. See [Deprecated Package Platforms](#) to find the final supported versions.

## MariaDB 5.2.5 and earlier

### On Windows Vista/7 , changes to database or my.ini are not persistent, when mysqld.exe is run from the command line.

The reason for this behavior is Vista/Win7 file system redirection. Writes to protected locations (in this case a subdirectory of Program Files) are redirected to the user's so-called "Virtual Store".

Workarounds:

- Run mysqld.exe as service. See answer [here](#) on how to create a MariaDB service.

- Run mysqld.exe from the [elevated command prompt](#).
- [Change the ACL](#) of the data directory and add full control for the current user.

The Windows installer for [MariaDB 5.2.6](#) and higher will set the data directory ACL to include full access rights for the user who runs the setup to prevent this issue from happening.

## Systems with User Account Control

Running

`mysql_install_db.exe`  
from a standard command prompt might cause the error:

```
FATAL ERROR: OpenSCManager failed
```

To get rid of it, use the elevated command prompt, for example on Windows 7 start it via 'Run as administrator' option.

## 2.1.8.3 Troubleshooting MariaDB Installs on Red Hat/CentOS

The following article is about different issues people have encountered when installing MariaDB on Red Hat / CentOS.

It is highly recommended to [install with yum](#) where possible.

In Red Hat / CentOS it is also possible to install a [RPM](#) or a [tar ball](#). The RPM is the preferred version, except if you want to install many versions of MariaDB or install MariaDB in a non standard location.

## Replacing MySQL

If you removed an MySQL RPM to install MariaDB, note that the MySQL RPM on uninstall renames `/etc/my.cnf` to `/etc/my.cnf.rpmsave`.

After installing MariaDB you should do the following to restore your configuration options:

```
mv /etc/my.cnf.rpmsave /etc/my.cnf
```

## Unsupported configuration options

If you are using any of the following options in your `/etc/my.cnf` or other `my.cnf` file you should remove them. This is also true for MySQL 5.1 or newer:

```
skip-bdb
```

## 2.1.8.4.1 Differences in MariaDB in Debian (and Ubuntu)

### Contents

1. [Option File Locations](#)
2. [System Variables](#)
3. [Options](#)
4. [TLS](#)
5. [Authentication](#)
6. [See Also](#)
7. [More Information](#)

The

.deb

packages provided by MariaDB Foundation's and MariaDB Corporation's repositories are not identical to the official

.deb

packages provided by Debian's and Ubuntu's default repositories.

The packages provided by MariaDB Foundation's and MariaDB Corporation's repositories are generated using the Debian packaging in MariaDB's official [source code](#). The Debian packaging scripts are specifically in the

debian/  
directory.

The packages provided by Debian's and Ubuntu's default repositories are generated using the Debian packaging in Debian's mirror of MariaDB's source code, which contains some custom changes. The source tree can be found here:

- <https://anonscm.debian.org/cgit/pkg-mysql/mariadb-10.1.git/tree/debian>

As a consequence, MariaDB behaves a bit differently if it is installed from Debian's and Ubuntu's default repositories.

## Option File Locations

- The [option file](#) located at

/etc/mysql/my.cnf  
is handled by the

[update-alternatives](#)

mechanism when the

mysql-common

package is installed. It is a symbolic link that references either

mysql.cnf

or

mariadb.cnf

depending on whether MySQL or MariaDB is installed. Most of the MariaDB [option files](#) are therefore actually located in  
/etc/mysql/mariadb.d/

## System Variables

| Variable             | MariaDB in Debian  | Standard MariaDB  | Notes                                                            |
|----------------------|--------------------|-------------------|------------------------------------------------------------------|
| character_set_server | utf8mb4            | latin1            | Debian sets a default character set that can support emojis etc. |
| collation_server     | utf8mb4_general_ci | latin1_swedish_ci |                                                                  |

## Options

| Option | MariaDB in Debian | Standard<br>MariaDB | Notes |
|--------|-------------------|---------------------|-------|
|        |                   |                     |       |

|                                              |                                                                                                                                                                                                |
|----------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <pre>add plugin-load- auth_socket.so -</pre> | <p>Before <a href="#">MariaDB 10.4.3</a>, MariaDB did not enable the <a href="#">unix_socket</a> authentication plugin by default. This is default in Debian, allowing passwordless login.</p> |
|----------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

## TLS

- MariaDB binaries from

[.deb](#)

packages provided by Debian's and Ubuntu's default repositories are linked with a different TLS library than MariaDB binaries from

[.deb](#)

packages provided by MariaDB Foundation's and MariaDB Corporation's repositories.

- MariaDB Server binaries:

- In [MariaDB 10.4.6](#) and later, MariaDB Server is statically linked with the bundled [wolfSSL](#) libraries in

[.deb](#)

packages provided by Debian's and Ubuntu's default repositories.

- In [MariaDB 10.4.5](#) and before, MariaDB Server is statically linked with the bundled [yaSSL](#) libraries in

[.deb](#)

packages provided by Debian's and Ubuntu's default repositories.

- In contrast, MariaDB Server is dynamically linked with the system's [OpenSSL](#) libraries in

[.deb](#)

packages provided by MariaDB Foundation and MariaDB Corporation.

- MariaDB [client and utility](#) binaries:

- In [MariaDB 10.4.6](#) and later, MariaDB's [clients and utilities](#) and [MariaDB Connector/C](#) are dynamically linked with the system's [GnuTLS](#) libraries in

[.deb](#)

packages provided by Debian's and Ubuntu's default repositories. [libmysqlclient](#) is still statically linked with the bundled [wolfSSL](#) libraries.

- In [MariaDB 10.2](#) and later, MariaDB's [clients and utilities](#) and [MariaDB Connector/C](#) are dynamically linked with the system's [GnuTLS](#) libraries in

[.deb](#)

packages provided by Debian's and Ubuntu's default repositories. [libmysqlclient](#) is still statically linked with the bundled [yaSSL](#) libraries.

- In [MariaDB 10.1](#) and earlier, MariaDB's [clients and utilities](#) and [libmysqlclient](#) are statically linked with the bundled [yaSSL](#) libraries in

[.deb](#)

packages provided by Debian's and Ubuntu's default repositories.

- In contrast, MariaDB's [clients and utilities](#), [libmysqlclient](#), and [MariaDB Connector/C](#) are dynamically linked with the system's [OpenSSL](#) libraries in

[.deb](#)

packages provided by MariaDB Foundation's and MariaDB Corporation's repositories.

- See [TLS and Cryptography Libraries Used by MariaDB](#) for more information about which libraries are used on which platforms.

## Authentication

- The

[unix\\_socket](#)

authentication plugin is installed by default in **new installations** that use the

.deb

packages provided by Debian's default repositories in Debian 9 and later and Ubuntu's default repositories in Ubuntu 15.10 and later.

- The

root@localhost  
created by

`mysql_install_db`

will also be created to authenticate via the

`unix_socket`

authentication plugin in these builds.

## 2.1.8.4.2 Moving from MySQL to MariaDB in Debian 9

MariaDB 10.1 is now the default mysql server in Debian 9 "Stretch". This page provides information on this change and instructions to help with upgrading your Debian 8 "Jessie" version of MySQL or MariaDB to [MariaDB 10.1](#) in Debian 9 "Stretch".

### Contents

  3. [Suggested upgrade procedure for replication](#)
  4. [Other resources to consult before beginning your upgrade](#)
3. [Upgrading to MariaDB 10.1 from MySQL 5.5](#)
4. [Upgrading to MariaDB 10.1 from an older version of MariaDB](#)
5. [MariaDB Galera Cluster](#)
6. [Configuration options for advanced database users](#)
7. [Secure passwordless root accounts only on new installs](#)
8. [See also](#)
9. [Comments and suggestions](#)
10. [Notes](#)

## Background information

The version of MySQL in Debian 8 "Jessie" is 5.5. When installing, most users will install the

`mysql-server`  
package, which depends on the  
`mysql-server-5.5` package  
. In Debian 9 "Stretch" the  
`mysql-server`  
package depends on a new package called  
`default-mysql-server`  
. This package in turn depends on

```
mariadb-server-10.1
. There is no
default-mysql-server
package in Jessie.
```

In both Jessie and Stretch there is also a

```
mariadb-server
package which is a MariaDB-specific analog to the
mysql-server
package. In Jessie this package depends on
mariadb-server-10.0
and in Stretch this package depends on
mariadb-server-10.1
(the same as the
default-mysql-server
package).
```

So, the main repository difference in Debian 9 "Stretch" is that when you install the

```
mysql-server
package on Stretch you will get MariaDB 10.1 instead of MySQL, like you would with previous versions of Debian. Note that
mysql-server
is just an empty transitional meta-package and users are encouraged to install MariaDB using the actual package
mariadb-server
```

All apps and tools, such as the popular LAMP stack, in the repositories that depend on the

```
mysql-server
package will continue to work using MariaDB as the database. For new installs there is nothing different that needs to be done when installing
the mysql-server or mariadb-server packages.
```

## Before you upgrade

If you are currently running MySQL 5.5 on Debian 8 "Jessie" and are planning an upgrade to [MariaDB 10.1](#) on Debian 9 "Stretch", there are some things to keep in mind:

### Backup before you begin

This is a major upgrade, and so complete database backups are strongly suggested before you begin. [MariaDB 10.1](#) is compatible on disk and wire with MySQL 5.5, and the MariaDB developer team has done extensive development and testing to make upgrades as painless and trouble-free as possible. Even so, it's always a good idea to do regular backups, especially before an upgrade. As the database has to shutdown anyway for the upgrade, this is a good opportunity to do a backup!

### Changed, renamed, and removed options

Some default values have been changed, some have been renamed, and others have been removed between MySQL 5.5 and [MariaDB 10.1](#). The following sections detail them.

#### Options with changed default values

Most of the following options have increased a bit in value to give better performance. They should not use much additional memory, but some of them do use a bit more disk space.

| Option                                     | Old default value | New default value |
|--------------------------------------------|-------------------|-------------------|
| <a href="#">aria-sort-buffer-size</a>      | 128M              | 256M              |
| <a href="#">back_log</a>                   | 50                | 150               |
| <a href="#">innodb-concurrency-tickets</a> | 500               | 5000              |

|                                          |      |                                                         |
|------------------------------------------|------|---------------------------------------------------------|
| <code>innodb-log-file-size</code>        | 5M   | 48M                                                     |
| <code>innodb_log_compressed_pages</code> | ON   | OFF                                                     |
| <code>innodb-old-blocks-time</code>      | 0    | 1000                                                    |
| <code>innodb-open-files</code>           | 300  | 400<br>[2]                                              |
| <code>innodb-purge-batch-size</code>     | 20   | 300                                                     |
| <code>innodb-undo-logs</code>            | ON   | 20                                                      |
| <code>join_buffer_size</code>            | 128K | 256K                                                    |
| <code>max_allowed_packet</code>          | 1M   | 4M                                                      |
| <code>max-connect-errors</code>          | 10   | 100                                                     |
| <code>max-relay-log-size</code>          | 0    | 1024M                                                   |
| <code>myisam-sort-buffer-size</code>     | 8M   | 128M                                                    |
| <code>optimizer-switch</code>            | ...  | Added<br><code>extended_keys=on, exists_to_in=on</code> |

|                                      |       |                                                              |
|--------------------------------------|-------|--------------------------------------------------------------|
| <code>query_alloc_block_size</code>  | 8192  | 16384                                                        |
| <code>query_cache_size</code>        | 0     | 1M                                                           |
| <code>query_cache_type</code>        | ON    | OFF                                                          |
| <code>query_prealloc_size</code>     | 8192  | 24576                                                        |
| <code>secure_auth</code>             | OFF   | ON                                                           |
| <code>sql_log_bin</code>             |       | No longer affects replication of events in a Galera cluster. |
| <code>sql_mode</code>                | empty | <code>NO_AUTO_CREATE_USER, NO_ENGINE_SUBSTITUTION</code>     |
| <code>sync_master_info</code>        | 0     | 10000                                                        |
| <code>sync_relay_log</code>          | 0     | 10000                                                        |
| <code>sync_relay_log_info</code>     | 0     | 10000                                                        |
| <code>table_open_cache</code>        | 400   | 2000                                                         |
| <code>thread_pool_max_threads</code> | 500   | 1000                                                         |

#### Options that have been removed or renamed

The following options should be removed or renamed if you use them in your config files:

| Option                                | Reason                                                                            |
|---------------------------------------|-----------------------------------------------------------------------------------|
| engine-condition-pushdown             | Replaced with<br><code>set optimizer_switch='engine_condition_pushdown=on'</code> |
| innodb-adaptive-flushing-method       | Removed by <a href="#">XtraDB</a>                                                 |
| innodb-autoextend-increment           | Removed by <a href="#">XtraDB</a>                                                 |
| innodb-blocking-buffer-pool-restore   | Removed by <a href="#">XtraDB</a>                                                 |
| innodb-buffer-pool-pages              | Removed by <a href="#">XtraDB</a>                                                 |

## Suggested upgrade procedure for replication

If you have a [master-slave setup](#), the normal procedure is to first upgrade your slaves to MariaDB, then move one of your slaves to be the master and then upgrade your original master. In this scenario you can upgrade from MySQL to MariaDB or upgrade later to a new version of MariaDB without any downtime.

## Other resources to consult before beginning your upgrade

It may also be useful to check out the [Upgrading MariaDB](#) section. It contains several articles on upgrading from MySQL to MariaDB and from one version of MariaDB to another. For upgrade purposes, MySQL 5.5 and [MariaDB 5.5](#) are very similar. In particular, see the [Upgrading from MariaDB 5.5 to MariaDB 10.0](#) and [Upgrading from MariaDB 10.0 to MariaDB 10.1](#) articles.

If you need help with upgrading or setting up replication, you can always [contact the MariaDB corporation](#) to find experts to help you with this.

# Upgrading to MariaDB 10.1 from MySQL 5.5

The suggested upgrade procedure is:

1. Set `innodb_fast_shutdown` to  
0
  - . This is to ensure that if you make a backup as part of the upgrade, all data is written to the InnoDB data files, which simplifies any restore in the future.
2. Shutdown MySQL 5.5
3. Take a `backup`
  - when the server is shut down is the perfect time to take a backup of your databases
  - store a copy of the backup on external media or a different machine for safety
4. Perform the upgrade from Debian 8 to Debian 9
5. During the upgrade, the `mysql_upgrade` script will be run automatically; this script does two things:
  1. Upgrades the permission tables in the  
`mysql`  
database with some new fields
  2. Does a very quick check of all tables and marks them as compatible with **MariaDB 10.1**
    - In most cases this should be a fast operation (depending of course on the number of tables)
6. Add new options to `my.cnf` to enable features
  - If you change  
`my.cnf`  
then you need to restart  
`mysqld`  
with e.g.  
`sudo service mysql restart`  
or  
`sudo service mariadb restart`

## Upgrading to MariaDB 10.1 from an older version of MariaDB

If you have installed **MariaDB 5.5** or **MariaDB 10.0** on your Debian 8 "Jessie" machine from the MariaDB repositories you will need to upgrade to **MariaDB 10.1** when upgrading to Debian 9 "Stretch". You can choose to continue using the MariaDB repositories or move to using the Debian repositories.

If you want to continue using the MariaDB repositories edit the MariaDB entry in your `sources.list` and change every instance of 5.5 or 10.0 to 10.1. Then upgrade as suggested [above](#).

If you want to move to using **MariaDB 10.1** from the Debian repositories, delete or comment out the MariaDB entries in your `sources.list` file. Then upgrade as suggested [above](#).

If you are already using **MariaDB 10.1** on your Debian 8 "Jessie" machine, you can choose to continue to use the MariaDB repositories or move to using the Debian repositories as with **MariaDB 5.5** and 10.0. In either case, the upgrade will at most be just a minor upgrade from one version of **MariaDB 10.1** to a newer version. In the case that you are already on the current version of MariaDB that exists in the Debian repositories or a newer one) MariaDB will not be upgraded during the system upgrade but will be upgraded when future versions of MariaDB are released.

You should always perform a compete backup of your data prior to performing any major system upgrade, even if MariaDB itself is not being upgraded!

## MariaDB Galera Cluster

If you have been using MariaDB Galera Cluster 5.5 or 10.0 on Debian 8 "Jessie" it is worth mentioning that **Galera Cluster** is included by default in **MariaDB 10.1**, there is no longer a need to install a separate

```
mariadb-galera-server  
package.
```

## Configuration options for advanced database users

To get better performance from MariaDB used in production environments, here are some suggested additions to `your configuration file` which in Debian is at

```
/etc/mysql/mariadb.d/my.cnf  
:  
:
```

```
[[mysqld]]  
# Cache for disk based temporary files  
aria_pagecache_buffer_size=128M  
# If you are not using MyISAM tables directly (most people are using InnoDB)  
key_buffer_size=64K
```

The reason for the above change is that MariaDB is using the newer **Aria** storage engine for disk based temporary files instead of MyISAM. The main

benefit of Aria is that it can cache both indexes and rows and thus gives better performance than MyISAM for large queries.

## Secure passwordless root accounts only on new installs

Unlike the old MySQL packages in Debian, [MariaDB 10.0](#) onwards in Debian uses unix socket authentication on new installs to avoid root password management issues and thus be more secure and easier to use with provision systems of the cloud age.

This only affects new installs. Upgrades from old versions will continue to use whatever authentication and user accounts already existed. This is however good to know, because it can affect upgrades of dependant systems, typically e.g. require users to rewrite their Ansible scripts and similar tasks. The new feature is much easier than the old, so adjusting for it requires little work.

## Comments and suggestions

If you have comments or suggestions on things we can add or change to improve this page. Please add them as comments below.

## Notes

1. ↑ The

```
innodb-open-files  
variable defaults to the value of  
table-open-cache  
(  
400  
is the default) if it is set to any value less than  
10  
so long as  
innodb-file-per-table  
is set to  
1  
or  
TRUE  
(the default). If  
innodb_file_per_table  
is set to  
0  
or  
FALSE  
and  
innodb-open-files  
is set to a value less than  
10  
, the default is  
300
```

### 2.1.8.4.3 Creating a Debian Repository

Below are instructions for creating your own Debian repository. The instructions are based on <http://www.debian.org/doc/manuals/repository-howto/repository-howto.en.html>

```
REPO_DIR={pick some location}  
mkdir $REPO_DIR  
mkdir $REPO_DIR/binary  
mkdir $REPO_DIR/source  
cp *.deb *.ddeb $REPO_DIR/binary  
cd $REPO_DIR  
dpkg-scanpackages binary /dev/null | gzip -9c > binary/Packages.gz  
dpkg-scansources source /dev/null | gzip -9c > source/Sources.gz
```

## Using the Debian repository you just created

One needs to add a new file to the  
/etc/apt/sources.list.d/  
directory. For instance a new file called  
mariadb.list

```
# sergey's MariaDB repository
#
deb file:///home/psergey/testrepo binary/
deb-src file:///home/psergey/testrepo source/
```

after which one can run

```
apt-get update # Let apt learn about the new repository
apt-get install mariadb-server
```

and collect bugs :-).

"apt-get install" will spray output of scripts and servers all over /var/log. It is also possible to set DEBIAN\_SCRIPT\_DEBUG=1 to get some (not all) of it to stdout.

## Cleaning up after failed installation

Run

```
dpkg --get-selections | grep mariadb
dpkg --get-selections | grep mysql
```

to see what is installed, and then

```
dpkg --purge <packages>
```

until the former produces empty output. Note: after some failures, /etc/mysql and /var/lib/mysql are not cleaned and still need to be removed manually.

## 2.1.8.4.4 apt-upgrade Fails, But the Database is Running

After running

```
apt-upgrade mariadb
, it's possible that apt shows a fail in trying to start the server, but in fact the database is up and running, which then provokes apt to remain in a non finished state.
```

For example:

```
# apt-get upgrade
Reading package lists... Done
Building dependency tree
Reading state information... Done
Calculating upgrade... Done
0 upgraded, 0 newly installed, 0 to remove and 0 not upgraded.
2 not fully installed or removed.
After this operation, 0 B of additional disk space will be used.
Do you want to continue? [Y/n]
Setting up mariadb-server-10.1 (10.1.10+maria-1~trusty) ...
 * Stopping MariaDB database server mysqld
   ...done.
 * Starting MariaDB database server mysqld
   ...fail!
invoke-rc.d: initscript mysql, action "start" failed.
dpkg: error processing package mariadb-server-10.1 (--configure):
 subprocess installed post-installation script returned error exit status 1
dpkg: dependency problems prevent configuration of mariadb-server:
 mariadb-server depends on mariadb-server-10.1 (= 10.1.10+maria-1~trusty); however:
  Package mariadb-server-10.1 is not configured yet.

dpkg: error processing package mariadb-server (--configure):
 dependency problems - leaving unconfigured
No apport report written because the error message indicates its a followup error from a previous failure.
Errors were encountered while processing:
 mariadb-server-10.1
 mariadb-server
E: Sub-process /usr/bin/dpkg returned an error code (1)
```

This situation could occur if the timeout for the init script was too short. For example, see [MDEV-9382](#), a situation where the timeout was 30 seconds, but the server was taking 48 seconds to start.

To overcome this, the timeout needs to be increased. This can be achieved as follows:

- **On systems where systemd is not enabled/supported:** The timeout can be increased by setting MYSQLD\_STARTUP\_TIMEOUT either directly in the script or via the command line. In [MariaDB 10.1.13](#) and later versions, the init script also sources /etc/default/mariadb, so it can also be used to set MYSQLD\_STARTUP\_TIMEOUT to persistently change the startup timeout. The default timeout has been increased from 30s to 60s in [MariaDB 10.1.13](#).
- **On systems that support systemd:** The startup timeout can be increased by setting `TimeoutStartSec` `systemd` option.

## 2.1.8.5 What to Do if MariaDB Doesn't Start

### Contents

1. [The Error Log and the Data Directory](#)
2. [Option Files](#)
  1. [Invalid Option or Option Value](#)
  3. [Can't Open Privilege Tables](#)
  4. [Can't Create Test File](#)
  5. [InnoDB](#)
    1. [Cannot Allocate Memory for the InnoDB Buffer Pool](#)
    2. [InnoDB Table Corruption](#)
  6. [MyISAM](#)
  7. [systemd](#)
  8. [SELinux](#)

There could be many reasons that MariaDB fails to start. This page will help troubleshoot some of the more common reasons and provide solutions.

If you have tried everything here, and still need help, you can ask for help on IRC or on the forums - see [Where to find other MariaDB users and developers](#) - or ask a question at the [Starting and Stopping MariaDB](#) page.

## The Error Log and the Data Directory

The reason for the failure will almost certainly be written in the [error log](#) and, if you are starting MariaDB manually, to the console. By default, the error log is named *host-name*.err and is written to the data directory.

Common Locations:

- /var/log/
- /var/log/mysql
- C:\Program Files\MariaDB x.y\data (x.y refers to the version number)
- C:\Program Files (x86)\MariaDB x.y\data (32bit version on 64bit Windows)

It's also possible that the error log has been explicitly written to another location. This is often done by changing the

`datadir`

or

`log_error`

system variables in an [option file](#). See [Option Files](#) below for more information about that.

A quick way to get the values of these system variables is to execute the following commands:

```
mysqld --help --verbose | grep 'log-error' | tail -1  
mysqld --help --verbose | grep 'datadir' | tail -1
```

## Option Files

Another kind of file to consider when troubleshooting is [option files](#). The default option file is called

`my.cnf`

Option files contain configuration options, such as the location of the data directory mentioned above. If you're unsure where the option file is located, see [Configuring MariaDB with Option Files: Default Option File Locations](#) for information on the default locations.

You can check which configuration options MariaDB server will use from its option files by executing the following command:

```
mysqld --print-defaults
```

You can also check by executing the following command:

```
my_print_defaults --mysqld
```

See [Configuring MariaDB with Option Files: Checking Program Options](#) for more information on checking configuration options.

## Invalid Option or Option Value

Another potential reason for a startup failure is that an [option file](#) contains an invalid option or an invalid option value. In those cases, the [error log](#) should contain an error similar to this:

```
140514 12:19:37 [ERROR] /usr/local/mysql/bin/mysqld: unknown variable 'option=value'
```

This is more likely to happen when you upgrade to a new version of MariaDB. In most cases the [option file](#) from the old version of MariaDB will work just fine with the new version. However, occasionally, options are removed in new versions of MariaDB, or the valid values for options are changed in new versions of MariaDB. Therefore, it's possible for an [option file](#) to stop working after an upgrade.

Also remember that option names are case sensitive.

Examine the specifics of the error. Possible fixes are usually one of the following:

- If the option is completely invalid, then remove it from the [option file](#).
- If the option's name has changed, then fix the name.
- If the option's valid values have changed, then change the option's value to a valid one.
- If the problem is caused by a simple typo, then fix the typo.

## Can't Open Privilege Tables

It is possible to see errors similar to the following:

```
System error 1067 has occurred.  
Fatal error: Can't open privilege tables: Table 'mysql.host' doesn't exist
```

If errors like this occur, then critical [system tables](#) are either missing or are in the wrong location. The above error is quite common after an upgrade if the [option files](#) set the

[basedir](#)

or

[datadir](#)

to a non-standard location, but the new server is using the default location. Therefore, make sure that the

[basedir](#)

and

[datadir](#)

variables are correctly set.

If you're unsure where the option file is located, see [Configuring MariaDB with Option Files: Default Option File Locations](#) for information on the default locations.

If the [system tables](#) really do not exist, then you may need to create them with

[mysql\\_install\\_db](#)

. See [Installing System Tables \(mysql\\_install\\_db\)](#) for more information.

## Can't Create Test File

One of the first tests on startup is to check whether MariaDB can write to the data directory. When this fails, it will log an error like this:

```
May 13 10:24:28 mariadb3 mysqld[19221]: 2019-05-13 10:24:28 0 [Warning] Can't create test file /usr/local/data/mariadb/mariadb3.  
May 13 10:24:28 mariadb3 mysqld[19221]: 2019-05-13 10:24:28 0 [ERROR] Aborting
```

This is usually a permission error on the directory in which this file is being written. Ensure that the entire

[datadir](#)

```

is owned by the user running
mysqld
, usually
mysql
. Ensure that directories have the "x" (execute) directory permissions for the owner. Ensure that all the parent directories of the

datadir

upwards have "x" (execute) permissions for all (
user
,
group
, and
other
).

```

Once this is checked look at the [systemd](#) and [selinux](#) documentation below, or [apparmor](#).

## InnoDB

[InnoDB](#) is probably the MariaDB component that most frequently causes a crash. In the error log, lines containing InnoDB messages generally start with "InnoDB:".

### Cannot Allocate Memory for the InnoDB Buffer Pool

In a typical installation on a dedicated server, at least 70% of your memory should be assigned to [InnoDB buffer pool](#); sometimes it can even reach 85%. But be very careful: don't assign to the buffer pool more memory than it can allocate. If it cannot allocate memory, InnoDB will use the disk's swap area, which is very bad for performance. If swapping is disabled or the swap area is not big enough, InnoDB will crash. In this case, MariaDB will probably try to restart several times, and each time it will log a message like this:

```
140124 17:29:01 InnoDB: Fatal error: cannot allocate memory for the buffer pool
```

In that case, you will need to add more memory to your server/VM or decrease the value of the [innodb\\_buffer\\_pool\\_size](#) variables.

Remember that the buffer pool will slightly exceed that limit. Also, remember that MariaDB also needs allocate memory for other storage engines and several per-connection buffers. The operating system also needs memory.

### InnoDB Table Corruption

By default, InnoDB deliberately crashes the server when it detects table corruption. The reason for this behavior is preventing corruption propagation. However, in some situations, server availability is more important than data integrity. For this reason, we can avoid these crashes by changing the value of [innodb\\_corrupt\\_table\\_action](#) to 'warn'.

If InnoDB crashes the server after detecting data corruption, it writes a detailed message in the error log. The first lines are similar to the following:

```
InnoDB: Database page corruption on disk or a failed
InnoDB: file read of page 7.
InnoDB: You may have to recover from a backup.
```

Generally, it is still possible to recover most of the corrupted data. To do so, restart the server in [InnoDB recovery mode](#) and try to extract the data that you want to backup. You can save them in a CSV file or in a non-InnoDB table. Then, restart the server in normal mode and restore the data.

## MyISAM

Most tables in the [mysql](#) database are MyISAM tables. These tables are necessary for MariaDB to properly work, or even start.

A MariaDB crash could cause system tables corruption. With the default settings, MariaDB will simply not start if the system tables are corrupted. With [myisam\\_recover\\_options](#), we can force MyISAM to repair damaged tables.

## systemd

If you are using

```
systemd
```

, then there are a few relevant notes about startup failures:

- If MariaDB is configured to access files under  
/home

```
,  
/root  
, or  
/run/user  
, then the default systemd unit file will prevent access to these directories with a  
Permission Denied  
error. This happens because the unit file set
```

```
ProtectHome=true
```

. See [Systemd: Configuring Access to Home Directories](#) for information on how to work around this.

- The default systemd unit file also sets `ProtectSystem=full` , which places restrictions on writing to a few other directories. Overwriting this with `ProtectSystem=off` in the same way as above will restore access to these directories.
- If MariaDB takes longer than 90 seconds to start, then the default systemd unit file will cause it to fail with an error. This happens because the default value for the

```
TimeoutStartSec
```

option is 90 seconds. See [Systemd: Configuring the Systemd Service Timeout](#) for information on how to work around this.

- The systemd journal may also contain useful information about startup failures. See [Systemd: Systemd Journal](#) for more information.

See [systemd](#) documentation for further information on systemd configuration.

## SELinux

**Security-Enhanced Linux (SELinux)** is a Linux kernel module that provides a framework for configuring **mandatory access control (MAC)** system for many resources on the system. It is enabled by default on some Linux distributions, including RHEL, CentOS, Fedora, and other similar Linux distribution. SELinux prevents programs from accessing files, directories or ports unless it is configured to access those resources.

You might need to troubleshoot SELinux-related issues in cases, such as:

- MariaDB is using a non-default port.
- MariaDB is reading from or writing to some files (datadir, log files, option files, etc.) located at non-default paths.
- MariaDB is using a plugin that requires access to resources that default installations do not use.

Setting SELinux state to

```
permissive
```

is a common way to investigate what is going wrong while allowing MariaDB to function normally.

```
permissive
```

is supposed to produce a log entry every time it should block a resource access, without actually blocking it. However, [there are situations](#) when SELinux blocks resource accesses even in

```
permissive
```

mode.

See [SELinux](#) for more information.

## 2.1.8.6 Installing on an Old Linux Version

This article lists some typical errors that may happen when you try to use an incompatible MariaDB binary on a linux system:

The following example errors are from trying to install MariaDB built for SuSE 11.x on a SuSE 9.0 server:

```
> scripts/mysql_install_db  
.bin/my_print_defaults: /lib/i686/libc.so.6:  
version `GLIBC_2.4' not found (required by ./bin/my_print_defaults)
```

and

```
> ./bin/mysqld --skip-grant &  
.bin/mysqld: error while loading shared libraries: libwrap.so.0:  
cannot open shared object file: No such file or directory
```

If you see either of the above errors, the binary MariaDB package you installed is not compatible with your system.

The options you have are:

- Find another MariaDB package or tar from the [download page](#) that matches your system.  
or  
• [Download the source](#) and [build it](#) .

## 2.1.8.7 Error: symbol mysql\_get\_server\_name, version libmysqlclient\_16 not defined

If you see the error message:

```
symbol mysql_get_server_name, version libmysqlclient_16 not defined in file libmysqlclient.so.16 with link time reference
```

...then you are probably trying to use the mysql command-line client from MariaDB with libmysqlclient.so from MySQL.

The symbol

```
mysql_get_server_name()  
is something present in the MariaDB source tree and not in the MySQL tree.
```

If you have both the MariaDB client package and the MySQL client packages installed this error will happen if your system finds the MySQL version of libmysqlclient.so first.

To figure out which library is being linked in dynamically (ie, the wrong one) use the 'ldd' tool.

```
ldd $(which mysql) | grep mysql
```

or

```
ldd /path/to/the/binary | grep mysql
```

For example:

```
me@mybox:~$ ldd $(which mysql)|grep mysql  
libmysqlclient.so.16 => /usr/lib/libmysqlclient.so.16 (0xb74df000)
```

You can then use your package manager's tools to find out which package the library belongs to.

On CentOS the command to find out which package installed a specific file is:

```
rpm -qf /path/to/file
```

On Debian-based systems, the command is:

```
dpkg -S /path/to/file
```

Here's an example of locating the library and finding out which package it belongs to on an Ubuntu system:

```
me@mybox:~$ ldd $(which mysql)|grep mysql  
libmysqlclient.so.16 => /usr/lib/libmysqlclient.so.16 (0xb75f8000)  
me@mybox:~$ dpkg -S /usr/lib/libmysqlclient.so.16  
libmariadbclient16: /usr/lib/libmysqlclient.so.16
```

The above shows that the mysql command-line client is using the library

```
/usr/lib/libmysqlclient.so.16  
and that library is part of the  
libmariadbclient16  
Ubuntu package. Unsurprisingly, the mysql command-line client works perfectly on this system.
```

If the answer that came back had been something other than a MariaDB package, then it is likely there would have been issues with running the MariaDB mysql client application.

If the library that the system tries to use is not from a MariaDB package, the remedy is to remove the offending package (and possibly install or re-install the correct package) so that the correct library can be used.

## 2.1.9 Installing System Tables (mysql\_install\_db)

### 2.1.10 mysql\_install\_db.exe

#### Contents

1. [Functionality](#)
2. [Example](#)
3. [Removing Database Instances](#)

The

`mysql_install_db.exe`  
utility is the Windows equivalent of [mysql\\_install\\_db](#).

## Functionality

The functionality of

`mysql_install_db.exe`

is comparable with the shell script

`mysql_install_db`

used on Unix, however it has been extended with both Windows specific functionality (creating a Windows service) and to generally useful functionality. For example, it can set the 'root' user password during database creation. It also creates the

`my.ini`

configuration file in the data directory and adds most important parameters to it (e.g port).

`mysql_install_db.exe`

is used by the MariaDB installer for Windows if the "Database instance" feature is selected. It obsoletes similar utilities and scripts that were used in the past such as

`mysqld.exe`

--

install

,

`mysql_install_db.pl`

, and

`mysql_secure_installation.pl`

| Parameter                                                             | Description                        |
|-----------------------------------------------------------------------|------------------------------------|
| <code>-?</code><br>,<br><code>--</code><br><code>help</code>          | Display help message and exit      |
| <code>-d</code><br>,<br><code>--</code><br><code>datadir=name</code>  | Data directory of the new database |
| <code>-S</code><br>,<br><code>--</code><br><code>service=name</code>  | Name of the Windows service        |
| <code>-p</code><br>,<br><code>--</code><br><code>password=name</code> | Password of the root user          |

|                            |                                                        |
|----------------------------|--------------------------------------------------------|
| -P<br>,                    | mysqld port                                            |
| -W<br>,                    | named pipe name                                        |
| --socket=name              |                                                        |
| -D<br>,                    | Create default user                                    |
| --default-user             |                                                        |
| -R<br>,                    | Allow remote access from network for user root         |
| --allow-remote-root-access |                                                        |
| -N<br>,                    | Do not use TCP connections, use pipe instead           |
| --skip-networking          |                                                        |
| -i<br>,                    | Innodb page size, since <a href="#">MariaDB 10.2.5</a> |
| --innodb-page-size         |                                                        |
| -s<br>,                    | Print less information                                 |
| --silent                   |                                                        |
| -o<br>,                    | Include mysqld bootstrap output                        |
| --verbose-bootstrap        |                                                        |

|                       |                                                       |
|-----------------------|-------------------------------------------------------|
| -l<br>,               | Use large pages, since <a href="#">MariaDB 10.6.1</a> |
| --<br><br>large-pages |                                                       |

|                  |                                                                   |
|------------------|-------------------------------------------------------------------|
| -c<br>,          | my.ini config template file, since <a href="#">MariaDB 10.6.1</a> |
| --<br><br>config |                                                                   |

**Note :** to create a Windows service,

```
mysql_install_db.exe
```

should be run by a user with full administrator privileges (which means elevated command prompt on systems with UAC). For example, if you are running it on Windows 7, make sure that your command prompt was launched via 'Run as Administrator' option.

## Example

```
mysql_install_db.exe --datadir=C:\db --service=MyDB --password=secret
```

will create the database in the directory C:\db, register the auto-start Windows service "MyDB", and set the root password to 'secret'.

To start the service from the command line, execute

```
sc start MyDB
```

## Removing Database Instances

If you run your database instance as service, to remove it completely from the command line, use

```
sc stop <servicename>
sc delete <servicename>
rmdir /s /q <path-to-datadir>
```

## 2.1.11 Configuring MariaDB with Option Files

### 2.1.12 MariaDB Environment Variables

MariaDB makes use of numerous environment variables that may be set on your system. Environment variables have the lowest precedence, so any options set on the command line or in an option file will take precedence.

It's usually better not to rely on environment variables, and to rather set the options you need directly, as this makes the system a little more robust and easy to administer.

Here is a list of environment variables used by MariaDB.

| Environment Variable | Description                                                                                    |
|----------------------|------------------------------------------------------------------------------------------------|
| CXX                  | Name of the C++ compiler, used for running CMake.                                              |
| CC                   | Name of the C compiler, used for running CMake.                                                |
| DBI_USER             | Perl DBI default username.                                                                     |
| DBI_TRACE            | Perl DBI trace options.                                                                        |
| HOME                 | Default directory for the <a href="#">mysql_history file</a> .                                 |
| MYSQL_DEBUG          | Debug trace options used when debugging.                                                       |
| MYSQL_GROUP_SUFFIX   | In addition to the given option groups, also read groups with this suffix.                     |
| MYSQL_HISTFILE       | Path to the <a href="#">mysql_history file</a> , overriding the \$HOME/.mysql_history setting. |
| MYSQL_HOME           | Path to the directory containing the <a href="#">my.cnf file</a> used by the server.           |

|                 |                                                                                                                                                                         |
|-----------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| MYSQL_HOST      | Default host name used by the <a href="#">mysql command line client</a> .                                                                                               |
| MYSQL_PS1       | Command prompt for use by the <a href="#">mysql command line client</a> .                                                                                               |
| MYSQL_PWD       | Default password when connecting to mysqld. It is strongly recommended to use a more secure method of sending the password to the server.                               |
| MYSQL_TCP_PORT  | Default TCP/IP port number.                                                                                                                                             |
| MYSQL_UNIX_PORT | On Unix, default socket file used for localhost connections.                                                                                                            |
| PATH            | Path to directories that hold executable programs (such as the <a href="#">mysql client</a> , <a href="#">mysqladmin</a> ), so that these can be run from any location. |
| TMPDIR          | Directory where temporary files are created.                                                                                                                            |
| TZ              | Local <a href="#">time zone</a> .                                                                                                                                       |
| UMASK           | Creation mode when creating files. See <a href="#">Specifying Permissions for Schema (Data) Directories and Tables</a> .                                                |
| UMASK_DIR       | Creation mode when creating directories. See <a href="#">Specifying Permissions for Schema (Data) Directories and Tables</a> .                                          |
| USER            | On Windows, up to <a href="#">MariaDB 5.5</a> , the default user name when connecting to the mysqld server. API GetUserName() is used in later versions.                |

## 2.1.13 MariaDB on Amazon AWS

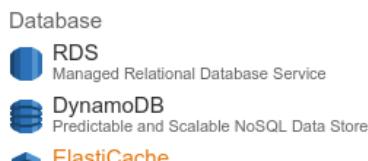

MariaDB is available on Amazon AWS through MariaDB SkySQL, as one of the database options when using Amazon's RDS service, or using a MariaDB AMI on Amazon EC2 from the AWS Marketplace.

### MariaDB SkySQL

Cloud database service is available through MariaDB SkySQL on Amazon AWS. MariaDB SkySQL delivers MariaDB with enterprise features for mission-critical workloads. Support is provided directly by MariaDB. Refer to [SkySQL Documentation](#) for complete details. [Get started](#) to launch a MariaDB database on AWS in minutes.

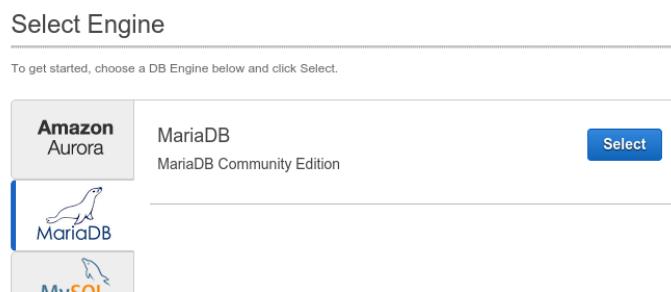

### Amazon RDS

To get started with MariaDB on Amazon's RDS service, click on the RDS link in the Database section of the [AWS console](#) .

Next, click on the **Get Started Now** button. Alternatively, you can click on the **Launch DB Instance** button from the [Instances](#) section of the [RDS Dashboard](#) .

In either case, you will be brought to the page where you can select the database engine you want to use. Click on the **MariaDB** logo and then click on the **Select** button.

You will then move to step 2 where you choose whether or not you want to use your MariaDB instance for production or non-production usage. Amazon has links on this page to documentation on the various options.

After selecting the choice you want you will move to step 3 where you specify the details for your database, including setting up an admin user in the database.

## Specify DB Details

### Instance Specifications

|                     |                                 |
|---------------------|---------------------------------|
| DB Engine           | mariadb                         |
| License Model       | general-public-license          |
| DB Engine Version   | 10.0.17                         |
| DB Instance Class   | db.t2.micro — 1 vCPU, 1 GiB RAM |
| Multi-AZ Deployment | No                              |
| Storage Type        | General Purpose (SSD)           |
| Allocated Storage*  | 5 GB                            |

**!** Provisioning less than 100 GB of General Purpose (SSD) storage for high throughput workloads could result in higher latencies upon exhaustion of the initial General Purpose (SSD) IO credit balance.  
[Click here](#) for more details.

### Settings

|                         |         |
|-------------------------|---------|
| DB Instance Identifier* | test-db |
| Master Username*        | admin   |
| Master Password*        | .....   |
| Confirm Password*       | .....   |

Retype the value you specified for Master Password.

\* Required

Cancel

Previous

Next Step

You will then move to step 4 where you can configure advanced settings, including security settings, various options, backup settings, maintenance defaults, and so on.

Refer to [Amazon's RDS documentation](#) for complete documentation on all the various settings and for information on connecting to and using your RDS MariaDB instances.

## AMI on EC2

MariaDB AMIs (Amazon Machine Images) are available in the AWS Marketplace. These AMIs, kept up-to-date with the most recently released versions of MariaDB, are a great way to try out the newest MariaDB versions before they make it to RDS and/or to use MariaDB in a more traditional server environment.

### 2.1.14 Migrating to MariaDB

#### 2.1.14.1 Migrating to MariaDB from MySQL

##### 2.1.14.1.1 MySQL vs MariaDB: Performance

## Title: MariaDB versus MySQL - Features

See also [MariaDB vs MySQL - Compatibility](#)

## Differences Per Releases

- For differences between MySQL 8.0 and [MariaDB 10.7](#) specifically, see [Incompatibilities and Feature Differences Between MariaDB 10.7 and MySQL 8.0](#)
- For differences between MySQL 8.0 and [MariaDB 10.6](#) specifically, see [Incompatibilities and Feature Differences Between MariaDB 10.6 and MySQL 8.0](#)
- For differences between MySQL 8.0 and [MariaDB 10.5](#) specifically, see [Incompatibilities and Feature Differences Between MariaDB 10.5 and MySQL 8.0](#)
- For differences between MySQL 8.0 and [MariaDB 10.4](#) specifically, see [Incompatibilities and Feature Differences Between MariaDB 10.4 and MySQL 8.0](#)
- For differences between MySQL 5.7 and [MariaDB 10.3](#) specifically, see [Incompatibilities and Feature Differences Between MariaDB 10.3 and MySQL 5.7](#)
- For differences between MySQL 5.7 and [MariaDB 10.2](#) specifically, see [Incompatibilities and Feature Differences Between MariaDB 10.2 and MySQL 5.7](#)
- For a detailed breakdown of system variable differences, see:
  - [System variable differences between MariaDB 10.7 and MySQL 8.0](#)
  - [System variable differences between MariaDB 10.6 and MySQL 8.0](#)
  - [System variable differences between MariaDB 10.5 and MySQL 8.0](#)
  - [System variable differences between MariaDB 10.4 and MySQL 8.0](#)

- System variable differences between MariaDB 10.3 and MySQL 8.0
- System variable differences between MariaDB 10.3 and MySQL 5.7
- System variable differences between MariaDB 10.2 and MySQL 5.7
- System variable differences between MariaDB 10.1 and MySQL 5.7
- System variable differences between MariaDB 10.1 and MySQL 5.6
- System variable differences between MariaDB 10.0 and MySQL 5.6
- System variable differences between MariaDB 5.5 and MySQL 5.5
- For a detailed breakdown of function differences, see:
  - Function Differences Between MariaDB 10.7 and MySQL 8.0
  - Function Differences Between MariaDB 10.6 and MySQL 8.0
  - Function Differences Between MariaDB 10.5 and MySQL 8.0
  - Function Differences Between MariaDB 10.4 and MySQL 8.0
  - Function Differences Between MariaDB 10.3 and MySQL 8.0
  - Function Differences Between MariaDB 10.3 and MySQL 5.7
  - Function Differences Between MariaDB 10.2 and MySQL 5.7

## More Storage Engines

In addition to the standard `MyISAM`, `BLACKHOLE`, `CSV`, `MEMORY`, `ARCHIVE`, and `MERGE` storage engines, the following are also included with MariaDB Source and Binary packages:

- `ColumnStore`, a column oriented storage engine optimized for Data warehousing.
- `MyRocks`, a storage engine with great compression, in 10.2
- `Aria`, MyISAM replacement with better caching.
- `FederatedX` (drop-in replacement for Federated)
- `OQGRAPH` (In MariaDB 5.2 and later. Disabled in MariaDB 5.5 only.)
- `SphinxSE` (In MariaDB 5.2 and later)
- `CONNECT` in MariaDB 10.0 and later.
- `SEQUENCE` in MariaDB 10.0 and later.
- `Spider` in MariaDB 10.0 and later.
- `TokuDB` (In MariaDB 5.5 and later, removed in 10.6)
- `Cassandra` (In MariaDB 10.0, removed in 10.6)

## Speed Improvements

- MariaDB now provides much faster privilege checks for setups with many user accounts or many database
- The new `FLUSH SSL` command allows SSL certificates to be reloaded without restarting the server
- Many optimizer enhancements in MariaDB 5.3. Subqueries are now finally usable. The complete list and a comparison with MySQL is [here](#). A benchmark can be found [here](#).
- Faster and safer replication: `Group commit for the binary log`. This makes many setups that use replication and lots of updates [more than 2x times faster](#).
- `Parallel replication` — new in 10.0
- `Improvements` for InnoDB asynchronous IO subsystem on Windows.
- Indexes for the `MEMORY(HEAP)` engine are faster. According to a simple test, 24% faster on INSERT for integer index and 60% faster for index on a CHAR(20) column. Fixed in MariaDB 5.5 and MySQL 5.7.
- `Segmented Key Cache` for MyISAM. Can speed up MyISAM tables with up to 4x — new in 5.2
- `Adjustable hash size` for MyISAM and Aria. This can greatly improve shutdown time (from hours to minutes) if using a lot of MyISAM/Aria tables with delayed keys — new in 10.0.13
- `CHECKSUM TABLE` is faster.
- We improved the performance of character set conversions (and removed conversions when they were not really needed). Overall speed improvement is 1-5 % (according to sql-bench) but can be higher for big result sets with all characters between 0x00-0x7f.
- `Pool of Threads` in MariaDB 5.1 and even better in MariaDB 5.5. This allows MariaDB to run with 200,000+ connections and with a notable speed improvement when using many connections.
- Several speed improvements when a client connects to MariaDB. Many of the improvements were done in MariaDB 10.1 and MariaDB 10.2.
- There are some improvements to the DBUG code to make its execution faster when debug is compiled in but not used.
- Our use of the Aria storage engine enables faster complex queries (queries which normally use disk-based temporary tables). The `Aria` storage engine is used for internal temporary tables, which should give a speedup when doing complex selects. Aria is usually faster for temporary tables when compared to MyISAM because Aria caches row data in memory and normally doesn't have to write the temporary rows to disk.
- The test suite has been extended and now runs much faster than before, even though it tests more things.

## Extensions & New Features

We've added a lot of [new features to MariaDB](#). If a patch or feature is useful, safe, and stable — we make every effort to include it in MariaDB. The most notable features are:

- Support introduced for `System-versioned tables`. Allows queries to access both current and historic data, aiding in managing retention, analysis and point-in-time recovery. — new in 10.3
- `ALTER TABLE... DROP COLUMN` can now run as Instant operations. Can also now change the ordering of columns. — new in 10.4
- Support introduced for password expiration, using the `user password expiry` — new in 10.4
- In order to support the use of multiple authentication plugins for a single user, the

system table has been retired in favor of the

```
mysql.glob_priv
```

system table. — new in 10.4

- The [unix\\_socket authentication plugin](#) is now the default on Unix-like systems. This represents a major change to authentication in MariaDB — new in 10.4
- Support introduced for [Optimizer Trace](#), which provides detailed information on how the Optimizer processes queries. To enable Optimizer Trace, set the

```
optimizer_trace
```

system variable — new in 10.4

- The MariaDB SQL/PL stored procedure dialect (enabled with [sql\\_mode=ORACLE](#)) now supports Oracle style packages. Support for the following statements are available: [CREATE PACKAGE](#), [CREATE PACKAGE BODY](#), [DROP PACKAGE](#), [DROP PACKAGE BODY](#), [SHOW CREATE PACKAGE](#), [SHOW CREATE PACKAGE BODY](#) — new in 10.4
- Automatic collection of [Engine Independent Table Statistics](#) — new in 10.4
- Support for the use of parentheses (brackets) for specifying precedence in the ordering of execution for

```
SELECT
```

statements and [Table Value Operations](#), (including the use of [UNION](#), [EXCEPT](#), [INTERSECT](#) operations) — new in 10.4

- Support for [anchored data types](#) added to local stored procedure variables. — new in 10.3
- Support added for [Stored Aggregate](#) functions — new in 10.3
- Oracle compatible [SUBSTR\(\)](#) function is available — new in 10.3
- Oracle compatible [SEQUENCE](#) support is provided — new in 10.3
- Support for [anchored data types](#) added to [stored routine](#) variables — new in 10.3
- Support for [anchored data types](#) added to stored routine parameters — new in 10.3
- [Cursors](#) with parameters are now supported — new in 10.3
- [INVISIBLE](#) columns are now supported — new in 10.3
- Instant [ADD COLUMN](#) is now available for InnoDB — new in 10.3
- [Window functions](#) are supported — new in 10.2
- Number of supported decimals in [DECIMAL](#) has increased from

```
30  
to  
38
```

— new in 10.2

- [Recursive Common Table Expressions](#) — new in 10.2

- New [WITH](#) statement.

```
WITH
```

is a common table expression that allows one to refer to a subquery expression many times in a query — new in 10.2

- [CHECK CONSTRAINT](#) — new in 10.2

- [DEFAULT expression](#), including

```
DEFAULT  
for  
BLOB  
and  
TEXT
```

— new in 10.2

- Added catchall for [list partitions](#) — new in 10.2
- Oracle-style [EXECUTE IMMEDIATE](#) statement — new in 10.2
- Several new [JSON functions](#) — new in 10.2
- Microsecond Precision in Processlist
- [Table Elimination](#)
- [Virtual Columns](#) — new in 5.2
- Microseconds in MariaDB — new in 5.3
- Extended User Statistics — new in 5.2
- [KILL](#) all queries for a user — new in 5.3,
- [KILL QUERY ID](#) - terminates the query by [query\\_id](#), leaving the connection intact — new in 10.0.5,
- Pluggable Authentication — new in 5.2
- Storage-engine-specific [CREATE TABLE](#) — new in 5.2
- Enhancements to [INFORMATION SCHEMA.PLUGINS](#) table — new in 5.2
- Group commit for the binary log . This makes replication notably faster! — new in 5.3
- Added

--

```
rewrite-db
```

[mysqldbinlog](#) option to change the used database — new in 5.2

- Progress reporting for

[ALTER TABLE](#)

and

[LOAD DATA INFILE](#)

— new in 5.3

- Faster joins and subqueries — new in 5.3
- HandlerSocket and faster HANDLER calls — new in 5.3
- Dynamic Columns support — new in 5.3
- GIS Functionality — new in 5.3
- Multi-source replication — new in 10.0
- Global Transaction ID — new in 10.0
- SHOW EXPLAIN gives the EXPLAIN plan for a query running in another thread. — new in 10.0
- Roles — new in 10.0
- PCRE Regular Expressions (including

[REGEXP\\_REPLACE\(\)](#)

) — new in 10.0

- CREATE OR REPLACE
- DELETE ... RETURNING — new in 10.0
- MariaDB supports more collations than MySQL.

For a full list, please see [features for each release](#)

## Better Testing

- More tests in the test suite.
- Bugs in tests fixed.
- Test builds with different configure options to get better feature testing.
- Remove invalid tests. (e.g. don't test feature "X" if that feature is not in the tested build)

## Fewer Warnings and Fewer Bugs

- Bugs are bad. Fix as many bugs as possible and try to not introduce new ones.
- Compiler warnings are also bad. Eliminate as many compiler warnings as possible.

## Truly Open Source

- All code in MariaDB is released under GPL, LGPL or BSD.
- MariaDB does not have closed source modules like the ones that can be found in MySQL Enterprise Edition. In fact, all the closed source features in MySQL 5.5 Enterprise Edition are found in the MariaDB open source version.
- MariaDB client libraries (for C, for Java (JDBC), for Windows (ODBC)) are released under LGPL to allow linking with closed source software. MySQL client libraries are released under GPL that does not allow linking with closed source software.
- MariaDB includes test cases for all fixed bugs. Oracle doesn't provide test cases for new bugs fixed in MySQL 5.5.
- All [bugs](#) and [development plans](#) are public.
- MariaDB is [developed by the community](#) in true open source spirit.

## Replacement for MySQL

Until [MariaDB 5.5](#), MariaDB versions functioned as a "drop-in replacement" for the equivalent MySQL version, with some limitations. From [MariaDB 10.0](#), it is usually still very easy to upgrade from MySQL.

- MariaDB's data files are generally binary compatible with those from the equivalent MySQL version.
  - All filenames and paths are generally the same.
  - Data and table definition files (.frm) files are binary compatible.
  - See note below for an incompatibility with views!
- MariaDB's client protocol is binary compatible with MySQL's client protocol.
  - All client APIs and structs are identical.
  - All ports and sockets are generally the same.
  - All MySQL connectors (PHP, Perl, Python, Java, .NET, MyODBC, Ruby, MySQL C connector etc) work unchanged with MariaDB.
  - There are some [installation issues with PHP5](#) that you should be aware of (a bug in how the old PHP5 client checks library compatibility).

This means that for many cases, you can just uninstall MySQL and [install MariaDB](#) and you are good to go. There is not generally any need to convert any data files.

However, you must still run [mysql\\_upgrade](#) to finish the upgrade. This is needed to ensure that your mysql privilege and event tables are updated with the new fields MariaDB uses.

That said, MariaDB has a lot of [new options, extension, storage engines and bug fixes](#) that are not in MySQL. You can find the feature set for the different MariaDB versions on the [What is in the different MariaDB Releases](#) page.

## Drop-in Compatibility of Specific MariaDB Versions

[MariaDB 10.2](#), [MariaDB 10.3](#), and [MariaDB 10.4](#) function as limited drop-in replacements for MySQL 5.7, as far as [InnoDB](#) is concerned. However, the implementation differences continue to grow in each new MariaDB version.

[MariaDB 10.0](#) and [MariaDB 10.1](#) function as limited drop-in replacements for MySQL 5.6, as far as [InnoDB](#) is concerned. However, there are some implementation differences in some features.

[MariaDB 5.5](#) functions as a drop-in replacement for MySQL 5.5.

[MariaDB 5.1](#), [MariaDB 5.2](#), and [MariaDB 5.3](#) function as drop-in replacements for MySQL 5.1.

## Replication Compatibility

Replication compatibility depends on:

- The MariaDB Server version
- The MySQL Server version
- The role of each server

Replication compatibility details are described below for each MySQL version that is still currently supported.

For replication compatibility details between MariaDB versions, see [Cross-Version Replication Compatibility](#).

### MySQL 5.7

MariaDB Server 10.2 and later can replicate from a MySQL 5.7 primary server.

MariaDB Server does not support the MySQL implementation of Global Transaction IDs (GTIDs), so the MariaDB replica server must use the binary log file and position for replication. If GTID mode is enabled on the MySQL primary server, the MariaDB replica server will remove the MySQL GTID events and replace them with MariaDB GTID events.

Although MariaDB Server and MySQL 5.7 are compatible at the replication level, they may have some incompatibilities at the SQL (detailed below). Those differences can cause replication failures in some cases. To decrease the risk of compatibility issues, it is recommended to set `binlog_format` to `ROW`. When you want to replicate from MySQL 5.7 to MariaDB Server, it is recommended to test your application, so that any compatibility issues can be found and fixed.

MariaDB can't make any claims about whether a MySQL 5.7 replica server can replicate from a MariaDB primary server.

### MySQL 8.0

MariaDB Server cannot replicate from a MySQL 8.0 primary server, because MySQL 8.0 has a binary log format that is incompatible.

## Incompatibilities between Currently Supported MariaDB Versions and MySQL

### Incompatibilities between MariaDB 10.7 and MySQL 8.0

See [Incompatibilities and Feature Differences Between MariaDB 10.7 and MySQL 8.0](#) for details.

### Incompatibilities between MariaDB 10.6 and MySQL 8.0

See [Incompatibilities and Feature Differences Between MariaDB 10.6 and MySQL 8.0](#) for details.

### Incompatibilities between MariaDB 10.5 and MySQL 8.0

See [Incompatibilities and Feature Differences Between MariaDB 10.5 and MySQL 8.0](#) for details.

### Incompatibilities between MariaDB 10.4 and MySQL 8.0

See [Incompatibilities and Feature Differences Between MariaDB 10.4 and MySQL 8.0](#) for details.

### Incompatibilities between MariaDB 10.3 and MySQL 5.7

See [Incompatibilities and Feature Differences Between MariaDB 10.3 and MySQL 5.7](#) for details.

### Incompatibilities between MariaDB 10.2 and MySQL 5.7

See [Incompatibilities and Feature Differences Between MariaDB 10.2 and MySQL 5.7](#) for details.

## Incompatibilities between Currently Unsupported MariaDB Versions and MySQL

### Incompatibilities between MariaDB 10.1 and MySQL 5.7

- MariaDB 10.1 and above does not support MySQL 5.7's packed JSON objects. MariaDB follows the SQL standard and stores the JSON as a normal TEXT/BLOB. If you want to replicate JSON columns from MySQL to MariaDB, you should store JSON objects in MySQL in a TEXT column or use statement based replication. If you are using JSON columns and want to upgrade to MariaDB, you can either convert the JSON columns to TEXT or use `mysqldump` to copy these tables to MariaDB. In MySQL, JSON is compared according to json values. In MariaDB JSON strings are normal strings and compared as strings.
- MariaDB 10.1's InnoDB encryption is implemented differently than MySQL 5.7's InnoDB encryption.
- MariaDB 10.1 does not support the ngram and MeCab full-text parser plugins - MDEV-10267 , MDEV-10268 .
- MariaDB 10.1 does not support multiple triggers for a table - MDEV-6112 . This is fixed in MariaDB 10.2
- MariaDB 10.1 does not support `CREATE TABLESPACE` for InnoDB.
- MariaDB 10.1 does not support MySQL 5.7's "native" InnoDB partitioning handler.
- MariaDB does not support MySQL 5.7's X protocol.
- MariaDB 10.1 does not support the use of multiple triggers of the same type for a table. This feature was introduced in MariaDB 10.2.2 .
- MariaDB 10.1 does not support MySQL 5.7's transportable tablespaces for partitioned InnoDB tables. `ALTER TABLE ... {DISCARD|IMPORT}` PARTITION is not supported. For a workaround see the following blog post .
- MariaDB 10.1 does not support MySQL 5.7's online undo tablespace truncation. However, this feature was added to MariaDB 10.2 .
- MySQL 5.7 features a new implementation of the
 

```
performance_schema  
and a  
sys  
schema wrapper. These are not yet supported in MariaDB.
```
- MySQL 5.7 adds multi-source replication and replication channels. Multi-source replication was added to MariaDB previously, in MariaDB 10.0 , and uses a different syntax.
- MySQL 5.7 adds group replication. This feature is incompatible with MariaDB's galera-cluster replication.
- MariaDB 10.1 does not support MySQL 5.7's,
 

```
ACCOUNT LOCK/UNLOCK  
syntax for  
CREATE USER  
and  
ALTER USER  
statements.
```
- MariaDB 10.1 does not support MySQL 5.7's
 

```
ALTER TABLE...RENAME INDEX  
statements.
```
- MariaDB 10.1 does not support MySQL 5.7's
 

```
STACKED  
operation for
```
- MariaDB 10.1 does not support MySQL 5.7's
 

```
GET DIAGNOSTICS
```
- MariaDB 10.1 does not support MySQL 5.7's
 

```
{WITH|WITHOUT} VALIDATION  
syntax for  
ALTER TABLE.. EXCHANGE PARTITION  
statements.
```
- MariaDB does not support the optional `init_vector` argument for `AES_ENCRYPT` and `AES_DECRYPT` or the `block_encryption_mode` variable - MDEV-9069
- MariaDB does not support the
 

```
--initialize  
option. Use
```
- MariaDB does not support the
 

```
mysql_install_db
```
- Instead of - MDEV-19010
  - Also see Incompatibilities between MariaDB 10.0 and MySQL 5.6.
  - Also see a detailed breakdown of System variable differences between MariaDB 10.1 and MySQL 5.7 .

## Incompatibilities between MariaDB 10.0 and MySQL 5.6

- MySQL does not support MariaDB's Spider Storage Engine .
- All MySQL binaries (
 

```
mysqld  
, myisamchk etc.) give a warning if one uses a prefix of an option (such as  
--big-table  
instead of  
--big-tables  
)
```

MariaDB binaries work in the same way as most other Unix commands and don't give warnings when using unique prefixes.
- MariaDB GTID is not compatible with MySQL 5.6. This means that one can't have MySQL 5.6 as a slave for MariaDB 10.0 . However MariaDB 10.0 can be a slave of MySQL 5.6 or any earlier MySQL/MariaDB version. Note that MariaDB and MySQL also have different GTID system variables , so these need to be adjusted when migrating.
- MariaDB 10.0 multi-source replication is not supported in MySQL 5.6.
- To make `CREATE TABLE ... SELECT` work the same way in statement based and row based replication it's by default executed as `CREATE OR`

[REPLACE TABLE](#) on the slave. One benefit of this is that if the slave dies in the middle of CREATE ... SELECT it will be able to continue.

- One can use the [slave-dll-exec-mode](#) variable to specify how

```
CREATE TABLE  
and  
DROP TABLE  
is replicated.
```

- See also a detailed breakdown of [System variable differences between MariaDB 10.0 and MySQL 5.6](#) .
- MySQL 5.6 has [performance schema](#) enabled by default. For performance reasons [MariaDB 10.0](#) has it disabled by default. You can enable it by starting

```
mysqld  
with the option  
--performance-schema
```

- [MariaDB 10.0](#) does not support the MySQL Memcached plugin. However, data stored using memcached can be retrieved because the data is stored as InnoDB tables. MariaDB is able to start successfully with an error message of not being able to find libmemcached.so library.
- Users created with MySQL's SHA256 password algorithm cannot be used in [MariaDB 10.0](#) as MariaDB does not include MySQL's sha256\_password plugin.
- [MariaDB 10.0](#) does not support delayed replication - [MDEV-7145](#) .
- Also see a detailed breakdown of [System variable differences between MariaDB 10.0 and MySQL 5.6](#) .
- The low-level temporal format used by TIME, DATETIME and TIMESTAMP is different in MySQL 5.6 and [MariaDB 10.0](#) . (In [MariaDB 10.1](#) , the MySQL implementation is used by default - see [mysql56\\_temporal\\_format](#) .)
- MariaDB implements some changes in the SQL query optimizer over what's available in MySQL. This can result in

```
EXPLAIN
```

statements showing different plans.

- MySQL delayed replication, (through  
[MASTER\\_DELAY](#)  
( ), is not supported in [MariaDB 10.0](#) , it was implemented in [MariaDB 10.2.5](#)
- MariaDB does not support the optional *init\_vector* argument for [AES\\_ENCRYPT](#) and [AES\\_DECRYPT](#) or the [block\\_encryption\\_mode](#) variable - [MDEV-9069](#)

## Incompatibilities between [MariaDB 5.5](#) and MySQL 5.5

- Views with definition ALGORITHM=MERGE or ALGORITHM=TEMPTABLE got accidentally swapped between MariaDB and MySQL! You have to re-create views created with either of these definitions!
- [INSERT IGNORE](#) also gives warnings for duplicate key errors. You can turn this off by setting  
[OLD\\_MODE=NO\\_DUP\\_KEY\\_WARNINGS\\_WITH\\_IGNORE](#)  
(see [OLD\\_MODE](#) ).
- Before [MariaDB 5.5.31](#) ,  
`X'HHHH'`, the standard SQL syntax for binary string literals, erroneously worked in the same way as  
`0xHHHH`, which could work as a number or string depending on the context. In 5.5.31 this was fixed to behave as a string in all contexts (and never as a number), introducing an incompatibility with previous versions of MariaDB, and all versions of MySQL. See [CAST](#) and [Hexadecimal Literals](#) for more details and examples.
- MariaDB [dynamic columns](#) are not supported by MySQL.
- MariaDB [virtual columns](#) are not supported by MySQL.
- MariaDB's [HandlerSocket plugin](#) is not supported by MySQL.
- MariaDB's [Cassandra Storage Engine](#) is not supported by MySQL.
- As of [MariaDB 5.5.35](#) , [EXTRACT \(HOUR FROM ...\)](#) adheres to the SQL standard and returns a result from 0 to 23. In MySQL, and earlier versions of MariaDB, the result can be greater than 23.
- See also a detailed breakdown of [System variable differences between MariaDB 5.5 and MySQL 5.5](#) .

## Incompatibilities between [MariaDB 5.3](#) and MySQL 5.1

- Views with definition ALGORITHM=MERGE or ALGORITHM=TEMPTABLE got accidentally swapped between [MariaDB 5.2](#) and [MariaDB 5.3](#) ! You have to re-create views created with either of these definitions!
- A few error messages related to wrong conversions are different as MariaDB provides more information in the message about what went wrong.
- Error numbers for MariaDB-specific errors have been moved to start from 1900 so as not to conflict with MySQL errors.
- Microseconds now work in all contexts; MySQL, in some contexts, lost the microsecond part from datetime and time.
- [UNIX\\_TIMESTAMP](#) (constant-date-string) returns a timestamp with 6 decimals in MariaDB while MySQL returns it without a decimal. This can cause a problem if you are using [UNIX\\_TIMESTAMP\(\)](#) as a partitioning function. You can fix this by using [FLOOR](#) ([UNIX\\_TIMESTAMP\(..\)](#)) or changing the date string to a date number, like 20080101000000.
- MariaDB performs stricter checking of date, datetime and timestamp values. For example [UNIX\\_TIMESTAMP](#) ('x') now returns NULL instead of 0.
- The old  
`--maria-`  
startup options are removed. You should use the  
`--aria-`  
prefix instead. ( [MariaDB 5.2](#) supports both

- ```
--maria-
and
--aria-
)
```
- SHOW PROCESSLIST**

has an extra  
Progress  
column which shows progress for some commands. You can disable it by starting  
mysqld  
with either  
--old-mode=NO\_PROGRESS\_INFO  
or with the  
--old  
flag (see [OLD\\_MODE](#) ).
- INFORMATION\_SCHEMA.PROCESSLIST**  
has three new columns for progress reporting:  
STAGE  
,  
MAX\_STAGE  
, and  
PROGRESS
- **Long comments** which start with  
/\*M!  
or  
/\*M!#####  
are executed.
  - If you use [max\\_user\\_connections=0](#) (which means any number of connections) when starting mysqld, you can't change the global variable anymore while mysqld remains running. This is because when mysqld is started with  
max\_user\_connections=0  
it does not allocate counting structures (which also involve a mutex for each connection). This would lead to wrong counters if you later changed the variable. If you want to be able to change this variable at runtime, set it to a high value at startup.
  - You can set  
max\_user\_connections  
(both the global variable and the  
GRANT  
option) to  
-1  
to stop users from connecting to the server. The global  
max\_user\_connections  
variable does not affect users with the  
SUPER  
privilege.
  - The [IGNORE](#) directive does not ignore all errors (like fatal errors), only things that are safe to ignore.

## Incompatibilities between MariaDB 5.2 and MySQL 5.1

The list is the same as between [MariaDB 5.1](#) and MySQL 5.1, with one addition:

- A new [SQL\\_MODE](#) value was added:  
IGNORE\_BAD\_TABLE\_OPTIONS  
. If it is not set, using a table, field, or index attribute (option) that is not supported by the chosen storage engine will cause an error. This change might cause warnings in the error log about incorrectly defined tables from the  
mysql  
database, fix that with [mysql\\_upgrade](#) .

For all practical purposes, [MariaDB 5.2](#) is a drop in replacement for [MariaDB 5.1](#) and MySQL 5.1.

## Incompatibilities between MariaDB 5.1 and MySQL 5.1

In some few cases MariaDB has to be incompatible to allow MariaDB to provide more and better information than MySQL.

Here is the list of all known user level incompatibilities you may see when using [MariaDB 5.1](#) instead of MySQL 5.1.

- The installation package names start with MariaDB instead of MySQL.
- Timings may be different as MariaDB is in many cases faster than MySQL.
- mysqld in MariaDB also reads the  
[mariadb]  
sections of your my.cnf files.

- You can't use a binary only storage engine library with MariaDB if it's not compiled for exactly the same MariaDB version. (This is because the server internal structure THD is different between MySQL and MariaDB. This is common also between different MySQL versions). This should not be a problem as most people don't load new storage engines and MariaDB comes with [more storage engines](#) than MySQL.
- ```
CHECKSUM TABLE
may give different result as MariaDB doesn't ignore NULL's in the columns as MySQL 5.1 does (Future MySQL versions should calculate
checksums the same way as MariaDB). You can get the 'old style' checksum in MariaDB by starting mysqld with the
--old
option. Note however that that the MyISAM and Aria storage engines in MariaDB are using the new checksum internally, so if you are
using
--old
,the
CHECKSUM
command will be slower as it needs to calculate the checksum row by row.
```
- The slow query log has [more information](#) about the query, which may be a problem if you have a script which parses the slow query log.
- MariaDB by default takes a bit more memory than MySQL because we have by default enabled the [Aria storage engine](#) for handling internal temporary tables. If you need MariaDB to take very little memory (at the expense of performance), you can set the value of
 

```
aria_pagecache_buffer_size
to
1M
(the default is
128M
).
```
- If you are using [new command options](#), [new features of MariaDB](#) or [new storage engines](#), you can't move easily back and forth between MySQL and MariaDB anymore.

## Old, Unsupported Configuration Options

If you are using any of the following options in your

```
/etc/my.cnf
or other
my.cnf
file you should remove them. This is also true for MySQL 5.1 or newer:
```

- ```
skip-bdb
```

## Replacing a MySQL RPM

If you uninstalled a MySQL RPM to install MariaDB, note that the MySQL RPM on uninstall renames

```
/etc/my.cnf
to
/etc/my.cnf.rpmsave
```

After installing MariaDB you should do the following to restore your old configuration options:

```
mv -vi /etc/my.cnf.rpmsave /etc/my.cnf
```

## Incompatibilities between MariaDB and MySQL-Proxy

A MySQL client API is able to connect to MariaDB using MySQL-Proxy but a MariaDB client API will receive progress reporting informations that MySQL-Proxy does not implement, to get full compatibility in all case just disable progress reporting on the client or server side.

Another option is to use the [MariaDB MaxScale proxy](#), that works with both MySQL and MariaDB.

### 2.1.14.1.3 Upgrading from MySQL to MariaDB

#### 2.1.14.1.4

# 3 High Availability & Performance Tuning

## 4 Columns, Storage Engines, and Plugins

### 4.1 Data Types

#### 4.1.1 Numeric Data Types

##### 4.1.1.1 Numeric Data Type Overview

###### Contents

- 1. [SIGNED, UNSIGNED and ZEROFILL](#)
  - 1. [Examples](#)
- 2. [Range](#)
  - 1. [Examples](#)
- 3. [Auto\\_increment](#)

There are a number of numeric data types:

- [TINYINT](#)
- [BOOLEAN](#) - Synonym for TINYINT(1)
- [INT1](#) - Synonym for TINYINT
- [SMALLINT](#)
- [INT2](#) - Synonym for SMALLINT
- [MEDIUMINT](#)
- [INT3](#) - Synonym for MEDIUMINT
- [INT](#), [INTEGER](#)
- [INT4](#) - Synonym for INT
- [BIGINT](#)
- [INT8](#) - Synonym for BIGINT
- [DECIMAL](#), [DEC](#), [NUMERIC](#), [FIXED](#)
- [FLOAT](#)
- [DOUBLE](#), [DOUBLE PRECISION](#), [REAL](#)
- [BIT](#)

See the specific articles for detailed information on each.

### SIGNED, UNSIGNED and ZEROFILL

Most numeric types can be defined as

SIGNED  
,  
UNSIGNED  
or  
ZEROFILL  
, for example:

`TINYINT[(M)] [SIGNED | UNSIGNED | ZEROFILL]`

If

SIGNED  
, or no attribute, is specified, a portion of the numeric type will be reserved for the sign (plus or minus). For example, a TINYINT SIGNED can range from -128 to 127.

If

UNSIGNED  
is specified, no portion of the numeric type is reserved for the sign, so for integer types range can be larger. For example, a TINYINT UNSIGNED can range from 0 to 255. Floating point and fixed-point types also can be  
UNSIGNED  
, but this only prevents negative values from being stored and doesn't alter the range.

If

ZEROFILL  
is specified, the column will be set to UNSIGNED and the spaces used by default to pad the field are replaced with zeros.  
ZEROFILL  
is ignored in expressions or as part of a UNION .  
ZEROFILL  
is a non-standard MySQL and MariaDB enhancement.

Note that although the preferred syntax indicates that the attributes are exclusive, more than one attribute can be specified.

Until MariaDB 10.2.7 ( MDEV-8659 ), any combination of the attributes could be used in any order, with duplicates. In this case:

- the presence of  
    ZEROFILL  
    makes the column  
    UNSIGNED ZEROFILL
- the presence of  
    UNSIGNED  
    makes the column  
    UNSIGNED

From MariaDB 10.2.8 , only the following combinations are supported:

- SIGNED
- UNSIGNED
- ZEROFILL
- UNSIGNED ZEROFILL
- ZEROFILL UNSIGNED

The latter two should be replaced with simply

ZEROFILL

, but are still accepted by the parser.

## Examples

```
CREATE TABLE zf (
    i1 TINYINT SIGNED,
    i2 TINYINT UNSIGNED,
    i3 TINYINT ZEROFILL
);

INSERT INTO zf VALUES (2,2,2);

SELECT * FROM zf;
+---+---+---+
| i1 | i2 | i3 |
+---+---+---+
|   2 |   2 |  002 |
+---+---+---+
```

## Range

When attempting to add a value that is out of the valid range for the numeric type, MariaDB will react depending on the strict SQL\_MODE setting.

If strict\_mode has been set (the default from MariaDB 10.2.4 ), MariaDB will return an error.

If strict\_mode has not been set (the default until MariaDB 10.2.3 ), MariaDB will adjust the number to fit in the field, returning a warning.

## Examples

With strict\_mode set:

```

SHOW VARIABLES LIKE 'sql_mode';
+-----+-----+
| Variable_name | Value |
+-----+-----+
| sql_mode      | STRICT_TRANS_TABLES,ERROR_FOR_DIVISION_BY_ZERO,NO_AUTO_CREATE_USER,NO_ENGINE_SUBSTITUTION |
+-----+-----+

CREATE TABLE ranges (i1 TINYINT, i2 SMALLINT, i3 TINYINT UNSIGNED);

INSERT INTO ranges VALUES (257,257,257);
ERROR 1264 (22003): Out of range value for column 'i1' at row 1

SELECT * FROM ranges;
Empty set (0.10 sec)

```

With strict\_mode unset:

```

SHOW VARIABLES LIKE 'sql_mode%';
+-----+-----+
| Variable_name | Value |
+-----+-----+
| sql_mode      |       |
+-----+-----+

CREATE TABLE ranges (i1 TINYINT, i2 SMALLINT, i3 TINYINT UNSIGNED);

INSERT INTO ranges VALUES (257,257,257);
Query OK, 1 row affected, 2 warnings (0.00 sec)

SHOW WARNINGS;
+-----+-----+
| Level | Code | Message |
+-----+-----+
| Warning | 1264 | Out of range value for column 'i1' at row 1 |
| Warning | 1264 | Out of range value for column 'i3' at row 1 |
+-----+-----+
2 rows in set (0.00 sec)

SELECT * FROM ranges;
+-----+-----+
| i1 | i2 | i3 |
+-----+-----+
| 127 | 257 | 255 |
+-----+-----+

```

## Auto\_increment

The

`AUTO_INCREMENT`

attribute can be used to generate a unique identity for new rows. For more details, see [auto\\_increment](#).

### 4.1.1.2 TINYINT

#### Syntax

```
TINYINT[(M)] [SIGNED | UNSIGNED | ZEROFILL]
```

#### Contents

1. [Syntax](#)
2. [Description](#)
3. [Examples](#)
4. [See Also](#)

#### Description

A very small `integer`. The signed range is -128 to 127. The unsigned range is 0 to 255. For details on the attributes, see [Numeric Data Type Overview](#).

`INT1` is a synonym for

`TINYINT`

. `BOOL` and `BOOLEAN` are synonyms for

TINYINT(1)

## Examples

```
CREATE TABLE tinyints (a TINYINT,b TINYINT UNSIGNED,c TINYINT ZEROFILL);
```

With `strict_mode` set, the default from MariaDB 10.2.4 :

```
INSERT INTO tinyints VALUES (-10,-10,-10);
ERROR 1264 (22003): Out of range value for column 'b' at row 1

INSERT INTO tinyints VALUES (-10,10,-10);
ERROR 1264 (22003): Out of range value for column 'c' at row 1

INSERT INTO tinyints VALUES (-10,10,10);

SELECT * FROM tinyints;
+----+----+----+
| a | b | c |
+----+----+----+
| -10 | 10 | 010 |
+----+----+----+

INSERT INTO tinyints VALUES (128,128,128);
ERROR 1264 (22003): Out of range value for column 'a' at row 1

INSERT INTO tinyints VALUES (127,128,128);

SELECT * FROM tinyints;
+----+----+----+
| a | b | c |
+----+----+----+
| -10 | 10 | 010 |
| 127 | 128 | 128 |
+----+----+----+
```

With `strict_mode` unset, the default until MariaDB 10.2.3 :

```

INSERT INTO tinyints VALUES (-10,-10,-10);
Query OK, 1 row affected, 2 warnings (0.08 sec)
Warning (Code 1264): Out of range value for column 'b' at row 1
Warning (Code 1264): Out of range value for column 'c' at row 1

INSERT INTO tinyints VALUES (-10,10,-10);
Query OK, 1 row affected, 1 warning (0.11 sec)
Warning (Code 1264): Out of range value for column 'c' at row 1

INSERT INTO tinyints VALUES (-10,10,10);

SELECT * FROM tinyints;
+-----+-----+
| a    | b    | c    |
+-----+-----+
| -10  | 0   | 000 |
| -10  | 10  | 000 |
| -10  | 10  | 010 |
+-----+-----+

INSERT INTO tinyints VALUES (128,128,128);
Query OK, 1 row affected, 1 warning (0.19 sec)
Warning (Code 1264): Out of range value for column 'a' at row 1

INSERT INTO tinyints VALUES (127,128,128);

SELECT * FROM tinyints;
+-----+-----+
| a    | b    | c    |
+-----+-----+
| -10  | 0   | 000 |
| -10  | 10  | 000 |
| -10  | 10  | 010 |
| 127  | 128 | 128 |
| 127  | 128 | 128 |
+-----+-----+

```

## See Also

- [SMALLINT](#)
- [MEDIUMINT](#)
- [INTEGER](#)
- [BIGINT](#)
- [BOOLEAN](#)

## 4.1.1.3 BOOLEAN

### Syntax

BOOL, BOOLEAN

### Description

These types are synonyms for [TINYINT\(1\)](#). A value of zero is considered false. Non-zero values are considered true.

However, the values TRUE and FALSE are merely aliases for 1 and 0. See [Boolean Literals](#), as well as the [IS operator](#) for testing values against a boolean.

### Examples

```

CREATE TABLE boo (i BOOLEAN);

DESC boo;
+-----+-----+-----+-----+-----+
| Field | Type      | Null | Key | Default | Extra |
+-----+-----+-----+-----+-----+
| i     | tinyint(1) | YES  |     | NULL    |       |
+-----+-----+-----+-----+-----+

```

```

SELECT IF(0, 'true', 'false');
+-----+
| IF(0, 'true', 'false') |
+-----+
| false |
+-----+

SELECT IF(1, 'true', 'false');
+-----+
| IF(1, 'true', 'false') |
+-----+
| true |
+-----+

SELECT IF(2, 'true', 'false');
+-----+
| IF(2, 'true', 'false') |
+-----+
| true |
+-----+

```

TRUE and FALSE as aliases for 1 and 0:

```

SELECT IF(0 = FALSE, 'true', 'false');
+-----+
| IF(0 = FALSE, 'true', 'false') |
+-----+
| true |
+-----+

SELECT IF(1 = TRUE, 'true', 'false');
+-----+
| IF(1 = TRUE, 'true', 'false') |
+-----+
| true |
+-----+

SELECT IF(2 = TRUE, 'true', 'false');
+-----+
| IF(2 = TRUE, 'true', 'false') |
+-----+
| false |
+-----+

SELECT IF(2 = FALSE, 'true', 'false');
+-----+
| IF(2 = FALSE, 'true', 'false') |
+-----+
| false |
+-----+

```

The last two statements display the results shown because 2 is equal to neither 1 nor 0.

- [Boolean Literals](#)
- [IS operator](#)

## 4.1.1.4 SMALLINT

### Syntax

```
SMALLINT[(M)] [SIGNED | UNSIGNED | ZEROFILL]
```

### Description

A small [integer](#). The signed range is -32768 to 32767. The unsigned range is 0 to 65535.

If a column has been set to ZEROFILL, all values will be prepended by zeros so that the SMALLINT value contains a number of M digits.

**Note:** If the `ZEROFILL` attribute has been specified, the column will automatically become `UNSIGNED`.

```
INT2  
is a synonym for  
SMALLINT
```

For more details on the attributes, see [Numeric Data Type Overview](#).

## Examples

```
CREATE TABLE smallints (a SMALLINT,b SMALLINT UNSIGNED,c SMALLINT ZEROFILL);
```

With `strict_mode` set, the default from MariaDB 10.2.4 :

```
INSERT INTO smallints VALUES (-10,-10,-10);
ERROR 1264 (22003): Out of range value for column 'b' at row 1

INSERT INTO smallints VALUES (-10,10,-10);
ERROR 1264 (22003): Out of range value for column 'c' at row 1

INSERT INTO smallints VALUES (-10,10,10);

INSERT INTO smallints VALUES (32768,32768,32768);
ERROR 1264 (22003): Out of range value for column 'a' at row 1

INSERT INTO smallints VALUES (32767,32768,32768);

SELECT * FROM smallints;
+----+----+----+
| a | b | c |
+----+----+----+
| -10 | 10 | 00010 |
| 32767 | 32768 | 32768 |
+----+----+----+
```

With `strict_mode` unset, the default until MariaDB 10.2.3 :

```
INSERT INTO smallints VALUES (-10,-10,-10);
Query OK, 1 row affected, 2 warnings (0.09 sec)
Warning (Code 1264): Out of range value for column 'b' at row 1
Warning (Code 1264): Out of range value for column 'c' at row 1

INSERT INTO smallints VALUES (-10,10,-10);
Query OK, 1 row affected, 1 warning (0.08 sec)
Warning (Code 1264): Out of range value for column 'c' at row 1

INSERT INTO smallints VALUES (-10,10,10);

INSERT INTO smallints VALUES (32768,32768,32768);
Query OK, 1 row affected, 1 warning (0.04 sec)
Warning (Code 1264): Out of range value for column 'a' at row 1

INSERT INTO smallints VALUES (32767,32768,32768);

SELECT * FROM smallints;
+----+----+----+
| a | b | c |
+----+----+----+
| -10 | 0 | 00000 |
| -10 | 10 | 00000 |
| -10 | 10 | 00010 |
| 32767 | 32768 | 32768 |
| 32767 | 32768 | 32768 |
+----+----+----+
```

- [INTEGER](#)

- BIGINT

## 4.1.1.5 MEDIUMINT

### Syntax

```
MEDIUMINT[(M)] [SIGNED | UNSIGNED | ZEROFILL]
```

### Description

A medium-sized integer. The signed range is -8388608 to 8388607. The unsigned range is 0 to 16777215.

ZEROFILL  
pads the integer with zeroes and assumes  
UNSIGNED  
(even if  
UNSIGNED  
is not specified).

INT3  
is a synonym for  
MEDIUMINT

For details on the attributes, see [Numeric Data Type Overview](#).

### Examples

```
CREATE TABLE mediumints (a MEDIUMINT,b MEDIUMINT UNSIGNED,c MEDIUMINT ZEROFILL);

DESCRIBE mediumints;
+-----+-----+-----+-----+
| Field | Type            | Null | Key | Default | Extra |
+-----+-----+-----+-----+
| a     | mediumint(9)    | YES  |     | NULL    |       |
| b     | mediumint(8) unsigned | YES  |     | NULL    |       |
| c     | mediumint(8) unsigned zerofill | YES  |     | NULL    |       |
+-----+-----+-----+-----+
```

With `strict_mode` set, the default from MariaDB 10.2.4 :

```
INSERT INTO mediumints VALUES (-10,-10,-10);
ERROR 1264 (22003): Out of range value for column 'b' at row 1

INSERT INTO mediumints VALUES (-10,10,-10);
ERROR 1264 (22003): Out of range value for column 'c' at row 1

INSERT INTO mediumints VALUES (-10,10,10);

INSERT INTO mediumints VALUES (8388608,8388608,8388608);
ERROR 1264 (22003): Out of range value for column 'a' at row 1

INSERT INTO mediumints VALUES (8388607,8388608,8388608);

SELECT * FROM mediumints;
+-----+-----+-----+
| a     | b     | c     |
+-----+-----+-----+
| -10   | 10   | 00000010 |
| 8388607 | 8388608 | 08388608 |
+-----+-----+-----+
```

With `strict_mode` unset, the default until MariaDB 10.2.3 :

```

INSERT INTO mediumints VALUES (-10,-10,-10);
Query OK, 1 row affected, 2 warnings (0.05 sec)
Warning (Code 1264): Out of range value for column 'b' at row 1
Warning (Code 1264): Out of range value for column 'c' at row 1

INSERT INTO mediumints VALUES (-10,10,-10);
Query OK, 1 row affected, 1 warning (0.08 sec)
Warning (Code 1264): Out of range value for column 'c' at row 1

INSERT INTO mediumints VALUES (-10,10,10);

INSERT INTO mediumints VALUES (8388608,8388608,8388608);
Query OK, 1 row affected, 1 warning (0.05 sec)
Warning (Code 1264): Out of range value for column 'a' at row 1

INSERT INTO mediumints VALUES (8388607,8388608,8388608);

SELECT * FROM mediumints;
+-----+-----+-----+
| a    | b    | c    |
+-----+-----+-----+
| -10  | 0   | 00000000 |
| -10  | 0   | 00000000 |
| -10  | 10  | 00000000 |
| -10  | 10  | 00000010 |
| 8388607 | 8388608 | 08388608 |
| 8388607 | 8388608 | 08388608 |
+-----+-----+-----+

```

## 4.1.1.6 INT

### Syntax

```

INT[(M)] [SIGNED | UNSIGNED | ZEROFILL]
INTEGER[(M)] [SIGNED | UNSIGNED | ZEROFILL]

```

### Description

A normal-size integer. When marked UNSIGNED, it ranges from 0 to 4294967295, otherwise its range is -2147483648 to 2147483647 (SIGNED is the default). If a column has been set to ZEROFILL, all values will be prepended by zeros so that the INT value contains a number of M digits. INTEGER is a synonym for INT.

**Note:** If the ZEROFILL attribute has been specified, the column will automatically become UNSIGNED.

```

INT4
is a synonym for
INT

```

For details on the attributes, see [Numeric Data Type Overview](#).

### Examples

```

CREATE TABLE ints (a INT,b INT UNSIGNED,c INT ZEROFILL);

```

With `strict_mode` set, the default from MariaDB 10.2.4 :

```

INSERT INTO ints VALUES (-10,-10,-10);
ERROR 1264 (22003): Out of range value for column 'b' at row 1

INSERT INTO ints VALUES (-10,10,-10);
ERROR 1264 (22003): Out of range value for column 'c' at row 1

INSERT INTO ints VALUES (-10,10,10);

INSERT INTO ints VALUES (2147483648,2147483648,2147483648);
ERROR 1264 (22003): Out of range value for column 'a' at row 1

INSERT INTO ints VALUES (2147483647,2147483648,2147483648);

SELECT * FROM ints;
+-----+-----+-----+
| a      | b      | c      |
+-----+-----+-----+
| -10    | 10    | 0000000010 |
| 2147483647 | 2147483648 | 2147483648 |
+-----+-----+-----+

```

With `strict_mode` unset, the default until MariaDB 10.2.3 :

```

INSERT INTO ints VALUES (-10,-10,-10);
Query OK, 1 row affected, 2 warnings (0.10 sec)
Warning (Code 1264): Out of range value for column 'b' at row 1
Warning (Code 1264): Out of range value for column 'c' at row 1

INSERT INTO ints VALUES (-10,10,-10);
Query OK, 1 row affected, 1 warning (0.08 sec)
Warning (Code 1264): Out of range value for column 'c' at row 1

INSERT INTO ints VALUES (-10,10,10);

INSERT INTO ints VALUES (2147483648,2147483648,2147483648);
Query OK, 1 row affected, 1 warning (0.07 sec)
Warning (Code 1264): Out of range value for column 'a' at row 1

INSERT INTO ints VALUES (2147483647,2147483648,2147483648);

SELECT * FROM ints;
+-----+-----+-----+
| a      | b      | c      |
+-----+-----+-----+
| -10    | 0     | 0000000000 |
| -10    | 10    | 0000000000 |
| -10    | 10    | 0000000010 |
| 2147483647 | 2147483648 | 2147483648 |
| 2147483647 | 2147483648 | 2147483648 |
+-----+-----+-----+

```

- [MEDIUMINT](#)
- [BIGINT](#)

## 4.1.1.7 INTEGER

### Syntax

```
INTEGER[(M)] [SIGNED | UNSIGNED | ZEROFILL]
```

### Description

This type is a synonym for [INT](#).

## 4.1.1.8 BIGINT

### Syntax

```
BIGINT[(M)] [SIGNED | UNSIGNED | ZEROFILL]
```

### Description

A large integer. The signed range is

```
-9223372036854775808  
to  
9223372036854775807  
. The unsigned range is  
0  
to  
18446744073709551615
```

If a column has been set to ZEROFILL, all values will be prepended by zeros so that the BIGINT value contains a number of M digits.

**Note:** If the ZEROFILL attribute has been specified, the column will automatically become UNSIGNED.

For more details on the attributes, see [Numeric Data Type Overview](#).

SERIAL

is an alias for:

```
BIGINT UNSIGNED NOT NULL AUTO_INCREMENT UNIQUE
```

INT8

is a synonym for

BIGINT

### Examples

```
CREATE TABLE bigints (a BIGINT,b BIGINT UNSIGNED,c BIGINT ZEROFILL);
```

With `strict_mode` set, the default from MariaDB 10.2.4 :

```
INSERT INTO bigints VALUES (-10,-10,-10);  
ERROR 1264 (22003): Out of range value for column 'b' at row 1  
  
INSERT INTO bigints VALUES (-10,10,-10);  
ERROR 1264 (22003): Out of range value for column 'c' at row 1  
  
INSERT INTO bigints VALUES (-10,10,10);  
  
INSERT INTO bigints VALUES (9223372036854775808,9223372036854775808,9223372036854775808);

## 4.1.1.9 DECIMAL

### Syntax

```
DECIMAL[(M[,D])] [SIGNED | UNSIGNED | ZEROFILL]
```

### Contents

1. [Syntax](#)
2. [Description](#)
3. [Examples](#)
4. [See Also](#)

### Description

A packed "exact" fixed-point number.

M  
is the total number of digits (the precision) and

D  
is the number of digits after the decimal point (the scale).

- The decimal point and (for negative numbers) the "-" sign are not counted in

M

.

- If

D

is

0

, values have no decimal point or fractional part and on [INSERT](#) the value will be rounded to the nearest DECIMAL

- The maximum number of digits (

M

) for

- The maximum number of supported decimals ( DECIMAL ) is 65.

D  
)  
is  
30  
before [Mariadb 10.2.1](#) and  
38  
afterwards.  
• If  
D  
is omitted, the default is  
0  
. If  
M  
is omitted, the default is  
10

UNSIGNED  
, if specified, disallows negative values.

ZEROFILL  
, if specified, pads the number with zeros, up to the total number of digits specified by M

All basic calculations (+, -, \*, /) with  
DECIMAL  
columns are done with a precision of 65 digits.

For more details on the attributes, see [Numeric Data Type Overview](#).

DEC  
,  
NUMERIC  
and  
FIXED  
are synonyms, as well as  
NUMBER  
in [Oracle mode from MariaDB 10.3](#).

## Examples

```
CREATE TABLE t1 (d DECIMAL UNSIGNED ZEROFILL);

INSERT INTO t1 VALUES (1),(2),(3),(4.0),(5.2),(5.7);
Query OK, 6 rows affected, 2 warnings (0.16 sec)
Records: 6  Duplicates: 0  Warnings: 2

Note (Code 1265): Data truncated for column 'd' at row 5
Note (Code 1265): Data truncated for column 'd' at row 6
```

```
SELECT * FROM t1;
+-----+
| d      |
+-----+
| 000000001 |
| 000000002 |
| 000000003 |
| 000000004 |
| 000000005 |
| 000000006 |
+-----+
```

With `strict_mode` set, the default from MariaDB 10.2.4 :

```
INSERT INTO t1 VALUES (-7);
ERROR 1264 (22003): Out of range value for column 'd' at row 1
```

With `strict_mode` unset, the default until MariaDB 10.2.3 :

```
INSERT INTO t1 VALUES (-7);
Query OK, 1 row affected, 1 warning (0.02 sec)
Warning (Code 1264): Out of range value for column 'd' at row 1

SELECT * FROM t1;
+-----+
| d    |
+-----+
| 0000000001 |
| 0000000002 |
| 0000000003 |
| 0000000004 |
| 0000000005 |
| 0000000006 |
| 0000000000 |
+-----+
```

## See Also

- [Numeric Data Type Overview](#)
- [Oracle mode from MariaDB 10.3](#)

## 4.1.1.10 DEC, NUMERIC, FIXED

### Syntax

```
DEC[(M[,D])] [SIGNED | UNSIGNED | ZEROFILL]
NUMERIC[(M[,D])] [SIGNED | UNSIGNED | ZEROFILL]
FIXED[(M[,D])] [SIGNED | UNSIGNED | ZEROFILL]
```

### Description

These types are synonyms for [DECIMAL](#) . The

`FIXED`  
synonym is available for compatibility with other database systems.

## 4.1.1.11 NUMBER

MariaDB starting with 10.3

```
NUMBER[(M[,D])] [SIGNED | UNSIGNED | ZEROFILL]
```

In Oracle mode from MariaDB 10.3 ,  
`NUMBER`  
is a synonym for [DECIMAL](#) .

## 4.1.1.12 FLOAT

### Syntax

```
FLOAT[(M,D)] [SIGNED | UNSIGNED | ZEROFILL]
```

### Contents

1. [Syntax](#)
2. [Description](#)

### Description

A small (single-precision) floating-point number (see [DOUBLE](#) for a regular-size floating point number). Allowable values are:

- -3.402823466E+38 to -1.175494351E-38
- 0
- 1.175494351E-38 to 3.402823466E+38.

These are the theoretical limits, based on the IEEE standard. The actual range might be slightly smaller depending on your hardware or operating system.

M is the total number of digits and D is the number of digits following the decimal point. If M and D are omitted, values are stored to the limits allowed by the hardware. A single-precision floating-point number is accurate to approximately 7 decimal places.

**UNSIGNED**, if specified, disallows negative values.

Using FLOAT might give you some unexpected problems because all calculations in MariaDB are done with double precision. See [Floating Point Accuracy](#).

For more details on the attributes, see [Numeric Data Type Overview](#).

## 4.1.1.13 DOUBLE

### Syntax

```
DOUBLE[(M,D)] [SIGNED | UNSIGNED | ZEROFILL]
DOUBLE PRECISION[(M,D)] [SIGNED | UNSIGNED | ZEROFILL]
REAL[(M,D)] [SIGNED | UNSIGNED | ZEROFILL]
```

### Contents

1. [Syntax](#)
2. [Description](#)
3. [Examples](#)

### Description

A normal-size (double-precision) floating-point number (see [FLOAT](#) for a single-precision floating-point number).

Allowable values are:

- -1.7976931348623157E+308  
to  
-2.2250738585072014E-308
- 0
- 2.2250738585072014E-308  
to  
1.7976931348623157E+308

These are the theoretical limits, based on the IEEE standard. The actual range might be slightly smaller depending on your hardware or operating system.

M

is the total number of digits and

D

is the number of digits following the decimal point. If

M

and

D

are omitted, values are stored to the limits allowed by the hardware. A double-precision floating-point number is accurate to approximately 15 decimal places.

**UNSIGNED**

, if specified, disallows negative values.

**ZEROFILL**

, if specified, pads the number with zeros, up to the total number of digits specified by

M

REAL and DOUBLE PRECISION are synonyms, unless the REAL\_AS\_FLOAT [SQL mode](#) is enabled, in which case REAL is a synonym for [FLOAT](#) rather than DOUBLE.

See [Floating Point Accuracy](#) for issues when using floating-point numbers.

For more details on the attributes, see [Numeric Data Type Overview](#).

## Examples

```
CREATE TABLE t1 (d DOUBLE(5,0) zerofill);
INSERT INTO t1 VALUES (1),(2),(3),(4);
SELECT * FROM t1;
+---+
| d |
+---+
| 00001 |
| 00002 |
| 00003 |
| 00004 |
+---+
```

### 4.1.1.14 DOUBLE PRECISION

#### Syntax

```
DOUBLE PRECISION[(M,D)] [SIGNED | UNSIGNED | ZEROFILL]
REAL[(M,D)] [SIGNED | UNSIGNED | ZEROFILL]
```

#### Description

REAL and DOUBLE PRECISION are synonyms for [DOUBLE](#).

Exception: If the REAL\_AS\_FLOAT [SQL mode](#) is enabled, REAL is a synonym for [FLOAT](#) rather than [DOUBLE](#).

### 4.1.1.15 BIT

#### Syntax

```
BIT[(M)]
```

#### Description

A bit-field type.

M  
indicates the number of bits per value, from  
1  
to  
64  
. The default is  
1  
if  
M  
is omitted.

Bit values can be inserted with

b'value'  
notation, where  
value  
is the bit value in 0's and 1's.

Bit fields are automatically zero-padded from the left to the full length of the bit, so for example in a BIT(4) field, '10' is equivalent to '0010'.

Bits are returned as binary, so to display them, either add 0, or use a function such as [HEX](#), [OCT](#) or [BIN](#) to convert them.

## Examples

```
CREATE TABLE b ( b1 BIT(8) );
```

With `strict_mode` set, the default from MariaDB 10.2.4 :

```
INSERT INTO b VALUES (b'11111111');
INSERT INTO b VALUES (b'01010101');
INSERT INTO b VALUES (b'11111111111111');
ERROR 1406 (22001): Data too long for column 'b1' at row 1

SELECT b1+0, HEX(b1), OCT(b1), BIN(b1) FROM b;
+-----+-----+-----+
| b1+0 | HEX(b1) | OCT(b1) | BIN(b1) |
+-----+-----+-----+
| 255 | FF      | 377    | 11111111 |
| 85  | 55      | 125    | 1010101  |
+-----+-----+-----+
```

With `strict_mode` unset, the default until MariaDB 10.2.3 :

```
INSERT INTO b VALUES (b'11111111'),(b'01010101'),(b'111111111111');
Query OK, 3 rows affected, 1 warning (0.10 sec)
Records: 3  Duplicates: 0  Warnings: 1

SHOW WARNINGS;
+-----+-----+
| Level | Code | Message           |
+-----+-----+
| Warning | 1264 | Out of range value for column 'b1' at row 3 |
+-----+-----+

SELECT b1+0, HEX(b1), OCT(b1), BIN(b1) FROM b;
+-----+-----+-----+
| b1+0 | HEX(b1) | OCT(b1) | BIN(b1) |
+-----+-----+-----+
| 255 | FF      | 377    | 11111111 |
| 85  | 55      | 125    | 1010101  |
| 255 | FF      | 377    | 11111111 |
+-----+-----+-----+
```

## 4.1.1.16 Floating-point Accuracy

Due to their nature, not all floating-point numbers can be stored with exact precision. Hardware architecture, the CPU or even the compiler version and optimization level may affect the precision.

If you are comparing `DOUBLES` or `FLOATS` with numeric decimals, it is not safe to use the `equality` operator.

Sometimes, changing a floating-point number from single-precision (`FLOAT`) to double-precision (`DOUBLE`) will fix the problem.

### Example

f1, f2 and f3 have seemingly identical values across each row, but due to floating point accuracy, the results may be unexpected.

```
CREATE TABLE fpn (id INT, f1 FLOAT, f2 DOUBLE, f3 DECIMAL (10,3));
INSERT INTO fpn VALUES (1,2,2,2),(2,0.1,0.1,0.1);

SELECT * FROM fpn WHERE f1*f1 = f2*f2;
+-----+-----+-----+
| id  | f1   | f2   | f3   |
+-----+-----+-----+
| 1   | 2    | 2    | 2.000 |
+-----+-----+-----+
```

The reason why only one instead of two rows was returned becomes clear when we see how the floating point squares were evaluated.

```

SELECT f1*f1, f2*f2, f3*f3 FROM fpn;
+-----+-----+-----+
| f1*f1 | f2*f2 | f3*f3 |
+-----+-----+-----+
| 4 | 4 | 4.000000 |
| 0.01000000298023226 | 0.0100000000000002 | 0.010000 |
+-----+-----+-----+

```

## 4.1.1.17 INT1

INT1

is a synonym for TINYINT .

```

CREATE TABLE t1 (x INT1);

DESC t1;
+-----+-----+-----+-----+
| Field | Type      | Null | Key | Default | Extra |
+-----+-----+-----+-----+
| x     | tinyint(4) | YES  |      | NULL    |       |
+-----+-----+-----+-----+

```

## 4.1.1.18 INT2

INT2

is a synonym for SMALLINT .

```

CREATE TABLE t1 (x INT2);

DESC t1;
+-----+-----+-----+-----+
| Field | Type      | Null | Key | Default | Extra |
+-----+-----+-----+-----+
| x     | smallint(6) | YES  |      | NULL    |       |
+-----+-----+-----+-----+

```

## 4.1.1.19 INT3

INT3

is a synonym for MEDIUMINT .

```

CREATE TABLE t1 (x INT3);

DESC t1;
+-----+-----+-----+-----+
| Field | Type      | Null | Key | Default | Extra |
+-----+-----+-----+-----+
| x     | mediumint(9) | YES  |      | NULL    |       |
+-----+-----+-----+-----+

```

## 4.1.1.20 INT4

INT4

is a synonym for INT .

```

CREATE TABLE t1 (x INT4);

DESC t1;
+-----+-----+-----+-----+
| Field | Type      | Null | Key | Default | Extra |
+-----+-----+-----+-----+
| x     | int(11)   | YES  |      | NULL    |       |
+-----+-----+-----+-----+

```

## 4.1.1.21 INT8

INT8  
is a synonym for [BIGINT](#).

```
CREATE TABLE t1 (x INT8);

DESC t1;
+-----+-----+-----+-----+
| Field | Type      | Null | Key | Default | Extra |
+-----+-----+-----+-----+
| x     | bigint(20) | YES  |      | NULL    |       |
+-----+-----+-----+-----+
```

## 4.1.2 String Data Types

### 4.1.2.1 String Literals

Strings are sequences of characters and are enclosed with quotes.

The syntax is:

```
[_charset_name]'string' [COLLATE collation_name]
```

For example:

```
'The MariaDB Foundation'
_utf8 'Foundation' COLLATE utf8_unicode_ci;
```

Strings can either be enclosed in single quotes or in double quotes (the same character must be used to both open and close the string).

The ANSI SQL-standard does not permit double quotes for enclosing strings, and although MariaDB does by default, if the MariaDB server has enabled the [ANSI\\_QUOTES\\_SQL\\_MODE](#), double quotes will be treated as being used for [identifiers](#) instead of strings.

Strings that are next to each other are automatically concatenated. For example:

```
'The ' 'MariaDB ' 'Foundation'
```

and

```
'The MariaDB Foundation'
```

are equivalent.

The

\ (backslash character) is used to escape characters (unless the [SQL\\_MODE](#) hasn't been set to [NO\\_BACKSLASH\\_ESCAPES](#)). For example:

```
'MariaDB\'s new features'
```

is not a valid string because of the single quote in the middle of the string, which is treated as if it closes the string, but is actually meant as part of the string, an apostrophe. The backslash character helps in situations like this:

```
'MariaDB\'s new features'
```

is now a valid string, and if displayed, will appear without the backslash.

```
SELECT 'MariaDB\'s new features';
+-----+
| MariaDB's new features |
+-----+
| MariaDB's new features |
+-----+
```

Another way to escape the quoting character is repeating it twice:

```
SELECT 'I''m here', """Double""";
+-----+-----+
| I'm here | "Double" |
+-----+-----+
| I'm here | "Double" |
+-----+-----+
```

## Escape Sequences

There are other escape sequences also. Here is a full list:

Escape sequence	Character
\0	ASCII NUL (0x00).
\'	Single quote ("").
\"	Double quote (""").
\b	Backspace.
\n	Newline, or linefeed.,
\r	Carriage return.
\t	Tab.
\z	ASCII 26 (Control+Z). See note following the table.
\\\	Backslash ("\").
\%	"%" character. See note following the table.
\_	A "_" character. See note following the table.

Escaping the

%  
and  
-

characters can be necessary when using the [LIKE](#) operator, which treats them as special characters.

The ASCII 26 character (

\z

) needs to be escaped when included in a batch file which needs to be executed in Windows. The reason is that ASCII 26, in Windows, is the end of file (EOF).

Backslash (

\

), if not used as an escape character, must always be escaped. When followed by a character that is not in the above table, backslashes will simply be ignored.

## 4.1.2.2 BINARY

## Syntax

BINARY(M)

### Contents

1. [Description](#)
2. [Examples](#)
3. [See Also](#)

## Description

The

BINARY

type is similar to the

CHAR

type, but stores binary byte strings rather than non-binary character strings.

M

represents the column length in bytes.

It contains no character set, and comparison and sorting are based on the numeric value of the bytes.

If the maximum length is exceeded, and [SQL strict mode](#) is not enabled, the extra characters will be dropped with a warning. If strict mode is enabled, an error will occur.

BINARY values are right-padded with

0x00

(the zero byte) to the specified length when inserted. The padding is *not* removed on select, so this needs to be taken into account when sorting and comparing, where all bytes are significant. The zero byte,

0x00

is less than a space for comparison purposes.

## Examples

Inserting too many characters, first with strict mode off, then with it on:

```
CREATE TABLE bins (a BINARY(10));

INSERT INTO bins VALUES('12345678901');
Query OK, 1 row affected, 1 warning (0.04 sec)

SELECT * FROM bins;
+-----+
| a      |
+-----+
| 1234567890 |
+-----+

SET sql_mode='STRICT_ALL_TABLES';

INSERT INTO bins VALUES('12345678901');
ERROR 1406 (22001): Data too long for column 'a' at row 1
```

Sorting is performed with the byte value:

```

TRUNCATE bins;

INSERT INTO bins VALUES('A'),('B'),('a'),('b');

SELECT * FROM bins ORDER BY a;
+-----+
| a    |
+-----+
| A    |
| B    |
| a    |
| b    |
+-----+

```

Using `CAST` to sort as a `CHAR` instead:

```

SELECT * FROM bins ORDER BY CAST(a AS CHAR);
+-----+
| a    |
+-----+
| a    |
| A    |
| b    |
| B    |
+-----+

```

The field is a `BINARY(10)`, so padding of two `\0`'s are inserted, causing comparisons that don't take this into account to fail:

```

TRUNCATE bins;

INSERT INTO bins VALUES('12345678');

SELECT a = '12345678', a = '12345678\0\0' from bins;
+-----+-----+
| a = '12345678' | a = '12345678\0\0' |
+-----+-----+
|          0      |          1      |
+-----+-----+

```

## See Also

- [CHAR](#)

### 4.1.2.3 BLOB

## Syntax

`BLOB[(M)]`

### Contents

1. [Syntax](#)
2. [Description](#)
  1. [Indexing](#)
  2. [Oracle Mode](#)
3. [See Also](#)

## Description

A

BLOB  
column with a maximum length of  
65,535  
(  
2

- 1  
) bytes. Each  
BLOB  
value is stored using a two-byte length prefix that indicates the number of bytes in the value.

An optional length

M  
can be given for this type. If this is done, MariaDB creates the column as the smallest  
BLOB  
type large enough to hold values  
M  
bytes long.

BLOBS can also be used to store [dynamic columns](#).

Before [MariaDB 10.2.1](#),

BLOB  
and  
TEXT  
columns could not be assigned a [DEFAULT](#) value. This restriction was lifted in [MariaDB 10.2.1](#).

## Indexing

MariaDB starting with [10.4](#)

From [MariaDB 10.4](#), it is possible to set a [unique index](#) on a column that uses the  
BLOB  
data type. In previous releases this was not possible, as the index would only guarantee the uniqueness of a fixed number of characters.

## Oracle Mode

MariaDB starting with [10.3](#)

In [Oracle mode from MariaDB 10.3](#),

BLOB  
is a synonym for  
LONGBLOB  
.

## See Also

- [BLOB and TEXT Data Types](#)
- [Data Type Storage Requirements](#)
- [Oracle mode from MariaDB 10.3](#)

### 4.1.2.4 BLOB and TEXT Data Types

## Description

A

BLOB  
is a binary large object that can hold a variable amount of data. The four  
BLOB  
types are

- [TINYBLOB](#),
- [BLOB](#),
- [MEDIUMBLOB](#), and
- [LONGBLOB](#).

These differ only in the maximum length of the values they can hold.

The

TEXT  
types are

- [TINYTEXT](#),
- [TEXT](#),
- [MEDIUMTEXT](#), and
- [LONGTEXT](#).

- [JSON](#) (alias for LONGTEXT)

These correspond to the four

BLOB

types and have the same maximum lengths and [storage requirements](#).

MariaDB starting with [10.2.1](#)

Starting from [MariaDB 10.2.1](#),

BLOB

and

TEXT

columns can have a

DEFAULT

value.

MariaDB starting with [10.4.3](#)

From [MariaDB 10.4](#), it is possible to set a [unique index](#) on columns that use the

BLOB

or

TEXT

data types.

## 4.1.2.5 CHAR

This article covers the CHAR data type. See [CHAR Function](#) for the function.

### Syntax

```
[NATIONAL] CHAR[(M)] [CHARACTER SET charset_name] [COLLATE collation_name]
```

### Contents

- [1. Syntax](#)
- [2. Description](#)
- [3. Examples](#)
- [4. NO PAD Collations](#)
- [5. See Also](#)

### Description

A fixed-length string that is always right-padded with spaces to the specified length when stored.

M

represents the column length in characters. The range of

M

is

0

to

255

. If

M

is omitted, the length is

1

.

CHAR(0) columns can contain 2 values: an empty string or NULL. Such columns cannot be part of an index. The [CONNECT](#) storage engine does not support CHAR(0).

**Note:** Trailing spaces are removed when

CHAR

values are retrieved unless the

PAD\_CHAR\_TO\_FULL\_LENGTH

[SQL mode](#) is enabled.

Before [MariaDB 10.2](#), all collations were of type PADSPACE, meaning that CHAR (as well as [VARCHAR](#) and [TEXT](#)) values are compared without regard for trailing spaces. This does not apply to the [LIKE](#) pattern-matching operator, which takes into account trailing spaces.

If a unique index consists of a column where trailing pad characters are stripped or ignored, inserts into that column where values differ only by the number of trailing pad characters will result in a duplicate-key error.

# Examples

Trailing spaces:

```
CREATE TABLE strtest (c CHAR(10));
INSERT INTO strtest VALUES('Maria   ');

SELECT c='Maria',c='Maria   ' FROM strtest;
+-----+-----+
| c='Maria' | c='Maria   ' |
+-----+-----+
|      1    |          1   |
+-----+-----+

SELECT c LIKE 'Maria',c LIKE 'Maria   ' FROM strtest;
+-----+-----+
| c LIKE 'Maria' | c LIKE 'Maria   ' |
+-----+-----+
|          1     |          0   |
+-----+-----+
```

## NO PAD Collations

MariaDB starting with [10.2](#)

NO PAD collations regard trailing spaces as normal characters. You can get a list of all NO PAD collations by querying the [Information Schema Collations table](#), for example:

```
SELECT collation_name FROM information_schema.collations
  WHERE collation_name LIKE "%nopad%";

+-----+
| collation_name           |
+-----+
| big5_chinese_nopad_ci   |
| big5_nopad_bin           |
...

```

## See Also

- [CHAR Function](#)
- [VARCHAR](#)
- [BINARY](#)
- [Data Type Storage Requirements](#)

## 4.1.2.6 CHAR BYTE

### Description

The

`CHAR BYTE`  
data type is an alias for the

`BINARY`

data type. This is a compatibility feature.

## 4.1.2.7 ENUM

### Syntax

```
ENUM('value1','value2',...) [CHARACTER SET charset_name] [COLLATE collation_name]
```

## Contents

1. [Syntax](#)
2. [Description](#)
  1. [NULL and empty values](#)
  2. [Numeric index](#)
3. [Examples](#)
4. [See Also](#)

## Description

An enumeration. A string object that can have only one value, chosen from the list of values 'value1', 'value2', ..., NULL or the special " error value. In theory, an

ENUM

column can have a maximum of 65,535 distinct values; in practice, the real maximum depends on many factors.

ENUM

values are represented internally as integers.

Trailing spaces are automatically stripped from ENUM values on table creation.

ENUMs require relatively little storage space compared to strings, either one or two bytes depending on the number of enumeration values.

## NULL and empty values

An ENUM can also contain NULL and empty values. If the ENUM column is declared to permit NULL values, NULL becomes a valid value, as well as the default value (see below). If strict SQL Mode is not enabled, and an invalid value is inserted into an ENUM, a special empty string, with an index value of zero (see Numeric index, below), is inserted, with a warning. This may be confusing, because the empty string is also a possible value, and the only difference if that is this case its index is not 0. Inserting will fail with an error if strict mode is active.

If a

DEFAULT

clause is missing, the default value will be:

- NULL  
if the column is nullable;
- otherwise, the first value in the enumeration.

## Numeric index

ENUM values are indexed numerically in the order they are defined, and sorting will be performed in this numeric order. We suggest not using ENUM to store numerals, as there is little to no storage space benefit, and it is easy to confuse the enum integer with the enum numeral value by leaving out the quotes.

An ENUM defined as ENUM('apple','orange','pear') would have the following index values:

Index	Value
NULL	NULL
0	"
1	'apple'
2	'orange'
3	'pear'

## Examples

```

CREATE TABLE fruits (
    id INT NOT NULL auto_increment PRIMARY KEY,
    fruit ENUM('apple','orange','pear'),
    bushels INT);

DESCRIBE fruits;
+-----+-----+-----+-----+
| Field | Type            | Null | Key | Default | Extra       |
+-----+-----+-----+-----+
| id    | int(11)          | NO   | PRI | NULL    | auto_increment |
| fruit | enum('apple','orange','pear') | YES  |     | NULL    |             |
| bushels | int(11)          | YES  |     | NULL    |             |
+-----+-----+-----+-----+

INSERT INTO fruits
(fruit,bushels) VALUES
('pear',20),
('apple',100),
('orange',25);

INSERT INTO fruits
(fruit,bushels) VALUES
('avocado',10);
ERROR 1265 (01000): Data truncated for column 'fruit' at row 1

SELECT * FROM fruits;
+-----+-----+
| id | fruit | bushels |
+-----+-----+
| 1  | pear  |      20 |
| 2  | apple  |      100 |
| 3  | orange |      25 |
+-----+-----+

```

Selecting by numeric index:

```

SELECT * FROM fruits WHERE fruit=2;
+-----+-----+
| id | fruit | bushels |
+-----+-----+
| 3  | orange |      25 |
+-----+-----+

```

Sorting is according to the index value:

```

CREATE TABLE enums (a ENUM('2','1'));

INSERT INTO enums VALUES ('1'),('2');

SELECT * FROM enums ORDER BY a ASC;
+-----+
| a   |
+-----+
| 2   |
| 1   |
+-----+

```

It's easy to get confused between returning the enum integer with the stored value, so we don't suggest using ENUM to store numerals. The first example returns the 1st indexed field ('2' has an index value of 1, as it's defined first), while the second example returns the string value '1'.

```

SELECT * FROM enums WHERE a=1;
+-----+
| a   |
+-----+
| 2   |
+-----+

SELECT * FROM enums WHERE a='1';
+-----+
| a   |
+-----+
| 1   |
+-----+

```

### 4.1.2.9 JSON Data Type

MariaDB starting with [10.2.7](#)

The JSON alias was added in [MariaDB 10.2.7](#). This was done to make it possible to use JSON columns in [statement based replication](#) from MySQL to MariaDB and to make it possible for MariaDB to read [mysqldumps](#) from MySQL.

#### Contents

1. [Examples](#)
2. [Replicating JSON Data Between MySQL and MariaDB](#)
3. [Converting a MySQL TABLE with JSON Fields to MariaDB](#)
4. [Differences Between MySQL JSON Strings and MariaDB JSON Strings](#)
5. [See Also](#)

JSON is an alias for [LONGTEXT](#) introduced for compatibility reasons with MySQL's JSON data type. MariaDB implements this as a LONGTEXT rather, as the JSON data type contradicts the SQL standard, and MariaDB's benchmarks indicate that performance is at least equivalent.

In order to ensure that a valid json document is inserted, the [JSON\\_VALID](#) function can be used as a [CHECK constraint](#). This constraint is automatically included for types using the JSON alias from [MariaDB 10.4.3](#).

## Examples

```
CREATE TABLE t (j JSON);

DESC t;
+-----+-----+-----+-----+
| Field | Type   | Null | Key | Default | Extra |
+-----+-----+-----+-----+
| j     | longtext | YES  |      | NULL    |       |
+-----+-----+-----+-----+
```

With validation:

```
CREATE TABLE t2 (
  j JSON
  CHECK (JSON_VALID(j))
);

INSERT INTO t2 VALUES ('invalid');
ERROR 4025 (23000): CONSTRAINT `j` failed for `test`.`t2`

INSERT INTO t2 VALUES ('{"id": 1, "name": "Monty"}');
Query OK, 1 row affected (0.13 sec)
```

## Replicating JSON Data Between MySQL and MariaDB

The JSON type in MySQL stores the JSON object in a compact form, not as [LONGTEXT](#) as in MariaDB. This means that row based replication will not work for JSON types from MySQL to MariaDB.

There are a few different ways to solve this:

- Use statement based replication.
- Change the JSON column to type TEXT in MySQL
- If you must use row-based replication and cannot change the MySQL master from JSON to TEXT, you can try to introduce an intermediate MySQL slave and change the column type from JSON to TEXT on it. Then you replicate from this intermediate slave to MariaDB.

## Converting a MySQL TABLE with JSON Fields to MariaDB

MariaDB can't directly access MySQL's JSON format.

There are a few different ways to move the table to MariaDB:

- Change the JSON column to type TEXT in MySQL. After this, MariaDB can directly use the table without any need for a dump and restore.

- Use mariadb-dump/mysqldump to copy the table .

## Differences Between MySQL JSON Strings and MariaDB JSON Strings

- In MySQL, JSON is an object and is compared according to json values . In MariaDB JSON strings are normal strings and compared as strings. One exception is when using [JSON\\_EXTRACT\(\)](#) in which case strings are unescaped before comparison.

- [MDEV-9144](#)

## 4.1.2.10 MEDIUMBLOB

### Syntax

```
MEDIUMBLOB
```

### Description

A [BLOB](#) column with a maximum length of 16,777,215 ( $2^{24} - 1$ ) bytes. Each MEDIUMBLOB value is stored using a three-byte length prefix that indicates the number of bytes in the value.

### See Also

- [BLOB](#)
- [BLOB and TEXT Data Types](#)
- [Data Type Storage Requirements](#)

## 4.1.2.11 MEDIUMTEXT

### Syntax

```
MEDIUMTEXT [CHARACTER SET charset_name] [COLLATE collation_name]
```

### Description

A [TEXT](#) column with a maximum length of 16,777,215 (

2

$2^{24}$

- 1

) characters. The effective maximum length is less if the value contains multi-byte characters. Each MEDIUMTEXT value is stored using a three-byte length prefix that indicates the number of bytes in the value.

### See Also

- [TEXT](#)
- [BLOB and TEXT Data Types](#)
- [Data Type Storage Requirements](#)

## 4.1.2.12 LONGBLOB

### Syntax

```
LONGBLOB
```

### Description

A [BLOB](#) column with a maximum length of 4,294,967,295 bytes or 4GB ( $2^{32} - 1$ ). The effective maximum length of LONGBLOB columns depends on the configured maximum packet size in the client/server protocol and available memory. Each LONGBLOB value is stored using a four-byte length prefix that indicates the number of bytes in the value.

## Oracle Mode

MariaDB starting with [10.3](#)

In Oracle mode from MariaDB 10.3 ,

BLOB  
is a synonym for  
LONGBLOB  
.

## See Also

- [BLOB](#)
- [BLOB and TEXT Data Types](#)
- [Data Type Storage Requirements](#)
- [Oracle mode from MariaDB 10.3](#)

## 4.1.2.13 LONG and LONG VARCHAR

LONG  
and  
LONG VARCHAR  
are synonyms for [MEDIUMTEXT](#) .

```
CREATE TABLE t1 (a LONG, b LONG VARCHAR);
```

```
DESC t1;
```

Field	Type	Null	Key	Default	Extra
a	mediumtext	YES		NULL	
b	mediumtext	YES		NULL	

## 4.1.2.14 LONGTEXT

### Syntax

```
LONGTEXT [CHARACTER SET charset_name] [COLLATE collation_name]
```

### Contents

1. [Syntax](#)
2. [Description](#)
3. [Oracle Mode](#)
4. [See Also](#)

### Description

A [TEXT](#) column with a maximum length of 4,294,967,295 or 4GB (

2

32

- 1

) characters. The effective maximum length is less if the value contains multi-byte characters. The effective maximum length of LONGTEXT columns also depends on the configured maximum packet size in the client/server protocol and available memory. Each LONGTEXT value is stored using a four-byte length prefix that indicates the number of bytes in the value.

From [MariaDB 10.2.7](#) , JSON is an alias for LONGTEXT. See [JSON Data Type](#) for details.

# Oracle Mode

MariaDB starting with 10.3

In Oracle mode from MariaDB 10.3 ,

CLOB  
is a synonym for  
LONGTEXT

## See Also

- [TEXT](#)

## 4.1.2.15 ROW

MariaDB starting with 10.3.0

The

ROW  
data type was introduced in MariaDB 10.3.0 .

## Syntax

```
ROW (<field name> <data type> [{, <field name> <data type>}... ])
```

### Contents

1. [Syntax](#)
2. [Description](#)
3. [Features](#)
  1. [ROW fields as normal variables](#)
  2. [ROW type variables as FETCH targets](#)
  3. [ROW type variables as SELECT...INTO targets](#)
4. [Features not implemented](#)
5. [Examples](#)
  1. [Declaring a ROW in a stored procedure](#)
  2. [FETCH Examples](#)
  3. [SELECT...INTO Examples](#)
6. [See Also](#)

## Description

ROW

is a data type for [stored procedure](#) variables.

## Features

### ROW fields as normal variables

ROW

fields (members) act as normal variables, and are able to appear in all query parts where a stored procedure variable is allowed:

- Assignment is using the  
:=  
operator and the [SET](#) command:

```
a.x:= 10;  
a.x:= b.x;  
SET a.x= 10, a.y=20, a.z= b.z;
```

- Passing to functions and operators:

```
SELECT f1(rec.a), rec.a<10;
```

- Clauses (select list, WHERE, HAVING, LIMIT, etc...):

```
SELECT var.a, t1.b FROM t1 WHERE t1.b=var.b LIMIT var.c;
```

- INSERT  
    values:

```
INSERT INTO t1 VALUES (rec.a, rec.b, rec.c);
```

- SELECT .. INTO  
    targets

```
SELECT a,b INTO rec.a, rec.b FROM t1 WHERE t1.id=10;
```

- Dynamic SQL out parameters ( [EXECUTE](#) and [EXECUTE IMMEDIATE](#) )

```
EXECUTE IMMEDIATE 'CALL proc_with_out_param(?)' USING rec.a;
```

## ROW type variables as FETCH targets

ROW  
type variables are allowed as [FETCH](#) targets:

```
FETCH cur INTO rec;
```

where

cur  
is a  
CURSOR  
and  
rec  
is a  
ROW  
type stored procedure variable.

Note, currently an attempt to use

    FETCH  
    for a  
    ROW  
    type variable returns this error:

```
ERROR 1328 (HY000): Incorrect number of FETCH variables
```

    FETCH  
    from a cursor  
    cur  
    into a  
    ROW  
    variable  
    rec  
    works as follows:

- The number of fields in  
        cur

must match the number of fields in  
rec  
. Otherwise, an error is reported.

- Assignment is done from left to right. The first cursor field is assigned to the first variable field, the second cursor field is assigned to the second variable field, etc.
- Field names in  
rec  
are not important and can differ from field names in  
cur

See [FETCH Examples](#) (below) for examples of using this with

```
sql_mode=ORACLE
and
sql_mode=DEFAULT
```

## ROW type variables as

```
SELECT...INTO
targets
```

ROW  
type variables are allowed as  
SELECT..INTO  
targets with some differences depending on which  
sql\_mode  
is in use.

- When using

```
sql_mode=ORACLE
,
table%ROWTYPE
and
cursor%ROWTYPE
variables can be used as
SELECT...INTO
targets.
```

- Using multiple

```
ROW
variables in the
SELECT..INTO
list will report an error.
```

- Using

```
ROW
variables with a different column count than in the
SELECT..INTO
list will report an error.
```

See [SELECT...INTO Examples](#) (below) for examples of using this with

```
sql_mode=ORACLE
and
sql_mode=DEFAULT
```

## Features not implemented

The following features are planned, but not implemented yet:

- Returning a ROW type expression from a stored function (see [MDEV-12252](#) ). This will need some grammar change to support field names after parentheses:

```
SELECT f1().x FROM DUAL;
```

- Returning a ROW type expression from a built-in hybrid type function, such as  
CASE  
,  
IF  
, etc.

- ROW of ROWs

## Examples

### Declaring a ROW in a stored procedure

```
DELIMITER $$  
CREATE PROCEDURE p1()  
BEGIN  
    DECLARE r ROW (c1 INT, c2 VARCHAR(10));  
    SET r.c1= 10;  
    SET r.c2= 'test';  
    INSERT INTO t1 VALUES (r.c1, r.c2);  
END;  
$$  
DELIMITER ;  
CALL p1();
```

### FETCH Examples

A complete

```
FETCH  
example for  
sql_mode=ORACLE  
:  
  
DROP TABLE IF EXISTS t1;  
CREATE TABLE t1 (a INT, b VARCHAR(32));  
INSERT INTO t1 VALUES (10,'b10');  
INSERT INTO t1 VALUES (20,'b20');  
INSERT INTO t1 VALUES (30,'b30');  
  
SET sql_mode=oracle;  
DROP PROCEDURE IF EXISTS p1;  
DELIMITER $$  
CREATE PROCEDURE p1 AS  
    rec ROW(a INT, b VARCHAR(32));  
    CURSOR c IS SELECT a,b FROM t1;  
BEGIN  
    OPEN c;  
    LOOP  
        FETCH c INTO rec;  
        EXIT WHEN c%NOTFOUND;  
        SELECT ('rec=(\' || rec.a ||','|| rec.b||\')');  
    END LOOP;  
    CLOSE c;  
END;  
$$  
DELIMITER ;  
CALL p1();
```

A complete

```
FETCH  
example for  
sql_mode=DEFAULT  
:
```

```

DROP TABLE IF EXISTS t1;
CREATE TABLE t1 (a INT, b VARCHAR(32));
INSERT INTO t1 VALUES (10,'b10');
INSERT INTO t1 VALUES (20,'b20');
INSERT INTO t1 VALUES (30,'b30');

SET sql_mode=DEFAULT;
DROP PROCEDURE IF EXISTS p1;
DELIMITER $$ 
CREATE PROCEDURE p1()
BEGIN
    DECLARE done INT DEFAULT FALSE;
    DECLARE rec ROW(a INT, b VARCHAR(32));
    DECLARE c CURSOR FOR SELECT a,b FROM t1;
    DECLARE CONTINUE HANDLER FOR NOT FOUND SET done = TRUE;
    OPEN c;
    read_loop:
    LOOP
        FETCH c INTO rec;
        IF done THEN
            LEAVE read_loop;
        END IF;
        SELECT CONCAT('rec=(',rec.a,',',rec.b,')');
    END LOOP;
    CLOSE c;
END;
$$
DELIMITER ;
CALL p1();

```

## SELECT...INTO Examples

A

```

SELECT...INTO
example for
sql_mode=DEFAULT
:

SET sql_mode=DEFAULT;
DROP TABLE IF EXISTS t1;
DROP PROCEDURE IF EXISTS p1;
CREATE TABLE t1 (a INT, b VARCHAR(32));
INSERT INTO t1 VALUES (10,'b10');
DELIMITER $$ 
CREATE PROCEDURE p1()
BEGIN
    DECLARE rec1 ROW(a INT, b VARCHAR(32));
    SELECT * FROM t1 INTO rec1;
    SELECT rec1.a, rec1.b;
END;
$$
DELIMITER ;
CALL p1();

```

The above example returns:

rec1.a	rec1.b
10	b10

A

```

SELECT...INTO
example for
sql_mode=ORACLE
:

```

```

SET sql_mode=ORACLE;
DROP TABLE IF EXISTS t1;
DROP PROCEDURE IF EXISTS p1;
CREATE TABLE t1 (a INT, b VARCHAR(32));
INSERT INTO t1 VALUES (10,'b10');
DELIMITER $$ 
CREATE PROCEDURE p1 AS
    rec1 ROW(a INT, b VARCHAR(32));
BEGIN
    SELECT * FROM t1 INTO rec1;
    SELECT rec1.a, rec1.b;
END;
$$
DELIMITER ;
CALL p1();

```

The above example returns:

rec1.a	rec1.b
10	b10

An example for

```

sql_mode=ORACLE
using
table%ROWTYPE
variables as
SELECT..INTO
targets:

```

```

SET sql_mode=ORACLE;
DROP TABLE IF EXISTS t1;
DROP PROCEDURE IF EXISTS p1;
CREATE TABLE t1 (a INT, b VARCHAR(32));
INSERT INTO t1 VALUES (10,'b10');
DELIMITER $$ 
CREATE PROCEDURE p1 AS
    rec1 t1%ROWTYPE;
BEGIN
    SELECT * FROM t1 INTO rec1;
    SELECT rec1.a, rec1.b;
END;
$$
DELIMITER ;
CALL p1();

```

The above example returns:

rec1.a	rec1.b
10	b10

An example for

```

sql_mode=ORACLE
using
cursor%ROWTYPE
variables as
SELECT..INTO
targets:

```

```

SET sql_mode=ORACLE;
DROP TABLE IF EXISTS t1;
DROP PROCEDURE IF EXISTS p1;
CREATE TABLE t1 (a INT, b VARCHAR(32));
INSERT INTO t1 VALUES (10,'b10');
DELIMITER $$ 
CREATE PROCEDURE p1 AS
    CURSOR cur1 IS SELECT * FROM t1;
    rec1 cur1%ROWTYPE;
BEGIN
    SELECT * FROM t1 INTO rec1;
    SELECT rec1.a, rec1.b;
END;
$$
DELIMITER ;
CALL p1();

```

The above example returns:

rec1.a	rec1.b
10	b10

## 4.1.2.16 TEXT

### Syntax

```
TEXT[(M)] [CHARACTER SET charset_name] [COLLATE collation_name]
```

### Contents

1. [Syntax](#)
2. [Description](#)
3. [Examples](#)
4. [Indexing](#)
5. [Difference between VARCHAR and TEXT](#)
  1. [For Storage Engine Developers](#)
6. [See Also](#)

### Description

A

```

TEXT
column with a maximum length of
65,535
(
2

```

16

```

- 1
) characters. The effective maximum length is less if the value contains multi-byte characters. Each
TEXT
value is stored using a two-byte length prefix that indicates the number of bytes in the value. If you need a bigger storage, consider using
MEDIUMTEXT instead.

```

An optional length

```

M
can be given for this type. If this is done, MariaDB creates the column as the smallest
TEXT
type large enough to hold values
M

```

characters long.

Before MariaDB 10.2 , all MariaDB [collations](#) were of type PADSPACE, meaning that TEXT (as well as VARCHAR and CHAR values) are compared without regard for trailing spaces. This does not apply to the LIKE pattern-matching operator, which takes into account trailing spaces.

Before MariaDB 10.2.1 ,

BLOB

and

TEXT

columns could not be assigned a [DEFAULT](#) value. This restriction was lifted in MariaDB 10.2.1 .

## Examples

Trailing spaces:

```
CREATE TABLE strtest (d TEXT(10));
INSERT INTO strtest VALUES('Maria   ');

SELECT d='Maria',d='Maria   ' FROM strtest;
+-----+-----+
| d='Maria' | d='Maria   ' |
+-----+-----+
|      1 |          1 |
+-----+-----+

SELECT d LIKE 'Maria',d LIKE 'Maria   ' FROM strtest;
+-----+-----+
| d LIKE 'Maria' | d LIKE 'Maria   ' |
+-----+-----+
|          0 |          1 |
+-----+-----+
```

## Indexing

TEXT

columns can only be indexed over a specified length. This means that they cannot be used as the [primary key](#) of a table norm until MariaDB 10.4 , can a [unique index](#) be created on them.

MariaDB starting with 10.4

Starting with MariaDB 10.4 , a unique index can be created on a

TEXT

column.

Internally, this uses hash indexing to quickly check the values and if a hash collision is found, the actual stored values are compared in order to retain the uniqueness.

## Difference between VARCHAR and TEXT

- VARCHAR columns can be fully indexed.

TEXT

columns can only be indexed over a specified length.

- Using TEXT or BLOB in a SELECT query that uses temporary tables for storing intermediate results will force the temporary table to be disk based (using the [Aria storage engine](#) instead of the [memory storage engine](#) , which is a bit slower. This is not that bad as the [Aria storage engine](#) caches the rows in memory. To get the benefit of this, one should ensure that the [aria\\_pagecache\\_buffer\\_size](#) variable is big enough to hold most of the row and index data for temporary tables.

## For Storage Engine Developers

- Internally the full length of the VARCHAR column is allocated inside each TABLE objects record[] structure. As there are three such buffers, each open table will allocate 3 times max-length-to-store-varchar bytes of memory.

- 

TEXT

and

BLOB

columns are stored with a pointer (4 or 8 bytes) + a 1-4 bytes length. The

TEXT

data is only stored once. This means that internally

TEXT

uses less memory for each open table but instead has the additional overhead that each

## TEXT

object needs to be allocated and freed for each row access (with some caching in between).

## 4.1.2.17 TINYBLOB

### Syntax

```
TINYBLOB
```

### Description

A [BLOB](#) column with a maximum length of 255 ( $2^8 - 1$ ) bytes. Each TINYBLOB value is stored using a one-byte length prefix that indicates the number of bytes in the value.

## See Also

- [BLOB](#)
- [BLOB and TEXT Data Types](#)
- [Data Type Storage Requirements](#)

## 4.1.2.18 TINYTEXT

### Syntax

```
TINYTEXT [CHARACTER SET charset_name] [COLLATE collation_name]
```

### Description

A [TEXT](#) column with a maximum length of 255 (

2

8

- 1

) characters. The effective maximum length is less if the value contains multi-byte characters. Each TINYTEXT value is stored using a one-byte length prefix that indicates the number of bytes in the value.

## See Also

- [TEXT](#)
- [BLOB and TEXT Data Types](#)
- [Data Type Storage Requirements](#)

## 4.1.2.19 VARBINARY

### Syntax

```
VARBINARY(M)
```

## Contents

1. [Syntax](#)
2. [Description](#)
  1. [Oracle Mode](#)
3. [Examples](#)
4. [See Also](#)

## Description

The VARBINARY type is similar to the VARCHAR type, but stores binary byte strings rather than non-binary character strings.

M

represents the maximum column length in bytes.

It contains no [character set](#), and comparison and sorting are based on the numeric value of the bytes.

If the maximum length is exceeded, and [SQL strict mode](#) is not enabled, the extra characters will be dropped with a warning. If strict mode is enabled, an error will occur.

Unlike [BINARY](#) values, VARBINARYs are not right-padded when inserting.

## Oracle Mode

MariaDB starting with 10.3

In [Oracle mode from MariaDB 10.3](#),

RAW  
is a synonym for  
VARBINARY

## Examples

Inserting too many characters, first with strict mode off, then with it on:

```
CREATE TABLE varbins (a VARBINARY(10));

INSERT INTO varbins VALUES('12345678901');
Query OK, 1 row affected, 1 warning (0.04 sec)

SELECT * FROM varbins;
+-----+
| a      |
+-----+
| 1234567890 |
+-----+

SET sql_mode='STRICT_ALL_TABLES';

INSERT INTO varbins VALUES('12345678901');
ERROR 1406 (22001): Data too long for column 'a' at row 1
```

Sorting is performed with the byte value:

```
TRUNCATE varbins;

INSERT INTO varbins VALUES('A'),('B'),('a'),('b');

SELECT * FROM varbins ORDER BY a;
+-----+
| a    |
+-----+
| A    |
| B    |
| a    |
| b    |
+-----+
```

Using [CAST](#) to sort as a [CHAR](#) instead:

```
SELECT * FROM varbins ORDER BY CAST(a AS CHAR);
+----+
| a |
+----+
| a |
| A |
| b |
| B |
+----+
```

## See Also

- [VARCHAR](#)
- [Data Type Storage Requirements](#)
- [Oracle mode from MariaDB 10.3](#)

## 4.1.2.20 VARCHAR

### Syntax

```
[NATIONAL] VARCHAR(M) [CHARACTER SET charset_name] [COLLATE collation_name]
```

### Contents

1. [Syntax](#)
2. [Description](#)
3. [Examples](#)
4. [Truncation](#)
5. [Difference Between VARCHAR and TEXT](#)
6. [Oracle Mode](#)
  1. [For Storage Engine Developers](#)
7. [See Also](#)

### Description

A variable-length string. M represents the maximum column length in characters. The range of M is 0 to 65,532. The effective maximum length of a VARCHAR is subject to the maximum row size and the character set used. For example, utf8 characters can require up to three bytes per character, so a VARCHAR column that uses the utf8 character set can be declared to be a maximum of 21,844 characters.

**Note:** For the [ColumnStore](#) engine, M represents the maximum column length in bytes.

MariaDB stores VARCHAR values as a one-byte or two-byte length prefix plus data. The length prefix indicates the number of bytes in the value. A VARCHAR column uses one length byte if values require no more than 255 bytes, two length bytes if values may require more than 255 bytes.

MariaDB follows the standard SQL specification, and does not remove trailing spaces from VARCHAR values.

VARCHAR(0) columns can contain 2 values: an empty string or NULL. Such columns cannot be part of an index. The [CONNECT](#) storage engine does not support VARCHAR(0).

VARCHAR is shorthand for CHARACTER VARYING. NATIONAL VARCHAR is the standard SQL way to define that a VARCHAR column should use some predefined character set. MariaDB uses utf8 as this predefined character set, as does MySQL 4.1 and up. NVARCHAR is shorthand for NATIONAL VARCHAR.

Before [MariaDB 10.2](#), all MariaDB [collations](#) were of type

PADSPACE

, meaning that VARCHAR (as well as [CHAR](#) and [TEXT](#) values) are compared without regard for trailing spaces. This does not apply to the [LIKE](#) pattern-matching operator, which takes into account trailing spaces. From [MariaDB 10.2](#), a number of [NO PAD collations](#) are available.

If a unique index consists of a column where trailing pad characters are stripped or ignored, inserts into that column where values differ only by the number of trailing pad characters will result in a duplicate-key error.

### Examples

The following are equivalent:

```
VARCHAR(30) CHARACTER SET utf8
NATIONAL VARCHAR(30)
NVARCHAR(30)
NCHAR VARCHAR(30)
NATIONAL CHARACTER VARYING(30)
NATIONAL CHAR VARYING(30)
```

Trailing spaces:

```
CREATE TABLE strtest (v VARCHAR(10));
INSERT INTO strtest VALUES('Maria   ');

SELECT v='Maria',v='Maria   ' FROM strtest;
+-----+
| v='Maria' | v='Maria   ' |
+-----+
|      1    |          1   |
+-----+

SELECT v LIKE 'Maria',v LIKE 'Maria   ' FROM strtest;
+-----+
| v LIKE 'Maria' | v LIKE 'Maria   ' |
+-----+
|        0       |          1   |
+-----+
```

## Truncation

- Depending on whether or not `strict sql mode` is set, you will either get a warning or an error if you try to insert a string that is too long into a `VARCHAR` column. If the extra characters are spaces, the spaces that can't fit will be removed and you will always get a warning, regardless of the `sql mode` setting.

## Difference Between VARCHAR and TEXT

- `VARCHAR` columns can be fully indexed. `TEXT` columns can only be indexed over a specified length.
- Using `TEXT` or `BLOB` in a `SELECT` query that uses temporary tables for storing intermediate results will force the temporary table to be disk based (using the `Aria storage engine` instead of the `memory storage engine`, which is a bit slower. This is not that bad as the `Aria storage engine` caches the rows in memory. To get the benefit of this, one should ensure that the `aria_pagecache_buffer_size` variable is big enough to hold most of the row and index data for temporary tables.

## Oracle Mode

MariaDB starting with 10.3

In Oracle mode from MariaDB 10.3 ,

`VARCHAR2`

is a synonym.

## For Storage Engine Developers

- Internally the full length of the `VARCHAR` column is allocated inside each TABLE objects record[] structure. As there are three such buffers, each open table will allocate 3 times max-length-to-store-varchar bytes of memory.
- `TEXT` and `BLOB` columns are stored with a pointer (4 or 8 bytes) + a 1-4 bytes length. The `TEXT` data is only stored once. This means that internally

`TEXT`

uses less memory for each open table but instead has the additional overhead that each

`TEXT`

object needs to be allocated and freed for each row access (with some caching in between).

## 4.1.2.21 SET Data Type

### Syntax

```
SET('value1','value2',...) [CHARACTER SET charset_name] [COLLATE collation_name]
```

# Description

A set. A string object that can have zero or more values, each of which must be chosen from the list of values 'value1', 'value2', ... A SET column can have a maximum of 64 members. SET values are represented internally as integers.

SET values cannot contain commas.

If a SET contains duplicate values, an error will be returned if [strict mode](#) is enabled, or a warning if strict mode is not enabled.

## 4.1.2.22 UUID Data Type

MariaDB starting with [10.7.0](#)

The UUID data type was added in a [MariaDB 10.7.0](#) preview.

## Syntax

UUID

### Contents

1. [Syntax](#)
2. [Description](#)
  1. [Retrieval](#)
  2. [Casting](#)
3. [Examples](#)
4. [See Also](#)

## Description

The

UUID

data type is intended for the storage of 128-bit UUID (Universally Unique Identifier) data. See the [UUID function](#) page for more details on UUIDs themselves.

## Retrieval

Data retrieved by this data type is in the string representation defined in [RFC4122](#).

## Casting

String literals of hexadecimal characters and [CHAR](#) / [VARCHAR](#) / [TEXT](#) can be cast to the UUID data type. Likewise [hexadecimal literals](#) , [binary-literals](#) , and [BINARY](#) / [VARBINARY](#) / [BLOB](#) types can also be cast to UUID.

The data type will not accept a short UUID generated with the [UUID\\_SHORT](#) function, but will accept a value without the

character generated by the [SYS\\_GUID](#) function (or inserted directly). Hyphens can be partially omitted as well, or included after any group of two digits.

The type does not accept UUIDs in braces, permitted by some implementations.

## Examples

```
CREATE TABLE t1 (id UUID);
```

Directly Inserting via [string literals](#) :

```
INSERT INTO t1 VALUES ('123e4567-e89b-12d3-a456-426655440000');
```

Directly Inserting via [hexadecimal literals](#) :

```
INSERT INTO t1 VALUES (x'fffffffffffffffffffe');
```

Generating and inserting via the [UUID function](#) .

```
INSERT INTO t1 VALUES (UUID());
```

Retrieval:

```
SELECT * FROM t1;
+-----+
| id |
+-----+
| 123e4567-e89b-12d3-a456-426655440000 |
| ffffffff-ffff-ffff-ffff-fffffffffe |
| 93aac041-1a14-11ec-ab4e-f859713e4be4 |
+-----+
```

The [UUID\\_SHORT](#) function does not generate valid full-length UUID:

```
INSERT INTO t1 VALUES (UUID_SHORT());
ERROR 1292 (22007): Incorrect uuid value: '99440417627439104'
for column `test`.`t1`.`id` at row 1
```

Accepting a value without the

character, either directly or generated by the [SYS\\_GUID](#) function:

```
INSERT INTO t1 VALUES (SYS_GUID());
SELECT * FROM t1;
+-----+
| id |
+-----+
| 123e4567-e89b-12d3-a456-426655440000 |
| ffffffff-ffff-ffff-ffff-fffffffffe |
| 93aac041-1a14-11ec-ab4e-f859713e4be4 |
| ea0368d3-1a14-11ec-ab4e-f859713e4be4 |
+-----+
SELECT SYS_GUID();
+-----+
| SYS_GUID() |
+-----+
| ff5b6bcc1a1411ecab4ef859713e4be4 |
+-----+
INSERT INTO t1 VALUES ('ff5b6bcc1a1411ecab4ef859713e4be4');
SELECT * FROM t1;
+-----+
| id |
+-----+
| 123e4567-e89b-12d3-a456-426655440000 |
| ffffffff-ffff-ffff-ffff-fffffffffe |
| 93aac041-1a14-11ec-ab4e-f859713e4be4 |
| ea0368d3-1a14-11ec-ab4e-f859713e4be4 |
| ff5b6bcc-1a14-11ec-ab4e-f859713e4be4 |
+-----+
```

Valid and invalid hyphen and brace usage:

```

TRUNCATE t1;

INSERT INTO t1 VALUES ('f8aa-ed66-1a1b-11ec-ab4e-f859-713e-4be4');

INSERT INTO t1 VALUES ('1b80667f1a1c-11ecab4ef859713e4be4');

INSERT INTO t1 VALUES ('2fd6c945-1a-1c-11ec-ab4e-f859713e4be4');

INSERT INTO t1 VALUES ('49-c9-f9-59-1a-1c-11ec-ab4e-f859713e4be4');

INSERT INTO t1 VALUES ('57-96-da-c1-1a-1c-11-ec-ab-4e-f8-59-71-3e-4b-e4');

INSERT INTO t1 VALUES ('6-eb74f8f-1a1c-11ec-ab4e-f859713e4be4');

INSERT INTO t1 VALUES ('{29bad136-1a1d-11ec-ab4e-f859713e4be4}');
ERROR 1292 (22007): Incorrect uuid value: '{29bad136-1a1d-11ec-ab4e-f859713e4be4}'
  for column `test`.`t1`.`id` at row 1

SELECT * FROM t1;
+-----+
| id   |
+-----+
| f8aaed66-1a1b-11ec-ab4e-f859713e4be4 |
| 1b80667f-1a1c-11ec-ab4e-f859713e4be4 |
| 2fd6c945-1a1c-11ec-ab4e-f859713e4be4 |
| 49c9f959-1a1c-11ec-ab4e-f859713e4be4 |
| 5796dac1-1a1c-11ec-ab4e-f859713e4be4 |
| 6eb74f8f-1a1c-11ec-ab4e-f859713e4be4 |
+-----+

```

character for Oracle compatibility

### 4.1.2.23 Data Type Storage Requirements

#### Contents

1. [Numeric Data Types](#)
  1. [Decimal](#)
2. [String Data Types](#)
  1. [Examples](#)
3. [Date and Time Data Types](#)
  1. [Microseconds](#)
    1. [MySQL 5.6+ and MariaDB 10.1+](#)
    2. [MariaDB 5.3 - MariaDB 10.0](#)

The following tables indicate the approximate data storage requirements for each data type.

## Numeric Data Types

Data Type	Storage Requirement
TINYINT	1 byte
SMALLINT	2 bytes
MEDIUMINT	3 bytes
INT	4 bytes
BIGINT	8 bytes
FLOAT (p)	4 bytes if p <= 24, otherwise 8 bytes
DOUBLE	8 bytes
DECIMAL	See table below
BIT (M)	(M+7)/8 bytes

Note that MEDIUMINT columns will require 4 bytes in memory (for example, in InnoDB buffer pool).

## Decimal

Decimals are stored using a binary format, with the integer and the fraction stored separately. Each nine-digit multiple requires 4 bytes, followed by a number of bytes for whatever remains, as follows:

Remaining digits	Storage Requirement
0	0 bytes
1	1 byte
2	1 byte
3	2 bytes
4	2 bytes
5	3 bytes
6	3 bytes
7	4 bytes
8	4 bytes

## String Data Types

In the descriptions below,

M

is the declared column length (in characters or in bytes), while

len

is the actual length in bytes of the value.

Data Type	Storage Requirement
ENUM	1 byte for up to 255 enum values, 2 bytes for 256 to 65,535 enum values
CHAR(M)	M × w bytes, where w is the number of bytes required for the maximum-length character in the character set
BINARY(M)	M bytes
VARCHAR(M) , VARBINARY(M)	len + 1 bytes if column is 0 – 255 bytes, len + 2 bytes if column may require more than 255 bytes
TINYBLOB , TINYTEXT	len + 1 bytes
BLOB , TEXT	len + 2 bytes
MEDIUMBLOB , MEDIUMTEXT	len + 3 bytes
LONGBLOB , LONGTEXT	len + 4 bytes
SET	Given M members of the set, (M+7)/8 bytes, rounded up to 1, 2, 3, 4, or 8 bytes
INET6	16 bytes
UUID	16 bytes

In some [character sets](#), not all characters use the same number of bytes. utf8 encodes characters with one to three bytes per character, while utf8mb4 requires one to four bytes per character.

When using field the COMPRESSED attribute, 1 byte is reserved for metadata. For example, VARCHAR(255) will use +2 bytes instead of +1.

## Examples

Assuming a single-byte character-set:

Value	CHAR(2)	Storage Required	VARCHAR(2)	Storage Required
"	''	2 bytes	"	1 byte
'1'	'1 '	2 bytes	'1'	2 bytes
'12'	'12'	2 bytes	'12'	3 bytes

## Date and Time Data Types

Data Type	Storage Requirement
-----------	---------------------

DATE	3 bytes
TIME	3 bytes
DATETIME	8 bytes
TIMESTAMP	4 bytes
YEAR	1 byte

## Microseconds

MariaDB 5.3 and MySQL 5.6 introduced [microseconds](#). The underlying storage implementations were different, but from MariaDB 10.1, MariaDB defaults to the MySQL format (by means of the `mysql56_temporal_format` variable). Microseconds have the following additional storage requirements:

MySQL 5.6+ and MariaDB 10.1 +

Precision	Storage Requirement
0	0 bytes
1,2	1 byte
3,4	2 bytes
5,6	3 bytes

MariaDB 5.3 - MariaDB 10.0

Precision	Storage Requirement
0	0 bytes
1,2	1 byte
3,4,5	2 bytes
6	3 bytes

## 4.1.2.24 Supported Character Sets and Collations

### Contents

1. [Character Sets](#)
2. [Collations](#)
3. [NO PAD collations](#)
4. [Changes](#)
5. [See Also](#)

## Character Sets

MariaDB 10.2 supports the following character sets:

Note that the Mroonga Storage Engine only supports a limited number of character sets. See [Mroonga available character sets](#).

Charset	Description	Default collation	Maxlen
armSCII8	ARMSCII-8 Armenian	armSCII8_general_ci	1
ascii	US ASCII	ascii_general_ci	1
big5	Big5 Traditional Chinese	big5_chinese_ci	2
binary	Binary pseudo charset	binary	1
cp1250	Windows Central European	cp1250_general_ci	1
cp1251	Windows Cyrillic	cp1251_general_ci	1
cp1256	Windows Arabic	cp1256_general_ci	1
cp1257	Windows Baltic	cp1257_general_ci	1
cp850	DOS West European	cp850_general_ci	1
cp852	DOS Central European	cp852_general_ci	1
cp866	DOS Russian	cp866_general_ci	1
cp932	SJIS for Windows Japanese	cp932_japanese_ci	2

dec8	DEC West European	dec8_swedish_ci	1
eucjpm	UJIS for Windows Japanese	eucjpm_japanese_ci	3
euckr	EUC-KR Korean	euckr_korean_ci	2
gb2312	GB2312 Simplified Chinese	gb2312_chinese_ci	2
gbk	GBK Simplified Chinese	gbk_chinese_ci	2
geostd8	GEOSTD8 Georgian	geostd8_general_ci	1
greek	ISO 8859-7 Greek	greek_general_ci	1
hebrew	ISO 8859-8 Hebrew	hebrew_general_ci	1
hp8	HP West European	hp8_english_ci	1
keybcs2	DOS Kamenicky Czech-Slovak	keybcs2_general_ci	1
koi8r	KOI8-R Relcom Russian	koi8r_general_ci	1
koi8u	KOI8-U Ukrainian	koi8u_general_ci	1
latin1	cp1252 West European	latin1_swedish_ci	1
latin2	ISO 8859-2 Central European	latin2_general_ci	1
latin5	ISO 8859-9 Turkish	latin5_turkish_ci	1
latin7	ISO 8859-13 Baltic	latin7_general_ci	1
macce	Mac Central European	macce_general_ci	1
macroman	Mac West European	macroman_general_ci	1
sjis	Shift-JIS Japanese	sjis_japanese_ci	2
swe7	7bit Swedish	swe7_swedish_ci	1
tis620	TIS620 Thai	tis620_thai_ci	1
ucs2	UCS-2 Unicode	ucs2_general_ci	2
ujis	EUC-JP Japanese	ujis_japanese_ci	3
utf8	UTF-8 Unicode	utf8_general_ci	3/4 (see <a href="#">OLD_MODE</a> )
utf16	UTF-16 Unicode	utf16_general_ci	4
utf16le	UTF-16LE Unicode	utf16le_general_ci	4
utf32	UTF-32 Unicode	utf32_general_ci	4
utf8mb3	UTF-8 Unicode	utf8mb3_general_ci	3
utf8mb4	UTF-8 Unicode	utf8mb4_general_ci	4

You can see which character sets are available in a particular version by running the `SHOW CHARACTER SET` statement or by querying the [Information Schema CHARACTER\\_SETS Table](#).

## Collations

MariaDB supports the following collations:

SHOW COLLATION;					
Collation	Charset	Id	Default	Compiled	Sortlen
big5_chinese_ci	big5	1	Yes	Yes	1
big5_bin	big5	84		Yes	1

From MariaDB 10.6.1 , the

```
utf8*
collations listed above are renamed
utf8mb3*
```

A '

```
ci
' at the end of a collation name indicates the collation is case insensitive. A '
cs
' at the end of a collation name indicates the collation is case sensitive. A '
nopad
' as part of the name indicates that the collation is of type
NO PAD
as opposed to
PADSPACE
(see below).
```

## NO PAD collations

MariaDB starting with 10.2

Until MariaDB 10.1 , all collations were of type

```
PADSPACE
. From MariaDB 10.2 , 88 new
NO PAD
collations are available.
NO PAD
collations regard trailing spaces as normal characters. You can get a list of all of these by querying the Information Schema COLLATIONS Table as follows:
```

```
SELECT collation_name FROM information_schema.COLLATIONS
WHERE collation_name LIKE "%nopad%";
```

collation_name
big5_chinese_nopad_ci
big5_nopad_bin
...

## Changes

- MariaDB 10.6.1 changed the  
utf8  
character set by default to be an alias for utf8mb3 rather than the other way around. It can be set to imply  
utf8mb4  
by changing the value of the `old_mode` system variable.
- MariaDB 10.2.2 added 88  
NO PAD  
collations.
- MariaDB 10.1.15 added the  
utf8\_thai\_520\_w2  
,  
utf8mb4\_thai\_520\_w2  
,  
ucs2\_thai\_520\_w2  
,  
utf16\_thai\_520\_w2  
and  
utf32\_thai\_520\_w2  
collations.
- MariaDB 10.0.7 added the  
utf8\_myanmar\_ci  
,  
ucs2\_myanmar\_ci  
,  
utf8mb4\_myanmar\_ci  
,  
utf16\_myanmar\_ci

- and  
utf32\_myanmar\_ci  
collations.
- MariaDB 10.0.5 added the  
utf8\_german2\_ci  
,  
utf8mb4\_german2\_ci  
,  
ucs2\_german2\_ci  
,  
utf16\_german2\_ci  
and  
utf32\_german2\_ci  
collations.
  - MariaDB 5.1.41 added a Croatian collation patch from [Alexander Barkov](#) to fix some problems with the Croatian character set and LIKE queries. This patch added  
utf8\_croatian\_ci  
and  
ucs2\_croatian\_ci  
collations to MariaDB.

### 4.1.2.25 Character Sets and Collations

Simply put, a character set defines how and which characters are stored to support a particular language or languages. A collation, on the other hand, defines the order used when comparing strings (i.e. the position of any given character within the alphabet of that language)

#### Character Set and Collation Overview

*Introduction to character sets and collations.*

#### Supported Character Sets and Collations

*MariaDB supports the following character sets and collations.*

#### Setting Character Sets and Collations

*Changing from the default character set and collation.*

#### Unicode

*Unicode support.*

#### SHOW CHARACTER SET

*Available character sets.*

#### SHOW COLLATION

### 4.1.3 Data and Time Data Types

## 4.1.3.1 DATE

### Contents

1. [Syntax](#)
2. [Description](#)
  1. [Oracle Mode](#)
3. [Examples](#)
4. [See Also](#)

## Syntax

DATE

## Description

A date. The supported range is '

1000-01-01

' to '

9999-12-31

'. MariaDB displays

DATE

values in '

YYYY-MM-DD

' format, but can be assigned dates in looser formats, including strings or numbers, as long as they make sense. These include a short year,

YY-MM-DD

, no delimiters,

YYMMDD

, or any other acceptable delimiter, for example

YYYY/MM/DD

. For details, see [date and time literals](#).

0000-00-00

' is a permitted special value (zero-date), unless the [NO\\_ZERO\\_DATE SQL\\_MODE](#) is used. Also, individual components of a date can be set to 0 (for example: '

2015-00-12

'), unless the [NO\\_ZERO\\_IN\\_DATE SQL\\_MODE](#) is used. In many cases, the result of an expression involving a zero-date, or a date with zero-parts, is

NULL

. If the [ALLOW\\_INVALID\\_DATES SQL\\_MODE](#) is enabled, if the day part is in the range between 1 and 31, the date does not produce any error, even for months that have less than 31 days.

## Oracle Mode

MariaDB starting with 10.3

In [Oracle mode from MariaDB 10.3](#),

DATE

with a time portion is a synonym for [DATETIME](#). See also [mariadb\\_schema](#).

## Examples

```
CREATE TABLE t1 (d DATE);

INSERT INTO t1 VALUES ("2010-01-12"), ("2011-2-28"), ('120314'),('13*04*21');

SELECT * FROM t1;
+-----+
| d      |
+-----+
| 2010-01-12 |
| 2011-02-28 |
| 2012-03-14 |
| 2013-04-21 |
+-----+
```

## See Also

### 4.1.3.2 TIME

#### Syntax

```
TIME [(<microsecond precision>)]
```

#### Contents

1. [Syntax](#)
2. [Description](#)
3. [Internal Format](#)
4. [Examples](#)
5. [See also](#)

#### Description

A time. The range is

```
'-838:59:59.999999'  
to  
'838:59:59.999999'  
. Microsecond precision can be from 0-6; if not specified 0 is used. Microseconds have been available since MariaDB 5.3 .
```

MariaDB displays

```
TIME  
values in  
'HH:MM:SS.#####'  
format, but allows assignment of times in looser formats, including 'D HH:MM:SS', 'HH:MM:SS', 'HH:MM', 'D HH:MM', 'D HH', 'SS', or  
'HHMMSS', as well as permitting dropping of any leading zeros when a delimiter is provided, for example '3:9:10'. For details, see date and time literals .
```

MariaDB starting with [10.1.2](#)

[MariaDB 10.1.2](#) introduced the [--mysql56-temporal-format](#) option, on by default, which allows MariaDB to store TIMES using the same low-level format MySQL 5.6 uses.

#### Internal Format

In [MariaDB 10.1.2](#) a new temporal format was introduced from MySQL 5.6 that alters how the

```
TIME  
,  
DATETIME  
and  
TIMESTAMP  
columns operate at lower levels. These changes allow these temporal data types to have fractional parts and negative values. You can disable  
this feature using the
```

[mysql56\\_temporal\\_format](#)

system variable.

Tables that include

```
TIMESTAMP  
values that were created on an older version of MariaDB or that were created while the
```

[mysql56\\_temporal\\_format](#)

system variable was disabled continue to store data using the older data type format.

In order to update table columns from the older format to the newer format, execute an

[ALTER TABLE... MODIFY COLUMN](#)

statement that changes the column to the \*same\* data type. This change may be needed if you want to export the table's tablespace and import it onto a server that has

```
mysql56_temporal_format=ON  
set (see MDEV-15225 ).
```

For instance, if you have a

TIME

column in your table:

```
SHOW VARIABLES LIKE 'mysql156_temporal_format';

+-----+-----+
| Variable_name      | Value   |
+-----+-----+
| mysql156_temporal_format | ON      |
+-----+-----+

ALTER TABLE example_table MODIFY ts_col TIME;
```

When MariaDB executes the

ALTER TABLE

statement, it converts the data from the older temporal format to the newer one.

In the event that you have several tables and columns using temporal data types that you want to switch over to the new format, make sure the system variable is enabled, then perform a dump and restore using

mysqldump

. The columns using relevant temporal data types are restored using the new temporal format.

Starting from MariaDB 10.5.1 columns with old temporal formats are marked with a

/\* mariadb-5.3 \*/

comment in the output of

SHOW CREATE TABLE

,

SHOW COLUMNS

,

DESCRIBE

statements, as well as in the

COLUMN\_TYPE

column of the

INFORMATION\_SCHEMA.COLUMNS Table

```
SHOW CREATE TABLE mariadb5312_time\G
***** 1. row *****
Table: mariadb5312_time
Create Table: CREATE TABLE `mariadb5312_time` (
  `t0` time /* mariadb-5.3 */ DEFAULT NULL,
  `t6` time(6) /* mariadb-5.3 */ DEFAULT NULL
) ENGINE=MyISAM DEFAULT CHARSET=latin1
```

Note, columns with the current format are not marked with a comment.

## Examples

```

INSERT INTO time VALUES ('90:00:00'), ('800:00:00'), (800), (22), (151413), ('9:6:3'), ('12 09');

SELECT * FROM time;
+-----+
| t    |
+-----+
| 90:00:00 |
| 800:00:00 |
| 00:08:00 |
| 00:00:22 |
| 15:14:13 |
| 09:06:03 |
| 297:00:00 |
+-----+

```

## See also

- [Data Type Storage Requirements](#)

### 4.1.3.3 DATETIME

#### Contents

1. [Syntax](#)
2. [Description](#)
3. [Supported Values](#)
4. [Time Zones](#)
5. [Oracle Mode](#)
6. [Internal Format](#)
7. [Examples](#)
8. [See Also](#)

## Syntax

```
DATETIME [(microsecond precision)]
```

## Description

A date and time combination.

MariaDB displays

```

DATETIME
values in '
YYYY-MM-DD HH:MM:SS.fffffff
' format, but allows assignment of values to
DATETIME
columns using either strings or numbers. For details, see date and time literals.

```

DATETIME columns also accept `CURRENT_TIMESTAMP` as the default value.

[MariaDB 10.1.2](#) introduced the `--mysql56-temporal-format` option, on by default, which allows MariaDB to store DATETIMEs using the same low-level format MySQL 5.6 uses. For more information, see [Internal Format](#), below.

For storage requirements, see [Data Type Storage Requirements](#).

## Supported Values

MariaDB stores values that use the

```

DATETIME
data type in a format that supports values between
1000-01-01 00:00:00.000000
and
9999-12-31 23:59:59.999999

```

MariaDB can also store `microseconds` with a precision between 0 and 6. If no microsecond precision is specified, then 0 is used by default.

MariaDB also supports '

```

0000-00-00
' as a special zero-date value, unless NO_ZERO_DATE is specified in the SQL_MODE. Similarly, individual components of a date can be set to
```

0  
(for example: '2015-00-12')  
'), unless `NO_ZERO_DATE` is specified in the `SQL_MODE`. In many cases, the result of an expression involving a zero-date, or a date with zero-parts, is  
NULL  
. If the `ALLOW_INVALID_DATES` `SQL_MODE` is enabled, if the day part is in the range between 1 and 31, the date does not produce any error, even for months that have less than 31 days.

## Time Zones

If a column uses the

`DATETIME`

data type, then any inserted values are stored as-is, so no automatic time zone conversions are performed.

MariaDB also does not currently support time zone literals that contain time zone identifiers. See [MDEV-11829](#) for more information.

MariaDB validates

`DATETIME`

literals against the session's time zone. For example, if a specific time range never occurred in a specific time zone due to daylight savings time, then

`DATETIME`

values within that range would be invalid for that time zone.

For example, daylight savings time started on March 10, 2019 in the US, so the time range between 02:00:00 and 02:59:59 is invalid for that day in US time zones:

```
SET time_zone = 'America/New_York';
Query OK, 0 rows affected (0.000 sec)

INSERT INTO timestamp_test VALUES ('2019-03-10 02:55:05');
ERROR 1292 (22007): Incorrect datetime value: '2019-03-10 02:55:05' for column `db1`.`timestamp_test`.`timestamp_test` at row 1
```

But that same time range is fine in other time zones, such as [Coordinated Universal Time \(UTC\)](#). For example:

```
SET time_zone = 'UTC';
Query OK, 0 rows affected (0.000 sec)

INSERT INTO timestamp_test VALUES ('2019-03-10 02:55:05');
Query OK, 1 row affected (0.002 sec)
```

## Oracle Mode

MariaDB starting with 10.3

In [Oracle mode from MariaDB 10.3](#),

`DATE`

with a time portion is a synonym for

`DATETIME`

. See also [mariadb\\_schema](#).

## Internal Format

In [MariaDB 10.1.2](#) a new temporal format was introduced from MySQL 5.6 that alters how the

`TIME`

,

`DATETIME`

and

`TIMESTAMP`

columns operate at lower levels. These changes allow these temporal data types to have fractional parts and negative values. You can disable this feature using the `mysql56_temporal_format` system variable.

Tables that include

`TIMESTAMP`

values that were created on an older version of MariaDB or that were created while the `mysql56_temporal_format` system variable was disabled continue to store data using the older data type format.

In order to update table columns from the older format to the newer format, execute an `ALTER TABLE... MODIFY COLUMN` statement that changes the column to the \*same\* data type. This change may be needed if you want to export the table's tablespace and import it onto a server that has

`mysql56_temporal_format=ON`

set (see [MDEV-15225](#) ).

For instance, if you have a

DATETIME

column in your table:

```
SHOW VARIABLES LIKE 'mysql56_temporal_format';

+-----+-----+
| Variable_name      | Value   |
+-----+-----+
| mysql56_temporal_format | ON    |
+-----+-----+

ALTER TABLE example_table MODIFY ts_col DATETIME;
```

When MariaDB executes the `ALTER TABLE` statement, it converts the data from the older temporal format to the newer one.

In the event that you have several tables and columns using temporal data types that you want to switch over to the new format, make sure the system variable is enabled, then perform a dump and restore using

`mysqldump`

. The columns using relevant temporal data types are restored using the new temporal format.

Starting from [MariaDB 10.5.1](#) columns with old temporal formats are marked with a

```
/* mariadb-5.3 */
comment in the output of SHOW CREATE TABLE , SHOW COLUMNS , DESCRIBE statements, as well as in the
COLUMN_TYPE
column of the INFORMATION_SCHEMA.COLUMNS Table .
```

```
SHOW CREATE TABLE mariadb5312_datetime\G
***** 1. row *****
Table: mariadb5312_datetime
Create Table: CREATE TABLE `mariadb5312_datetime` (
`dt0` datetime /* mariadb-5.3 */ DEFAULT NULL,
`dt6` datetime(6) /* mariadb-5.3 */ DEFAULT NULL
) ENGINE=MyISAM DEFAULT CHARSET=latin1
```

## Examples

```
CREATE TABLE t1 (d DATETIME);

INSERT INTO t1 VALUES ("2011-03-11"), ("2012-04-19 13:08:22"),
("2013-07-18 13:44:22.123456");

SELECT * FROM t1;
+-----+
| d          |
+-----+
| 2011-03-11 00:00:00 |
| 2012-04-19 13:08:22 |
| 2013-07-18 13:44:22 |
+-----+
```

```
CREATE TABLE t2 (d DATETIME(6));

INSERT INTO t2 VALUES ("2011-03-11"), ("2012-04-19 13:08:22"),
("2013-07-18 13:44:22.123456");

SELECT * FROM t2;
+-----+
| d          |
+-----+
| 2011-03-11 00:00:00.000000 |
| 2012-04-19 13:08:22.000000 |
| 2013-07-18 13:44:22.123456 |
+-----+
```

Strings used in datetime context are automatically converted to datetime(6). If you want to have a datetime without seconds, you should use `CONVERT(..,datetime)` .

```

SELECT CONVERT('2007-11-30 10:30:19',datetime);
+-----+
| CONVERT('2007-11-30 10:30:19',datetime) |
+-----+
| 2007-11-30 10:30:19 |
+-----+

SELECT CONVERT('2007-11-30 10:30:19',datetime(6));
+-----+
| CONVERT('2007-11-30 10:30:19',datetime(6)) |
+-----+
| 2007-11-30 10:30:19.000000 |
+-----+

```

## 4.1.3.4 TIMESTAMP

### Syntax

`TIMESTAMP [(<microsecond precision>)]`

### Contents

1. [Syntax](#)
2. [Description](#)
3. [Supported Values](#)
4. [Automatic Values](#)
5. [Time Zones](#)
6. [Limitations](#)
7. [SQL\\_MODE=MAXDB](#)
8. [Internal Format](#)
9. [Examples](#)
10. [See Also](#)

### Description

A timestamp in the format

`YYYY-MM-DD HH:MM:SS.fffffff`

The timestamp field is generally used to define at which moment in time a row was added or updated and by default will automatically be assigned the current datetime when a record is inserted or updated. The automatic properties only apply to the first TIMESTAMP in the record; subsequent TIMESTAMP columns will not be changed.

MariaDB starting with [10.1.2](#)

MariaDB [10.1.2](#) introduced the `--mysql56-temporal-format` option, on by default, which allows MariaDB to store TIMESTAMPs using the same low-level format MySQL 5.6 uses.

For more information, see [Internal Format](#).

### Supported Values

MariaDB stores values that use the

`TIMESTAMP` data type as the number of seconds since '1970-01-01 00:00:00' ( [UTC](#) ). This means that the

`TIMESTAMP` data type can hold values between '1970-01-01 00:00:01' ( [UTC](#) ) and '2038-01-19 03:14:07' ( [UTC](#) ).

MariaDB can also store `microseconds` with a precision between 0 and 6. If no microsecond precision is specified, then 0 is used by default.

### Automatic Values

MariaDB has special behavior for the first column that uses the  
TIMESTAMP  
data type in a specific table. For the first column that uses the  
TIMESTAMP  
data type in a specific table, MariaDB automatically assigns the following properties to the column:

- DEFAULT CURRENT\_TIMESTAMP
- ON UPDATE CURRENT\_TIMESTAMP

This means that if the column is not explicitly assigned a value in an  
INSERT  
or  
UPDATE  
query, then MariaDB will automatically initialize the column's value with the current date and time.

This automatic initialization for

INSERT  
and  
UPDATE  
queries can also be **explicitly enabled** for a column that uses the  
TIMESTAMP  
data type by specifying the  
DEFAULT CURRENT\_TIMESTAMP  
and  
ON UPDATE CURRENT\_TIMESTAMP  
clauses for the column. In these clauses, any synonym of

CURRENT\_TIMESTAMP

is accepted, including

CURRENT\_TIMESTAMP()

,

NOW()

,

LOCALTIME

,

LOCALTIME()

,

LOCALTIMESTAMP

, and

LOCALTIMESTAMP()

.

This automatic initialization for

INSERT  
queries can also be **explicitly disabled** for a column that uses the  
TIMESTAMP  
data type by specifying a constant  
DEFAULT  
value. For example,  
DEFAULT 0

.

This automatic initialization for

UPDATE  
queries can also be **explicitly disabled** for a column that uses the  
TIMESTAMP  
data type by specifying a  
DEFAULT  
clause for the column, but no  
ON UPDATE  
clause. If a  
DEFAULT  
clause is explicitly specified for a column that uses the  
TIMESTAMP  
data type, but an  
ON UPDATE  
clause is not specified for the column, then the timestamp value will not automatically change when an  
UPDATE

statement is executed.

MariaDB also has special behavior if

NULL  
is assigned to column that uses the  
TIMESTAMP  
data type. If the column is assigned the  
NULL  
value in an  
INSERT  
or  
UPDATE  
query, then MariaDB will automatically initialize the column's value with the current date and time. For details, see [NULL values in MariaDB](#).

This automatic initialization for

NULL  
values can also be **explicitly disabled** for a column that uses the  
TIMESTAMP  
data type by specifying the  
NULL  
attribute for the column. In this case, if the column's value is set to  
NULL  
, then the column's value will actually be set to  
NULL

## Time Zones

If a column uses the

TIMESTAMP  
data type, then any inserted values are converted from the session's time zone to [Coordinated Universal Time \(UTC\)](#) when stored, and converted back to the session's time zone when retrieved.

MariaDB does not currently store any time zone identifier with the value of the

TIMESTAMP  
data type. See [MDEV-10018](#) for more information.

MariaDB does not currently support time zone literals that contain time zone identifiers. See [MDEV-11829](#) for more information.

## Limitations

- Because the TIMESTAMP value is stored as Epoch Seconds, the timestamp value '1970-01-01 00:00:00' (UTC) is reserved since the second #0 is used to represent '0000-00-00 00:00:00'.
- In [MariaDB 5.5](#) and before there could only be one TIMESTAMP column per table that had CURRENT\_TIMESTAMP defined as its default value. This limit has no longer applied since [MariaDB 10.0](#).

## SQL\_MODE=MAXDB

If the `SQL_MODE` is set to

MAXDB  
, TIMESTAMP fields will be silently converted to [DATETIME](#).

## Internal Format

In [MariaDB 10.1.2](#) a new temporal format was introduced from MySQL 5.6 that alters how the

TIME  
,  
DATETIME  
and  
TIMESTAMP  
columns operate at lower levels. These changes allow these temporal data types to have fractional parts and negative values. You can disable this feature using the

`mysql56_temporal_format`

system variable.

Tables that include

TIMESTAMP  
values that were created on an older version of MariaDB or that were created while the

## mysql156\_temporal\_format

system variable was disabled continue to store data using the older data type format.

In order to update table columns from the older format to the newer format, execute an

```
ALTER TABLE... MODIFY COLUMN
```

statement that changes the column to the \*same\* data type. This change may be needed if you want to export the table's tablespace and import it onto a server that has

```
mysql156_temporal_format=ON  
set (see MDEV-15225 ).
```

For instance, if you have a

```
TIMESTAMP  
column in your table:
```

```
SHOW VARIABLES LIKE 'mysql156_temporal_format';  
  
+-----+  
| Variable_name      | Value |  
+-----+  
| mysql156_temporal_format | ON    |  
+-----+  
  
ALTER TABLE example_table MODIFY ts_col TIMESTAMP;
```

When MariaDB executes the

```
ALTER TABLE
```

statement, it converts the data from the older temporal format to the newer one.

In the event that you have several tables and columns using temporal data types that you want to switch over to the new format, make sure the system variable is enabled, then perform a dump and restore using

```
mysqldump  
. The columns using relevant temporal data types are restored using the new temporal format.
```

Starting from MariaDB 10.5.1 columns with old temporal formats are marked with a

```
/* mariadb-5.3 */  
comment in the output of
```

```
SHOW CREATE TABLE
```

```
,  
SHOW COLUMNS
```

```
,  
DESCRIBE
```

statements, as well as in the

```
COLUMN_TYPE  
column of the
```

```
INFORMATION_SCHEMA.COLUMNS Table
```

```
SHOW CREATE TABLE mariadb5312_timestamp\G  
***** 1. row *****  
Table: mariadb5312_timestamp  
Create Table: CREATE TABLE `mariadb5312_timestamp` (  
  `ts0` timestamp /* mariadb-5.3 */ NOT NULL DEFAULT current_timestamp() ON UPDATE current_timestamp(),  
  `ts6` timestamp(6) /* mariadb-5.3 */ NOT NULL DEFAULT '0000-00-00 00:00:00.000000'  
) ENGINE=MyISAM DEFAULT CHARSET=latin1
```

**Note:** Prior to MySQL 4.1 a different format for the TIMESTAMP datatype was used. This format is unsupported in MariaDB 5.1 and upwards.

# Examples

```
CREATE TABLE t (id INT, ts TIMESTAMP);

DESC t;
+-----+-----+-----+-----+
| Field | Type      | Null | Key | Default            | Extra          |
+-----+-----+-----+-----+
| id    | int(11)   | YES  |     | NULL               |                |
| ts    | timestamp  | NO   |     | CURRENT_TIMESTAMP | on update CURRENT_TIMESTAMP |
+-----+-----+-----+-----+

INSERT INTO t(id) VALUES (1),(2);

SELECT * FROM t;
+-----+-----+
| id  | ts        |
+-----+-----+
| 1   | 2013-07-22 12:50:05 |
| 2   | 2013-07-22 12:50:05 |
+-----+-----+

INSERT INTO t VALUES (3,NULL),(4,'2001-07-22 12:12:12');

SELECT * FROM t;
+-----+-----+
| id  | ts        |
+-----+-----+
| 1   | 2013-07-22 12:50:05 |
| 2   | 2013-07-22 12:50:05 |
| 3   | 2013-07-22 12:51:56 |
| 4   | 2001-07-22 12:12:12 |
+-----+-----+
```

Converting to Unix epoch:

```
SELECT ts, UNIX_TIMESTAMP(ts) FROM t;
+-----+-----+
| ts           | UNIX_TIMESTAMP(ts) |
+-----+-----+
| 2013-07-22 12:50:05 | 1374490205 |
| 2013-07-22 12:50:05 | 1374490205 |
| 2013-07-22 12:51:56 | 1374490316 |
| 2001-07-22 12:12:12 | 995796732 |
+-----+-----+
```

Update also changes the timestamp:

```
UPDATE t set id=5 WHERE id=1;

SELECT * FROM t;
+-----+-----+
| id  | ts        |
+-----+-----+
| 5   | 2013-07-22 14:52:33 |
| 2   | 2013-07-22 12:50:05 |
| 3   | 2013-07-22 12:51:56 |
| 4   | 2001-07-22 12:12:12 |
+-----+-----+
```

Default NULL:

```

CREATE TABLE t2 (id INT, ts TIMESTAMP NULL ON UPDATE CURRENT_TIMESTAMP);

INSERT INTO t2(id) VALUES (1),(2);

SELECT * FROM t2;

INSERT INTO t2(id) VALUES (1),(2);

SELECT * FROM t2;
+-----+
| id   | ts    |
+-----+
| 1    | NULL  |
| 2    | NULL  |
+-----+

UPDATE t2 SET id=3 WHERE id=1;

SELECT * FROM t2;
+-----+
| id   | ts      |
+-----+
| 3    | 2013-07-22 15:32:22 |
| 2    | NULL    |
+-----+

```

Only the first timestamp is automatically inserted and updated:

```

CREATE TABLE t3 (id INT, ts1 TIMESTAMP, ts2 TIMESTAMP);

INSERT INTO t3(id) VALUES (1),(2);

SELECT * FROM t3;
+-----+
| id   | ts1           | ts2           |
+-----+
| 1    | 2013-07-22 15:35:07 | 0000-00-00 00:00:00 |
| 2    | 2013-07-22 15:35:07 | 0000-00-00 00:00:00 |
+-----+

DESC t3;
+-----+
| Field | Type      | Null | Key | Default          | Extra          |
+-----+
| id    | int(11)   | YES  |      | NULL             |                |
| ts1   | timestamp  | NO   |      | CURRENT_TIMESTAMP | on update CURRENT_TIMESTAMP |
| ts2   | timestamp  | NO   |      | 0000-00-00 00:00:00 |
+-----+

```

Explicitly setting a timestamp with the `CURRENT_TIMESTAMP` function:

```

INSERT INTO t3(id,ts2) VALUES (3,CURRENT_TIMESTAMP());

SELECT * FROM t3;
+-----+
| id   | ts1           | ts2           |
+-----+
| 1    | 2013-07-22 15:35:07 | 0000-00-00 00:00:00 |
| 2    | 2013-07-22 15:35:07 | 0000-00-00 00:00:00 |
| 3    | 2013-07-22 15:38:52 | 2013-07-22 15:38:52 |
+-----+

```

Specifying the timestamp as NOT NULL:

```

CREATE TABLE t4 (id INT, ts TIMESTAMP NOT NULL);

INSERT INTO t4(id) VALUES (1);
SELECT SLEEP(1);
INSERT INTO t4(id,ts) VALUES (2,NULL);

SELECT * FROM t4;

```

## See Also

- Data Type Storage Requirements

## 4.1.3.5 YEAR Data Type

### Syntax

```
YEAR[(4)]
```

### Description

A year in two-digit or four-digit format. The default is four-digit format. Note that the two-digit format has been deprecated since [MariaDB 5.5.27](#).

In four-digit format, the allowable values are 1901 to 2155, and 0000. In two-digit format, the allowable values are 70 to 69, representing years from 1970 to 2069. MariaDB displays YEAR values in YYYY format, but allows you to assign values to YEAR columns using either strings or numbers.

Inserting numeric zero has a different result for YEAR(4) and YEAR(2). For YEAR(2), the value

00

reflects the year 2000. For YEAR(4), the value

0000

reflects the year zero. This only applies to numeric zero. String zero always reflects the year 2000.

### Examples

Accepting a string or a number:

```
CREATE TABLE y(y YEAR);

INSERT INTO y VALUES (1990),('2012');

SELECT * FROM y;
+---+
| y   |
+---+
| 1990 |
| 2012 |
+---+
```

With `strict_mode` set, the default from [MariaDB 10.2.4](#):

Out of range:

```
INSERT INTO y VALUES (1005),('3080');
ERROR 1264 (22003): Out of range value for column 'y' at row 1

INSERT INTO y VALUES ('2013-12-12');
ERROR 1265 (01000): Data truncated for column 'y' at row 1

SELECT * FROM y;
+---+
| y   |
+---+
| 1990 |
| 2012 |
+---+
```

With `strict_mode` unset, the default until [MariaDB 10.2.3](#):

Out of range:

```

INSERT INTO y VALUES (1005),('3080');
Query OK, 2 rows affected, 2 warnings (0.05 sec)
Records: 2 Duplicates: 0 Warnings: 2

SHOW WARNINGS;
+-----+
| Level | Code | Message |
+-----+
| Warning | 1264 | Out of range value for column 'y' at row 1 |
| Warning | 1264 | Out of range value for column 'y' at row 2 |
+-----+

SELECT * FROM y;
+---+
| y |
+---+
| 1990 |
| 2012 |
| 0000 |
| 0000 |
+---+

```

Truncating:

```

INSERT INTO y VALUES ('2013-12-12');
Query OK, 1 row affected, 1 warning (0.05 sec)

SHOW WARNINGS;
+-----+
| Level | Code | Message |
+-----+
| Warning | 1265 | Data truncated for column 'y' at row 1 |
+-----+

SELECT * FROM y;
+---+
| y |
+---+
| 1990 |
| 2012 |
| 0000 |
| 0000 |
| 2013 |
+---+

```

Difference between YEAR(2) and YEAR(4), and string and numeric zero:

```

CREATE TABLE y2(y YEAR(4), y2 YEAR(2));
Query OK, 0 rows affected, 1 warning (0.40 sec)

Note (Code 1287): 'YEAR(2)' is deprecated and will be removed in a future release.
Please use YEAR(4) instead

INSERT INTO y2 VALUES(0,0),('0','0');

SELECT YEAR(y),YEAR(y2) FROM y2;
+-----+
| YEAR(y) | YEAR(y2) |
+-----+
| 0 | 2000 |
| 2000 | 2000 |
+-----+

```

## 4.1.4 Geometry Types

## Contents

1. Description
2. Examples
  1. POINT
  2. LINESTRING
  3. POLYGON
  4. MULTIPOINT
  5. MULTILINESTRING
  6. MULTIPOLYGON
  7. GEOMETRYCOLLECTION
  8. GEOMETRY

## Description

MariaDB provides a standard way of creating spatial columns for geometry types, for example, with `CREATE TABLE` or `ALTER TABLE`. Currently, spatial columns are supported for `MyISAM`, `InnoDB`, `NDB`, and `ARCHIVE` tables. See also `SPATIAL INDEX`.

The basic geometry type is

`GEOMETRY`

. But the type can be more specific. The following types are supported:

Geometry Types
<code>POINT</code>
<code>LINESTRING</code>
<code>POLYGON</code>
<code>MULTIPOINT</code>
<code>MULTILINESTRING</code>
<code>MULTIPOLYGON</code>
<code>GEOMETRYCOLLECTION</code>
<code>GEOMETRY</code>

## Examples

**Note:** For clarity, only one type is listed per table in the examples below, but a table row can contain multiple types. For example:

```
CREATE TABLE object (shapeA POLYGON, shapeB LINESTRING);
```

## POINT

```
CREATE TABLE gis_point (g POINT);
SHOW FIELDS FROM gis_point;
INSERT INTO gis_point VALUES
(PointFromText('POINT(10 10)'), 
(PointFromText('POINT(20 10)'), 
(PointFromText('POINT(20 20)'), 
(PointFromWKB(AsWKB(PointFromText('POINT(10 20))));
```

## LINESTRING

```
CREATE TABLE gis_line (g LINESTRING);
SHOW FIELDS FROM gis_line;
INSERT INTO gis_line VALUES
(LineFromText('LINESTRING(0 0,0 10,10 0)'), 
(LineStringFromText('LINESTRING(10 10,20 10,20 20,10 20,10 10)'), 
(LineStringFromWKB(AsWKB(LineString(Point(10, 10), Point(40, 10))));
```

## POLYGON

```

CREATE TABLE gis_polygon  (g POLYGON);
SHOW FIELDS FROM gis_polygon;
INSERT INTO gis_polygon VALUES
  (PolygonFromText('POLYGON((10 10,20 10,20 20,10 20,10 10))')),
  (PolyFromText('POLYGON((0 0,50 0,50 50,0 50,0 0), (10 10,20 10,20 20,10 20,10 10))')),
  (PolyFromWKB(AsWKB(Polygon(LineString(Point(0, 0), Point(30, 0), Point(30, 30), Point(0, 0))))));

```

## MULTIPOINT

```

CREATE TABLE gis_multi_point (g MULTIPOINT);
SHOW FIELDS FROM gis_multi_point;
INSERT INTO gis_multi_point VALUES
  (MultiPointFromText('MULTIPOINT(0 0,10 10,20,20 20)')),
  (MPointFromText('MULTIPOINT(1 1,11 11,11 21,21 21)')),
  (MPointFromWKB(AsWKB(MultiPoint(Point(3, 6), Point(4, 10))))));

```

## MULTILINESTRING

```

CREATE TABLE gis_multi_line (g MULTILINESTRING);
SHOW FIELDS FROM gis_multi_line;
INSERT INTO gis_multi_line VALUES
  (MultiLineStringFromText('MULTILINESTRING((10 48,10 21,10 0),(16 0,16 23,16 48))'),
  (MLineFromText('MULTILINESTRING((10 48,10 21,10 0))')),
  (MLineFromWKB(AsWKB(MultiLineString(LineString(Point(1, 2), Point(3, 5)), LineString(Point(2, 5), Point(5, 8), Point(21, 7))))));

```

## MULTIPOLYGON

```

CREATE TABLE gis_multi_polygon (g MULTIPOLYGON);
SHOW FIELDS FROM gis_multi_polygon;
INSERT INTO gis_multi_polygon VALUES
  (MultiPolygonFromText('MULTIPOLYGON(((28 26,28 0,84 0,84 42,28 26),(52 18,66 23,73 9,48 6,52 18)),((59 18,67 18,67 13,59 13,
  (MPolyFromText('MULTIPOLYGON(((28 26,28 0,84 0,84 42,28 26),(52 18,66 23,73 9,48 6,52 18)),((59 18,67 18,67 13,59 13,
  (MPolyFromWKB(AsWKB(MultiPolygon(Polygon(LineString(Point(0, 3), Point(3, 3), Point(3, 0), Point(0, 3))))));

```

## GEOMETRYCOLLECTION

```

CREATE TABLE gis_geometrycollection (g GEOMETRYCOLLECTION);
SHOW FIELDS FROM gis_geometrycollection;
INSERT INTO gis_geometrycollection VALUES
  (GeomCollFromText('GEOMETRYCOLLECTION(POINT(0 0), LINESTRING(0 0,10 10))'),
  (GeometryFromWKB(AsWKB(GeometryCollection(Point(44, 6), LineString(Point(3, 6), Point(7, 9))))),
  (GeomFromText('GeometryCollection()')),
  (GeomFromText('GeometryCollection EMPTY')));

```

## GEOMETRY

```

CREATE TABLE gis_geometry (g GEOMETRY);
SHOW FIELDS FROM gis_geometry;
INSERT into gis_geometry SELECT * FROM gis_point;
INSERT into gis_geometry SELECT * FROM gis_line;
INSERT into gis_geometry SELECT * FROM gis_polygon;
INSERT into gis_geometry SELECT * FROM gis_multi_point;
INSERT into gis_geometry SELECT * FROM gis_multi_line;
INSERT into gis_geometry SELECT * FROM gis_multi_polygon;
INSERT into gis_geometry SELECT * FROM gis_geometrycollection;

```

## 4.1.5 AUTO\_INCREMENT

## Contents

1. Description
2. Setting or Changing the Auto\_Increment Value
3. InnoDB
4. Setting Explicit Values
5. Missing Values
6. Replication
7. CHECK Constraints, DEFAULT Values and Virtual Columns
8. Generating Auto\_Increment Values When Adding the Attribute
9. See Also

## Description

The

AUTO\_INCREMENT

attribute can be used to generate a unique identity for new rows. When you insert a new record to the table (or upon adding an AUTO\_INCREMENT attribute with the ALTER TABLE statement), and the auto\_increment field is NULL or DEFAULT (in the case of an INSERT), the value will automatically be incremented. This also applies to 0, unless the NO\_AUTO\_VALUE\_ON\_ZERO SQL\_MODE is enabled.

AUTO\_INCREMENT

columns start from 1 by default. The automatically generated value can never be lower than 0.

Each table can have only one

AUTO\_INCREMENT

column. It must be defined as a key (not necessarily the

PRIMARY KEY

or

UNIQUE

key). In some storage engines (including the default InnoDB ), if the key consists of multiple columns, the

AUTO\_INCREMENT

column must be the first column. Storage engines that permit the column to be placed elsewhere are Aria , MyISAM , MERGE , Spider , TokuDB , BLACKHOLE , FederatedX and Federated .

```
CREATE TABLE animals (
    id MEDIUMINT NOT NULL AUTO_INCREMENT,
    name CHAR(30) NOT NULL,
    PRIMARY KEY (id)
);

INSERT INTO animals (name) VALUES
    ('dog'), ('cat'), ('penguin'),
    ('fox'), ('whale'), ('ostrich');
```

```
SELECT * FROM animals;
```

id	name
1	dog
2	cat
3	penguin
4	fox
5	whale
6	ostrich

SERIAL

is an alias for

BIGINT UNSIGNED NOT NULL AUTO\_INCREMENT UNIQUE

```

CREATE TABLE t (id SERIAL, c CHAR(1)) ENGINE=InnoDB;

SHOW CREATE TABLE t
***** 1. row *****
  Table: t
Create Table: CREATE TABLE `t` (
  `id` bigint(20) unsigned NOT NULL AUTO_INCREMENT,
  `c` char(1) DEFAULT NULL,
  UNIQUE KEY `id` (`id`)
) ENGINE=InnoDB DEFAULT CHARSET=latin1

```

## Setting or Changing the Auto\_Increment Value

You can use an

`ALTER TABLE`

statement to assign a new value to the `auto_increment` table option, or set the `insert_id` server system variable to change the next `AUTO_INCREMENT` value inserted by the current session.

`LAST_INSERT_ID()`

can be used to see the last `AUTO_INCREMENT` value inserted by the current session.

```

ALTER TABLE animals AUTO_INCREMENT=8;

INSERT INTO animals (name) VALUES ('aardvark');

SELECT * FROM animals;
+----+-----+
| id | name   |
+----+-----+
| 1  | dog    |
| 2  | cat    |
| 3  | penguin |
| 4  | fox    |
| 5  | whale   |
| 6  | ostrich |
| 8  | aardvark|
+----+-----+

SET insert_id=12;

INSERT INTO animals (name) VALUES ('gorilla');

SELECT * FROM animals;
+----+-----+
| id | name   |
+----+-----+
| 1  | dog    |
| 2  | cat    |
| 3  | penguin |
| 4  | fox    |
| 5  | whale   |
| 6  | ostrich |
| 8  | aardvark|
| 12 | gorilla|
+----+-----+

```

## InnoDB

Until [MariaDB 10.2.3](#), InnoDB used an auto-increment counter that is stored in memory. When the server restarts, the counter is re-initialized to the highest value used in the table, which cancels the effects of any `AUTO_INCREMENT = N` option in the table statements.

From [MariaDB 10.2.4](#), this restriction has been lifted and `AUTO_INCREMENT` is persistent.

See also [AUTO\\_INCREMENT Handling in InnoDB](#).

## Setting Explicit Values

It is possible to specify a value for an

`AUTO_INCREMENT`

column. If the key is primary or unique, the value must not already exist in the key.

If the new value is higher than the current maximum value, the

`AUTO_INCREMENT`

value is updated, so the next value will be higher. If the new value is lower than the current maximum value, the

`AUTO_INCREMENT`

value remains unchanged.

The following example demonstrates these behaviors:

```
CREATE TABLE t (id INTEGER UNSIGNED AUTO_INCREMENT PRIMARY KEY) ENGINE = InnoDB;

INSERT INTO t VALUES (NULL);
SELECT id FROM t;
+----+
| id |
+----+
| 1 |
+----+

INSERT INTO t VALUES (10); -- higher value
SELECT id FROM t;
+----+
| id |
+----+
| 1 |
| 10 |
+----+

INSERT INTO t VALUES (2); -- Lower value
INSERT INTO t VALUES (NULL); -- auto value
SELECT id FROM t;
+----+
| id |
+----+
| 1 |
| 2 |
| 10 |
| 11 |
+----+
```

The [ARCHIVE](#) storage engine does not allow to insert a value that is lower than the current maximum.

## Missing Values

An AUTO\_INCREMENT column normally has missing values. This happens because if a row is deleted, or an AUTO\_INCREMENT value is explicitly updated, old values are never re-used. The REPLACE statement also deletes a row, and its value is wasted. With InnoDB, values can be reserved by a transaction; but if the transaction fails (for example, because of a ROLLBACK) the reserved value will be lost.

Thus AUTO\_INCREMENT values can be used to sort results in a chronological order, but not to create a numeric sequence.

## Replication

To make master-master or Galera safe to use

`AUTO_INCREMENT`

one should use the system variables `auto_increment_increment` and `auto_increment_offset` to generate unique values for each server.

## CHECK Constraints, DEFAULT Values and Virtual Columns

MariaDB starting with 10.2.6

From MariaDB 10.2.6 auto\_increment columns are no longer permitted in CHECK constraints , DEFAULT value expressions and virtual columns . They were permitted in earlier versions, but did not work correctly. See [MDEV-11117](#) .

## Generating Auto\_Increment Values When Adding the Attribute

```
CREATE OR REPLACE TABLE t1 (a INT);
INSERT t1 VALUES (0),(0),(0);
ALTER TABLE t1 MODIFY a INT NOT NULL AUTO_INCREMENT PRIMARY KEY;
SELECT * FROM t1;
+---+
| a |
+---+
| 1 |
| 2 |
| 3 |
+---+
```

```
CREATE OR REPLACE TABLE t1 (a INT);
INSERT t1 VALUES (5),(0),(8),(0);
ALTER TABLE t1 MODIFY a INT NOT NULL AUTO_INCREMENT PRIMARY KEY;
SELECT * FROM t1;
+---+
| a |
+---+
| 5 |
| 6 |
| 8 |
| 9 |
+---+
```

If the `NO_AUTO_VALUE_ON_ZERO SQL_MODE` is set, zero values will not be automatically incremented:

```
SET SQL_MODE='no_auto_value_on_zero';
CREATE OR REPLACE TABLE t1 (a INT);
INSERT t1 VALUES (3), (0);
ALTER TABLE t1 MODIFY a INT NOT NULL AUTO_INCREMENT PRIMARY KEY;
SELECT * FROM t1;
+---+
| a |
+---+
| 0 |
| 3 |
+---+
```

13. How to start a table with a set AUTO\_INCREMENT value?
14. See Also

## How do I get the last inserted auto\_increment value?

Use the [LAST\\_INSERT\\_ID\(\)](#) function:

```
SELECT LAST_INSERT_ID();
```

## What if someone else inserts before I select my id?

[LAST\\_INSERT\\_ID\(\)](#) is connection specific, so there is no problem from race conditions.

## How do I get the next value to be inserted?

You don't. Insert, then find out what you did with [LAST\\_INSERT\\_ID\(\)](#).

## How do I change what number auto\_increment starts with?

```
ALTER TABLE yourTable AUTO_INCREMENT = x;  
— Next insert will contain
```

x  
or

MAX(autoField) + 1  
, whichever is higher

or

```
INSERT INTO yourTable (autoField) VALUES (x);
```

— Next insert will contain

x+1  
or  
MAX(autoField) + 1  
, whichever is higher

Issuing [TRUNCATE TABLE](#) will delete all the rows in the table, and will reset the auto\_increment value to 0 in most cases (some earlier versions mapped TRUNCATE to DELETE for InnoDB tables, meaning the auto\_increment value would not be reset).

## How do I renumber rows once I've deleted some in the middle?

Typically, you don't want to. Gaps are hardly ever a problem; if your application can't handle gaps in the sequence, you probably should rethink your application.

## Can I do group-wise auto\_increment?

Yes, if you use the MyISAM engine .

## How do I get the auto\_increment value in a BEFORE INSERT trigger?

You don't. It's only available after insert.

## How do I assign two fields the same auto\_increment value in one query?

You can't, not even with an AFTER INSERT trigger. Insert, then go back and update using

```
LAST_INSERT_ID()  
. Those two statements could be wrapped into one stored procedure if you wish.
```

However, you can mimic this behavior with a BEFORE INSERT trigger and a second table to store the sequence position:

```
CREATE TABLE sequence (table_name VARCHAR(255), position INT UNSIGNED);  
INSERT INTO sequence VALUES ('testTable', 0);  
CREATE TABLE testTable (firstAuto INT UNSIGNED, secondAuto INT UNSIGNED);  
DELIMITER //  
CREATE TRIGGER testTable_BI BEFORE INSERT ON testTable FOR EACH ROW BEGIN  
    UPDATE sequence SET position = LAST_INSERT_ID(position + 1) WHERE table_name = 'testTable';  
    SET NEW.firstAuto = LAST_INSERT_ID();  
    SET NEW.secondAuto = LAST_INSERT_ID();  
END//  
DELIMITER ;  
INSERT INTO testTable VALUES (NULL, NULL), (NULL, NULL);  
SELECT * FROM testTable;  
  
+-----+-----+  
| firstAuto | secondAuto |  
+-----+-----+  
| 1 | 1 |  
| 2 | 2 |  
+-----+-----+
```

The same sequence table can maintain separate sequences for multiple tables (or separate sequences for different fields in the same table) by adding extra rows.

## Does the auto\_increment field have to be primary key?

No, it only has to be indexed. It doesn't even have to be unique.

## InnoDB and AUTO\_INCREMENT

See [AUTO\\_INCREMENT handling in XtraDB/InnoDB](#)

## General Information To Read

[AUTO\\_INCREMENT](#)

## Manual Notes

There can be only one

```
AUTO_INCREMENT  
column per table, it must be indexed, and it cannot have a  
DEFAULT  
value. An  
AUTO_INCREMENT
```

column works properly only if it contains only positive values. Inserting a negative number is regarded as inserting a very large positive number. This is done to avoid precision problems when numbers wrap over from positive to negative and also to ensure that you do not accidentally get an

```
AUTO_INCREMENT  
column that contains 0.
```

## How to start a table with a set AUTO\_INCREMENT value?

```

CREATE TABLE autoinc_test (
    h INT UNSIGNED PRIMARY KEY AUTO_INCREMENT,
    m INT UNSIGNED
) AUTO_INCREMENT = 100;

INSERT INTO autoinc_test (m) VALUES (1);

SELECT * FROM autoinc_test;
+-----+-----+
| h    | m    |
+-----+-----+
| 100 | 1   |
+-----+-----+

```

## 4.1.8 NULL Values

### Contents

1. [Syntax](#)
2. [Comparison Operators](#)
3. [Ordering](#)
4. [Functions](#)
5. [AUTO\\_INCREMENT, TIMESTAMP and Virtual Columns](#)
6. [Inserting](#)
  1. [Examples](#)
7. [Primary Keys and UNIQUE Indexes](#)
8. [Oracle Compatibility](#)
9. [See Also](#)

NULL represents an unknown value. It is *not* an empty string (by default), or a zero value. These are all valid values, and are not NULLs.

When a table is [created](#) or the format [altered](#), columns can be specified as accepting NULL values, or not accepting them, with the

NULL  
and  
NOT NULL  
clauses respectively.

For example, a customer table could contain dates of birth. For some customers, this information is unknown, so the value could be NULL.

The same system could allocate a customer ID for each customer record, and in this case a NULL value would not be permitted.

```

CREATE TABLE customer (
    id INT NOT NULL,
    date_of_birth DATE NULL
    ...
)

```

User-defined variables are NULL until a value is explicitly assigned.

Stored routines parameters and local variables can always be set to NULL. If no DEFAULT value is specified for a local variable, its initial value will be NULL. If no value is assigned to an OUT parameter in a stored procedure, NULL is assigned at the end of the procedure.

## Syntax

The case of

NULL  
is not relevant.  
\N  
(uppercase) is an alias for  
NULL

The

IS

operator accepts  
UNKNOWN  
as an alias for  
NULL  
, which is meant for [boolean contexts](#).

## Comparison Operators

NULL values cannot be used with most [comparison operators](#). For example, =, >, >=, <, <=, or != cannot be used, as any comparison with a NULL always returns a NULL value, never true (1) or false (0).

```
SELECT NULL = NULL;
+-----+
| NULL = NULL |
+-----+
|      NULL |
+-----+  
  
SELECT 99 = NULL;
+-----+
| 99 = NULL |
+-----+
|      NULL |
+-----+
```

To overcome this, certain operators are specifically designed for use with NULL values. To cater for testing equality between two values that may contain NULLs, there's [<=>](#), NULL-safe equal.

```
SELECT 99 <=> NULL, NULL <=> NULL;
+-----+
| 99 <=> NULL | NULL <=> NULL |
+-----+
|          0 |           1 |
+-----+
```

Other operators for working with NULLs include [IS NULL](#) and [IS NOT NULL](#), [ISNULL](#) (for testing an expression) and [COALESCE](#) (for returning the first non-NULL parameter).

## Ordering

When you order by a field that may contain NULL values, any NULLs are considered to have the lowest value. So ordering in DESC order will see the NULLs appearing last. To force NULLs to be regarded as highest values, one can add another column which has a higher value when the main field is NULL. Example:

```
SELECT col1 FROM tab ORDER BY ISNULL(col1), col1;
```

Descending order, with NULLs first:

```
SELECT col1 FROM tab ORDER BY IF(col1 IS NULL, 0, 1), col1 DESC;
```

All NULL values are also regarded as equivalent for the purposes of the DISTINCT and GROUP BY clauses.

## Functions

In most cases, functions will return NULL if any of the parameters are NULL. There are also functions specifically for handling NULLs. These include [IFNULL\(\)](#), [NULLIF\(\)](#) and [COALESCE\(\)](#).

```

SELECT IFNULL(1,0);
+-----+
| IFNULL(1,0) |
+-----+
|      1      |
+-----+

SELECT IFNULL(NULL,10);
+-----+
| IFNULL(NULL,10) |
+-----+
|      10      |
+-----+

SELECT COALESCE(NULL,NULL,1);
+-----+
| COALESCE(NULL,NULL,1) |
+-----+
|      1      |
+-----+

```

Aggregate functions, such as `SUM` and `AVG` ignore NULLs.

```

CREATE TABLE t(x INT);

INSERT INTO t VALUES (1),(9),(NULL);

SELECT SUM(x) FROM t;
+-----+
| SUM(x) |
+-----+
|    10   |
+-----+

SELECT AVG(x) FROM t;
+-----+
| AVG(x) |
+-----+
| 5.0000 |
+-----+

```

The one exception is `COUNT(*)`, which counts rows, and doesn't look at whether a value is NULL or not. Compare for example, `COUNT(x)`, which ignores the NULL, and `COUNT(*)`, which counts it:

```

SELECT COUNT(x) FROM t;
+-----+
| COUNT(x) |
+-----+
|      2   |
+-----+

SELECT COUNT(*) FROM t;
+-----+
| COUNT(*) |
+-----+
|      3   |
+-----+

```

## AUTO\_INCREMENT, TIMESTAMP and Virtual Columns

MariaDB handles NULL values in a special way if the field is an `AUTO_INCREMENT`, a `TIMESTAMP` or a `virtual column`. Inserting a NULL value into a numeric `AUTO_INCREMENT` column will result in the next number in the auto increment sequence being inserted instead. This technique is frequently used with `AUTO_INCREMENT` fields, which are left to take care of themselves.

```

CREATE TABLE t2(id INT PRIMARY KEY AUTO_INCREMENT, letter CHAR(1));

INSERT INTO t2(letter) VALUES ('a'),('b');

SELECT * FROM t2;
+-----+
| id | letter |
+-----+
| 1  | a      |
| 2  | b      |
+-----+

```

Similarly, if a NULL value is assigned to a TIMESTAMP field, the current date and time is assigned instead.

```

CREATE TABLE t3 (x INT, ts TIMESTAMP);

INSERT INTO t3(x) VALUES (1),(2);

```

After a pause,

```

INSERT INTO t3(x) VALUES (3);

SELECT* FROM t3;
+-----+
| x    | ts          |
+-----+
| 1   | 2013-09-05 10:14:18 |
| 2   | 2013-09-05 10:14:18 |
| 3   | 2013-09-05 10:14:29 |
+-----+

```

If a

NULL  
is assigned to a  
VIRTUAL  
or  
PERSISTENT  
column, the default value is assigned instead.

```

CREATE TABLE virt (c INT, v INT AS (c+10) PERSISTENT) ENGINE=InnoDB;

INSERT INTO virt VALUES (1, NULL);

SELECT c, v FROM virt;
+-----+
| c    | v    |
+-----+
| 1    | 11  |
+-----+

```

In all these special cases,

NULL  
is equivalent to the  
DEFAULT  
keyword.

## Inserting

If a NULL value is single-row inserted into a column declared as NOT NULL, an error will be returned. However, if the [SQL mode](#) is not `strict` (default until [MariaDB 10.2.3](#)), if a NULL value is multi-row inserted into a column declared as NOT NULL, the implicit default for the column type will be inserted (and NOT the default value in the table definition). The implicit defaults are an empty string for string types, and the zero value for numeric, date and time types.

Since [MariaDB 10.2.4](#), by default both cases will result in an error.

## Examples

```
CREATE TABLE nulltest (
  a INT(11),
  x VARCHAR(10) NOT NULL DEFAULT 'a',
  y INT(11) NOT NULL DEFAULT 23
);
```

Single-row insert:

```
INSERT INTO nulltest (a,x,y) VALUES (1,NULL,NULL);
ERROR 1048 (23000): Column 'x' cannot be null
```

Multi-row insert with [SQL mode not strict](#) (default until MariaDB 10.2.3):

```
show variables like 'sql_mode%';
+-----+-----+
| Variable_name | Value           |
+-----+-----+
| sql_mode      | NO_AUTO_CREATE_USER,NO_ENGINE_SUBSTITUTION |
+-----+-----+

INSERT INTO nulltest (a,x,y) VALUES (1,NULL,NULL),(2,NULL,NULL);
Query OK, 2 rows affected, 4 warnings (0.08 sec)
Records: 2  Duplicates: 0  Warnings: 4
```

The specified defaults have not been used; rather, the implicit column type defaults have been inserted

```
SELECT * FROM nulltest;
+---+---+---+
| a | x | y |
+---+---+---+
| 1 | 0 |   |
| 2 | 0 |   |
+---+---+---+
```

## Primary Keys and UNIQUE Indexes

UNIQUE indexes can contain multiple NULL values.

Primary keys are never nullable.

MariaDB starting with 10.3

## Oracle Compatibility

In [Oracle mode](#), NULL can be used as a statement:

```
IF a=10 THEN NULL; ELSE NULL; END IF
```

In [Oracle mode](#), CONCAT and the Logical OR operator || ignore NULL .

When setting `sql_mode=EMPTY_STRING_IS_NULL`, empty strings and NULLs are the same thing. For example:

```
SET sql_mode=EMPTY_STRING_IS_NULL;
SELECT '' IS NULL; -- returns TRUE
INSERT INTO t1 VALUES (''); -- inserts NULL
```

## 4.2 Character Sets and Collations

### 4.2.1 Character Set and Collation Overview

#### Contents

1. [What Are Character Sets and Collations](#)
2. [Viewing Character Sets and Collations](#)
3. [Changing Character Sets and Collations](#)

## What Are Character Sets and Collations

A character set is a set of characters while a collation is the rules for comparing and sorting a particular character set.

For example, a subset of a character set could consist of the letters

A  
,  
B  
and  
C  
. A default collation could define these as appearing in an ascending order of  
A, B, C  
.

If we consider different case characters, more complexity is added. A binary collation would evaluate the characters

A  
and  
a  
differently, ordering them in a particular way. A case-insensitive collation would evaluate  
A  
and  
a  
equivalently, while the German phone book collation evaluates the characters  
ue  
and  
ü  
equivalently.

A character set can have many collations associated with it, while each collation is only associated with one character set. In MariaDB, the character set name is always part of the collation name. For example, the

latin1\_german1\_ci  
collation applies only to the  
latin1  
character set. Each character set also has one default collation. The  
latin1  
default collation is  
latin1\_swedish\_ci  
.

As an example, by default, the character

y  
comes between  
x  
and  
z  
, while in Lithuanian, it's sorted between  
i  
and  
k  
. Similarly, the German phone book order is different to the German dictionary order, so while they share the same character set, the collation is different.

## Viewing Character Sets and Collations

In MariaDB, the default character set is latin1, and the default collation is latin1\_swedish\_ci (however this may differ in some distros, see for example [Differences in MariaDB in Debian](#)). You can view a full list of character sets and collations supported by MariaDB at [Supported Character Sets and Collations](#), or see what's supported on your server with the `SHOW CHARACTER SET` and `SHOW COLLATION` commands.

By default,

A  
comes before

Z

, so the following evaluates to true:

```
SELECT "A" < "Z";
+-----+
| "A" < "Z" |
+-----+
|      1 |
+-----+
```

By default, comparisons are case-insensitive:

```
SELECT "A" < "a", "A" = "a";
+-----+-----+
| "A" < "a" | "A" = "a" |
+-----+-----+
|      0 |      1 |
+-----+-----+
```

## Changing Character Sets and Collations

Character sets and collations can be set from the server level right down to the column level, as well as for client-server communication.

For example,

ue  
and  
ü

are by default evaluated differently.

```
SELECT 'Mueller' = 'Müller';
+-----+
| 'Müller' = 'Mueller' |
+-----+
|          0 |
+-----+
```

By using the [collation\\_connection](#) system variable to change the connection character set to

latin1\_german2\_ci  
, or German phone book, the same two characters will evaluate as equivalent.

```
SET collation_connection = latin1_german2_ci;

SELECT 'Mueller' = 'Müller';
+-----+
| 'Mueller' = 'Müller' |
+-----+
|          1 |
+-----+
```

See [Setting Character Sets and Collations](#) for more.

### 4.2.2 Supported Character Sets and Collations

### 4.2.3 Setting Character Sets and Collations

9. See Also

In MariaDB, the default [character set](#) is latin1, and the default collation is latin1\_swedish\_ci (however this may differ in some distros, see for example [Differences in MariaDB in Debian](#)). Both character sets and collations can be specified from the server right down to the column level, as well as for client-server connections. When changing a character set and not specifying a collation, the default collation for the new character set is always used.

Character sets and collations always cascade down, so a column without a specified collation will look for the table default, the table for the database, and the database for the server. It's therefore possible to have extremely fine-grained control over all the character sets and collations used in your data.

Default collations for each character set can be viewed with the [SHOW COLLATION](#) statement, for example, to find the default collation for the latin2 character set:

```
SHOW COLLATION LIKE 'latin2%';
+-----+-----+-----+-----+-----+
| Collation      | Charset | Id | Default | Compiled | Sortlen |
+-----+-----+-----+-----+-----+
| latin2_czech_cs | latin2   | 2  |        | Yes      |     4    |
| latin2_general_ci | latin2   | 9  | Yes    | Yes      |     1    |
| latin2_hungarian_ci | latin2   | 21 |        | Yes      |     1    |
| latin2_croatian_ci | latin2   | 27 |        | Yes      |     1    |
| latin2_bin       | latin2   | 77 |        | Yes      |     1    |
+-----+-----+-----+-----+-----+
```

## Server Level

The [character\\_set\\_server](#) system variable can be used to change the default server character set. It can be set both on startup or dynamically, with the [SET](#) command:

```
SET character_set_server = 'latin2';
```

Similarly, the [collation\\_server](#) variable is used for setting the default server collation.

```
SET collation_server = 'latin2_czech_cs';
```

## Database Level

The [CREATE DATABASE](#) and [ALTER DATABASE](#) statements have optional character set and collation clauses. If these are left out, the server defaults are used.

```
CREATE DATABASE czech_slovak_names
  CHARACTER SET = 'keybcs2'
  COLLATE = 'keybcs2_bin';
```

```
ALTER DATABASE czech_slovak_names COLLATE = 'keybcs2_general_ci';
```

To determine the default character set used by a database, use:

```
SHOW CREATE DATABASE czech_slovak_names;
+-----+-----+
| Database      | Create Database           |
+-----+-----+
| czech_slovak_names | CREATE DATABASE `czech_slovak_names` /*!40100 DEFAULT CHARACTER SET keybcs2 */ |
```

or alternatively, for the character set and collation:

CATALOG_NAME	SCHEMA_NAME	DEFAULT_CHARACTER_SET_NAME	DEFAULT_COLLATION_NAME	SQL_PATH
def	czech_slovak_names	keybcs2	keybcs2_general_ci	NULL
def	information_schema	utf8	utf8_general_ci	NULL
def	mysql	latin1	latin1_swedish_ci	NULL
def	performance_schema	utf8	utf8_general_ci	NULL
def	test	latin1	latin1_swedish_ci	NULL

It is also possible to specify only the collation, and, since each collation only applies to one character set, the associated character set will automatically be specified.

CREATE DATABASE danish_names COLLATE 'utf8_danish_ci';
SHOW CREATE DATABASE danish_names;
+-----+   Database   Create Database   +-----+   danish_names   CREATE DATABASE `danish_names` /*!40100 DEFAULT CHARACTER SET utf8 COLLATE utf8_danish_ci */   +-----+

Although there are `character_set_database` and `collation_database` system variables which can be set dynamically, these are used for determining the character set and collation for the default database, and should only be set by the server.

## Table Level

The `CREATE TABLE` and `ALTER TABLE` statements support optional character set and collation clauses, a MariaDB and MySQL extension to standard SQL.

```
CREATE TABLE english_names (id INT, name VARCHAR(40))
  CHARACTER SET 'utf8'
  COLLATE 'utf8_icelandic_ci';
```

If neither character set nor collation is provided, the database default will be used. If only the character set is provided, the default collation for that character set will be used . If only the collation is provided, the associated character set will be used. See [Supported Character Sets and Collations](#) .

```
ALTER TABLE table_name
  CONVERT TO CHARACTER SET charset_name [COLLATE collation_name];
```

If no collation is provided, the collation will be set to the default collation for that character set. See [Supported Character Sets and Collations](#) .

For `VARCHAR` or `TEXT` columns, `CONVERT TO CHARACTER SET` changes the data type if needed to ensure the new column is long enough to store as many characters as the original column.

For example, an ascii `TEXT` column requires a single byte per character, so the column can hold up to 65,535 characters. If the column is converted to `utf8`, 3 bytes can be required for each character, so the column will be converted to `MEDIUMTEXT` to be able to hold the same number of characters.

CONVERT TO CHARACTER SET `binary`  
 will convert `CHAR` , `VARCHAR` and `TEXT` columns to `BINARY` , `VARBINARY` and `BLOB` respectively, and from that point will no longer have a character set, or be affected by future  
`CONVERT TO CHARACTER SET`  
 statements.

To avoid data type changes resulting from

```
CONVERT TO CHARACTER SET
, use
```

```
MODIFY
```

on the individual columns instead. For example:

```
ALTER TABLE table_name MODIFY ascii_text_column TEXT CHARACTER SET utf8;
ALTER TABLE table_name MODIFY ascii_varchar_column VARCHAR(M) CHARACTER SET utf8;
```

## Column Level

Character sets and collations can also be specified for columns that are character types `CHAR`, `TEXT` or `VARCHAR`. The `CREATE TABLE` and `ALTER TABLE` statements support optional character set and collation clauses for this purpose - unlike those at the table level, the column level definitions are standard SQL.

```
CREATE TABLE european_names (
    croatian_names VARCHAR(40) COLLATE 'cp1250_croatian_ci',
    greek_names VARCHAR(40) CHARACTER SET 'greek');
```

If neither collation nor character set is provided, the table default is used. If only the character set is specified, that character set's default collation is used, while if only the collation is specified, the associated character set is used.

When using [ALTER TABLE](#) to change a column's character set, you need to ensure the character sets are compatible with your data. MariaDB will map the data as best it can, but it's possible to lose data if care is not taken.

The [SHOW CREATE TABLE](#) statement or INFORMATION SCHEMA database can be used to determine column character sets and collations.

```
SHOW CREATE TABLE european_names\nG
*****
1. row *****

Table: european_names
Create Table: CREATE TABLE `european_names` (
`croatian_names` varchar(40) CHARACTER SET cp1250 COLLATE cp1250_croatian_ci DEFAULT NULL,
`greek_names` varchar(40) CHARACTER SET greek DEFAULT NULL
) ENGINE=InnoDB DEFAULT CHARSET=utf8 COLLATE=utf8_danish_ci
```

```
SELECT * FROM INFORMATION_SCHEMA.COLUMNS WHERE TABLE_NAME LIKE 'european%'\nG
*****
1. row *****

```

## Filenames

Since [MariaDB 5.1](#), the `character_set_filesystem` system variable has controlled interpretation of file names that are given as literal strings. This affects the following statements and functions:

- [SELECT INTO DUMPFILE](#)
- [SELECT INTO OUTFILE](#)
- [LOAD DATA INFILE](#)

- [LOAD XML](#)
- [LOAD\\_FILE\(\)](#)

## Literals

By default, the character set and collation used for literals is determined by the [character\\_set\\_connection](#) and [collation\\_connection](#) system variables. However, they can also be specified explicitly:

```
[_charset_name]'string' [COLLATE collation_name]
```

The character set of string literals that do not have a character set introducer is determined by the [character\\_set\\_connection](#) system variable.

This query:

```
SELECT CHARSET('a'), @@character_set_connection;
```

always returns the same character set name in both columns.

[character\\_set\\_client](#) and [character\\_set\\_connection](#) are normally (e.g. during handshake, or after a SET NAMES query) are set to equal values. However, it's possible to set to different values.

## Examples

Examples when setting @@character\_set\_client and @@character\_set\_connection to different values can be useful:

Example 1:

Suppose, we have a utf8 database with this table:

```
CREATE TABLE t1 (a VARCHAR(10)) CHARACTER SET utf8 COLLATE utf8_general_ci;
INSERT INTO t1 VALUES ('oe'),('ö');
```

Now we connect to it using "mysql.exe", which uses the DOS character set (cp850 on a West European machine), and want to fetch all records that are equal to 'ö' according to the German phonebook rules.

It's possible with the following:

```
SET @@character_set_client=cp850, @@character_set_connection=utf8;
SELECT a FROM t1 WHERE a='ö' COLLATE utf8_german2_ci;
```

This will return:

```
+----+
| a   |
+----+
| oe  |
| ö   |
+----+
```

It works as follows:

1. The client sends the query using cp850.
2. The server, when parsing the query, creates a utf8 string literal by converting 'ö' from @@character\_set\_client (cp850) to @@character\_set\_connection (utf8)
3. The server applies the collation "utf8\_german2\_ci" to this string literal.
4. The server uses utf8\_german2\_ci for comparison.

Note, if we rewrite the script like this:

```
SET NAMES cp850;
SELECT a FROM t1 WHERE a='ö' COLLATE utf8_german2_ci;
```

we'll get an error:

```
ERROR 1253 (42000): COLLATION 'utf8_german2_ci' is not valid for CHARACTER SET 'cp850'
```

because:

- on step #2, the literal is not converted to utf8 any more and is created using cp850.
- on step #3, the server fails to apply utf8\_german2\_ci to an cp850 string literal.

Example 2:

Suppose we have a utf8 database and use "mysql.exe" from a West European machine again.

We can do this:

```
SET @@character_set_client=cp850, @@character_set_connection=utf8;
CREATE TABLE t2 AS SELECT 'ö';
```

It will create a table with a column of the type

VARCHAR(1) CHARACTER SET utf8

Note, if we rewrite the query like this:

```
SET NAMES cp850;
CREATE TABLE t2 AS SELECT 'ö';
```

It will create a table with a column of the type

VARCHAR(1) CHARACTER SET cp850  
, which is probably not a good idea.

## N

Also,

N  
or  
n

can be used as prefix to convert a literal into the National Character set (which in MariaDB is always utf8).

For example:

```
SELECT _latin2 'Müller';
+-----+
| MÃ¶ller   |
+-----+
| MÃ¶ller   |
+-----+
```

```
SELECT CHARSET(N'a string');
+-----+
| CHARSET(N'a string') |
+-----+
| utf8                |
+-----+
```

```
SELECT 'Mueller' = 'Müller' COLLATE 'latin1_german2_ci';
+-----+
| 'Mueller' = 'Müller' COLLATE 'latin1_german2_ci' |
+-----+
|                      1 |
+-----+
```

## Stored Programs and Views

The literals which occur in stored programs and views, by default, use the character set and collation which was specified by the `character_set_connection` and `collation_connection` system variables when the stored program was created. These values can be seen using the SHOW CREATE statements. To change the character sets used for literals in an existing stored program, it is necessary to drop and recreate the stored program.

For stored routines parameters and return values, a character set and a collation can be specified via the CHARACTER SET and COLLATE clauses. Before 5.5, specifying a collation was not supported.

The following example shows that the character set and collation are determined at the time of creation:

```

SET @@local.character_set_connection='latin1';

DELIMITER ||
CREATE PROCEDURE `test`.`x`()
BEGIN
  SELECT CHARSET('x');
END;
||
Query OK, 0 rows affected (0.00 sec)

DELIMITER ;
SET @@local.character_set_connection='utf8';

CALL `test`.`x`();
+-----+
| CHARSET('x') |
+-----+
| latin1        |
+-----+

```

The following example shows how to specify a function parameters character set and collation:

```

CREATE FUNCTION `test`.`y`(`str` TEXT CHARACTER SET utf8 COLLATE utf8_bin)
  RETURNS TEXT CHARACTER SET latin1 COLLATE latin1_bin
BEGIN
  SET @param_coll = COLLATION(`str`);
  RETURN `str`;
END;

-- return value's collation:
SELECT COLLATION(`test`.`y`('Hello, planet!'));
+-----+
| COLLATION(`test`.`y`('Hello, planet!')) |
+-----+
| latin1_bin                                |
+-----+

-- parameter's collation:
SELECT @param_coll;
+-----+
| @param_coll | 
+-----+
| utf8_bin   | 
+-----+

```

## Illegal Collation Mix

MariaDB 10.1.28 - 10.1.29

In MariaDB 10.1.28 , you may encounter Error 1267 when performing comparison operations in views on tables that use binary constants. For instance,

```

CREATE TABLE test.t1 (
  a TEXT CHARACTER SET gbk
) ENGINE=InnoDB
CHARSET=latin1
COLLATE=latin1_general_ci;

INSERT INTO t1 VALUES ('user_a');

CREATE VIEW v1 AS
SELECT a <> 0xEE5D FROM t1;

SELECT * FROM v1;
Error 1267 (HY000): Illegal mix of collations (gbk_chinese_ci, IMPLICIT)
and (latin_swedish_ci, COERCIBLE) for operation

```

When the view query is written to file, MariaDB converts the binary character into a string literal, which causes it to be misinterpreted when you execute the

```
SELECT
```

statement. If you encounter this issue, set the character set in the view to force it to the value you want.

MariaDB throws this error due to a bug that was fixed in [MariaDB 10.1.29](#) . Later releases do not throw errors in this situation.

## Example: Changing the Default Character Set To UTF-8

To change the default character set from latin1 to UTF-8, the following settings should be specified in the my.cnf configuration file.

```
[mysql]
...
default-character-set=utf8mb4
...
[mysqld]
...
collation-server = utf8mb4_unicode_ci
init-connect='SET NAMES utf8mb4'
character-set-server = utf8mb4
...
```

Note that the

```
default-character-set
option is a client option, not a server option.
```

- [String literals](#)
- [CAST\(\)](#)
- [CONVERT\(\)](#)

## 4.2.4 Unicode

Unicode is a standard for encoding text across multiple writing systems. MariaDB supports a number of [character sets](#) for storing Unicode data:

Character Set	Description
ucs2	UCS-2, each character is represented by a 2-byte code with the most significant byte first. Fixed-length 16-bit encoding.
utf8	Until <a href="#">MariaDB 10.5</a> , this was a UTF-8 encoding using one to three bytes per character. Basic Latin letters, numbers and punctuation use one byte. European and Middle East letters mostly fit into 2 bytes. Korean, Chinese, and Japanese ideographs use 3-bytes. No supplementary characters are stored. From <a href="#">MariaDB 10.6</a> , utf8 is an alias for utf8mb3 , but this can changed to ut8mb4 by changing the default value of the <code>old_mode</code> system variable.
utf8mb3	UTF-8 encoding using one to three bytes per character. Basic Latin letters, numbers and punctuation use one byte. European and Middle East letters mostly fit into 2 bytes. Korean, Chinese, and Japanese ideographs use 3-bytes. No supplementary characters are stored. Until <a href="#">MariaDB 10.5</a> , this was an alias for utf8 . From <a href="#">MariaDB 10.6</a> , utf8 is by default an alias for utf8mb3 , but this can changed to ut8mb4 by changing the default value of the <code>old_mode</code> system variable.
utf8mb4	UTF-8 encoding the same as utf8mb3 but which stores supplementary characters in four bytes.
utf16	UTF-16, same as ucs2, but stores supplementary characters in 32 bits. 16 or 32-bits.
utf32	UTF-32, fixed-length 32-bit encoding.

## 4.2.5 SHOW CHARACTER SET

## 4.2.6 SHOW COLLATION

## Syntax

```
SHOW COLLATION  
[LIKE 'pattern' | WHERE expr]
```

## Contents

1. [Syntax](#)
2. [Description](#)
3. [Examples](#)
4. [See Also](#)

## Description

The output from

```
SHOW COLLATION  
includes all available collations. The  
LIKE  
clause, if present on its own, indicates which collation names to match. The  
WHERE  
and  
LIKE  
clauses can be given to select rows using more general conditions, as discussed in Extended SHOW.
```

The same information can be queried from the [Information Schema COLLATIONS](#) table.

See [Setting Character Sets and Collations](#) for details on specifying the collation at the server, database, table and column levels.

## Examples

```
SHOW COLLATION LIKE 'latin1%';  
+-----+-----+-----+-----+-----+  
| Collation      | Charset | Id | Default | Compiled | Sortlen |  
+-----+-----+-----+-----+-----+  
| latin1_german1_ci | latin1   | 5  |       | Yes     |      1 |  
| latin1_swedish_ci | latin1   | 8  | Yes   | Yes    |      1 |  
| latin1_danish_ci | latin1   | 15 |       | Yes    |      1 |  
| latin1_german2_ci | latin1   | 31 |       | Yes    |      2 |  
| latin1_bin        | latin1   | 47 |       | Yes    |      1 |  
| latin1_general_ci | latin1   | 48 |       | Yes    |      1 |  
| latin1_general_cs | latin1   | 49 |       | Yes    |      1 |  
| latin1_spanish_ci | latin1   | 94 |       | Yes    |      1 |  
+-----+-----+-----+-----+-----+
```

```
SHOW COLLATION WHERE Sortlen LIKE '8' AND Charset LIKE 'utf8';  
+-----+-----+-----+-----+-----+  
| Collation      | Charset | Id | Default | Compiled | Sortlen |  
+-----+-----+-----+-----+-----+  
| utf8_unicode_ci | utf8    | 192 |       | Yes    |      8 |  
| utf8_icelandic_ci | utf8    | 193 |       | Yes    |      8 |  
| utf8_latvian_ci | utf8    | 194 |       | Yes    |      8 |  
| utf8_romanian_ci | utf8    | 195 |       | Yes    |      8 |  
| utf8_slovenian_ci | utf8    | 196 |       | Yes    |      8 |  
| utf8_polish_ci | utf8    | 197 |       | Yes    |      8 |  
| utf8_estonian_ci | utf8    | 198 |       | Yes    |      8 |  
| utf8_spanish_ci | utf8    | 199 |       | Yes    |      8 |  
| utf8_swedish_ci | utf8    | 200 |       | Yes    |      8 |  
| utf8_turkish_ci | utf8    | 201 |       | Yes    |      8 |  
| utf8_czech_ci | utf8    | 202 |       | Yes    |      8 |  
| utf8_danish_ci | utf8    | 203 |       | Yes    |      8 |  
| utf8_lithuanian_ci | utf8    | 204 |       | Yes    |      8 |  
| utf8_slovak_ci | utf8    | 205 |       | Yes    |      8 |  
| utf8_spanish2_ci | utf8    | 206 |       | Yes    |      8 |  
| utf8_roman_ci | utf8    | 207 |       | Yes    |      8 |  
| utf8_persian_ci | utf8    | 208 |       | Yes    |      8 |  
| utf8_esperanto_ci | utf8    | 209 |       | Yes    |      8 |  
| utf8_hungarian_ci | utf8    | 210 |       | Yes    |      8 |  
| utf8_sinhala_ci | utf8    | 211 |       | Yes    |      8 |  
| utf8_croatian_ci | utf8    | 213 |       | Yes    |      8 |  
+-----+-----+-----+-----+-----+
```

## 4.3 Storage Engines

### 4.3.1 Choosing the Right Storage Engine

#### Contents

1. Topic List
  1. General Purpose
  2. Scaling, Partitioning
  3. Compression / Archive
  4. Connecting to Other Data Sources
  5. Search Optimized
  6. Cache, Read-only
  7. Other Specialized Storage Engines
2. Alphabetical List

A high-level overview of the main reasons for choosing a particular storage engine:

#### Topic List

##### General Purpose

- InnoDB is a good general transaction storage engine, and, from MariaDB 10.2, the best choice in most cases. It is the default storage engine from MariaDB 10.2. For earlier releases, XtraDB was a performance enhanced fork of InnoDB and is usually preferred.
- XtraDB is the best choice in MariaDB 10.1 and earlier in the majority of cases. It is a performance-enhanced fork of InnoDB and is MariaDB's default engine until MariaDB 10.1.
- Aria, MariaDB's more modern improvement on MyISAM, has a small footprint and allows for easy copying between systems.
- MyISAM has a small footprint and allows for easy copying between systems. MyISAM is MySQL's oldest storage engine. There is usually little reason to use it except for legacy purposes. Aria is MariaDB's more modern improvement.

##### Scaling, Partitioning

When you want to split your database load on several servers or optimize for scaling. We also suggest looking at [Galera](#), a synchronous multi-master cluster.

- [Spider](#) uses partitioning to provide data sharding through multiple servers.
- [ColumnStore](#) utilizes a massively parallel distributed data architecture and is designed for big data scaling to process petabytes of data.
- The [MERGE](#) storage engine is a collection of identical [MyISAM](#) tables that can be used as one. "Identical" means that all tables have identical column and index information.
- [TokuDB](#) is a transactional storage engine which is optimized for workloads that do not fit in memory, and provides a good compression ratio. TokuDB has been deprecated by its upstream developers, and is disabled in [MariaDB 10.5](#), and removed in [MariaDB 10.6](#).

## Compression / Archive

- [MyRocks](#) enables greater compression than InnoDB, as well as less write amplification giving better endurance of flash storage and improving overall throughput.
- The [Archive](#) storage engine is, unsurprisingly, best used for archiving.
- [TokuDB](#) is a transactional storage engine which is optimized for workloads that do not fit in memory, and provides a good compression ratio. TokuDB has been deprecated by its upstream developers, and is disabled in [MariaDB 10.5](#), and removed in [MariaDB 10.6](#).

## Connecting to Other Data Sources

When you want to use data not stored in a MariaDB database.

- [CONNECT](#) allows access to different kinds of text files and remote resources as if they were regular MariaDB tables.
- The [CSV](#) storage engine can read and append to files stored in CSV (comma-separated-values) format. However, since [MariaDB 10.0](#), CONNECT is a better choice and is more flexibly able to read and write such files.
- [FederatedX](#) uses libmysql to talk to the data source, the data source being a remote RDBMS. Currently, since FederatedX only uses libmysql, it can only talk to another MySQL RDBMS.
- [CassandraSE](#) is a storage engine allowing access to an older version of Apache Cassandra NoSQL DBMS. It was relatively experimental, is no longer being actively developed and has been removed in [MariaDB 10.6](#).

## Search Optimized

Search engines optimized for search.

- [SphinxSE](#) is used as a proxy to run statements on a remote Sphinx database server (mainly useful for advanced fulltext searches).
- [Mroonga](#) provides fast CJK-ready full text searching using column store.

## Cache, Read-only

- [MEMORY](#) does not write data on-disk (all rows are lost on crash) and is best-used for read-only caches of data from other tables, or for temporary work areas. With the default [InnoDB](#) and other storage engines having good caching, there is less need for this engine than in the past.

## Other Specialized Storage Engines

- [S3 Storage Engine](#) is a read-only storage engine that stores its data in Amazon S3.
- [Sequence](#) allows the creation of ascending or descending sequences of numbers (positive integers) with a given starting value, ending value and increment, creating virtual, ephemeral tables automatically when you need them.
- The [BLACKHOLE](#) storage engine accepts data but does not store it and always returns an empty result. This can be useful in [replication](#) environments, for example, if you want to run complex filtering rules on a slave without incurring any overhead on a master.
- [OQGRAPH](#) allows you to handle hierarchies (tree structures) and complex graphs (nodes having many connections in several directions).

## Alphabetical List

- The [Archive](#) storage engine is, unsurprisingly, best used for archiving.
- [Aria](#), MariaDB's more modern improvement on MyISAM, has a small footprint and allows for easy copy between systems.
- The [BLACKHOLE](#) storage engine accepts data but does not store it and always returns an empty result. This can be useful in [replication](#) environments, for example, if you want to run complex filtering rules on a slave without incurring any overhead on a master.
- [CassandraSE](#) is a storage engine allowing access to an older version of Apache Cassandra NoSQL DBMS. It was relatively experimental, is no longer being actively developed and has been removed in [MariaDB 10.6](#).
- [ColumnStore](#) utilizes a massively parallel distributed data architecture and is designed for big data scaling to process petabytes of data.
- [CONNECT](#) allows access to different kinds of text files and remote resources as if they were regular MariaDB tables.
- The [CSV](#) storage engine can read and append to files stored in CSV (comma-separated-values) format. However, since [MariaDB 10.0](#), CONNECT is a better choice and is more flexibly able to read and write such files.
- [FederatedX](#) uses libmysql to talk to the data source, the data source being a remote RDBMS. Currently, since FederatedX only uses libmysql, it can only talk to another MySQL RDBMS.
- [InnoDB](#) is a good general transaction storage engine, and, from [MariaDB 10.2](#), the best choice in most cases. It is the default storage engine from [MariaDB 10.2](#). For earlier releases, XtraDB was a performance enhanced fork of InnoDB and is usually preferred.
- The [MERGE](#) storage engine is a collection of identical MyISAM tables that can be used as one. "Identical" means that all tables have identical column and index information.
- [MEMORY](#) does not write data on-disk (all rows are lost on crash) and is best-used for read-only caches of data from other tables, or for temporary work areas. With the default [InnoDB](#) and other storage engines having good caching, there is less need for this engine than in the past.

- [Moonga](#) provides fast CJK-ready full text searching using column store.
- [MyISAM](#) has a small footprint and allows for easy copying between systems. MyISAM is MySQL's oldest storage engine. There is usually little reason to use it except for legacy purposes. Aria is MariaDB's more modern improvement.
- [MyRocks](#) enables greater compression than InnoDB, as well as less write amplification giving better endurance of flash storage and improving overall throughput.
- [OQGRAPH](#) allows you to handle hierarchies (tree structures) and complex graphs (nodes having many connections in several directions).
- [S3 Storage Engine](#) is a read-only storage engine that stores its data in Amazon S3.
- [Sequence](#) allows the creation of ascending or descending sequences of numbers (positive integers) with a given starting value, ending value and increment, creating virtual, ephemeral tables automatically when you need them.
- [SphinxSE](#) is used as a proxy to run statements on a remote Sphinx database server (mainly useful for advanced fulltext searches).
- [Spider](#) uses partitioning to provide data sharding through multiple servers.
- [TokuDB](#) is a transactional storage engine which is optimized for workloads that do not fit in memory, and provides a good compression ratio. TokuDB has been deprecated by its upstream developers, and is disabled in [MariaDB 10.5](#), and removed in [MariaDB 10.6](#)
- [XtraDB](#) is the best choice in [MariaDB 10.1](#) and earlier in the majority of cases. It is a performance-enhanced fork of InnoDB and is MariaDB's default engine until [MariaDB 10.1](#).

## 4.3.2 InnoDB

### 4.3.2.1 InnoDB Versions

#### MariaDB starting with 10.3.7

In [MariaDB 10.3.7](#) and later, the InnoDB implementation has diverged substantially from the InnoDB in MySQL. Therefore, in these versions, the InnoDB version is no longer associated with a MySQL release version.

#### MariaDB starting with 10.2

In [MariaDB 10.2](#) and later, the default InnoDB implementation is based on InnoDB from MySQL 5.7. See [Why MariaDB uses InnoDB instead of XtraDB from MariaDB 10.2](#) for more information.

#### MariaDB until 10.1

In [MariaDB 10.1](#) and before, the default InnoDB implementation is based on Percona's XtraDB. XtraDB is a performance enhanced fork of InnoDB. For compatibility reasons, the [system variables](#) still retain their original

`innodb`

prefixes. If the documentation says that something applies to InnoDB, then it usually also applies to the XtraDB fork, unless explicitly stated otherwise. In these versions, it is still possible to use InnoDB instead of XtraDB. See [Using InnoDB instead of XtraDB](#) for more information.

## Divergences

Some examples of divergences between MariaDB's InnoDB and MySQL's InnoDB are:

- [MariaDB 10.1](#) (which is based on MySQL 5.6) included encryption and variable-size page compression before MySQL 5.7 introduced them.
- [MariaDB 10.2](#) (based on MySQL 5.7) introduced persistent AUTO\_INCREMENT ([MDEV-6076](#)) in a GA release before MySQL 8.0.
- [MariaDB 10.3](#) (based on MySQL 5.7) introduced instant ADD COLUMN ([MDEV-11369](#)) before MySQL.

## InnoDB Versions Included in MariaDB Releases

### MariaDB 10.3

InnoDB Version	Introduced
No longer reported	<a href="#">MariaDB 10.3.7</a>
InnoDB 5.7.20	<a href="#">MariaDB 10.3.3</a>
InnoDB 5.7.19	<a href="#">MariaDB 10.3.1</a>
InnoDB 5.7.14	<a href="#">MariaDB 10.3.0</a>

### MariaDB 10.2

InnoDB Version	Introduced
InnoDB 5.7.29	<a href="#">MariaDB 10.2.33</a>
InnoDB 5.7.23	<a href="#">MariaDB 10.2.17</a>

InnoDB 5.7.22	<a href="#">MariaDB 10.2.15</a>
InnoDB 5.7.21	<a href="#">MariaDB 10.2.13</a>
InnoDB 5.7.20	<a href="#">MariaDB 10.2.10</a>
InnoDB 5.7.19	<a href="#">MariaDB 10.2.8</a>
InnoDB 5.7.18	<a href="#">MariaDB 10.2.7</a>
InnoDB 5.7.14	<a href="#">MariaDB 10.2.2</a>

## MariaDB 10.1

InnoDB Version	Introduced
InnoDB 5.6.49	<a href="#">MariaDB 10.1.46</a>
InnoDB 5.6.47	<a href="#">MariaDB 10.1.44</a>
InnoDB 5.6.44	<a href="#">MariaDB 10.1.39</a>
InnoDB 5.6.42	<a href="#">MariaDB 10.1.37</a>
InnoDB 5.6.39	<a href="#">MariaDB 10.1.31</a>
InnoDB 5.6.37	<a href="#">MariaDB 10.1.26</a>
InnoDB 5.6.36	<a href="#">MariaDB 10.1.24</a>
InnoDB 5.6.35	<a href="#">MariaDB 10.1.21</a>
InnoDB 5.6.33	<a href="#">MariaDB 10.1.18</a>
InnoDB 5.6.32	<a href="#">MariaDB 10.1.17</a>
InnoDB 5.6.31	<a href="#">MariaDB 10.1.16</a>
InnoDB 5.6.30	<a href="#">MariaDB 10.1.14</a>
InnoDB 5.6.29	<a href="#">MariaDB 10.1.12</a>

## MariaDB 10.0

InnoDB Version	Introduced
InnoDB 5.6.43	<a href="#">MariaDB 10.0.38</a>
InnoDB 5.6.42	<a href="#">MariaDB 10.0.37</a>
InnoDB 5.6.40	<a href="#">MariaDB 10.0.35</a>
InnoDB 5.6.39	<a href="#">MariaDB 10.0.34</a>
InnoDB 5.6.38	<a href="#">MariaDB 10.0.33</a>
InnoDB 5.6.37	<a href="#">MariaDB 10.0.32</a>
InnoDB 5.6.36	<a href="#">MariaDB 10.0.31</a>
InnoDB 5.6.35	<a href="#">MariaDB 10.0.29</a>
InnoDB 5.6.33	<a href="#">MariaDB 10.0.28</a>
InnoDB 5.6.32	<a href="#">MariaDB 10.0.27</a>
InnoDB 5.6.31	<a href="#">MariaDB 10.0.26</a>
InnoDB 5.6.30	<a href="#">MariaDB 10.0.25</a>
InnoDB 5.6.29	<a href="#">MariaDB 10.0.24</a>
InnoDB 5.6.28	<a href="#">MariaDB 10.0.23</a>
InnoDB 5.6.27	<a href="#">MariaDB 10.0.22</a>
InnoDB 5.6.26	<a href="#">MariaDB 10.0.21</a>
InnoDB 5.6.25	<a href="#">MariaDB 10.0.20</a>
InnoDB 5.6.24	<a href="#">MariaDB 10.0.18</a>
InnoDB 5.6.23	<a href="#">MariaDB 10.0.17</a>
InnoDB 5.6.22	<a href="#">MariaDB 10.0.16</a>

InnoDB 5.6.21	MariaDB 10.0.15
InnoDB 5.6.20	MariaDB 10.0.14
InnoDB 5.6.19	MariaDB 10.0.13
InnoDB 5.6.17	MariaDB 10.0.11
InnoDB 5.6.15	MariaDB 10.0.9
InnoDB 5.6.14	MariaDB 10.0.8

### 4.3.2.2 InnoDB Limitations

#### Contents

1. [Limitations on Schema](#)
2. [Limitations on Size](#)
  1. [Page Sizes](#)
  2. [Large Prefix Size](#)
3. [Limitations on Tables](#)
  1. [Table Analysis](#)
  2. [Table Status](#)
  3. [Auto-incrementing Columns](#)
4. [Transactions and Locks](#)

The [InnoDB storage engine](#) has the following limitations.

## Limitations on Schema

- InnoDB tables can have a maximum of 1,017 columns. This includes [virtual generated columns](#).
- InnoDB tables can have a maximum of 64 secondary indexes.
- A multicolumn index on InnoDB can use a maximum of 16 columns. If you attempt to create a multicolumn index that uses more than 16 columns, MariaDB returns an Error 1070.

## Limitations on Size

- With the exception of variable-length columns (that is, [VARBINARY](#), [VARCHAR](#), [BLOB](#) and [TEXT](#)), rows in InnoDB have a maximum length of roughly half the page size for 4KB, 8KB, 16KB and 32KB page sizes.
- The maximum size for [BLOB](#) and [TEXT](#) columns is 4GB. This also applies to [LONGBLOB](#) and [LONGTEXT](#).
- MariaDB imposes a row-size limit of 65,535 bytes for the combined sizes of all columns. If the table contains [BLOB](#) or [TEXT](#) columns, these only count for 9 - 12 bytes in this calculation, given that their content is stored separately.
- 32-bit operating systems have a maximum file size limit of 2GB. When working with large tables using this architecture, configure InnoDB to use smaller data files.
- The maximum size for the combined InnoDB log files is 512GB.
- With tablespaces, the minimum size is 10MB, the maximum varies depending on the InnoDB Page Size.

InnoDB Page Size	Maximum Tablespace Size
4KB	16TB
8KB	32TB
16KB	64TB
32KB	128TB
64KB	256TB

## Page Sizes

Using the [innodb\\_page\\_size](#) system variable, you can configure the size in bytes for InnoDB pages. Pages default to 16KB. There are certain limitations on how you use this variable.

- MariaDB instances using one page size cannot use data files or log files from an instance using a different page size.
- When using a Page Size of 4KB or 8KB, the maximum index key length is lowered proportionately.

InnoDB Page Size	Index Key Length
------------------	------------------

4KB	768B
8KB	1536B
16KB	3072B

## Large Prefix Size

Until MariaDB 10.3.1 , the `innodb_large_prefix` system variable enabled large prefix sizes. That is, when enabled (the default from MariaDB 10.2 ), InnoDB uses 3072B index key prefixes for

DYNAMIC

and

COMPRESSED

row formats. When disabled, it uses 787B key prefixes for tables of any row format. Using an index key that exceeds this limit throws an error.

From MariaDB 10.3.1 , InnoDB always uses large index key prefixes.

## Limitations on Tables

InnoDB has the following table-specific limitations.

- When you issue a `DELETE` statement, InnoDB doesn't regenerate the table, rather it deletes each row from the table one by one.
- When running MariaDB on Windows, InnoDB stores databases and tables in lowercase. When moving databases and tables in a binary format from Windows to a Unix-like system or from a Unix system to Windows, you need to rename these to use lowercase.
- When using cascading `foreign keys` , operations in the cascade don't activate triggers.

## Table Analysis

MariaDB supports the use of the `ANALYZE TABLE` SQL statement to analyze and store table key distribution. When MariaDB executes this statement, it calculates index cardinality through random dives on index trees. This makes it fast, but not always accurate as it does not check all rows. The data is only an estimate and repeated executions of this statement may return different results.

In situations where accurate data from `ANALYZE TABLE` statements is important, enable the `innodb_stats_persistent` system variable. Additionally, you can use the `innodb_stats_transient_sample_pages` system variable to change the number of random dives it performs.

When running `ANALYZE TABLE` twice on a table in which statements or transactions are running, MariaDB blocks the second `ANALYZE TABLE` until the statement or transaction is complete. This occurs because the statement or transaction blocks the second `ANALYZE TABLE` statement from reloading the table definition, which it must do since the old one was marked as obsolete after the first statement.

## Table Status

Similar to the `ANALYZE TABLE` statement, `SHOW TABLE STATUS` statements do not provide accurate statistics for InnoDB, except for the physical table size.

The InnoDB storage engine does not maintain internal row counts. Transactions isolate writes, which means that concurrent transactions will not have the same row counts.

## Auto-incrementing Columns

- When defining an index on an auto-incrementing column, it must be defined in a way that allows the equivalent of
 

```
SELECT MAX(col)
      lookups on the table.
```
- Restarting MariaDB may cause InnoDB to reuse old auto-increment values, such as in the case of a transaction that was rolled back.
- When auto-incrementing columns run out of values, `INSERT` statements generate duplicate-key errors.

## Transactions and Locks

- You can modify data on a maximum of 96 \* 1023 concurrent transactions that generate undo records.
- Of the 128 rollback segments, InnoDB assigns 32 to non-redo logs for transactions that modify temporary tables and related objects, reducing the maximum number of concurrent data-modifying transactions to 96,000, from 128,000.
- The limit is 32,000 concurrent transactions when all data-modifying transactions also modify temporary tables.
- Issuing a `LOCK TABLES` statement sets two locks on each table when the `innodb_table_locks` system variable is enabled (the default).
- When you commit or roll back a transaction, any locks set in the transaction are released. You don't need to issue `LOCK TABLES` statements when the `autocommit` variable is enabled, as InnoDB would immediately release the table locks.

### 4.3.2.3 InnoDB Troubleshooting

#### 4.3.2.3.1 InnoDB Troubleshooting Overview

## Contents

### 1. See Also

As with most errors, first take a look at the contents of the [MariaDB error log](#). If dealing with a deadlock, setting the `innodb_print_all_deadlocks` option (off by default) will output details of all deadlocks to the error log.

It can also help to enable the various [InnoDB Monitors](#) relating to the problem you are experiencing. There are four types: the standard InnoDB monitor, the InnoDB Lock Monitor, InnoDB Tablespace Monitor and the InnoDB Table Monitor.

Running `CHECK TABLE` will help determine whether there are errors in the table.

For problems with the InnoDB Data Dictionary, see [InnoDB Data Dictionary Troubleshooting](#).

### 4.3.2.3.2 InnoDB Data Dictionary Troubleshooting

## Contents

### 1. Can't Open File 2. Removing Orphan Intermediate Tables 3. See Also

## Can't Open File

If InnoDB returns something like the following error:

```
ERROR 1016: Can't open file: 'x.ibd'. (errno: 1)
```

it may be that an orphan

`.frm`

file exists. Something like the following may also appear in the [error log](#):

```
InnoDB: Cannot find table test/x from the internal data dictionary
InnoDB: of InnoDB though the .frm file for the table exists. Maybe you
InnoDB: have deleted and recreated InnoDB data files but have forgotten
InnoDB: to delete the corresponding .frm files of InnoDB tables?
```

If this is the case, as the text describes, delete the orphan

`.frm`

file on the filesystem.

## Removing Orphan Intermediate Tables

An orphan intermediate table may prevent you from dropping the tablespace even if it is otherwise empty, and generally takes up unnecessary space.

It may come about if MariaDB exits in the middle of an `ALTER TABLE ... ALGORITHM=INPLACE` operation. They will be listed in the `INFORMATION_SCHEMA.INNODB_SYS_TABLES` table, and always start with an

```
#sql-ib
prefix. The accompanying
.frm
file also begins with
#sql-
, but has a different name.
```

To identify orphan tables, run:

```
SELECT * FROM INFORMATION_SCHEMA.INNODB_SYS_TABLES WHERE NAME LIKE '%#sql%';
```

When `innodb_file_per_table` is set, the

```
#sql-* .ibd
file will also be visible in the database directory.
```

To remove an orphan intermediate table:

- Rename the  
`#sql-* .frm`  
file (in the database directory) to match the base name of the orphan intermediate table, for example:

```
mv #sql-36ab_2.frm #sql-ib87-856498050.frm
```

- Drop the table, for example:

```
DROP TABLE `#mysql150##sql-ib87-856498050`;
```

### 4.3.2.3.3 InnoDB Recovery Modes

The InnoDB recovery mode is a mode used for recovering from emergency situations. You should ensure you have a backup of your database before making changes in case you need to restore it. The `innodb_force_recovery` server system variable sets the recovery mode. A mode of 0 is normal use, while the higher the mode, the more stringent the restrictions. Higher modes incorporate all limitations of the lower modes.

The recovery mode should never be set to a value other than zero except in an emergency situation.

Generally, it is best to start with a recovery mode of 1, and increase in single increments if needs be. With a recovery mode < 4, only corrupted pages should be lost. With 4, secondary indexes could be corrupted. With 5, results could be inconsistent and secondary indexes could be corrupted (even if they were not with 4). A value of 6 leaves pages in an obsolete state, which might cause more corruption.

Until [MariaDB 10.2.7](#), mode

0

was the only mode permitting changes to the data. From [MariaDB 10.2.7](#), write transactions are permitted with mode

3

or less.

To recover the tables, you can execute `SELECTs` to dump data, and `DROP TABLE` (when write transactions are permitted) to remove corrupted tables.

The following modes are available:

## Recovery Modes

Recovery mode behaviour differs per version (server/storage/innobase/include/srv0srv.h)

[MariaDB 10.4](#) and before:

Mode	Description
0	The default mode while InnoDB is running normally. Until <a href="#">MariaDB 10.2.7</a> , it was the only mode permitting changes to the data. From <a href="#">MariaDB 10.2.7</a> , write transactions are permitted with <code>innodb_force_recovery&lt;=3</code> .
1	( <code>SRV_FORCE_IGNORE_CORRUPT</code> ) allows the the server to keep running even if corrupt pages are detected. It does so by making redo log based recovery ignore certain errors, such as missing data files or corrupted data pages. Any redo log for affected files or pages will be skipped. You can facilitate dumping tables by getting the <code>SELECT * FROM table_name</code> statement to jump over corrupt indexes and pages.
2	( <code>SRV_FORCE_NO_BACKGROUND</code> ) stops the master thread from running, preventing a crash that occurs during a purge. No purge will be performed, so the undo logs will keep growing.
3	( <code>SRV_FORCE_NO_TRX_UNDO</code> ) does not roll back transactions after the crash recovery. Does not affect rollback of currently active transactions. Starting with <a href="#">MariaDB 10.2.7</a> , will also prevent some undo-generating background tasks from running. These tasks could hit a lock wait due to the recovered incomplete transactions whose rollback is being prevented.
4	( <code>SRV_FORCE_NO_IBUF_MERGE</code> ) does not calculate tables statistics and prevents insert buffer merges.
5	( <code>SRV_FORCE_NO_UNDO_LOG_SCAN</code> ) treats incomplete transactions as committed, and does not look at the <code>undo logs</code> when starting.
6	( <code>SRV_FORCE_NO_LOG_REDO</code> ) does not perform redo log roll-forward as part of recovery. Running queries that require indexes are likely to fail with this mode active. However, if a table dump still causes a crash, you can try using a <code>SELECT * FROM tab ORDER BY primary_key DESC</code> to dump all the data portion after the corrupted part.

From [MariaDB 10.5](#) to [MariaDB 10.6.4](#):

Mode	Description
0	The default mode while InnoDB is running normally. Write transactions are permitted with <code>innodb_force_recovery&lt;=4</code> .
1	( <code>SRV_FORCE_IGNORE_CORRUPT</code> ) allows the the server to keep running even if corrupt pages are detected. It does so by making redo log based recovery ignore certain errors, such as missing data files or corrupted data pages. Any redo log for affected files or pages will be skipped. You can facilitate dumping tables by getting the <code>SELECT * FROM table_name</code> statement to jump over corrupt indexes and pages.

2	(SRV_FORCE_NO_BACKGROUND) stops the master thread from running, preventing a crash that occurs during a purge. No purge will be performed, so the undo logs will keep growing.
3	(SRV_FORCE_NO_TRX_UNDO) does not roll back transactions after the crash recovery. Does not affect rollback of currently active transactions. Will also prevent some undo-generating background tasks from running. These tasks could hit a lock wait due to the recovered incomplete transactions whose rollback is being prevented.
4	(SRV_FORCE_NO_IBUF_MERGE) The same as 3.
5	(SRV_FORCE_NO_UNDO_LOG_SCAN) treats incomplete transactions as committed, and does not look at the <a href="#">undo logs</a> when starting.
6	(SRV_FORCE_NO_LOG_REDO) does not perform redo log roll-forward as part of recovery. Running queries that require indexes are likely to fail with this mode active. However, if a table dump still causes a crash, you can try using a SELECT * FROM tab ORDER BY primary_key DESC to dump all the data portion after the corrupted part.

From [MariaDB 10.6.5](#)

Mode	Description
0	The default mode while InnoDB is running normally. Write transactions are permitted with innodb_force_recovery<=4.
1	(SRV_FORCE_IGNORE_CORRUPT) allows the server to keep running even if corrupt pages are detected. It does so by making redo log based recovery ignore certain errors, such as missing data files or corrupted data pages. Any redo log for affected files or pages will be skipped. You can facilitate dumping tables by getting the SELECT * FROM table_name statement to jump over corrupt indexes and pages.
2	(SRV_FORCE_NO_BACKGROUND) stops the master thread from running, preventing a crash that occurs during a purge. No purge will be performed, so the undo logs will keep growing.
3	(SRV_FORCE_NO_TRX_UNDO) does not roll back DML transactions after the crash recovery. Does not affect rollback of currently active DML transactions. Will also prevent some undo-generating background tasks from running. These tasks could hit a lock wait due to the recovered incomplete transactions whose rollback is being prevented.
4	(SRV_FORCE_NO_DDL_UNDO) does not roll back transactions after the crash recovery. Does not affect rollback of currently active transactions. Will also prevent some undo-generating background tasks from running. These tasks could hit a lock wait due to the recovered incomplete transactions whose rollback is being prevented.
5	(SRV_FORCE_NO_UNDO_LOG_SCAN) treats incomplete transactions as committed, and does not look at the <a href="#">undo logs</a> when starting. Any DDL log for InnoDB tables will be essentially ignored by InnoDB, but the server will start up
6	(SRV_FORCE_NO_LOG_REDO) does not perform redo log roll-forward as part of recovery. Running queries that require indexes are likely to fail with this mode active. However, if a table dump still causes a crash, you can try using a SELECT * FROM tab ORDER BY primary_key DESC to dump all the data portion after the corrupted part.

Note also that XtraDB (<= MariaDB 10.2.6 ) by default will crash the server when it detects corrupted data in a single-table tablespace. This behaviour can be changed - see the [innodb\\_corrupt\\_table\\_action](#) system variable.

## Fixing Things

Try to set innodb\_force\_recovery to 1 and start mariadb. If that fails, try a value of "2". If a value of 2 works, then there is a chance the only corruption you have experienced is within the innodb "undo logs". If that gets mariadb started, you should be able to dump your database with mysqldump. You can verify any other issues with any tables by running "mysqlcheck --all-databases".

If you were able to successfully dump your databases, or had previously known good backups, drop your database(s) from the mariadb command line like "[DROP DATABASE](#) yourdatabase". Stop mariadb. Go to /var/lib/mysql (or wherever your mysql data directory is located) and "rm -i ib\*". Start mariadb, create the database(s) you dropped (" [CREATE DATABASE](#) yourdatabase"), and then import your most recent dumps: "mysql < mydatabasedump.sql"

### 4.3.2.3.4 Troubleshooting Row Size Too Large Errors with InnoDB

With InnoDB, users can see the following message as an error or warning:

```
ERROR 1118 (42000): Row size too large (> 8126). Changing some columns to
TEXT or BLOB may help. In current row format, BLOB prefix of 0 bytes is stored
inline.
```

And they can also see the following message as an error or warning in the [error log](#) :

```
[Warning] InnoDB: Cannot add field col in table db1.tab because after adding it,
the row size is 8478 which is greater than maximum allowed size (8126) for a
record on index leaf page.
```

## Contents

1. Example of the Problem
2. Root Cause of the Problem
3. Checking Existing Tables for the Problem
4. Finding All Tables That Currently Have the Problem
5. Solving the Problem
  1. Converting the Table to the DYNAMIC Row Format
  2. Fitting More Columns on Overflow Pages
    1. Converting Some Columns to BLOB or TEXT
    2. Increasing the Length of VARBINARY Columns
    3. Increasing the Length of VARCHAR Columns
6. Working Around the Problem
  1. Refactoring the Table into Multiple Tables
  2. Refactoring Some Columns into JSON
  3. Disabling InnoDB Strict Mode

These messages indicate that the table's definition allows rows that the table's InnoDB row format can't actually store.

These messages are raised in the following cases:

- If **InnoDB strict mode** is **enabled** and if a **DDL** statement is executed that touches the table, such as

`CREATE TABLE`

or

`ALTER TABLE`

, then InnoDB will raise an **error** with this message

- If **InnoDB strict mode** is **disabled** and if a **DDL** statement is executed that touches the table, such as

`CREATE TABLE`

or

`ALTER TABLE`

, then InnoDB will raise a **warning** with this message.

- Regardless of whether **InnoDB strict mode** is enabled, if a **DML** statement is executed that attempts to write a row that the table's InnoDB row format can't store, then InnoDB will raise an **error** with this message.

## Example of the Problem

Here is an example of the problem:

```
SET GLOBAL innodb_default_row_format='dynamic';

SET SESSION innodb_strict_mode=ON;

CREATE OR REPLACE TABLE tab (
    col1 varchar(40) NOT NULL,
    col2 varchar(40) NOT NULL,
    col3 varchar(40) NOT NULL,
    col4 varchar(40) NOT NULL,
    col5 varchar(40) NOT NULL,
    col6 varchar(40) NOT NULL,
    col7 varchar(40) NOT NULL,
    col8 varchar(40) NOT NULL,
    col9 varchar(40) NOT NULL,
    col10 varchar(40) NOT NULL,
    col11 varchar(40) NOT NULL,
    col12 varchar(40) NOT NULL,
    col13 varchar(40) NOT NULL,
    col14 varchar(40) NOT NULL,
    col15 varchar(40) NOT NULL)
```

```
col15 varchar(40) NOT NULL,
col16 varchar(40) NOT NULL,
col17 varchar(40) NOT NULL,
col18 varchar(40) NOT NULL,
col19 varchar(40) NOT NULL,

col145 varchar(40) NOT NULL,
col146 varchar(40) NOT NULL,
col147 varchar(40) NOT NULL,
col148 varchar(40) NOT NULL,
PRIMARY KEY (col1)
) ENGINE=InnoDB DEFAULT CHARSET=utf8mb4;
ERROR 1118 (42000): Row size too large (> 8126). Changing some columns to
TEXT or BLOB may help. In current row format, BLOB prefix of 0 bytes is stored inline.

```

## Root Cause of the Problem

The root cause is that InnoDB has a maximum row size that is roughly equivalent to half of the value of the

[innodb\\_page\\_size](#)

system variable. See [InnoDB Row Formats Overview: Maximum Row Size](#) for more information.

InnoDB's row formats work around this limit by storing certain kinds of variable-length columns on overflow pages. However, different row formats can store different types of data on overflow pages. Some row formats can store more data in overflow pages than others. For example, the

[DYNAMIC](#)

and

[COMPRESSED](#)

row formats can store the most data in overflow pages. To learn how the various InnoDB row formats use overflow pages, see the following pages:

- [InnoDB REDUNDANT Row Format: Overflow Pages with the REDUNDANT Row Format](#)
- [InnoDB COMPACT Row Format: Overflow Pages with the COMPACT Row Format](#)
- [InnoDB DYNAMIC Row Format: Overflow Pages with the DYNAMIC Row Format](#)
- [InnoDB COMPRESSED Row Format: Overflow Pages with the COMPRESSED Row Format](#)

## Checking Existing Tables for the Problem

InnoDB does not currently have an easy way to check all existing tables to determine which tables have this problem. See [MDEV-20400](#) for more information.

One method to check a single existing table for this problem is to enable [InnoDB strict mode](#), and then try to create a duplicate of the table with

[CREATE TABLE ... LIKE](#)

. If the table has this problem, then the operation will fail. For example:

```

SET SESSION innodb_strict_mode=ON;

CREATE TABLE tab_dup LIKE tab;
ERROR 1118 (42000): Row size too large (> 8126). Changing some columns to
TEXT or BLOB may help. In current row format, BLOB prefix of 0 bytes is stored inline.

```

## Finding All Tables That Currently Have the Problem

The following shell script will read through a MariaDB server to identify every table that has a row size definition that is too large for its row format and the server's page size. It runs on most common distributions of Linux.

To run the script, copy the code below to a shell-script named

```

rowcount.sh
, make it executable with the command
chmod 755 ./rowsize.sh
, and invoke it with the following parameters:

```

```
./rowsize.sh host user password
```

When the script runs, it displays the name of the temporary database it creates, so that if the script is interrupted before cleaning up, the database can be easily identified and removed manually.

As the script runs it will output one line reporting the database and tablename for each table it finds that has the oversize row problem. If it finds none, it will print the following message: "No tables with rows size too big found."

In either case, the script prints one final line to announce when it's done:

```
./rowsize.sh done.
```

```

#!/bin/bash

[ -z "$3" ] && echo "Usage: $0 host user password" >&2 && exit 1

dt="tmp_$(RANDOM$RANDOM"

mysql -h $1 -u $2 -p$p3 -ABNe "create database $dt;" 
[ $? -ne 0 ] && echo "Error: $0 terminating" >&2 exit 1

echo
echo "Created temporary database ${dt} on host $1"
echo

c=0
for d in $(mysql -h $1 -u $2 -p$p3 -ABNe "show databases;" | egrep -iv "information_schema|mysql|performance_schema|$dt")
do
  for t in $(mysql -h $1 -u $2 -p$p3 -ABNe "show tables;" $d)
  do
    tc=$(mysql -h $1 -u $2 -p$p3 -ABNe "show create table $t\G" $d | egrep -iv "^\*|^$")

    echo $tc | grep -iq "ROW_FORMAT"
    if [ $? -ne 0 ]
    then
      tf=$(mysql -h $1 -u $2 -p$p3 -ABNe "select row_format from information_schema.innodb_sys_tables where name = '$d/$t';")
      tc="$tc ROW_FORMAT=$tf"
    fi

    ef="/tmp/e$RANDOM$RANDOM"
    mysql -h $1 -u $2 -p$p3 -ABNe "set innodb_strict_mode=1; set foreign_key_checks=0; ${tc};" $dt >/dev/null 2>$ef
    [ $? -ne 0 ] && cat $ef | grep -q "Row size too large" && echo "${d}.${t}" && let c++ || mysql -h $1 -u $2 -p$p3 -ABNe "drop database $dt"
    rm -f $ef
  done
done
mysql -h $1 -u $2 -p$p3 -ABNe "set innodb_strict_mode=1; drop database $dt;"
[ $c -eq 0 ] && echo "No tables with rows size too large found." || echo && echo "$c tables found with row size too large."
echo
echo "$0 done."

```

## Solving the Problem

There are several potential solutions available to solve this problem.

## Converting the Table to the DYNAMIC Row Format

If the table is using either the

REDUNDANT

or the

COMPACT

row format, then one potential solution to this problem is to convert the table to use the

DYNAMIC

row format instead.

If your tables were originally created on an older version of MariaDB or MySQL, then your table may be using one of InnoDB's older row formats:

- In [MariaDB 10.1](#) and before, and in MySQL 5.6 and before, the

COMPACT

row format was the default row format.

- In MySQL 4.1 and before, the

REDUNDANT

row format was the default row format.

The

DYNAMIC

row format can store more data on overflow pages than these older row formats, so this row format may actually be able to store the table's data safely. See [InnoDB DYNAMIC Row Format: Overflow Pages with the DYNAMIC Row Format](#) for more information.

Therefore, a potential solution to the *Row size too large* error is to convert the table to use the

DYNAMIC

row format. For example:

```
ALTER TABLE tab ROW_FORMAT=DYNAMIC;
```

You can use the

INNODB\_SYS\_TABLES

table in the

information\_schema

database to find all tables that use the

REDUNDANT

or the

COMPACT

row formats. This is helpful if you would like to convert all of your tables that you still use the older row formats to the

DYNAMIC

row format. For example, the following query can find those tables, while excluding InnoDB's internal system tables :

```
SELECT NAME, ROW_FORMAT
FROM information_schema.INNODB_SYS_TABLES
WHERE ROW_FORMAT IN('Redundant', 'Compact')
AND NAME NOT IN('SYS_DATAFILES', 'SYS_FOREIGN', 'SYS_FOREIGN_COLS', 'SYS_TABLESPACES', 'SYS_VIRTUAL', 'SYS_ZIP_DICT', 'SYS_ZIP_D')
```

In MariaDB 10.2 and later, the

DYNAMIC

row format is the default row format. If your tables were originally created on one of these newer versions, then they may already be using this row format. In that case, you may need to try the next solution.

## Fitting More Columns on Overflow Pages

If the table is already using the

DYNAMIC

row format, then another potential solution to this problem is to change the table schema, so that the row format can store more columns on overflow pages.

In order for InnoDB to store some variable-length columns on overflow pages, the length of those columns may need to be increased.

Therefore, a counter-intuitive solution to the *Row size too large* error in a lot of cases is actually to **increase** the length of some variable-length columns, so that InnoDB's row format can store them on overflow pages.

Some possible ways to change the table schema are listed below.

### Converting Some Columns to

BLOB

or

TEXT

For

BLOB

and

TEXT

columns, the

DYNAMIC

row format can store these columns on overflow pages. See [InnoDB DYNAMIC Row Format: Overflow Pages with the DYNAMIC Row Format](#) for more information.

Therefore, a potential solution to the *Row size too large* error is to convert some columns to the

BLOB

or

TEXT

data types.

### Increasing the Length of VARBINARY Columns

For

VARBINARY

columns, the

DYNAMIC

row format can only store these columns on overflow pages if the maximum length of the column is 256 bytes or longer. See [InnoDB DYNAMIC Row Format: Overflow Pages with the DYNAMIC Row Format](#) for more information.

Therefore, a potential solution to the *Row size too large* error is to ensure that all

**VARBINARY**

columns are at least as long as  
varbinary(256)

## Increasing the Length of

**VARCHAR**  
Columns

For

**VARCHAR**

columns, the

**DYNAMIC**

row format can only store these columns on overflow pages if the maximum length of the column is 256 bytes or longer. See [InnoDB DYNAMIC Row Format: Overflow Pages with the DYNAMIC Row Format](#) for more information.

The original table schema shown earlier on this page causes the *Row size too large* error, because all of the table's

**VARCHAR**

columns are smaller than 256 bytes, which means that they have to be stored on the row's main data page.

Therefore, a potential solution to the *Row size too large* error is to ensure that all

**VARCHAR**

columns are at least as long as 256 bytes. The number of characters required to reach the 256 byte limit depends on the **character set** used by the column.

For example, when using InnoDB's

**DYNAMIC**

row format and a default character set of

**latin1**

(which requires up to 1 byte per character), the 256 byte limit means that a

**VARCHAR**

column will only be stored on overflow pages if it is at least as large as a

varchar(256)

:

```
SET GLOBAL innodb_default_row_format='dynamic';
SET SESSION innodb_strict_mode=ON;
CREATE OR REPLACE TABLE tab (
    col1 varchar(256) NOT NULL,
    col2 varchar(256) NOT NULL,
    col3 varchar(256) NOT NULL,
    col4 varchar(256) NOT NULL,
    col5 varchar(256) NOT NULL,
    col6 varchar(256) NOT NULL,
    col7 varchar(256) NOT NULL,
    col8 varchar(256) NOT NULL,
    col9 varchar(256) NOT NULL,
    col10 varchar(256) NOT NULL,
    col11 varchar(256) NOT NULL,
    col12 varchar(256) NOT NULL,
    col13 varchar(256) NOT NULL,
    col14 varchar(256) NOT NULL,
    col15 varchar(256) NOT NULL,
    col16 varchar(256) NOT NULL,
    col17 varchar(256) NOT NULL)
```

```
col11 varchar(256) NOT NULL,  
col18 varchar(256) NOT NULL,  
col19 varchar(256) NOT NULL,  
col20 varchar(256) NOT NULL,  
col21 varchar(256) NOT NULL,  
col22 varchar(256) NOT NULL,  
col23 varchar(256) NOT NULL,  
col24 varchar(256) NOT NULL,  
col25 varchar(256) NOT NULL,  
col26 varchar(256) NOT NULL,  
col27 varchar(256) NOT NULL,  
col28 varchar(256) NOT NULL,  
col29 varchar(256) NOT NULL,  
col30 varchar(256) NOT NULL,  
col31 varchar(256) NOT NULL,  
col32 varchar(256) NOT NULL,  
col33 varchar(256) NOT NULL,  
col34 varchar(256) NOT NULL,  
col35 varchar(256) NOT NULL,  
col36 varchar(256) NOT NULL,  
col37 varchar(256) NOT NULL,  
col38 varchar(256) NOT NULL,  
col39 varchar(256) NOT NULL,  
col40 varchar(256) NOT NULL,  
col41 varchar(256) NOT NULL,  
col42 varchar(256) NOT NULL,  
col43 varchar(256) NOT NULL,  
col44 varchar(256) NOT NULL,  
col45 varchar(256) NOT NULL,  
col46 varchar(256) NOT NULL,  
col47 varchar(256) NOT NULL,  
col48 varchar(256) NOT NULL,  
col49 varchar(256) NOT NULL,  
col50 varchar(256) NOT NULL,  
col51 varchar(256) NOT NULL,  
col52 varchar(256) NOT NULL,  
col53 varchar(256) NOT NULL,  
col54 varchar(256) NOT NULL,  
col55 varchar(256) NOT NULL,  
col56 varchar(256) NOT NULL,  
col57 varchar(256) NOT NULL,  
col58 varchar(256) NOT NULL,  
col59 varchar(256) NOT NULL,  
col60 varchar(256) NOT NULL,  
col61 varchar(256) NOT NULL,  
col62 varchar(256) NOT NULL,  
col63 varchar(256) NOT NULL,  
col64 varchar(256) NOT NULL,  
col65 varchar(256) NOT NULL,  
col66 varchar(256) NOT NULL,  
col67 varchar(256) NOT NULL,  
col68 varchar(256) NOT NULL,  
col69 varchar(256) NOT NULL,  
col70 varchar(256) NOT NULL,  
col71 varchar(256) NOT NULL,  
col72 varchar(256) NOT NULL,  
col73 varchar(256) NOT NULL,  
col74 varchar(256) NOT NULL,  
col75 varchar(256) NOT NULL,  
col76 varchar(256) NOT NULL,  
col77 varchar(256) NOT NULL,  
col78 varchar(256) NOT NULL,  
col79 varchar(256) NOT NULL,  
col80 varchar(256) NOT NULL,  
col81 varchar(256) NOT NULL,  
col82 varchar(256) NOT NULL,  
col83 varchar(256) NOT NULL,  
col84 varchar(256) NOT NULL,  
col85 varchar(256) NOT NULL,  
col86 varchar(256) NOT NULL,  
col87 varchar(256) NOT NULL,  
col88 varchar(256) NOT NULL,  
col89 varchar(256) NOT NULL,  
col90 varchar(256) NOT NULL,  
col91 varchar(256) NOT NULL,  
col92 varchar(256) NOT NULL,  
col93 varchar(256) NOT NULL,  
col94 varchar(256) NOT NULL,
```

```

col112 varchar(256) NOT NULL,
col113 varchar(256) NOT NULL,
col114 varchar(256) NOT NULL,
col115 varchar(256) NOT NULL,
col116 varchar(256) NOT NULL,
col117 varchar(256) NOT NULL,
col118 varchar(256) NOT NULL,
col119 varchar(256) NOT NULL,
col120 varchar(256) NOT NULL,
col121 varchar(256) NOT NULL,
col122 varchar(256) NOT NULL,
col123 varchar(256) NOT NULL,
col124 varchar(256) NOT NULL,
col125 varchar(256) NOT NULL,
col126 varchar(256) NOT NULL,
col127 varchar(256) NOT NULL,
PRIMARY KEY (col1)
) ENGINE=InnoDB DEFAULT CHARSET=latin1;

```

And when using InnoDB's

DYNAMIC

row format and a default character set of

utf8

(which requires up to 3 bytes per character), the 256 byte limit means that a

VARCHAR

column will only be stored on overflow pages if it is at least as large as a

varchar(86)

:

```

SET GLOBAL innodb_default_row_format='dynamic';
SET SESSION innodb_strict_mode=ON;
CREATE OR REPLACE TABLE tab (
    col1 varchar(86) NOT NULL,
    col2 varchar(86) NOT NULL,
    col3 varchar(86) NOT NULL,
    col4 varchar(86) NOT NULL,
    col5 varchar(86) NOT NULL,
    col6 varchar(86) NOT NULL,
    col7 varchar(86) NOT NULL,
    col8 varchar(86) NOT NULL,
    col9 varchar(86) NOT NULL,
    col10 varchar(86) NOT NULL,
    col11 varchar(86) NOT NULL,
    col12 varchar(86) NOT NULL,
    col13 varchar(86) NOT NULL,
    col14 varchar(86) NOT NULL,
    col15 varchar(86) NOT NULL,
    col16 varchar(86) NOT NULL,
    col17 varchar(86) NOT NULL,
    col18 varchar(86) NOT NULL,
    col19 varchar(86) NOT NULL,
    col20 varchar(86) NOT NULL,
    col21 varchar(86) NOT NULL,
    col22 varchar(86) NOT NULL,
    col23 varchar(86) NOT NULL,
    col24 varchar(86) NOT NULL,
    col25 varchar(86) NOT NULL,
    col26 varchar(86) NOT NULL,
    col27 varchar(86) NOT NULL,

```

```
col28 varchar(86) NOT NULL,
col29 varchar(86) NOT NULL,
col30 varchar(86) NOT NULL,
col31 varchar(86) NOT NULL,
col32 varchar(86) NOT NULL,
col33 varchar(86) NOT NULL,
col34 varchar(86) NOT NULL,
col35 varchar(86) NOT NULL,
col36 varchar(86) NOT NULL,
col37 varchar(86) NOT NULL,
col38 varchar(86) NOT NULL,
col39 varchar(86) NOT NULL,
col40 varchar(86) NOT NULL,
col41 varchar(86) NOT NULL,
col42 varchar(86) NOT NULL,
col43 varchar(86) NOT NULL,
col44 varchar(86) NOT NULL,

col195 varchar(86) NOT NULL,
col196 varchar(86) NOT NULL,
col197 varchar(86) NOT NULL,
col198 varchar(86) NOT NULL,
PRIMARY KEY (col1)
) ENGINE=InnoDB DEFAULT CHARSET=utf8;

```

And when using InnoDB's

DYNAMIC

row format and a default character set of

utf8mb4

(which requires up to 4 bytes per character), the 256 byte limit means that a

VARCHAR

column will only be stored on overflow pages if it is at least as large as a

varchar(64)

:

```

SET GLOBAL innodb_default_row_format='dynamic';
SET SESSION innodb_strict_mode=ON;
CREATE OR REPLACE TABLE tab (
    col1 varchar(64) NOT NULL,
    col2 varchar(64) NOT NULL,
    col3 varchar(64) NOT NULL,

PRIMARY KEY (col1)  
) ENGINE=InnoDB DEFAULT CHARSET=utf8mb4;
```

## Working Around the Problem

There are a few ways to work around this problem.

If you would like a solution for the problem instead of just working around it, then see the solutions mentioned in the previous section.

### Refactoring the Table into Multiple Tables

A *safe* workaround is to refactor the single wide table, so that its columns are spread among multiple tables.

This workaround can even work if your table is so wide that the previous solutions have failed to solve them problem for your table.

### Refactoring Some Columns into JSON

A *safe* workaround is to refactor some of the columns into a JSON document.

The JSON document can be queried and manipulated using MariaDB's [JSON functions](#).

The JSON document can be stored in a column that uses one of the following data types:

•

[TEXT](#)

: The maximum size of a

[TEXT](#)

column is 64 KB.

•

[MEDIUMTEXT](#)

: The maximum size of a

[MEDIUMTEXT](#)

column is 16 MB.

•

[LONGTEXT](#)

: The maximum size of a

[LONGTEXT](#)

column is 4 GB.

•

[JSON](#)

: This is just an alias for the

[LONGTEXT](#)

data type.

This workaround can even work if your table is so wide that the previous solutions have failed to solve them problem for your table.

### Disabling InnoDB Strict Mode

An *unsafe* workaround is to disable [InnoDB strict mode](#). [InnoDB strict mode](#) can be disabled by setting the

`innodb_strict_mode`

system variable to  
OFF

For example, even though the following table schema is too large for most InnoDB row formats to store, it can still be created when [InnoDB strict mode](#) is disabled:

```
SET GLOBAL innodb_default_row_format='dynamic';
SET SESSION innodb_strict_mode=OFF;
CREATE OR REPLACE TABLE tab (
    col1 varchar(40) NOT NULL,
    col2 varchar(40) NOT NULL,
    col3 varchar(40) NOT NULL,
    col4 varchar(40) NOT NULL,
    col5 varchar(40) NOT NULL,
    col6 varchar(40) NOT NULL,
    col7 varchar(40) NOT NULL,
    col8 varchar(40) NOT NULL,
    col9 varchar(40) NOT NULL,
    col10 varchar(40) NOT NULL,
    col11 varchar(40) NOT NULL,
    col12 varchar(40) NOT NULL,
    col13 varchar(40) NOT NULL,
    col14 varchar(40) NOT NULL,
    col15 varchar(40) NOT NULL,
    col16 varchar(40) NOT NULL,
    col17 varchar(40) NOT NULL,
    col18 varchar(40) NOT NULL,
    col19 varchar(40) NOT NULL,
    col20 varchar(40) NOT NULL,
    col21 varchar(40) NOT NULL,
    col22 varchar(40) NOT NULL,
    col23 varchar(40) NOT NULL,
    col24 varchar(40) NOT NULL,
    col25 varchar(40) NOT NULL,
    col26 varchar(40) NOT NULL,
    col27 varchar(40) NOT NULL,
    col28 varchar(40) NOT NULL,
    col29 varchar(40) NOT NULL,
    col30 varchar(40) NOT NULL,
    col31 varchar(40) NOT NULL,
    col32 varchar(40) NOT NULL,
    col33 varchar(40) NOT NULL,
    col34 varchar(40) NOT NULL,
    col35 varchar(40) NOT NULL,
    col36 varchar(40) NOT NULL,
    col37 varchar(40) NOT NULL,
    col38 varchar(40) NOT NULL,

) ENGINE=InnoDB DEFAULT CHARSET=utf8mb4;

```

But as mentioned above, if [InnoDB strict mode](#) is **disabled** and if a [DDL](#) statement is executed, then InnoDB will still raise a **warning** with this message. The

`SHOW WARNINGS`

statement can be used to view the warning. For example:

```

SHOW WARNINGS;
+-----+-----+
| Level | Code | Message |
+-----+-----+
| Warning | 139 | Row size too large (> 8126). Changing some columns to TEXT or BLOB may help. In current row format, BLOB prefix
+-----+-----+
1 row in set (0.000 sec)

```

As mentioned above, even though InnoDB is allowing the table to be created, there is still an opportunity for errors. Regardless of whether [InnoDB strict mode](#) is enabled, if a [DML](#) statement is executed that attempts to write a row that the table's InnoDB row format can't store, then InnoDB will raise an **error** with this message. This creates a somewhat *unsafe* situation, because it means that the application has the chance to encounter an additional error while executing [DML](#).

This page documents system variables related to the [InnoDB storage engine](#). For options that are not system variables, see [InnoDB Options](#).

See [Server System Variables](#) for a complete list of system variables and instructions on setting them.

Also see the [Full list of MariaDB options, system and status variables](#).

## have\_innodb

- **Description:** If the server supports [InnoDB tables](#), will be set to

YES  
, otherwise will be set to  
NO

. Removed in [MariaDB 10.0](#), use the [Information Schema PLUGINS](#) table or [SHOW ENGINES](#) instead.

- **Scope:** Global
- **Dynamic:** No
- **Removed:** [MariaDB 10.0](#)

## ignore\_builtin\_innodb

- **Description:** Setting this to

1

results in the built-in InnoDB storage engine being ignored. In some versions of MariaDB, XtraDB is the default and is always present, so this variable is ignored and setting it results in a warning. From [MariaDB 10.0.1](#) to [MariaDB 10.0.8](#), when InnoDB was the default instead of XtraDB, this variable needed to be set. Usually used in conjunction with the [plugin-load=innodb=ha\\_innodb](#) option to use the InnoDB plugin.

- **Commandline:**

--ignore-built-in-innodb

- **Scope:** Global
- **Dynamic:** No
- **Data Type:**

boolean

- **Default Value:**

OFF

## innodb\_adaptive\_checkpoint

- **Description:** Replaced with [innodb\\_adaptive\\_flushing\\_method](#). Controls adaptive checkpointing. InnoDB's fuzzy checkpointing can cause stalls, as many dirty blocks are flushed at once as the checkpoint age nears the maximum. Adaptive checkpointing aims for more consistent flushing, approximately

```
modified age / maximum checkpoint age  
. Can result in larger transaction log files
```

- - reflex  
Similar to [innodb\\_max\\_dirty\\_pages\\_pct](#) flushing but flushes blocks constantly and contiguously based on the oldest modified age. If the age exceeds 1/2 of the maximum age capacity, flushing will be weak contiguous. If the age exceeds 3/4, flushing will be strong. Strength can be adjusted by the variable [innodb\\_io\\_capacity](#).

- - estimate  
The default, and independent of [innodb\\_io\\_capacity](#). If the oldest modified age exceeds 1/2 of the maximum age capacity, blocks will be flushed every second at a rate determined by the number of modified blocks, LSN progress speed and the average age of all modified blocks.

- - keep\_average  
Attempts to keep the I/O rate constant by using a shorter loop cycle of one tenth of a second. Designed for SSD cards.

- **Commandline:**

```
--innodb-adaptive-checkpoint=#
```

- **Scope:** Global

- **Dynamic:** Yes

- **Data Type:**

```
string
```

- **Default Value:**

```
estimate
```

- **Valid Values:**

```
none  
or  
0  
,  
reflex  
or  
1  
,  
estimate  
or  
2  
,  
keep_average  
or  
3
```

- **Removed:** XtraDB 5.5 - replaced with [innodb\\_adaptive\\_flushing\\_method](#)

---

## innodb\_adaptive\_flushing

- **Description:** If set to

```
1
```

, the default, the server will dynamically adjust the flush rate of dirty pages in the InnoDB buffer pool. This assists to reduce brief bursts of I/O activity. If set to

```
0
```

, adaptive flushing will only take place when the limit specified by [innodb\\_adaptive\\_flushing\\_lwm](#) is reached.

- **Commandline:**

```
--innodb-adaptive-flushing={0|1}
```

- **Scope:** Global

- **Dynamic:** Yes

- **Data Type:**

```
boolean
```

- **Default Value:**

```
ON
```

## `innodb_adaptive_flushing_lwm`

- **Description:** Adaptive flushing is enabled when this low water mark percentage of the [InnoDB redo log](#) capacity is reached. Takes effect even if `innodb_adaptive_flushing` is disabled.

- **Commandline:**

```
--innodb-adaptive-flushing-lwm=#
```

- **Scope:** Global

- **Dynamic:** Yes

- **Data Type:**

double

- **Default Value:**

10.000000

- **Range:**

0

to

70

## `innodb_adaptive_flushing_method`

- **Description:** Determines the method of flushing dirty blocks from the InnoDB [buffer pool](#). If set to

native

or

0

, the original InnoDB method is used. The maximum checkpoint age is determined by the total length of all transaction log files. When the checkpoint age reaches the maximum checkpoint age, blocks are flushed. This can cause lag if there are many updates per second and many blocks with an almost identical age need to be flushed. If set to

estimate

or

1

, the default, the oldest modified age will be compared with the maximum age capacity. If it's more than 1/4 of this age, blocks are flushed every second. The number of blocks flushed is determined by the number of modified blocks, the LSN progress speed and the average age of all modified blocks. It's therefore independent of the [innodb\\_io\\_capacity](#) for the 1-second loop, but not entirely so for the 10-second loop. If set to

keep\_average

or

2

, designed specifically for SSD cards, a shorter loop cycle is used in an attempt to keep the I/O rate constant. Removed in [MariaDB 10.0](#) /XtraDB 5.6 and replaced with InnoDB flushing method from MySQL 5.6.

- **Commandline:**

```
innodb-adaptive-flushing-method=value
```

- **Scope:** Global

- **Dynamic:** Yes

- **Data Type:**

enumeration

- **Default Value:**

estimate

- **Valid Values:**

native

or

0

,

estimate

or

1

,

keep\_average

or

2

- **Removed:** MariaDB 10.0 - replaced with InnoDB flushing method from MySQL 5.6
- 

## innodb\_adaptive\_hash\_index

- **Description:** If set to

1

, the default until MariaDB 10.5 , the InnoDB hash index is enabled. Based on performance testing ( MDEV-17492 ), the InnoDB adaptive hash index helps performance in mostly read-only workloads, and could slow down performance in other environments, especially [DROP TABLE](#) , [TRUNCATE TABLE](#) , [ALTER TABLE](#) , or [DROP INDEX](#) operations.

- **Commandline:**

--innodb-adaptive-hash-index={0|1}

- **Scope:** Global

- **Dynamic:** Yes

- **Data Type:**

boolean

- **Default Value:**

OFF

(>= MariaDB 10.5 ),

ON

(<= MariaDB 10.4 )

## innodb\_adaptive\_hash\_index\_partitions

- **Description:** Specifies the number of partitions for use in adaptive searching. If set to

1

, no extra partitions are created. XtraDB-only. From MariaDB 10.2.6 (which uses InnoDB as default instead of XtraDB), this is an alias for [innodb\\_adaptive\\_hash\\_index\\_parts](#) to allow for easier upgrades.

- **Commandline:**

innodb-adaptive-hash-index-partitions=#

- **Scope:** Global

- **Dynamic:** No

- **Data Type:**

numeric

- **Default Value:**

1

- **Range:**

1

to

64

## innodb\_adaptive\_hash\_index\_parts

- **Description:** Specifies the number of partitions for use in adaptive searching. If set to

1

, no extra partitions are created.

- **Commandline:**

innodb-adaptive-hash-index-parts=#

- **Scope:** Global

- **Dynamic:** No

- **Data Type:**

numeric

- **Default Value:**

8

- **Range:**

1  
to  
512

- **Introduced:** MariaDB 10.2.2
- 

### innodb\_adaptive\_max\_sleep\_delay

- **Description:** Maximum time in microseconds to automatically adjust the `innodb_thread_sleep_delay` value to, based on the workload. Useful in extremely busy systems with hundreds of thousands of simultaneous connections.

0  
disables any limit. Deprecated and ignored from MariaDB 10.5.5 .

- **Commandline:**

--innodb-adaptive-max-sleep-delay=#

- **Scope:** Global

- **Dynamic:** Yes

- **Data Type:**

numeric

- **Default Value:**

- 0  
(>= MariaDB 10.5.5 )
- 150000  
(<= MariaDB 10.5.4 )

- **Range:**

0  
to  
1000000

- **Introduced:** MariaDB 10.0

- **Deprecated:** MariaDB 10.5.5

- **Removed:** MariaDB 10.6.0
- 

### innodb\_additional\_mem\_pool\_size

- **Description:** Size in bytes of the InnoDB memory pool used for storing information about internal data structures. Defaults to 8MB, if your application has many tables and a large structure, and this is exceeded, operating system memory will be allocated and warning messages written to the error log, in which case you should increase this value. Deprecated in MariaDB 10.0 and removed in MariaDB 10.2 along with InnoDB's internal memory allocator.

- **Commandline:**

--innodb-additional-mem-pool-size=#

- **Scope:** Global

- **Dynamic:** No

- **Data Type:**

numeric

- **Default Value:**

8388608

- **Range:**

2097152  
to  
4294967295

- **Deprecated:** MariaDB 10.0

- **Removed:** MariaDB 10.2.2
-

## innodb\_api\_bk\_commit\_interval

- **Description:** Time in seconds between auto-commits for idle connections using the InnoDB memcached interface (not implemented in MariaDB).
  - **Commandline:**  
--innodb-api-bk-commit-interval=#
  - **Scope:** Global
  - **Dynamic:** Yes
  - **Data Type:**  
numeric
  - **Default Value:**  
5
  - **Range:**  
1  
to  
1073741824
  - **Introduced:** [MariaDB 10.0](#)
  - **Removed:** [MariaDB 10.2.4](#)
- 

## innodb\_api\_disable\_rowlock

- **Description:** For use with MySQL's memcached (not implemented in MariaDB)
  - **Commandline:**  
--innodb-api-disable-rowlock={0|1}
  - **Scope:** Global
  - **Dynamic:** No
  - **Data Type:**  
boolean
  - **Default Value:**  
OFF
  - **Introduced:** [MariaDB 10.0](#)
  - **Removed:** [MariaDB 10.2.4](#)
- 

## innodb\_api\_enable\_binlog

- **Description:** For use with MySQL's memcached (not implemented in MariaDB)
  - **Commandline:**  
--innodb-api-enable-binlog={0|1}
  - **Scope:** Global
  - **Dynamic:** No
  - **Data Type:**  
boolean
  - **Default Value:**  
OFF
  - **Introduced:** [MariaDB 10.0](#)
  - **Removed:** [MariaDB 10.2.4](#)
- 

## innodb\_api\_enable\_mdl

- **Description:** For use with MySQL's memcached (not implemented in MariaDB)
- **Commandline:**  
--innodb-api-enable-mdl={0|1}

- **Scope:** Global

- **Dynamic:** No

- **Data Type:**

boolean

- **Default Value:**

OFF

- **Introduced:** MariaDB 10.0

- **Removed:** MariaDB 10.2.4
- 

## innodb\_api\_trx\_level

- **Description:** For use with MySQL's memcached (not implemented in MariaDB)

- **Commandline:**

--innodb-api-trx-level=#

- **Scope:** Global

- **Dynamic:** Yes

- **Data Type:**

numeric

- **Default Value:**

0

- **Introduced:** MariaDB 10.0

- **Removed:** MariaDB 10.2.4
- 

## innodb\_auto\_lru\_dump

- **Description:** Renamed `innodb_buffer_pool_restore_at_startup` since XtraDB 5.5.10-20.1, which was in turn replaced by `innodb_buffer_pool_load_at_startup` in MariaDB 10.0 .

- **Commandline:**

--innodb-auto-lru-dump=#

- **Removed:** XtraDB 5.5.10-20.1
- 

## innodb\_autoextend\_increment

- **Description:** Size in MB to increment an auto-extending shared tablespace file when it becomes full. If `innodb_file_per_table` was set to

1

, this setting does not apply to the resulting per-table tablespace files, which are automatically extended in their own way.

- **Commandline:**

--innodb-autoextend-increment=#

- **Scope:** Global

- **Dynamic:** Yes

- **Data Type:**

numeric

- **Default Value:**

64

(from MariaDB 10.0 )

8

(before MariaDB 10.0 ),

- **Range:**

1

to

1000

## `innodb_autoinc_lock_mode`

- **Description:** The lock mode that is used when generating

`AUTO_INCREMENT`

values for InnoDB tables.

- Valid values are:

0

is the traditional lock mode.

1

is the consecutive lock mode.

2

is the interleaved lock mode.

- In order to use [Galera Cluster](#), the lock mode needs to be set to

2

- See [AUTO\\_INCREMENT Handling in InnoDB: AUTO\\_INCREMENT Lock Modes](#) for more information.

- **Commandline:**

`--innodb-autoinc-lock-mode=#`

- **Scope:** Global

- **Dynamic:** No

- **Data Type:**

numeric

- **Default Value:**

1

- **Range:**

0

to

2

## `innodb_background_scrub_data_check_interval`

- **Description:** Check if spaces needs scrubbing every `innodb_background_scrub_data_check_interval` seconds. See [Data Scrubbing](#). Deprecated and ignored from [MariaDB 10.5.2](#).

- **Commandline:**

`--innodb-background-scrub-data-check-interval=#`

- **Scope:** Global

- **Dynamic:** Yes

- **Data Type:**

numeric

- **Default Value:**

3600

- **Range:**

1

to

4294967295

- **Introduced:** [MariaDB 10.1.3](#)

- **Deprecated:** [MariaDB 10.5.2](#)

- **Removed:** [MariaDB 10.6.0](#)

## `innodb_background_scrub_data_compressed`

- **Description:** Enable scrubbing of compressed data by background threads (same as encryption\_threads). See [Data Scrubbing](#). Deprecated and ignored from [MariaDB 10.5.2](#).
  - **Commandline:**

```
--innodb-background-scrub-data-compressed={0|1}
```
  - **Scope:** Global
  - **Dynamic:** Yes
  - **Data Type:**  
boolean
  - **Default Value:**  
0
  - **Introduced:** [MariaDB 10.1.3](#)
  - **Deprecated:** [MariaDB 10.5.2](#)
  - **Removed:** [MariaDB 10.6.0](#)
- 

### innodb\_background\_scrub\_data\_interval

- **Description:** Scrub spaces that were last scrubbed longer than this number of seconds ago. See [Data Scrubbing](#). Deprecated and ignored from [MariaDB 10.5.2](#).
  - **Commandline:**

```
--innodb-background-scrub-data-interval=#
```
  - **Scope:** Global
  - **Dynamic:** Yes
  - **Data Type:**  
numeric
  - **Default Value:**  
604800
  - **Range:**  
1  
to  
4294967295
  - **Introduced:** [MariaDB 10.1.3](#)
  - **Deprecated:** [MariaDB 10.5.2](#)
  - **Removed:** [MariaDB 10.6.0](#)
- 

### innodb\_background\_scrub\_data\_uncompressed

- **Description:** Enable scrubbing of uncompressed data by background threads (same as encryption\_threads). See [Data Scrubbing](#). Deprecated and ignored from [MariaDB 10.5.2](#).
  - **Commandline:**

```
--innodb-background-scrub-data-uncompressed={0|1}
```
  - **Scope:** Global
  - **Dynamic:** Yes
  - **Data Type:**  
boolean
  - **Default Value:**  
0
  - **Introduced:** [MariaDB 10.1.3](#)
  - **Deprecated:** [MariaDB 10.5.2](#)
  - **Removed:** [MariaDB 10.6.0](#)
- 

### innodb\_blocking\_buffer\_pool\_restore

- **Description:** If set to

1

(

0

is default), XtraDB will wait until the least-recently used (LRU) dump is completely restored upon restart before reporting back to the server that it has successfully started up. Available with XtraDB only, not InnoDB.

- **Commandline:**

`innodb-blocking-buffer-pool-restore={0|1}`

- **Scope:** Global

- **Dynamic:** No

- **Data Type:**

boolean

- **Default Value:**

OFF

- **Removed:** MariaDB 10.0.0
- 

## innodb\_buf\_dump\_status\_frequency

- **Description:** Determines how often (as a percent) the buffer pool dump status should be printed in the logs. For example,

10

means that the buffer pool dump status is printed when every 10% of the number of buffer pool pages are dumped. The default is

0

(only start and end status is printed).

- **Commandline:**

`--innodb-buf-dump-status-frequency=#`

- **Scope:** Global

- **Dynamic:** Yes

- **Data Type:**

numeric

- **Default Value:**

0

- **Range:**

0

to

100

- **Introduced:** MariaDB 10.1.6
- 

## innodb\_buffer\_pool\_chunk\_size

- **Description:** Chunk size used for dynamically resizing the [buffer pool](#). Note that changing this setting can change the size of the buffer pool. When [large-pages](#) is used this value is effectively rounded up to the next multiple of [large-page-size](#). See [Setting Innodb Buffer Pool Size Dynamically](#). From [MariaDB 10.8.0](#), the variable is autosized based on the [buffer pool size](#).

- **Commandline:**

`--innodb-buffer-pool-chunk-size=#`

- **Scope:** Global

- **Dynamic:** No

- **Data Type:**

numeric

- **Default Value:**

◦

`autosize (0)`

, resulting in [innodb\\_buffer\\_pool\\_size](#) /64, if [large\\_pages](#) round down to multiple of largest page size, with 1MiB minimum (>= [MariaDB 10.8.1](#))

◦

`134217728`

(<= [MariaDB 10.8.0](#))

- **Range:**

- - 0 , as autosize, and then 1048576 to 18446744073709551615 (>= MariaDB 10.8 )
    - 1048576 to innodb\_buffer\_pool\_size / innodb\_buffer\_pool\_instances (<= MariaDB 10.7 )
  - **Introduced:** MariaDB 10.2.2
- 

## innodb\_buffer\_pool\_dump\_at\_shutdown

- **Description:** Whether to record pages cached in the [buffer pool](#) on server shutdown, which reduces the length of the warmup the next time the server starts. The related [innodb\\_buffer\\_pool\\_load\\_at\\_startup](#) specifies whether the buffer pool is automatically warmed up at startup.
  - **Commandline:**
    - innodb-buffer-pool-dump-at-shutdown={0|1}
  - **Scope:** Global
  - **Dynamic:** Yes
  - **Data Type:**
    - boolean
  - **Default Value:**
    - ON (>= MariaDB 10.2.2 )
    - OFF (<= MariaDB 10.2.1 )
  - **Introduced:** MariaDB 10.0
- 

## innodb\_buffer\_pool\_dump\_now

- **Description:** Immediately records pages stored in the [buffer pool](#). The related [innodb\\_buffer\\_pool\\_load\\_now](#) does the reverse, and will immediately warm up the buffer pool.
  - **Commandline:**
    - innodb-buffer-pool-dump-now={0|1}
  - **Scope:** Global
  - **Dynamic:** Yes
  - **Data Type:**
    - boolean
  - **Default Value:**
    - OFF
  - **Introduced:** MariaDB 10.0
- 

## innodb\_buffer\_pool\_dump\_pct

- **Description:** Dump only the hottest N% of each [buffer pool](#), defaults to 100 until MariaDB 10.2.1 . Since MariaDB 10.2.2 , defaults to 25% along with the changes to [innodb\\_buffer\\_pool\\_dump\\_at\\_shutdown](#) and [innodb\\_buffer\\_pool\\_load\\_at\\_startup](#).
- **Commandline:**
  - innodb-buffer-pool-dump-pct={0|1}
- **Scope:** Global
- **Dynamic:** Yes
- **Data Type:**
  - boolean

- **Default Value:**

- - 25  
( $\geq$  MariaDB 10.2.2)
  - - 100  
( $\leq$  MariaDB 10.2.1)

- **Range:**

- 1  
to  
100

- **Introduced:** MariaDB 10.1.10

---

### innodb\_buffer\_pool\_evict

- **Description:** Evict pages from the buffer pool. If set to "uncompressed" then all uncompressed pages are evicted from the buffer pool. Variable to be used only for testing. Only exists in DEBUG builds.

- **Commandline:**

- innodb-buffer-pool-evict=#

- **Scope:** Global

- **Dynamic:** Yes

- **Data Type:**

- string

- **Default Value:**

- ""

- **Valid Values:** "" or "uncompressed"

---

### innodb\_buffer\_pool\_filename

- **Description:** The file that holds the **buffer pool** list of page numbers set by [innodb\\_buffer\\_pool\\_dump\\_at\\_shutdown](#) and [innodb\\_buffer\\_pool\\_dump\\_now](#).

- **Commandline:**

- innodb-buffer-pool-filename=file

- **Scope:** Global

- **Dynamic:** Yes

- **Data Type:**

- string

- **Default Value:**

- ib\_buffer\_pool

- **Introduced:** MariaDB 10.0

---

### innodb\_buffer\_pool\_instances

- **Description:** If **innodb\_buffer\_pool\_size** is set to more than 1GB, **innodb\_buffer\_pool\_instances** divides the **InnoDB** buffer pool into this many instances. The default was 1 in [MariaDB 5.5](#), but for large systems with buffer pools of many gigabytes, many instances can help reduce contention concurrency. The default is 8 in MariaDB 10 (except on Windows 32-bit, where it varies according to **innodb\_buffer\_pool\_size**, or from [MariaDB 10.2.2](#), where it is set to 1 if **innodb\_buffer\_pool\_size** < 1GB). Each instance manages its own data structures and takes an equal portion of the total buffer pool size, so for example if **innodb\_buffer\_pool\_size** is 4GB and **innodb\_buffer\_pool\_instances** is set to 4, each instance will be 1GB. Each instance should ideally be at least 1GB in size. Deprecated and ignored from [MariaDB 10.5.1](#), as the original reasons for splitting the buffer pool have mostly gone away.

- **Commandline:**

- innodb-buffer-pool-instances=#

- **Scope:** Global

- **Dynamic:** No

- **Data Type:**

numeric

- **Default Value:** >= MariaDB 10.0.4 :

8

,

1

(>= MariaDB 10.2.2 if innodb\_buffer\_pool\_size < 1GB), or dependent on innodb\_buffer\_pool\_size (Windows 32-bit)

- **Deprecated:** MariaDB 10.5.1

- **Removed:** MariaDB 10.6.0

---

## innodb\_buffer\_pool\_load\_abort

- **Description:** Aborts the process of restoring buffer pool contents started by innodb\_buffer\_pool\_load\_at\_startup or innodb\_buffer\_pool\_load\_now .

- **Commandline:**

--innodb-buffer-pool-load-abort={0|1}

- **Scope:** Global

- **Dynamic:** Yes

- **Data Type:**

boolean

- **Default Value:**

OFF

---

## innodb\_buffer\_pool\_load\_at\_startup

- **Description:** Specifies whether the buffer pool is automatically warmed up when the server starts by loading the pages held earlier. The related innodb\_buffer\_pool\_dump\_at\_shutdown specifies whether pages are saved at shutdown. If the buffer pool is large and taking a long time to load, increasing innodb\_io\_capacity at startup may help.

- **Commandline:**

--innodb-buffer-pool-load-at-startup={0|1}

- **Scope:** Global

- **Dynamic:** No

- **Data Type:**

boolean

- **Default Value:**

◦

ON

(>= MariaDB 10.2.2 )

◦

OFF

(<= MariaDB 10.2.1 )

---

## innodb\_buffer\_pool\_load\_now

- **Description:** Immediately warms up the buffer pool by loading the stored data pages. The related innodb\_buffer\_pool\_dump\_now does the reverse, and immediately records pages stored in the buffer pool.

- **Commandline:**

--innodb-buffer-pool-load-now={0|1}

- **Scope:** Global

- **Dynamic:** Yes

- **Data Type:**

boolean

- **Default Value:**

OFF

- **Introduced:** MariaDB 10.0
- 

### innodb\_buffer\_pool\_load\_pages\_abort

- **Description:** Number of pages during a buffer pool load to process before signaling `innodb_buffer_pool_load_abort=1`. Debug builds only.
- **Commandline:**

```
--innodb-buffer-pool-load-pages-abort=#
```

- **Scope:** Global

- **Dynamic:** Yes

- **Data Type:**

numeric

- **Default Value:**

9223372036854775807

- **Range:**

1

to

9223372036854775807

- **Introduced:** MariaDB 10.3
- 

### innodb\_buffer\_pool\_populate

- **Description:** When set to

1

(

0

is default), XtraDB will preallocate pages in the buffer pool on starting up so that NUMA allocation decisions are made while the buffer cache is still clean. XtraDB only. This option was made ineffective in MariaDB 10.0.23 . Added as a deprecated and ignored option in MariaDB 10.2.6 (which uses InnoDB as default instead of XtraDB) to allow for easier upgrades.

- **Commandline:**

```
innodb-buffer-pool-populate={0|1}
```

- **Scope:** Global

- **Dynamic:** No

- **Data Type:**

boolean

- **Default Value:**

OFF

- **Deprecated:** MariaDB 10.0.23

- **Removed:** MariaDB 10.3.0
- 

### innodb\_buffer\_pool\_restore\_at\_startup

- **Description:** Time in seconds between automatic buffer pool dumps. If set to a non-zero value, XtraDB will also perform an automatic restore of the `buffer pool` at startup. If set to

0

, automatic dumps are not performed, nor automatic restores on startup. Replaced by `innodb_buffer_pool_load_at_startup` in MariaDB 10.0 .

- **Commandline:**

```
innodb-buffer-pool-restore-at-startup
```

- **Scope:** Global

- **Dynamic:** Yes

- **Data Type:**

numeric

- **Default Value:**

0

- **Range - 32 bit:**

0  
to  
4294967295

- **Range - 64 bit:**

0  
to  
18446744073709547520

- **Removed:** [MariaDB 10.0](#) - replaced by `innodb_buffer_pool_load_at_startup`
- 

### `innodb_buffer_pool_shm_checksum`

- **Description:** Used with Percona's SHM buffer pool patch in XtraDB 5.5. Was shortly deprecated and removed in XtraDB 5.6. XtraDB only.

- **Commandline:**

`innodb-buffer-pool-shm-checksum={0|1}`

- **Scope:** Global

- **Dynamic:** No

- **Data Type:**

boolean

- **Default Value:**

ON

- **Removed:** [MariaDB 10.0](#)
- 

### `innodb_buffer_pool_shm_key`

- **Description:** Used with Percona's SHM buffer pool patch in XtraDB 5.5. Later deprecated in XtraDB 5.5, and removed in XtraDB 5.6.

- **Commandline:**

`innodb-buffer-pool-shm-key={0|1}`

- **Scope:** Global

- **Dynamic:** No

- **Data Type:**

boolean

- **Default Value:**

0

- **Removed:** [MariaDB 10.0](#)
- 

### `innodb_buffer_pool_size`

- **Description:** InnoDB buffer pool size in bytes. The primary value to adjust on a database server with entirely/primarily [InnoDB](#) tables, can be set up to 80% of the total memory in these environments. See the [InnoDB Buffer Pool](#) for more on setting this variable, and also [Setting InnoDB Buffer Pool Size Dynamically](#) if doing so dynamically.

- **Commandline:**

`--innodb-buffer-pool-size=#`

- **Scope:** Global

- **Dynamic:** Yes ( $\geq$  [MariaDB 10.2.2](#)), No ( $\leq$  [MariaDB 10.2.1](#))

- **Data Type:**

numeric

- **Default Value:**

134217728  
(128iMB)

- **Range:**
  - Minimum:
    - 5242880  
(5MiB ) for [InnoDB Page Size](#) <= 16k otherwise
    - 25165824  
(24MiB) for [InnoDB Page Size](#) > 16k (for versions less than next line)
  - Minimum:
    - 2MiB  
[InnoDB Page Size](#) = 4k,
    - 3MiB  
[InnoDB Page Size](#) = 8k,
    - 5MiB  
[InnoDB Page Size](#) = 16k,
    - 10MiB  
[InnoDB Page Size](#) = 32k,
    - 20MiB  
[InnoDB Page Size](#) = 64k, (>= [MariaDB 10.2.42](#) , >= [MariaDB 10.3.33](#) , >= [MariaDB 10.4.23](#) , >= [MariaDB 10.5.14](#) , >= [MariaDB 10.6.6](#) , >= [MariaDB 10.7.2](#) )
  - Minimum: 1GiB for [innodb\\_buffer\\_pool\\_instances](#) > 1 (<= [MariaDB 10.7](#) )
  - Maximum:
    - 9223372036854775807  
(8192PB) (all versions)

## innodb\_change\_buffer\_dump

- **Description:** If set, causes the contents of the InnoDB change buffer to be dumped to the server error log at startup. Only available in debug builds.
- **Scope:** Global
- **Dynamic:** No
- **Data Type:**
  - boolean
- **Default Value:**
  - OFF
- **Introduced:** [MariaDB 10.2.28](#) , [MariaDB 10.3.19](#) , [MariaDB 10.4.9](#)

## innodb\_change\_buffer\_max\_size

- **Description:** Maximum size of the [InnoDB Change Buffer](#) as a percentage of the total buffer pool. The default is 25%, and this can be increased up to 50% for servers with high write activity, and lowered down to 0 for servers used exclusively for reporting.
- **Commandline:**
  - innodb-change-buffer-max-size=#
- **Scope:** Global
- **Dynamic:** Yes
- **Data Type:**
  - numeric
- **Default Value:**
  - 25
- **Range:**
  - 0
  - to
  - 50
- **Introduced:** [MariaDB 10.0](#)

## innodb\_change\_buffering

- **Description:** Sets how [InnoDB](#) change buffering is performed. See [InnoDB Change Buffering](#) for details on the settings. Deprecated and ignored

from [MariaDB 10.9.0](#) .

- **Commandline:**  
--innodb-change-buffering=#
- **Scope:** Global
- **Dynamic:** Yes
- **Data Type:**  
enumeration  
(>= [MariaDB 10.3.7](#) ),  
string  
(<= [MariaDB 10.3.6](#) )
- **Default Value:**
  - >= [MariaDB 10.5.15](#) , [MariaDB 10.6.7](#) , [MariaDB 10.7.3](#) , [MariaDB 10.8.2](#) :  
none
  - <= [MariaDB 10.5.14](#) , [MariaDB 10.6.6](#) , [MariaDB 10.7.2](#) , [MariaDB 10.8.1](#) :  
all
- **Valid Values:**  
inserts  
,  
none  
,  
deletes  
,  
purges  
,  
changes  
,  
all
- **Deprecated:** [MariaDB 10.9.0](#)

---

## innodb\_change\_buffering\_debug

- **Description:** If set to
  - 1  
, an [InnoDB Change Buffering](#) debug flag is set.
  - 1  
forces all changes to the change buffer, while
  - 2  
causes a crash at merge.
  - 0  
, the default, indicates no flag is set. Only available in debug builds.
- **Commandline:**  
--innodb-change-buffering-debug=#
- **Scope:** Global
- **Dynamic:** Yes
- **Data Type:**  
numeric
- **Default Value:**  
0
- **Range:**  
0  
to  
2

---

## innodb\_checkpoint\_age\_target

- **Description:** The maximum value of the checkpoint age. If set to
  - 0  
, has no effect. Removed in [MariaDB 10.0](#) /XtraDB 5.6 and replaced with InnoDB flushing method from MySQL 5.6.

- **Commandline:**

```
innodb_checkpoint_age_target=#
```

- **Scope:** Global

- **Dynamic:** Yes

- **Data Type:**

```
    numeric
```

- **Default Value:**

```
    0
```

- **Range:**

```
    0
```

```
    upwards
```

- **Removed:** MariaDB 10.0 - replaced with InnoDB flushing method from MySQL 5.6.

---

## innodb\_checksum\_algorithm

- **Description:** Specifies how the InnoDB tablespace checksum is generated and verified.

```
◦
```

```
    innodb
```

```
        : Backwards compatible with earlier versions (<= MariaDB 5.5 ). Deprecated in MariaDB 10.3.29 , MariaDB 10.4.19 , MariaDB 10.5.10 and removed in MariaDB 10.6 . If really needed, data files can still be converted with innoread .
```

```
◦
```

```
    crc32
```

```
        : A newer, faster algorithm, but incompatible with earlier versions. Tablespace blocks will be converted to the new format over time, meaning that a mix of checksums may be present.
```

```
◦
```

```
    full_crc32
```

```
    and
```

```
    strict_full_crc32
```

```
        : From MariaDB 10.4.3 . Permits encryption to be supported over a SPATIAL INDEX , which
```

```
    crc32
```

```
        does not support. Newly-created data files will carry a flag that indicates that all pages of the file will use a full CRC-32C checksum over the entire page contents (excluding the bytes where the checksum is stored, at the very end of the page). Such files will always use that checksum, no matter what parameter
```

```
    innodb_checksum_algorithm
```

```
    is assigned to. Even if
```

```
    innodb_checksum_algorithm
```

```
        is modified later, the same checksum will continue to be used. A special flag will be set in the FSP_SPACE_FLAGS in the first data page to indicate the new format of checksum and encryption/page_compressed. ROW_FORMAT=COMPRESSED tables will only use the old format. These tables do not support new features, such as larger innodb_page_size or instant ADD/DROP COLUMN. Also cleans up the MariaDB tablespace flags - flags are reserved to store the page_compressed compression algorithm, and to store the compressed payload length, so that checksum can be computed over the compressed (and possibly encrypted) stream and can be validated without decrypting or decompressing the page. In the full_crc32 format, there no longer are separate before-encryption and after-encryption checksums for pages. The single checksum is computed on the page contents that is written to the file. See MDEV-12026 for details.
```

```
◦
```

```
    none
```

```
        : Writes a constant rather than calculate a checksum. Deprecated in MariaDB 10.3.29 , MariaDB 10.4.19 , MariaDB 10.5.10 and removed in MariaDB 10.6 as was mostly used to disable the original, slow, page checksum for benchmarking purposes.
```

```
◦
```

```
    strict_crc32
```

```
,
```

```
    strict_innodb
```

```
    and
```

```
    strict_none
```

```
        : The options are the same as the regular options, but InnoDB will halt if it comes across a mix of checksum values. These are faster, as both new and old checksum values are not required, but can only be used when setting up tablespaces for the first time.
```

- **Commandline:**

```
--innodb_checksum_algorithm=#
```

- **Scope:** Global

- **Dynamic:** Yes

- **Data Type:**

```
    enumeration
```

- **Default Value:**

```
◦
```

```
    full_crc32
```

- - (>= MariaDB 10.5.0 )
- - crc32
    - (>= MariaDB 10.2.2 )
- - innodb
    - (<= MariaDB 10.2.1 )

• **Valid Values:**

- >= MariaDB 10.6.0 :
  - crc32
  - ,
  - full\_crc32
  - ,
  - strict\_crc32
  - ,
  - strict\_full\_crc32
- MariaDB 10.5 , >= MariaDB 10.4.3 :
  - innodb
  - ,
  - crc32
  - ,
  - full\_crc32
  - ,
  - none
  - ,
  - strict\_innodb
  - ,
  - strict\_crc32
  - ,
  - strict\_none
  - ,
  - strict\_full\_crc32
- <= MariaDB 10.4.2 :
  - innodb
  - ,
  - crc32
  - ,
  - none
  - ,
  - strict\_innodb
  - ,
  - strict\_crc32
  - ,
  - strict\_none

- **Introduced:** MariaDB 10.0
- 

### `innodb_checksums`

- **Description:** By default, InnoDB performs checksum validation on all pages read from disk, which provides extra fault tolerance. You would usually want this set to

```

1
in production environments, although setting it to
0
can provide marginal performance improvements. Deprecated and functionality replaced by innodb_checksum_algorithm in MariaDB
10.0 , and should be removed to avoid conflicts.
ON
is equivalent to
--innodb_checksum_algorithm=innodb
and
OFF
to
--innodb_checksum_algorithm=none
.
```

- **Commandline:**

```
--innodb-checksums
,
```

```
--skip-innodb-checksums
```

- **Scope:** Global
  - **Dynamic:** No
  - **Data Type:**  
boolean
  - **Default Value:**  
ON
  - **Deprecated:** MariaDB 10.0
  - **Removed:** MariaDB 10.5.0
- 

## innodb\_cleaner\_lsn\_age\_factor

- **Description:** XtraDB has enhanced page cleaner heuristics, and with these in place, the default InnoDB adaptive flushing may be too aggressive. As a result, a new LSN age factor formula has been introduced, controlled by this variable. The default setting,

high\_checkpoint  
, uses the new formula, while the alternative,  
legacy  
, uses the original algorithm. XtraDB only. Added as a deprecated and ignored option in MariaDB 10.2.6 (which uses InnoDB as default instead of XtraDB) to allow for easier upgrades.

- **Commandline:**  
`--innodb-cleaner-lsn-age-factor=value`

- **Scope:** Global
- **Dynamic:** Yes
- **Data Type:**  
enum

- **Default Value:**

- deprecated  
(>= MariaDB 10.2.6 )
- high\_checkpoint  
(<= MariaDB 10.1 )

- **Valid Values:**

- high\_checkpoint  
,  
legacy  
(<= MariaDB 10.1 )
- deprecated  
,  
high\_checkpoint  
,  
legacy  
(>= MariaDB 10.2.6 )

- **Introduced:** MariaDB 10.0.9
  - **Deprecated:** MariaDB 10.2.6
  - **Removed:** MariaDB 10.3.0
- 

## innodb\_cmp\_per\_index\_enabled

- **Description:** If set to

ON  
(  
OFF

is default), per-index compression statistics are stored in the INFORMATION\_SCHEMA.INNODB\_CMP\_PER\_INDEX table. These are expensive to record, so this setting should only be changed with care, such as for performance tuning on development or replica servers.

- **Commandline:**

`--innodb-cmp-per-index-enabled={0|1}`

- **Scope:** Global

- **Dynamic:** Yes

- **Data Type:**

boolean

- **Default Value:**

OFF

- **Introduced:** MariaDB 10.0
- 

## innodb\_commit\_concurrency

- **Description:** Limit to the number of transaction threads that can commit simultaneously. 0, the default, imposes no limit. While you can change from one positive limit to another at runtime, you cannot set this variable to 0, or change it from 0, while the server is running. Deprecated and ignored from MariaDB 10.5.5.

- **Commandline:**

--innodb-commit-concurrency=#

- **Scope:** Global

- **Dynamic:** Yes

- **Data Type:**

numeric

- **Default Value:**

0

- **Range:**

0

to

1000

- **Deprecated:** MariaDB 10.5.5

- **Removed:** MariaDB 10.6.0
- 

## innodb\_compression\_algorithm

- **Description:** Compression algorithm used for InnoDB page compression . The supported values are:

◦

none

: Pages are not compressed.

◦

zlib

: Pages are compressed using the bundled

[zlib](#)

compression algorithm.

◦

1z4

: Pages are compressed using the

[1z4](#)

compression algorithm.

◦

1zo

: Pages are compressed using the

[1zo](#)

compression algorithm.

◦

lzma

: Pages are compressed using the

[lzma](#)

- compression algorithm.
    - bzip2
      - : Pages are compressed using the
    - bzip2
      - bzip2
      - compression algorithm.
    - snappy
      - : Pages are compressed using the
    - snappy
      - snappy
      - algorithm.
  - On many distributions, MariaDB may not support all page compression algorithms by default. From [MariaDB 10.7](#), libraries can be installed as a plugin. See [Compression Plugins](#).
  - See [InnoDB Page Compression: Configuring the InnoDB Page Compression Algorithm](#) for more information.
- **Commandline:**
    - innodb-compression-algorithm=value
  - **Scope:** Global
  - **Dynamic:** Yes
  - **Data Type:**
    - enum
  - **Default Value:**
    - zlib
      - ([=> MariaDB 10.2.4](#) , [MariaDB 10.1.22](#) ),
      - none
        - (=< MariaDB 10.2.3 , [MariaDB 10.1.21](#) )
  - **Valid Values:**
    - none
    - ,
    - zlib
    - ,
    - lz4
    - ,
    - lzo
    - ,
    - lzma
    - ,
    - bzip2
    - or
    - snappy
    - ( [MariaDB 10.1.3](#) )
  - **Introduced:** [MariaDB 10.1.0](#)
- 

## innodb\_compression\_default

- **Description:** Whether or not [InnoDB page compression](#) is enabled by default for new tables.
    - The default value is
      - OFF
      - , which means new tables are not compressed.
    - See [InnoDB Page Compression: Enabling InnoDB Page Compression by Default](#) for more information.
    - **Commandline:**
      - innodb-compression-default={0|1}
    - **Scope:** Global, Session
    - **Dynamic:** Yes
    - **Data Type:**
      - boolean
    - **Default Value:**
      - OFF
    - **Introduced:** [MariaDB 10.2.3](#)
-

## `innodb_compression_failure_threshold_pct`

- **Description:** Specifies the percentage cutoff for expensive compression failures during updates to a table that uses [InnoDB page compression](#), after which free space is added to each new compressed page, dynamically adjusted up to the level set by `innodb_compression_pad_pct_max`. Zero disables checking of compression efficiency and adjusting padding.
    - See [InnoDB Page Compression: Configuring the Failure Threshold and Padding](#) for more information.
  - **Commandline:**

```
--innodb-compression-failure-threshold-pct=#
```
  - **Scope:** Global
  - **Dynamic:** Yes
  - **Data Type:**

numeric
  - **Default Value:**

5
  - **Range:**

0  
to  
100
  - **Introduced:** [MariaDB 10.0](#)
- 

## `innodb_compression_level`

- **Description:** Specifies the default level of compression for tables that use [InnoDB page compression](#).
    - Only a subset of InnoDB page compression algorithms support compression levels. If an InnoDB page compression algorithm does not support compression levels, then the compression level value is ignored.
    - The compression level can be set to any value between
      - 1
      - and
      - 9
      - . The default compression level is
      - 6
      - . The range goes from the fastest to the most compact, which means that
      - 1
      - is the fastest and
      - 9
      - is the most compact.
    - See [InnoDB Page Compression: Configuring the Default Compression Level](#) for more information.
  - **Commandline:**

```
--innodb-compression-level=#
```
  - **Scope:** Global
  - **Dynamic:** Yes
  - **Data Type:**

numeric
  - **Default Value:**

6
  - **Range:**

1  
to  
9
  - **Introduced:** [MariaDB 10.0](#)
- 

## `innodb_compression_pad_pct_max`

- **Description:** The maximum percentage of reserved free space within each compressed page for tables that use [InnoDB page compression](#). Reserved free space is used when the page's data is reorganized and might be recompressed. Only used when `innodb_compression_failure_threshold_pct` is not zero, and the rate of compression failures exceeds its setting.

- See [InnoDB Page Compression: Configuring the Failure Threshold and Padding](#) for more information.

- **Commandline:**

```
--innodb-compression-pad-pct-max=#
```

- **Scope:** Global

- **Dynamic:** Yes

- **Data Type:**

```
    numeric
```

- **Default Value:**

```
    50
```

- **Range:**

```
    0
```

```
    to
```

```
    75
```

- **Introduced:** [MariaDB 10.0](#)

---

## innodb\_concurrency\_tickets

- **Description:** Number of times a newly-entered thread can enter and leave InnoDB until it is again subject to the limitations of [innodb\\_thread\\_concurrency](#) and may possibly be queued. Deprecated and ignored from [MariaDB 10.5.5](#).

- **Commandline:**

```
--innodb-concurrency-tickets=#
```

- **Scope:** Global

- **Dynamic:** Yes

- **Data Type:**

```
    numeric
```

- **Default Value:**

```
    ◦
```

```
        0  
        (>= MariaDB 10.5.5 )
```

```
    ◦
```

```
        5000  
        (<= MariaDB 10.5.4 )
```

- **Range:**

```
    1
```

```
    to
```

```
    18446744073709551615
```

- **Deprecated:** [MariaDB 10.5.5](#)

- **Removed:** [MariaDB 10.6.0](#)

---

## innodb\_corrupt\_table\_action

- **Description:** What action to perform when a corrupt table is found. XtraDB only.

- When set to

```
    assert  
    , the default, XtraDB will intentionally crash the server when it detects corrupted data in a single-table tablespace, with an assertion failure.
```

- When set to

```
    warn  
    , it will pass corruption as corrupt table instead of crashing, and disable all further I/O (except for deletion) on the table file.
```

- If set to

```
    salvage  
    , read access is permitted, but corrupted pages are ignored. innodb\_file\_per\_table must be enabled for this option. Previously named
```

```
    innodb_pass_corrupt_table
```

◦ Added as a deprecated and ignored option in [MariaDB 10.2.6](#) (which uses InnoDB as default instead of XtraDB) to allow for easier upgrades.

- **Commandline:**

```
    innodb-corrupt-table-action=value
```

- **Scope:** Global
- **Dynamic:** Yes
- **Data Type:**  
enumeration

- **Default Value:**

- assert  
(<= MariaDB 10.1 )
- deprecated  
(<= MariaDB 10.2.6 )

- **Valid Values:**

- deprecated
- ,
- assert
- ,
- warn
- ,
- salvage  
(>= MariaDB 10.2.6 )
- assert
- ,
- warn
- ,
- salvage  
(<= MariaDB 10.1 )

- **Deprecated:** MariaDB 10.2.6

- **Removed:** MariaDB 10.3.0

---

## innodb\_data\_file\_path

- **Description:** Individual InnoDB data files, paths and sizes. The value of `innodb_data_home_dir` is joined to each path specified by `innodb_data_file_path` to get the full directory path. If `innodb_data_home_dir` is an empty string, absolute paths can be specified here. A file size is specified with K for kilobytes, M for megabytes and G for gigabytes, and whether or not to autoextend the data file is also specified.

- **Commandline:**

```
--innodb-data-file-path=name
```

- **Scope:** Global
- **Dynamic:** No
- **Data Type:**

numeric

- **Default Value:**

```
ibdata1:12M:autoextend  
(from MariaDB 10.0 ),  
ibdata1:10M:autoextend  
(before MariaDB 10.0 )
```

---

## innodb\_data\_home\_dir

- **Description:** Directory path for all InnoDB data files in the shared tablespace (assuming `innodb_file_per_table` is not enabled). File-specific information can be added in `innodb_data_file_path`, as well as absolute paths if `innodb_data_home_dir` is set to an empty string.

- **Commandline:**

```
--innodb-data-home-dir=path
```

- **Scope:** Global
- **Dynamic:** No
- **Data Type:**  
directory name

- **Default Value:**

The MariaDB data directory

## `innodb_deadlock_detect`

- **Description:** By default, the InnoDB deadlock detector is enabled. If set to off, deadlock detection is disabled and MariaDB will rely on `innodb_lock_wait_timeout` instead. This may be more efficient in systems with high concurrency as deadlock detection can cause a bottleneck when a number of threads have to wait for the same lock.

- **Commandline:**

```
--innodb-deadlock-detect
```

- **Scope:** Global

- **Dynamic:** Yes

- **Data Type:**

boolean

- **Default Value:**

1

- **Introduced:** [MariaDB 10.2.6](#)

## `innodb_deadlock_report`

- **Description:** How to report deadlocks (if `innodb_deadlock_detect=ON` ).

◦

off

: Do not report any details of deadlocks.

◦

basic

: Report transactions and waiting locks.

◦

full

: Default. Report transactions, waiting locks and blocking locks.

- **Commandline:**

```
--innodb-deadlock-report=val
```

- **Scope:** Global

- **Dynamic:** Yes

- **Data Type:**

enum

- **Default Value:**

full

- **Valid Values:**

off

,

basic

,

full

- **Introduced:** [MariaDB 10.6.0](#)

## `innodb_default_page_encryption_key`

- **Description:** Encryption key used for page encryption.

◦ See [Data-at-Rest Encryption](#) and [InnoDB Encryption Keys](#) for more information.

- **Commandline:**

```
--innodb-default-page-encryption-key=#
```

- **Scope:** Global

- **Dynamic:** Yes

- **Data Type:**

numeric

- **Default Value:**

1

- **Range:**

1  
to  
255

- **Introduced:** MariaDB 10.1.3

- **Removed:** MariaDB 10.1.4

---

## innodb\_default\_encryption\_key\_id

- **Description:** ID of encryption key used by default to encrypt InnoDB tablespaces.

- See [Data-at-Rest Encryption](#) and [InnoDB Encryption Keys](#) for more information.

- **Commandline:**

--innodb-default-encryption-key-id=#

- **Scope:** Global, Session

- **Dynamic:** Yes

- **Data Type:**

numeric

- **Default Value:**

1

- **Range:**

1  
to  
4294967295

- **Introduced:** MariaDB 10.1.4

---

## innodb\_default\_row\_format

- **Description:** Specifies the default [row format](#) to be used for InnoDB tables. The compressed row format cannot be set as the default.

- See [InnoDB Row Formats Overview: Default Row Format](#) for more information.

- **Commandline:**

--innodb-default-row-format=value

- **Scope:** Global

- **Dynamic:** Yes

- **Data Type:**

enum

- **Default Value:**

dynamic  
(>= MariaDB 10.2.2 ),  
compact  
(>= MariaDB 10.1.32 )

- **Valid Values:**

redundant  
,  
compact  
or  
dynamic

- **Introduced:** MariaDB 10.2.2 , Mariadb 10.1.32

---

## innodb\_defragment

- **Description:** When set to

```
1  
(the default is  
0
```

), InnoDB defragmentation is enabled. When set to FALSE, all existing defragmentation will be paused and new defragmentation commands will fail. Paused defragmentation commands will resume when this variable is set to true again. See [Defragmenting InnoDB Tablespaces](#).

- **Commandline:**

```
--innodb-defragment={0|1}
```

- **Scope:** Global

- **Dynamic:** Yes

- **Data Type:**

```
boolean
```

- **Default Value:**

```
OFF
```

- **Introduced:** [MariaDB 10.1.1](#)
- 

### `innodb_defragment_fill_factor`

- **Description:** . Indicates how full defragmentation should fill a page. Together with `innodb_defragment_fill_factor_n_recs` ensures defragmentation won't pack the page too full and cause page split on the next insert on every page. The variable indicating more defragmentation gain is the one effective. See [Defragmenting InnoDB Tablespaces](#).

- **Commandline:**

```
--innodb-defragment-fill-factor=#
```

- **Scope:** Global

- **Dynamic:** Yes

- **Data Type:**

```
double
```

- **Default Value:**

```
0.9
```

- **Range:**

```
0.7
```

```
to
```

```
1
```

- **Introduced:** [MariaDB 10.1.1](#)
- 

### `innodb_defragment_fill_factor_n_recs`

- **Description:** Number of records of space that defragmentation should leave on the page. This variable, together with `innodb_defragment_fill_factor`, is introduced so defragmentation won't pack the page too full and cause page split on the next insert on every page. The variable indicating more defragmentation gain is the one effective. See [Defragmenting InnoDB Tablespaces](#).

- **Commandline:**

```
--innodb-defragment-fill-factor-n-recs=#
```

- **Scope:** Global

- **Dynamic:** Yes

- **Data Type:**

```
numeric
```

- **Default Value:**

```
20
```

- **Range:**

```
1
```

```
to
```

```
100
```

- **Introduced:** [MariaDB 10.1.1](#)

## innodb\_defragment\_frequency

- **Description:** Maximum times per second for defragmenting a single index. This controls the number of times the defragmentation thread can request X\_LOCK on an index. The defragmentation thread will check whether 1/defragment\_frequency (s) has passed since it last worked on this index, and put the index back in the queue if not enough time has passed. The actual frequency can only be lower than this given number. See [Defragmenting InnoDB Tablespaces](#).

- **Commandline:**

```
--innodb-defragment-frequency=#
```

- **Scope:** Global

- **Dynamic:** Yes

- **Data Type:**

integer

- **Default Value:**

40

- **Range:**

1  
to  
1000

- **Introduced:** [MariaDB 10.1.1](#)

## innodb\_defragment\_n\_pages

- **Description:** Number of pages considered at once when merging multiple pages to defragment. See [Defragmenting InnoDB Tablespaces](#).

- **Commandline:**

```
--innodb-defragment-n-pages=#
```

- **Scope:** Global

- **Dynamic:** Yes

- **Data Type:**

numeric

- **Default Value:**

7

- **Range:**

2  
to  
32

- **Introduced:** [MariaDB 10.1.1](#)

## innodb\_defragment\_stats\_accuracy

- **Description:** Number of defragment stats changes there are before the stats are written to persistent storage. Defaults to zero, meaning disable defragment stats tracking. See [Defragmenting InnoDB Tablespaces](#).

- **Commandline:**

```
--innodb-defragment-stats-accuracy=#
```

- **Scope:** Global

- **Dynamic:** Yes

- **Data Type:**

numeric

- **Default Value:**

0

- **Range:**

0

to  
4294967295

- **Introduced:** MariaDB 10.1.1
- 

### innodb\_dict\_size\_limit

- **Description:** Size in bytes of a soft limit the memory used by tables in the data dictionary. Once this limit is reached, XtraDB will attempt to remove unused entries. If set to

0

, the default and standard InnoDB behavior, there is no limit to memory usage. Removed in MariaDB 10.0 /XtraDB 5.6 and replaced by MySQL 5.6's new [table\\_definition\\_cache](#) implementation.

- **Commandline:**

innodb-dict-size-limit=#

- **Scope:** Global

- **Dynamic:** Yes

- **Data Type:**

numeric

- **Default Value:**

0

- **Default Value - 32 bit:**

2147483648

- **Default Value - 64 bit:**

9223372036854775807

- **Removed:** MariaDB 10.0 - replaced by MySQL 5.6's [table\\_definition\\_cache](#) implementation.
- 

### innodb\_disable\_sort\_file\_cache

- **Description:** If set to

1

(

0

is default), the operating system file system cache for merge-sort temporary files is disabled.

- **Commandline:**

--innodb-disable-sort-file-cache={0|1}

- **Scope:** Global

- **Dynamic:** Yes

- **Data Type:**

boolean

- **Default Value:**

OFF

---

### innodb\_disallow\_writes

- **Description:** Tell InnoDB to stop any writes to disk.

- **Commandline:** None

- **Scope:** Global

- **Dynamic:** Yes

- **Data Type:**

boolean

- **Default Value:**

OFF

- **Introduced:** MariaDB 10.1.3
- 

## innodb\_doublewrite

- **Description:** If set to

1

, the default, to improve fault tolerance InnoDB first stores data to a [doublewrite buffer](#) before writing it to data file. Disabling will provide a marginal performance improvement.

- **Commandline:**

```
--innodb-doublewrite  
,  
--skip-innodb-doublewrite
```

- **Scope:** Global

- **Dynamic:** No

- **Data Type:**

boolean

- **Default Value:**

ON

## innodb\_doublewrite\_file

- **Description:** The absolute or relative path and filename to a dedicated tablespace for the [doublewrite buffer](#). In heavy workloads, the doublewrite buffer can impact heavily on the server, and moving it to a different drive will reduce contention on random reads. Since the doublewrite buffer is mostly sequential writes, a traditional HDD is a better choice than SSD. This Percona XtraDB variable has not been ported to XtraDB 5.6.

- **Commandline:**

```
innodb-doublewrite-file=filename
```

- **Scope:** Global

- **Dynamic:** No

- **Data Type:**

filename

- **Default Value:**

NULL

- **Removed:** MariaDB 10.0
- 

## innodb\_empty\_free\_list\_algorithm

- **Description:** XtraDB 5.6.13-61 introduced an algorithm to assist with reducing mutex contention when the buffer pool free list is empty, controlled by this variable. If set to

backoff

, the default until [MariaDB 10.1.24](#), the new algorithm will be used. If set to

legacy

, the original InnoDB algorithm will be used. XtraDB only. Added as a deprecated and ignored option in [MariaDB 10.2.6](#) (which uses InnoDB as default instead of XtraDB) to allow for easier upgrades. See [#1651657](#) for the reasons this was changed back to

legacy

in XtraDB 5.6.36-82.0. When upgrading from 10.0 to 10.1 ( $\geq 10.1.24$ ), for large buffer pools the default will remain

backoff

, while for small ones it will be changed to

legacy

- **Commandline:**

```
innodb-empty-free-list-algorithm=value
```

- **Scope:** Global

- **Dynamic:** Yes

- **Data Type:**

enum

- **Default Value:**

- - deprecated  
( $\geq$  MariaDB 10.2.6)
  - legacy  
( $\geq$  MariaDB 10.1.24)
  - backoff  
( $\leq$  MariaDB 10.1.23)

- **Valid Values:**

- - deprecated
  - ,
  - backoff
  - ,
  - legacy  
( $\geq$  MariaDB 10.2.6)
- - backoff
  - ,
  - legacy  
( $\leq$  MariaDB 10.1)

- **Introduced:** MariaDB 10.0.9

- **Deprecated:** MariaDB 10.2.6

- **Removed:** MariaDB 10.3.0

---

## innodb\_enable\_unsafe\_group\_commit

- **Description:** Unneeded after XtraDB 1.0.5. If set to

- 0
  - , the default, InnoDB will keep transactions between the transaction log and [binary log](#)s in the same order. Safer, but slower. If set to 1
  - , transactions can be group-committed, but there is no guarantee of the order being kept, and a small risk of the two logs getting out of sync. In write-intensive environments, can lead to a significant improvement in performance.

- **Commandline:**

```
--innodb-enable-unsafe-group-commit
```

- **Scope:** Global

- **Dynamic:** Yes

- **Data Type:**

numeric

- **Default Value:**

0

- **Range:**

0

to

1

- **Removed:** Not needed after XtraDB 1.0.5

---

## innodb\_encrypt\_log

- **Description:** Enables encryption of the [InnoDB redo log](#). This also enables encryption of some temporary files created internally by InnoDB, such as those used for merge sorts and row logs.

- See [Data-at-Rest Encryption](#) and [InnoDB / XtraDB Enabling Encryption: Enabling Encryption for Redo Log](#) for more information.

- **Commandline:**

```
--innodb-encrypt-log
```

- **Scope:** Global

- **Dynamic:** No

- **Data Type:**

boolean

- **Default Value:**

OFF

- **Introduced:** MariaDB 10.1.3
- 

## innodb\_encrypt\_tables

- **Description:** Enables automatic encryption of all InnoDB tablespaces.

◦

OFF

- Disables table encryption for all new and existing tables that have the

ENCRYPTED

table option set to

DEFAULT

◦

ON

- Enables table encryption for all new and existing tables that have the

ENCRYPTED

table option set to

DEFAULT

, but allows unencrypted tables to be created.

◦

FORCE

- Enables table encryption for all new and existing tables that have the

ENCRYPTED

table option set to

DEFAULT

, and doesn't allow unencrypted tables to be created (CREATE TABLE ... ENCRYPTED=NO will fail).

- See [Data-at-Rest Encryption](#) and [InnoDB / XtraDB Enabling Encryption: Enabling Encryption for Automatically Encrypted Tablespaces](#) for more information.

- **Commandline:**

--innodb-encrypt-tables={0|1}

- **Scope:** Global

- **Dynamic:** Yes

- **Data Type:**

boolean

- **Default Value:**

OFF

- **Valid Values:**

ON

,

OFF

,

FORCE

(from MariaDB 10.1.4 )

- **Introduced:** MariaDB 10.1.3
- 

## innodb\_encrypt\_temporary\_tables

- **Description:** Enables automatic encryption of the InnoDB temporary tablespace .

- See [Data-at-Rest Encryption](#) and [InnoDB / XtraDB Enabling Encryption: Enabling Encryption for Temporary Tablespaces](#) for more information.

- **Commandline:**

--innodb-encrypt-temporary-tables={0|1}

- **Scope:** Global
- **Dynamic:** No
- **Data Type:**  
boolean

- **Default Value:**

OFF

- **Valid Values:**

ON  
,  
OFF

- **Introduced:** MariaDB 10.2.26 , MariaDB 10.3.17 , MariaDB 10.4.7
- 

### innodb\_encryption\_rotate\_key\_age

- **Description:** Re-encrypt in background any page having a key older than this number of key versions. When setting up encryption, this variable must be set to a non-zero value. Otherwise, when you enable encryption through

#### [innodb\\_encrypt\\_tables](#)

MariaDB won't be able to automatically encrypt any unencrypted tables.

- See [Data-at-Rest Encryption](#) and [InnoDB / XtraDB Encryption Keys: Key Rotation](#) for more information.

- **Commandline:**

--innodb-encryption-rotate-key-age=#

- **Scope:** Global
- **Dynamic:** Yes
- **Data Type:**

numeric

- **Default Value:**

1

- **Range:**

0  
to  
4294967295

- **Introduced:** MariaDB 10.1.3
- 

### innodb\_encryption\_rotation\_iops

- **Description:** Use this many iops for background key rotation operations performed by the background encryption threads.

- See [Data-at-Rest Encryption](#) and [InnoDB / XtraDB Encryption Keys: Key Rotation](#) for more information.

- **Commandline:**

--innodb-encryption-rotation\_iops=#

- **Scope:** Global
- **Dynamic:** Yes
- **Data Type:**

numeric

- **Default Value:**

100

- **Range:**

0  
to  
4294967295

- **Introduced:** MariaDB 10.1.3
-

## innodb\_encryption\_threads

- **Description:** Number of background encryption threads performing background key rotation and [scrubbing](#). When setting up encryption, this variable must be set to a non-zero value. Otherwise, when you enable encryption through [innodb\\_encrypt\\_tables](#) MariaDB won't be able to automatically encrypt any unencrypted tables. Recommended never be set higher than 255.
  - See [Data-at-Rest Encryption](#) and [InnoDB Background Encryption Threads](#) for more information.
- **Commandline:**

```
--innodb-encryption-threads=#
```
- **Scope:** Global
- **Dynamic:** Yes
- **Data Type:**

```
numeric
```
- **Default Value:**

```
0
```
- **Range:**
  - ```
0
to
4294967295
(<= MariaDB 10.1.45 , MariaDB 10.2.32 , MariaDB 10.3.23 , MariaDB 10.4.13 , MariaDB 10.5.3 )
```
  - ```
0
to
255
(>= MariaDB 10.1.46 , MariaDB 10.2.33 , MariaDB 10.3.24 , MariaDB 10.4.14 , MariaDB 10.5.4 )
```
- **Introduced:** [MariaDB 10.1.3](#)

---

## innodb\_extra\_rsegments

- **Description:** Removed in XtraDB 5.5 and replaced by [innodb\\_rollback\\_segments](#). Usually there is one rollback segment protected by single mutex, a source of contention in high write environments. This option specifies a number of extra user rollback segments. Changing the default will make the data readable by XtraDB only, and is incompatible with InnoDB. After modifying, the server must be slow-shutdown. If there is existing data, it must be dumped before changing, and re-imported after the change has taken effect.
- **Commandline:**

```
--innodb-extra-rsegments=#
```
- **Scope:** Global
- **Dynamic:** No
- **Data Type:**

```
numeric
```
- **Default Value:**

```
0
```
- **Range:**

```
0
to
126
```
- **Removed:** XtraDB 5.5 - replaced by [innodb\\_rollback\\_segments](#)

---

## innodb\_extra\_undoslots

- **Description:** Usually, InnoDB has 1024 undo slots in its rollback segment, so 1024 transactions can run in parallel. New transactions will fail if all slots are used. Setting this variable to
  - 1expands the available undo slots to 4072. Not recommended unless you get the
  - Warning: cannot find a free slot for an undo log
  - error in the error log, as it makes data files unusable for ibbackup, or MariaDB servers not run with this option. See also [undo log](#).
- **Commandline:**

```
--innodb-extra-undoslots={0|1}
```

- **Scope:** Global
- **Dynamic:** No
- **Data Type:**  
boolean

- **Default Value:**  
OFF

- **Removed:** XtraDB 5.5
- 

### innodb\_fake\_changes

- **Description:** From MariaDB 5.5 until MariaDB 10.1, XtraDB-only option that enables the fake changes feature. In replication, setting up or restarting a replica can cause a replication reads to perform more slowly, as MariaDB is single-threaded and needs to read the data before it can execute the queries. This can be speeded up by prefetching threads to warm the server, replaying the statements and then rolling back at commit. This however has an overhead from locking rows only then to undo changes at rollback. Fake changes attempts to reduce this overhead by reading the rows for INSERT, UPDATE and DELETE statements but not updating them. The rollback is then very fast with little or nothing to do. Added as a deprecated and ignored option in MariaDB 10.2.6 (which uses InnoDB as default instead of XtraDB) to allow for easier upgrades. Not present in MariaDB 10.3 and beyond.

- **Commandline:**

```
--innodb-fake-changes={0|1}
```

- **Scope:** Global, Session

- **Dynamic:** Yes

- **Data Type:**

boolean

- **Default Value:**

OFF

- **Deprecated:** MariaDB 10.2.6

- **Removed:** MariaDB 10.3.0
- 

### innodb\_fast\_checksum

- **Description:** Implements a more CPU efficient XtraDB checksum algorithm, useful for write-heavy loads with high I/O. If set to

1

on a server with tables that have been created with it set to

0

, reads will be slower, so tables should be recreated (dumped and reloaded). XtraDB will fail to start if set to

0

and there are tables created while set to

1

. Replaced with innodb\_checksum\_algorithm in MariaDB 10.0 /XtraDB 5.6.

- **Commandline:**

```
--innodb-fast-checksum={0|1}
```

- **Scope:** Global

- **Dynamic:** No

- **Data Type:**

boolean

- **Default Value:**

OFF

- **Removed:** MariaDB 10.0 /XtraDB 5.6 - replaced with innodb\_checksum\_algorithm
- 

### innodb\_fast\_shutdown

- **Description:** The shutdown mode.

◦

0  
- InnoDB performs a slow shutdown, including full purge (before [MariaDB 10.3.6](#), not always, due to [MDEV-13603](#)) and change buffer merge. Can be very slow, even taking hours in extreme cases.

o 1  
- the default, InnoDB performs a fast shutdown, not performing a full purge or an insert buffer merge.

o 2  
, the [InnoDB redo log](#) is flushed and a cold shutdown takes place, similar to a crash. The resulting startup then performs crash recovery. Extremely fast, in cases of emergency, but risks corruption. Not suitable for upgrades between major versions!

o 3  
(from [MariaDB 10.3.6](#)) - active transactions will not be rolled back, but all changed pages will be written to data files. The active transactions will be rolled back by a background thread on a subsequent startup. The fastest option that will not involve [InnoDB redo log](#) apply on subsequent startup. See [MDEV-15832](#).

- **Commandline:**  
`--innodb-fast-shutdown[=#]`
- **Scope:** Global
- **Dynamic:** Yes
- **Data Type:**  
numeric
- **Default Value:**  
1
- **Range:**  
0  
to  
3  
( $\geq$  [MariaDB 10.3.6](#)),  
0  
to  
2  
( $\leq$  [MariaDB 10.3.5](#))

---

## innodb\_fatal\_semaphore\_wait\_threshold

- **Description:** In MariaDB, the fatal semaphore timeout is configurable. This variable sets the maximum number of seconds for semaphores to time out in InnoDB.
- **Commandline:**  
`--innodb-fatal-semaphore-wait-threshold=#`
- **Scope:** Global
- **Dynamic:** No
- **Data Type:**  
numeric
- **Default Value:**  
600
- **Range:**  
1  
to  
4294967295
- **Introduced:** [MariaDB 10.1.2](#)

---

## innodb\_file\_format

- **Description:** File format for new InnoDB tables. Can either be  
Antelope  
, the default and the original format, or  
Barracuda  
, which supports [compression](#). Note that this value is also used when a table is re-created with an [ALTER TABLE](#) which requires a table copy. See [XtraDB/InnoDB File Format](#) for more on the file formats. Removed in 10.3.1 and restored as a deprecated and unused variable in 10.4.3

for compatibility purposes.

- **Commandline:**

```
--innodb-file-format=value
```

- **Scope:** Global

- **Dynamic:** Yes

- **Data Type:**

string

- **Default Value:**

◦

Barracuda  
( $\geq$  MariaDB 10.2.2 )  
◦  
Antelope  
( $\leq$  MariaDB 10.2.1 )

- **Valid Values:**

Antelope

,

Barracuda

- **Deprecated:** MariaDB 10.2

- **Removed:** MariaDB 10.3.1

- **Re-introduced:** MariaDB 10.4.3 (for compatibility purposes)

- **Removed:** MariaDB 10.6.0

## innodb\_file\_format\_check

- **Description:** If set to

1

, the default, InnoDB checks the shared tablespace file format tag. If this is higher than the current version supported by XtraDB/InnoDB (for example Barracuda when only Antelope is supported), XtraDB/InnoDB will not start. If it the value is not higher, XtraDB/InnoDB starts correctly and the innodb\_file\_format\_max value is set to this value. If innodb\_file\_format\_check is set to

0

, no checking is performed. See [XtraDB/InnoDB File Format](#) for more on the file formats.

- **Commandline:**

```
--innodb-file-format-check={0|1}
```

- **Scope:** Global

- **Dynamic:** No

- **Data Type:**

boolean

- **Default Value:**

ON

- **Deprecated:** MariaDB 10.2

- **Removed:** MariaDB 10.3.1

## innodb\_file\_format\_max

- **Description:** The highest XtraDB/InnoDB file format. This is set to the value of the file format tag in the shared tablespace on startup (see [innodb\\_file\\_format\\_check](#)). If the server later creates a higher table format, innodb\_file\_format\_max is set to that value. See [XtraDB/InnoDB File Format](#) for more on the file formats.

- **Commandline:**

```
--innodb-file-format-max=value
```

- **Scope:** Global

- **Dynamic:** Yes

- **Data Type:**

string

- **Default Value:**

Antelope

- **Valid Values:**

Antelope  
,  
Barracuda

- **Deprecated:** [MariaDB 10.2](#)

- **Removed:** [MariaDB 10.3.1](#)

---

## innodb\_file\_per\_table

- **Description:** If set to

ON  
, then new [InnoDB](#) tables are created with their own [InnoDB file-per-table tablespaces](#). If set to  
OFF  
, then new tables are created in the [InnoDB system tablespace](#) instead. [Page compression](#) is only available with file-per-table  
tablespaces. Note that this value is also used when a table is re-created with an [ALTER TABLE](#) which requires a table copy.

- **Commandline:**

--innodb-file-per-table

- **Scope:** Global

- **Dynamic:** Yes

- **Data Type:**

boolean

- **Default Value:**

ON

---

## innodb\_fill\_factor

- **Description:** Percentage of B-tree page filled during bulk insert (sorted index build). Used as a hint rather than an absolute value. Setting to

70  
, for example, reserves 30% of the space on each B-tree page for the index to grow in future.

- **Commandline:**

--innodb-fill-factor=#

- **Scope:** Global

- **Dynamic:** Yes

- **Data Type:**

numeric

- **Default Value :**

100

- **Range:**

10

to

100

- **Introduced:** [MariaDB 10.2.2](#)

---

## innodb\_flush\_log\_at\_timeout

- **Description:** Interval in seconds to write and flush the [InnoDB redo log](#). Before MariaDB 10, this was fixed at one second, which is still the default, but this can now be changed. It's usually increased to reduce flushing and avoid impacting performance of binary log group commit.

- **Scope:** Global

- **Dynamic:** Yes

- **Data Type:**

numeric

- **Default Value:**

1

- **Range:**

0  
to  
2700

---

## innodb\_flush\_log\_at\_trx\_commit

- **Description:** Set to

1

, along with [sync\\_binlog=1](#) for the greatest level of fault tolerance. The value of [innodb\\_use\\_global\\_flush\\_log\\_at\\_trx\\_commit](#) determines whether this variable can be reset with a SET statement or not.

◦

1

The default, the log buffer is written to the [InnoDB redo log](#) file and a flush to disk performed after each transaction. This is required for full ACID compliance.

◦

0

Nothing is done on commit; rather the log buffer is written and flushed to the [InnoDB redo log](#) once a second. This gives better performance, but a server crash can erase the last second of transactions.

◦

2

The log buffer is written to the [InnoDB redo log](#) after each commit, but flushing takes place once a second. Performance is slightly better, but a OS or power outage can cause the last second's transactions to be lost.

◦

3

Emulates [MariaDB 5.5 group commit](#) (3 syncs per group commit). See [Binlog group commit and innodb\\_flush\\_log\\_at\\_trx\\_commit](#). This option has not been working correctly since 10.2 and may be removed in future, see <https://github.com/MariaDB/server/pull/1873>

- **Commandline:**

--innodb-flush-log-at-trx-commit[=#]

- **Scope:** Global

- **Dynamic:** Yes

- **Data Type:**

enumeration

- **Default Value:**

1

- **Valid Values:**

0

,

1

,

2

or

3

---

## innodb\_flush\_method

- **Description:** [InnoDB](#) flushing method. Windows always uses `async_unbuffered` and this variable then has no effect. On Unix, before [MariaDB 10.6.0](#) , by default `fsync()` is used to flush data and logs. Adjusting this variable can give performance improvements, but behavior differs widely on different filesystems, and changing from the default has caused problems in some situations, so test and benchmark carefully before adjusting. In MariaDB, Windows recognises and correctly handles the Unix methods, but if none are specified it uses own default - unbuffered write (analog of `O_DIRECT`) + syncs (e.g `FileFlushBuffers()`) for all files.

◦

`O_DSYNC`

- `O_DSYNC` is used to open and flush logs, and `fsync()` to flush the data files.

◦

`O_DIRECT`

- `O_DIRECT` or `directio()`, is used to open data files, and `fsync()` to flush data and logs. Default on Unix from [MariaDB 10.6.0](#) .

◦

`fsync`

- Default on Unix until [MariaDB 10.5](#). Can be specified directly, but if the variable is unset on Unix, fsync() will be used by default.
- o
  - O\_DIRECT\_NO\_FSYNC
    - introduced in [MariaDB 10.0](#). Uses O\_DIRECT during flushing I/O, but skips fsync() afterwards. Not suitable for XFS filesystems. Generally not recommended over O\_DIRECT, as does not get the benefit of [innodb\\_use\\_native\\_aio=ON](#).
  - ALL\_O\_DIRECT
    - introduced in [MariaDB 5.5](#) and available with XtraDB only. Uses O\_DIRECT for opening both data and logs and fsync() to flush data but not logs. Use with large InnoDB files only, otherwise may cause a performance degradation. Set [innodb\\_log\\_block\\_size](#) to 4096 on ext4 filesystems. This is the default log block size on ext4 and will avoid unaligned AIO/DIO warnings.
  - unbuffered
    - Windows-only default
  - async\_unbuffered
    - Windows-only, alias for unbuffered
  - normal
    - Windows-only, alias for fsync

- **Commandline:**

```
--innodb-flush-method=name
```

- **Scope:** Global

- **Dynamic:** No

- **Data Type:**

```
enumeration
(=> MariaDB 10.3.7 ),
string
(<= MariaDB 10.3.6 )
```

- **Default Value:**

- o
  - O\_DIRECT
    - (Unix, >= [MariaDB 10.6.0](#) )
  - fsync
    - (Unix, >= [MariaDB 10.3.7](#) , <= [MariaDB 10.5](#) )
- Not set (<= [MariaDB 10.3.6](#) )

- **Valid Values:**

- Unix:
  - fsync
  - ,
  - O\_DSYNC
  - ,
  - O\_DIRECT
  - ,
  - O\_DIRECT\_NO\_FSYNC
  - ,
  - ALL\_O\_DIRECT
    - (>= [MariaDB 5.5](#) to <= [MariaDB 10.1](#) , XtraDB only)
- Windows:
  - unbuffered
  - ,
  - async\_unbuffered
  - ,
  - normal

## [innodb\\_flush\\_neighbor\\_pages](#)

- **Description:** Determines whether, when dirty pages are flushed to the data file, neighboring pages in the data file are flushed at the same time. If set to

```
none
, the feature is disabled. If set to
area
```

, the default, the standard InnoDB behavior is used. For each page to be flushed, dirty neighboring pages are flushed too. If there's little head seek delay, such as SSD or large enough write buffer, one of the other two options may be more efficient. If set to

cont

, for each page to be flushed, neighboring contiguous blocks are flushed at the same time. Being contiguous, a sequential I/O is used, unlike the random I/O used in

area

. Replaced by [innodb\\_flush\\_neighbors](#) in MariaDB 10.0 /XtraDB 5.6.

- **Commandline:**

```
innodb-flush-neighbor-pages=value
```

- **Scope:** Global

- **Dynamic:** Yes

- **Data Type:**

enumeration

- **Default Value:**

area

- **Valid Values:**

none

or

0

,

area

or

1

,

cont

or

2

- **Removed:** MariaDB 10.0 /XtraDB 5.6 - replaced by [innodb\\_flush\\_neighbors](#)

---

## innodb\_flush\_neighbors

- **Description:** Determines whether flushing a page from the [buffer pool](#) will flush other dirty pages in the same group of pages (extent). In high write environments, if flushing is not aggressive enough, it can fall behind resulting in higher memory usage, or if flushing is too aggressive, cause excess I/O activity. SSD devices, with low seek times, would be less likely to require dirty neighbor flushing to be set.

◦

1

: The default, flushes contiguous dirty pages in the same extent from the buffer pool.

◦

0

: No other dirty pages are flushed.

◦

2

: Flushes dirty pages in the same extent from the buffer pool.

- **Commandline:**

```
--innodb-flush-neighbors=#
```

- **Scope:** Global

- **Dynamic:** Yes

- **Data Type:**

enumeration

- **Default Value:**

1

- **Valid Values:**

0

,

1

,

2

## innodb\_flush\_sync

- **Description:** If set to  
ON  
, the default, the [innodb\\_io\\_capacity](#) setting is ignored for I/O bursts occurring at checkpoints.
  - **Commandline:**  
--innodb-flush-sync={0|1}
  - **Scope:** Global
  - **Dynamic:** Yes
  - **Data Type:**  
boolean
  - **Default Value :**  
ON
  - **Introduced:** [MariaDB 10.2.2](#)
- 

## innodb\_flushing\_avg\_loops

- **Description:** Determines how quickly adaptive flushing will respond to changing workloads. The value is the number of iterations that a previously calculated flushing state snapshot is kept. Increasing the value smooths and slows the rate that the flushing operations change, while decreasing it causes flushing activity to spike quickly in response to workload changes.
  - **Commandline:**  
--innodb-flushing-avg-loops=#
  - **Scope:** Global
  - **Dynamic:** Yes
  - **Data Type:**  
numeric
  - **Default Value:**  
30
  - **Range:**  
1  
to  
1000
- 

## innodb\_force\_load\_corrupted

- **Description:** Set to  
0  
by default, if set to  
1  
, InnoDB will be permitted to load tables marked as corrupt. Only use this to recover data you can't recover any other way, or in troubleshooting. Always restore to  
0  
when returning to regular use. Given that [MDEV-11412](#) in [MariaDB 10.5.4](#) aims to allow any metadata for a missing or corrupted table to be dropped, and given that [MDEV-17567](#) and [MDEV-25506](#) and related tasks made DDL operations crash-safe, the parameter no longer serves any purpose and was removed in [MariaDB 10.6.6](#).
- **Commandline:**  
--innodb-force-load-corrupted
- **Scope:** Global
- **Dynamic:** No
- **Data Type:**  
boolean
- **Default Value:**  
OFF
- **Removed:** [MariaDB 10.6.6](#)

## innodb\_force\_primary\_key

- **Description:** If set to

```
1  
(  
0  
is default) CREATE TABLEs without a primary or unique key where all keyparts are NOT NULL will not be accepted, and will return an error.
```

- **Commandline:**

```
--innodb-force-primary-key
```

- **Scope:** Global

- **Dynamic:** Yes

- **Data Type:**

```
boolean
```

- **Default Value:**

```
OFF
```

- **Introduced:** MariaDB 10.1.0
- 

## innodb\_force\_recovery

- **Description:** InnoDB crash recovery mode.

```
0  
is the default. The other modes are for recovery purposes only, and no data can be changed while another mode is active. Some queries relying on indexes are also blocked. See InnoDB Recovery Modes for more on mode specifics.
```

- **Commandline:**

```
--innodb-force-recovery=#
```

- **Scope:** Global

- **Dynamic:** No

- **Data Type:**

```
enumeration
```

- **Default Value:**

```
0
```

- **Range:**

```
0
```

```
to
```

```
6
```

---

## innodb\_foreground\_preflush

- **Description:** Before XtraDB 5.6.13-61.0, if the checkpoint age is in the sync preflush zone while a thread is writing to the [XtraDB redo log](#), it will try to advance the checkpoint by issuing a flush list flush batch if this is not already being done. XtraDB has enhanced page cleaner tuning, and may already be performing furious flushing, resulting in the flush simply adding unneeded mutex pressure. Instead, the thread now waits for the flushes to finish, and then has two options, controlled by this variable. XtraDB only. Added as a deprecated and ignored option in [MariaDB 10.2.6](#) (which uses InnoDB as default instead of XtraDB) to allow for easier upgrades.

- - **exponential\_backoff**
    - thread sleeps while it waits for the flush list flush to occur. The sleep time randomly progressively increases, periodically reset to avoid runaway sleeps.
  - **sync\_preflush**
    - thread issues a flush list batch, and waits for it to complete. This is the same as is used when the page cleaner thread is not running.

- **Commandline:**

```
innodb-foreground-preflush=value
```

- **Scope:** Global

- **Dynamic:** Yes

- **Data Type:**

enum

- **Default Value:**

- - deprecated  
(>= MariaDB 10.2.6 )
  - exponential\_backoff  
(<= MariaDB 10.1 )

- **Valid Values:**

- - deprecated
  - ,
  - exponential\_backoff
  - ,
  - sync\_preflush  
(>= MariaDB 10.2.6 )
- - exponential\_backoff
  - ,
  - sync\_preflush  
(<= MariaDB 10.1 )

- **Introduced:** MariaDB 10.0.9

- **Deprecated:** MariaDB 10.2.6

- **Removed:** MariaDB 10.3.0

---

### innodb\_ft\_aux\_table

- **Description:** Diagnostic variable intended only to be set at runtime. It specifies the qualified name (for example

test/ft\_innodb  
) of an InnoDB table that has a FULLTEXT index , and after being set the INFORMATION\_SCHEMA tables INNODB\_FT\_INDEX\_TABLE , INNODB\_FT\_INDEX\_CACHE , INNODB\_FT\_CONFIG, INNODB\_FT\_DELETED , and INNODB\_FT\_BEING\_DELETED will contain search index information for the specified table.

- **Commandline:**

--innodb-ft-aux-table=value

- **Scope:** Global

- **Dynamic:** Yes

- **Data Type:**

string

---

### innodb\_ft\_cache\_size

- **Description:** Cache size available for a parsed document while creating an InnoDB FULLTEXT index .

- **Commandline:**

--innodb-ft-cache-size=#

- **Scope:** Global

- **Dynamic:** No

- **Data Type:**

numeric

- **Default Value:**

8000000

---

### innodb\_ft\_enable\_diag\_print

- **Description:** If set to

1

, additional [full-text](#) search diagnostic output is enabled.

- **Commandline:**

```
--innodb_ft-enable-diag-print={0|1}
```

- **Scope:** Global

- **Dynamic:** Yes

- **Data Type:**

boolean

- **Default Value:**

OFF

---

## innodb\_ft\_enable\_stopword

- **Description:** If set to

1

, the default, a set of [stopwords](#) is associated with an InnoDB [FULLTEXT index](#) when it is created. The stopword list comes from the table set by the session variable [innodb\\_ft\\_user\\_stopword\\_table](#), if set, otherwise the global variable [innodb\\_ft\\_server\\_stopword\\_table](#), if that is set, or the [built-in list](#) if neither variable is set.

- **Commandline:**

```
--innodb_ft-enable-stopword={0|1}
```

- **Scope:** Global

- **Dynamic:** Yes

- **Data Type:**

boolean

- **Default Value:**

ON

---

## innodb\_ft\_max\_token\_size

- **Description:** Maximum length of words stored in an InnoDB [FULLTEXT index](#). A larger limit will increase the size of the index, slowing down queries, but permit longer words to be searched for. In most normal situations, longer words are unlikely search terms.

- **Commandline:**

```
--innodb_ft-max-token-size=#
```

- **Scope:** Global

- **Dynamic:** No

- **Data Type:**

numeric

- **Default Value:**

84

- **Range:**

10

to

252

---

## innodb\_ft\_min\_token\_size

- **Description:** Minimum length of words stored in an InnoDB [FULLTEXT index](#). A smaller limit will increase the size of the index, slowing down queries, but permit shorter words to be searched for. For data stored in a Chinese, Japanese or Korean [character set](#), a value of 1 should be specified to preserve functionality.

- **Commandline:**

```
--innodb_ft-min-token-size=#
```

- **Scope:** Global

- **Dynamic:** No
- **Data Type:** numeric

- **Default Value:**

3

- **Range:**

0  
to  
16

---

### innodb\_ft\_num\_word\_optimize

- **Description:** Number of words processed during each [OPTIMIZE TABLE](#) on an InnoDB [FULLTEXT index](#). To ensure all changes are incorporated, multiple OPTIMIZE TABLE statements could be run in case of a substantial change to the index.

- **Commandline:**

--innodb-ft-num-word-optimize=#

- **Scope:** Global

- **Dynamic:** Yes

- **Data Type:**

numeric

- **Default Value:**

2000

---

### innodb\_ft\_result\_cache\_limit

- **Description:** Limit in bytes of the InnoDB [FULLTEXT index](#) query result cache per fulltext query. The latter stages of the full-text search are handled in memory, and limiting this prevents excess memory usage. If the limit is exceeded, the query returns an error.

- **Commandline:**

--innodb-ft-result-cache-limit=#

- **Scope:** Global

- **Dynamic:** Yes

- **Data Type:**

numeric

- **Default Value:**

2000000000

- **Range:**

1000000  
to  
4294967295  
(<= MariaDB 10.2.18 , MariaDB 10.1.36 , MariaDB 10.0.36 )

- **Range:**

1000000  
to  
18446744073709551615  
(64-bit, >= MariaDB 10.2.19 , MariaDB 10.1.37 , MariaDB 10.0.37 )

---

### innodb\_ft\_server\_stopword\_table

- **Description:** Table name containing a list of stopwords to ignore when creating an InnoDB [FULLTEXT index](#), in the format db\_name/table\_name. The specified table must exist before this option is set, and must be an InnoDB table with a single column, a [VARCHAR](#) named VALUE. See also [innodb\\_ft\\_enable\\_stopword](#).

- **Commandline:**

--innodb-ft-server-stopword-table=db\_name/table\_name

- **Scope:** Global
  - **Dynamic:** Yes
  - **Data Type:**  
string
  - **Default Value:** Empty
- 

### innodb\_ft\_sort\_pll\_degree

- **Description:** Number of parallel threads used when building an InnoDB [FULLTEXT index](#). See also [innodb\\_sort\\_buffer\\_size](#).
- **Commandline:**

```
--innodb-ft-sort-pll-degree=#
```

- **Scope:** Global
- **Dynamic:** No
- **Data Type:**  
numeric

- **Default Value:**

2

- **Range:**

1  
to  
32

---

### innodb\_ft\_total\_cache\_size

- **Description:** Total memory allocated for the cache for all InnoDB [FULLTEXT index](#) tables. A force sync is triggered if this limit is exceeded.
- **Commandline:**

```
--innodb-ft-total-cache-size=#
```

- **Scope:** Global
- **Dynamic:** No
- **Data Type:**  
numeric

- **Default Value:**

640000000

- **Range:**

32000000  
to  
1600000000

- **Introduced:** [MariaDB 10.0.9](#)
- 

### innodb\_ft\_user\_stopword\_table

- **Description:** Table name containing a list of stopwords to ignore when creating an InnoDB [FULLTEXT index](#), in the format db\_name/table\_name. The specified table must exist before this option is set, and must be an InnoDB table with a single column, a [VARCHAR](#) named VALUE. See also [innodb\\_ft\\_enable\\_stopword](#).

- **Commandline:**

```
--innodb-ft-user-stopword-table=db_name/table_name
```

- **Scope:** Session
- **Dynamic:** Yes
- **Data Type:**  
string

- **Default Value:** Empty
- 

### innodb\_ibuf\_accel\_rate

- **Description:** Allows the insert buffer activity to be adjusted. The following formula is used: [real activity] = [default activity] \* (innodb\_io\_capacity/100) \* (innodb\_ibuf\_accel\_rate/100). As innodb\_ibuf\_accel\_rate is increased from its default value of 100, the lowest setting, insert buffer activity is increased. See also [innodb\\_io\\_capacity](#). This Percona XtraDB variable has not been ported to XtraDB 5.6.

- **Commandline:**

```
innodb_ibuf_accel_rate=#
```

- **Scope:** Global

- **Dynamic:** Yes

- **Data Type:**

numeric

- **Default Value:**

100

- **Range:**

100  
to  
999999999

- **Removed:** MariaDB 10.0
- 

### innodb\_ibuf\_active\_contract

- **Description:** Specifies whether the insert buffer can be processed before it's full. If set to

0

, the standard InnoDB method is used, and the buffer is not processed until it's full. If set to

1

, the default, the insert buffer can be processed before it is full. This Percona XtraDB variable has not been ported to XtraDB 5.6.

- **Commandline:**

```
innodb_ibuf_active_contract=#
```

- **Scope:** Global

- **Dynamic:** Yes

- **Data Type:**

numeric

- **Default Value:**

1

- **Range:**

0

to

1

- **Removed:** MariaDB 10.0
- 

### innodb\_ibuf\_max\_size

- **Description:** Maximum size in bytes of the insert buffer. Defaults to half the size of the [buffer pool](#) so you may want to reduce if you have a very large buffer pool. If set to

0

, the insert buffer is disabled, which will cause all secondary index updates to be performed synchronously, usually at a cost to performance. This Percona XtraDB variable has not been ported to XtraDB 5.6.

- **Commandline:**

```
innodb_ibuf_max_size=#
```

- **Scope:** Global
  - **Dynamic:** No
  - **Data Type:**  
    numeric
  - **Default Value:** 1/2 the size of the InnoDB buffer pool
  - **Range:**  
    0  
    to 1/2 the size of the InnoDB buffer pool
  - **Removed:** [MariaDB 10.0](#)
- 

### innodb\_idle\_flush\_pct

- **Description:** Up to what percentage of dirty pages should be flushed when innodb finds it has spare resources to do so. Has had no effect since merging InnoDB 5.7 from mysql-5.7.9 ([MariaDB 10.2.2](#)). Deprecated in [MariaDB 10.2.37](#), [MariaDB 10.3.28](#), [MariaDB 10.4.18](#) and removed in [MariaDB 10.5.9](#).
  - **Commandline:**  
    --innodb-idle-flush-pct=#
  - **Scope:** Global
  - **Dynamic:** Yes
  - **Data Type:**  
    numeric
  - **Default Value:**  
    100
  - **Range:**  
    0  
    to  
    100
  - **Introduced:** [MariaDB 10.1.2](#)
  - **Deprecated:** [MariaDB 10.2.37](#), [MariaDB 10.3.28](#), [MariaDB 10.4.18](#)
  - **Removed:** [MariaDB 10.5.9](#)
- 

### innodb\_immediate\_scrub\_data\_uncompressed

- **Description:** Enable scrubbing of data. See [Data Scrubbing](#).
  - **Commandline:**  
    --innodb-immediate-scrub-data-uncompressed={0|1}
  - **Scope:** Global
  - **Dynamic:** Yes
  - **Data Type:**  
    boolean
  - **Default Value:**  
    OFF
  - **Introduced:** [MariaDB 10.1.3](#)
- 

### innodb\_import\_table\_from\_xtrabackup

- **Description:** If set to  
    1  
    , permits importing of .ibd files exported with the [XtraBackup](#) --export option. Previously named  
    innodb\_expand\_import  
    . Removed in [MariaDB 10.0](#) /XtraDB 5.6 and replaced with MySQL 5.6's transportable tablespaces.
- **Commandline:**

```
innodb-import-table-from-xtrabackup=#
```

- **Scope:** Global
- **Dynamic:** Yes
- **Data Type:**  
    numeric

- **Default Value:**

```
0
```

- **Range:**

```
0
```

```
to
```

```
1
```

- **Removed:** MariaDB 10.0

## innodb\_instant\_alter\_column\_allowed

- **Description:**

- If a table is altered using ALGORITHM=INSTANT, it can force the table to use a non-canonical format: A hidden metadata record at the start of the clustered index is used to store each column's DEFAULT value. This makes it possible to add new columns that have default values without rebuilding the table. Starting with MariaDB 10.4, a BLOB in the hidden metadata record is used to store column mappings. This makes it possible to drop or reorder columns without rebuilding the table. This also makes it possible to add columns to any position or drop columns from any position in the table without rebuilding the table. If a column is dropped without rebuilding the table, old records will contain garbage in that column's former position, and new records will be written with NULL values, empty strings, or dummy values.
- This is generally not a problem. However, there may be cases where you want to avoid putting a table into this format. For example, to ensure that future UPDATE operations after an ADD COLUMN will be performed in-place, to reduce write amplification. (Instantly added columns are essentially always variable-length.) Also avoid bugs similar to MDEV-19916, or to be able to export tables to older versions of the server.
- This variable has been introduced as a result, with the following values:
  - never  
(0): Do not allow instant add/drop/reorder, to maintain format compatibility with MariaDB 10.x and MySQL 5.x. If the table (or partition) is not in the canonical format, then any ALTER TABLE (even one that does not involve instant column operations) will force a table rebuild.
  - add\_last  
(1, default in 10.3): Store a hidden metadata record that allows columns to be appended to the table instantly ( MDEV-11369 ). In 10.4 or later, if the table (or partition) is not in this format, then any ALTER TABLE (even one that does not involve column changes) will force a table rebuild.
  - add\_drop\_reorder  
(2, default): From MariaDB 10.4 only. Like 'add\_last', but allow the metadata record to store a column map, to support instant add/drop/reorder of columns.

- **Commandline:**

```
--innodb-instant-alter-column-allowed=value
```

- **Scope:** Global
- **Dynamic:** Yes
- **Data Type:**

```
enum
```

- **Valid Values:**

- <= MariaDB 10.3 :

```
never  
,  
add_last
```

- >= MariaDB 10.4 :

```
never  
,  
add_last  
,  
add_drop_reorder
```

- **Default Value:**

- <= MariaDB 10.3 :

```
add_last
```

◦ >= MariaDB 10.4 :  
add\_drop\_reorder

- **Introduced:** MariaDB 10.3.23 , MariaDB 10.4.13 , MariaDB 10.5.3
- 

### innodb\_instrument\_semaphores

- **Description:** Enable semaphore request instrumentation. This could have some effect on performance but allows better information on long semaphore wait problems.

- **Commandline:**

--innodb-instrument-semaphores={0|1}

- **Scope:** Global

- **Dynamic:** Yes

- **Data Type:**

boolean

- **Default Value:**

OFF

- **Introduced:** MariaDB 10.1.3

- **Deprecated:** MariaDB 10.2.5 (treated as if

OFF

)

- **Removed:** MariaDB 10.3.0
- 

### innodb\_io\_capacity

- **Description:** Limit on I/O activity for InnoDB background tasks, including merging data from the insert buffer and flushing pages. Should be set to around the number of I/O operations per second that system can handle, based on the type of drive/s being used. You can also set it higher when the server starts to help with the extra workload at that time, and then reduce for normal use. Ideally, opt for a lower setting, as at higher value data is removed from the buffers too quickly, reducing the effectiveness of caching. See also [innodb\\_flush\\_sync](#) .

◦ See [InnoDB Page Flushing: Configuring the InnoDB I/O Capacity](#) for more information.

- **Commandline:**

--innodb-io-capacity=#

- **Scope:** Global

- **Dynamic:** Yes

- **Data Type:**

numeric

- **Default Value:**

200

- **Range:**

100

to

18446744073709551615

( $2^{64}-1$ )

---

### innodb\_io\_capacity\_max

- **Description:** Upper limit to which InnoDB can extend [innodb\\_io\\_capacity](#) in case of emergency. See [InnoDB Page Flushing: Configuring the InnoDB I/O Capacity](#) for more information.

- **Commandline:**

--innodb-io-capacity-max=#

- **Scope:** Global

- **Dynamic:** Yes

- **Data Type:**

numeric

- **Default Value:**

2000  
or twice `innodb_io_capacity`, whichever is higher.

- **Range :**

100  
to  
18446744073709551615  
( $2^{64}-1$ )

---

## `innodb_kill_idle_transaction`

- **Description:** Time in seconds before killing an idle XtraDB transaction. If set to

0

(the default), the feature is disabled. Used to prevent accidental user locks. XtraDB only. Added as a deprecated and ignored option in [MariaDB 10.2.6](#) (which uses InnoDB as default instead of XtraDB) to allow for easier upgrades.

- **Scope:** Global

- **Dynamic:** Yes

- **Data Type:**

numeric

- **Default Value:**

0

- **Range:**

0  
to  
9223372036854775807

- **Deprecated:** [MariaDB 10.2.6](#)

- **Removed:** [MariaDB 10.3.0](#)

---

## `innodb_large_prefix`

- **Description:** If set to

1

, tables that use specific `row formats` are permitted to have index key prefixes up to 3072 bytes (for 16k pages, `smaller otherwise`). If not set, the limit is 767 bytes.

◦ This applies to the

`DYNAMIC`

and

`COMPRESSED`

`row formats`.

◦ Removed in 10.3.1 and restored as a deprecated and unused variable in 10.4.3 for compatibility purposes.

- **Commandline:**

`--innodb-large-prefix`

- **Scope:** Global

- **Dynamic:** Yes

- **Data Type:**

boolean

- **Default Value:**

◦

`ON`  
( $\geq$  [MariaDB 10.2.2](#))

◦

`OFF`  
( $\leq$  [MariaDB 10.2.1](#))

- **Deprecated:** [MariaDB 10.2](#)

- **Removed:** [MariaDB 10.3.1](#)

- **Re-introduced:** [MariaDB 10.4.3](#) (for compatibility purposes)

- **Removed:** MariaDB 10.6.0
- 

## innodb\_lazy\_drop\_table

- **Description:** Deprecated and removed in XtraDB 5.6. `DROP TABLE` processing can take a long time when `innodb_file_per_table` is set to 1 and there's a large `buffer pool`. If

```
innodb_lazy_drop_table  
is set to  
1  
(  
0
```

is default), XtraDB attempts to optimize `DROP TABLE` processing by deferring the dropping of related pages from the `buffer pool` until there is time, only initially marking them.

- **Commandline:**

```
innodb-lazy-drop-table={0|1}
```

- **Scope:** Global

- **Dynamic:** Yes

- **Data Type:**

boolean

- **Default Value:**

0

- **Deprecated:** XtraDB 5.5.30-30.2

- **Removed:** MariaDB 10.0.0
- 

## innodb\_lock\_schedule\_algorithm

- **Description:** Specifies the algorithm that InnoDB/XtraDB uses to decide which of the waiting transactions should be granted the lock once it has been released. The possible values are:

FCFS  
(First-Come-First-Served) where locks are granted in the order they appear in the lock queue and  
VATS  
(Variance-Aware-Transaction-Scheduling) where locks are granted based on the Eldest-Transaction-First heuristic. Note that  
VATS  
should not be used with `Galera`. From [MariaDB 10.1.30](#), InnoDB will refuse to start if  
VATS  
is used with Galera. From [MariaDB 10.2](#),  
VATS  
is default, but from [MariaDB 10.2.12](#), the value will be changed to  
FCFS  
and a warning produced when using Galera.

- **Commandline:**

```
--innodb-lock-schedule-algorithm=#
```

- **Scope:** Global

- **Dynamic:** No (>= [MariaDB 10.2.12](#), [MariaDB 10.1.30](#)), Yes (<= [MariaDB 10.2.11](#), [MariaDB 10.1.29](#))

- **Data Type:**

enum

- **Valid Values:**

FCFS  
,  
VATS

- **Default Value:**

FCFS  
( [MariaDB 10.3.9](#), [MariaDB 10.2.17](#) ),  
VATS  
( [MariaDB 10.2.3](#) ),  
FCFS  
( [MariaDB 10.1](#) )

- **Introduced:** [MariaDB 10.2.3](#), [MariaDB 10.1.19](#)

- **Deprecated:** [MariaDB 10.5.7](#), [MariaDB 10.4.16](#), [MariaDB 10.3.26](#), [MariaDB 10.2.35](#)

- **Removed:** [MariaDB 10.6.0](#)

## innodb\_lock\_wait\_timeout

- **Description:** Time in seconds that an InnoDB transaction waits for an InnoDB record lock (or table lock) before giving up with the error  
ERROR 1205 (HY000): Lock wait timeout exceeded; try restarting transaction  
. When this occurs, the statement (not transaction) is rolled back. The whole transaction can be rolled back if the  
**innodb\_rollback\_on\_timeout** option is used. Increase this for data warehousing applications or where other long-running operations are common, or decrease for OLTP and other highly interactive applications. This setting does not apply to deadlocks, which InnoDB detects immediately, rolling back a deadlocked transaction.

0  
(from MariaDB 10.3.0 ) means no wait. See [WAIT](#) and [NOWAIT](#) . Setting to  
100000000  
or more (from MariaDB 10.6.3 ,  
100000000  
is the maximum) means the timeout is infinite.

- **Commandline:**

--innodb-lock-wait-timeout=#

- **Scope:** Global, Session

- **Dynamic:** Yes

- **Data Type:**

INT UNSIGNED  
(>= MariaDB 10.6.3 ),  
BIGINT UNSIGNED  
(<= MariaDB 10.6.2 )

- **Default Value:**

50

- **Range:**

- 0  
to  
100000000  
(>= MariaDB 10.6.3 )
- 0  
to  
1073741824  
(>= MariaDB 10.3 to <= MariaDB 10.6.2 )
- 1  
to  
1073741824  
(<= MariaDB 10.2 )

## innodb\_locking\_fake\_changes

- **Description:** From MariaDB 5.5 to MariaDB 10.1 , XtraDB-only option that if set to

OFF

, fake transactions (see [innodb\\_fake\\_changes](#) ) don't take row locks. This is an experimental feature to attempt to deal with drawbacks in fake changes blocking real locks. It is not safe for use in all environments. Added as a deprecated and ignored option in MariaDB 10.2.6 (which uses InnoDB as default instead of XtraDB) to allow for easier upgrades.

- **Commandline:**

--innodb-locking-fake-changes

- **Scope:** Global

- **Dynamic:** Yes

- **Data Type:**

boolean

- **Default Value:**

ON

- **Deprecated:** MariaDB 10.2.6

- **Removed:** MariaDB 10.3.0

## `innodb_locks_unsafe_for_binlog`

- **Description:** Set to

0

by default, in which case XtraDB/InnoDB uses [gap locking](#). If set to

1

, gap locking is disabled for searches and index scans. Deprecated in [MariaDB 10.0](#), and removed in [MariaDB 10.5](#), use [READ COMMITTED transaction isolation level](#) instead.

- **Commandline:**

`--innodb-locks-unsafe-for-binlog`

- **Scope:** Global

- **Dynamic:** No

- **Data Type:**

boolean

- **Default Value:**

OFF

- **Deprecated:** [MariaDB 10.0](#)

- **Removed:** [MariaDB 10.5.0](#)

## `innodb_log_arch_dir`

- **Description:** The directory for [XtraDB redo log](#) archiving. XtraDB only. Added as a deprecated and ignored option in [MariaDB 10.2.6](#) (which uses InnoDB as default instead of XtraDB) to allow for easier upgrades.

- **Commandline:**

`--innodb-log-arch-dir=name`

- **Scope:** Global

- **Dynamic:** No

- **Data Type:**

string

- **Default Value:**

`./`

- **Deprecated:** [MariaDB 10.2.6](#)

- **Removed:** [MariaDB 10.3.0](#)

## `innodb_log_arch_expire_sec`

- **Description:** Time in seconds since the last change after which the archived [XtraDB redo log](#) should be deleted. XtraDB only. Added as a deprecated and ignored option in [MariaDB 10.2.6](#) (which uses InnoDB as default instead of XtraDB) to allow for easier upgrades.

- **Commandline:**

`--innodb-log-arch-expire-sec=#`

- **Scope:** Global

- **Dynamic:** Yes

- **Data Type:**

numeric

- **Default Value:**

0

- **Deprecated:** [MariaDB 10.2.6](#)

- **Removed:** [MariaDB 10.3.0](#)

## `innodb_log_archive`

- **Description:** Whether or not [XtraDB redo log](#) archiving is enabled. XtraDB only. Added as a deprecated and ignored option in [MariaDB 10.2.6](#) (which uses InnoDB as default instead of XtraDB) to allow for easier upgrades.

- **Commandline:**

```
--innodb-log-archive={0|1}
```

- **Scope:** Global

- **Dynamic:** Yes

- **Data Type:**

boolean

- **Default Value:**

OFF

- **Deprecated:** [MariaDB 10.2.6](#)

- **Removed:** [MariaDB 10.3.0](#)

---

## innodb\_log\_block\_size

- **Description:** Size in bytes of the [XtraDB redo log](#) records. Generally

512

, the default, or

4096

, are the only two useful values. If the server is restarted and this value is changed, all old log files need to be removed. Should be set to  
4096

for SSD cards or if [innodb\\_flush\\_method](#) is set to

ALL\_O\_DIRECT

on ext4 filesystems. XtraDB only. Added as a deprecated and ignored option in [MariaDB 10.2.6](#) (which uses InnoDB as default instead of XtraDB) to allow for easier upgrades.

- **Commandline:**

```
innodb-log-block-size=#
```

- **Scope:** Global

- **Dynamic:** No

- **Data Type:**

numeric

- **Default Value:**

512

- **Deprecated:** [MariaDB 10.2.6](#)

- **Removed:** [MariaDB 10.3.0](#)

---

## innodb\_log\_buffer\_size

- **Description:** Size in bytes of the buffer for writing [InnoDB redo log](#) files to disk. Increasing this means larger transactions can run without needing to perform disk I/O before committing.

- **Commandline:**

```
--innodb-log-buffer-size=#
```

- **Scope:** Global

- **Dynamic:** No

- **Data Type:**

numeric

- **Default Value:**

16777216

(16MB) >= [MariaDB 10.1.9](#),

8388608

(8MB) <= [MariaDB 10.1.8](#)

- **Range:**

262144

to

4294967295

(256KB to 4096MB)

## innodb\_log\_checksum\_algorithm

- **Description:** Experimental feature (as of [MariaDB 10.0.9](#) ), this variable specifies how to generate and verify [XtraDB redo log](#) checksums. XtraDB only. Added as a deprecated and ignored option in [MariaDB 10.2.6](#) (which uses InnoDB as default instead of XtraDB) to allow for easier upgrades.

- - none
    - No checksum. A constant value is instead written to logs, and no checksum validation is performed.
  - innodb
    - The default, and the original InnoDB algorithm. This is inefficient, but compatible with all MySQL, MariaDB and Percona versions that don't support other checksum algorithms.
  - crc32
    - CRC32 © is used for log block checksums, which also permits recent CPUs to use hardware acceleration (on SSE4.2 x86 machines and Power8 or later) for the checksums.
  - strict\_\*
- Whether or not to accept checksums from other algorithms. If strict mode is used, checksums blocks will be considered corrupt if they don't match the specified algorithm. Normally they are considered corrupt only if no other algorithm matches.

- **Commandline:**

```
innodb-log-checksum-algorithm=value
```

- **Scope:** Global

- **Dynamic:** Yes

- **Data Type:**

enum

- **Default Value:**

- - deprecated
    - (>= [MariaDB 10.2.6](#) )
  - innodb
    - (<= [MariaDB 10.1](#) )

- **Valid Values:**

- - deprecated
  - ,
  - innodb
  - ,
  - none
  - ,
  - crc32
  - ,
  - strict\_none
  - ,
  - strict\_innodb
  - ,
  - strict\_crc32
  - (>= [MariaDB 10.2.6](#) )
- - innodb
  - ,
  - none
  - ,
  - crc32
  - ,
  - strict\_none
  - ,
  - strict\_innodb
  - ,
  - strict\_crc32
  - (<= [MariaDB 10.1](#) )

- **Deprecated:** [MariaDB 10.2.6](#)

- **Removed:** [MariaDB 10.3.0](#)

---

## innodb\_log\_checksums

- **Description:** If set to

1  
, the CRC32C for InnoDB or  
`innodb_log_checksum_algorithm`  
for XtraDB algorithm is used for [InnoDB redo log](#) pages. If disabled, the checksum field contents are ignored. From [MariaDB 10.5.0](#), the variable is deprecated, and checksums are always calculated, as previously, the InnoDB redo log used the slow innodb algorithm, but with hardware or SIMD assisted CRC-32C computation being available, there is no reason to allow checksums to be disabled on the redo log.

- **Commandline:**

```
innodb-log-checksums={0|1}
```

- **Scope:** Global

- **Dynamic:** Yes

- **Data Type:**

boolean

- **Default Value:**

ON

- **Introduced:** [MariaDB 10.2.2](#)

- **Deprecated:** [MariaDB 10.5.0](#)

- **Removed:** [MariaDB 10.6.0](#)
- 

## innodb\_log\_compressed\_pages

- **Description:** Whether or not images of recompressed pages are stored in the [InnoDB redo log](#). Deprecated and ignored from [MariaDB 10.5.3](#).

- **Commandline:**

```
--innodb-log-compressed-pages={0|1}
```

- **Scope:** Global

- **Dynamic:** Yes

- **Data Type:**

boolean

- **Default Value:**

◦

ON

(>= [MariaDB 10.2.4](#) , >= [MariaDB 10.1.26](#) , <= [MariaDB 10.1.1](#) )

◦

OFF

( [MariaDB 10.2.0](#) - [MariaDB 10.2.3](#) , [MariaDB 10.1.2](#) - [MariaDB 10.1.25](#) )

- **Deprecated:** [MariaDB 10.5.3](#)

- **Removed:** [MariaDB 10.6.0](#)
- 

## innodb\_log\_file\_size

- **Description:** Size in bytes of each [InnoDB redo log](#) file in the log group. The combined size can be no more than 512GB. Larger values mean less disk I/O due to less flushing checkpoint activity, but also slower recovery from a crash. In [MariaDB 10.5](#), crash recovery has been improved and shouldn't run out of memory, so the default has been increased. It can safely be set higher to reduce checkpoint flushing, even larger than [innodb\\_buffer\\_pool\\_size](#).

- **Commandline:**

```
--innodb-log-file-size=
```

- **Scope:** Global

- **Dynamic:** No

- **Data Type:**

numeric

- **Default Value:**

100663296

(96MB) (>= [MariaDB 10.5](#) ),

50331648

(48MB) (<= [MariaDB 10.4](#) )

- **Range:**

◦ >= [MariaDB 10.8.3](#) :

4194304

```
to  
512GB  
(4MB to 512GB)  
◦ <= MariaDB 10.8.2 :  
    1048576  
    to  
    512GB  
(1MB to 512GB)
```

---

## innodb\_log\_files\_in\_group

- **Description:** Number of physical files in the [InnoDB redo log](#). Deprecated and ignored from [MariaDB 10.5.2](#).
- **Commandline:**

```
--innodb-log-files-in-group=#
```

- **Scope:** Global

- **Dynamic:** No

- **Data Type:**

```
    numeric
```

- **Default Value:**

```
    1  
(>= MariaDB 10.5 ),  
    2  

```

- **Range:**

```
    1  
    to  
    100  
(>= MariaDB 10.2.4 ),  
    2  

```

- **Deprecated:** [MariaDB 10.5.2](#)

- **Removed:** [MariaDB 10.6.0](#)
- 

## innodb\_log\_group\_home\_dir

- **Description:** Path to the [InnoDB redo log](#) files. If none is specified, [innodb\\_log\\_files\\_in\\_group](#) files named ib\_logfile0 and so on, with a size of [innodb\\_log\\_file\\_size](#) are created in the data directory.

- **Commandline:**

```
--innodb-log-group-home-dir=path
```

- **Scope:** Global

- **Dynamic:** No

- **Data Type:**

```
    directory name
```

---

## innodb\_log\_optimize\_ddl

- **Description:** Whether [InnoDB redo log](#) activity should be reduced when natively creating indexes or rebuilding tables. Reduced logging requires additional page flushing and interferes with [Mariabackup](#). Enabling this may slow down backup and cause delay due to page flushing. Deprecated and ignored from [MariaDB 10.5.1](#). Deprecated (but not ignored) from [MariaDB 10.4.16](#), [MariaDB 10.3.26](#) and [MariaDB 10.2.35](#).

- **Commandline:**

```
--innodb-log-optimize-ddl={0|1}
```

- **Scope:** Global

- **Dynamic:** Yes

- **Data Type:**

```
    boolean
```

- **Default Value:**

- OFF  
( $\geq$  MariaDB 10.5.1 , MariaDB 10.4.16 , MariaDB 10.3.26 , MariaDB 10.2.35 )
- ON  
( $\leq$  MariaDB 10.5.0 , MariaDB 10.4.15 , MariaDB 10.3.25 , MariaDB 10.2.34 )

- **Introduced:** MariaDB 10.2.17 , MariaDB 10.3.9

- **Deprecated:** MariaDB 10.5.1 , MariaDB 10.4.16 , MariaDB 10.3.26 , MariaDB 10.2.35

- **Removed:** MariaDB 10.6.0

---

### innodb\_log\_write\_ahead\_size

- **Description:** InnoDB redo log write ahead unit size to avoid read-on-write. Should match the OS cache block IO size.

- **Commandline:**

```
--innodb-log-write-ahead-size=#
```

- **Scope:** Global

- **Dynamic:** Yes

- **Data Type:**

numeric

- **Default Value:**

8192

- **Range:**

512  
to innodb\_page\_size

- **Introduced:** MariaDB 10.2.2

---

### innodb\_lru\_flush\_size

- **Description:** Number of pages to flush on LRU eviction.

- **Commandline:**

```
--innodb-lru-flush-size=#
```

- **Scope:** Global

- **Dynamic:** Yes

- **Data Type:**

numeric

- **Default Value:**

32

- **Range:**

1  
to  
18446744073709551615

- **Introduced:** MariaDB 10.5.7

---

### innodb\_lru\_scan\_depth

- **Description:** Specifies how far down the buffer pool least-recently used (LRU) list the cleaning thread should look for dirty pages to flush. This process is performed once a second. In an I/O intensive-workload, can be increased if there is spare I/O capacity, or decreased if in a write-intensive workload with little spare I/O capacity.

- See [InnoDB Page Flushing](#) for more information.

- **Commandline:**

```
--innodb-lru-scan-depth=#
```

- **Scope:** Global

- **Dynamic:** Yes

- **Data Type:**

numeric

- **Default Value:**

◦

1536  
( $\geq$  MariaDB 10.5.7)

◦

1024  
( $\leq$  MariaDB 10.5.6)

- **Range - 32bit:**

100

to

2

32

-1

- **Range - 64bit:**

100

to

2

64

-1

## innodb\_max\_bitmap\_file\_size

- **Description:** Limit in bytes of the changed page bitmap files. For faster incremental backup with [Xtrabackup](#), XtraDB tracks pages with changes written to them according to the [XtraDB redo log](#) and writes the information to special changed page bitmap files. These files are rotated when the server restarts or when this limit is reached. XtraDB only. See also [innodb\\_track\\_changed\\_pages](#) and [innodb\\_max\\_changed\\_pages](#).

◦ Deprecated and ignored in MariaDB 10.2.6 (which uses InnoDB as default instead of XtraDB) to allow for easier upgrades.

- **Commandline:**

innodb-max-bitmap-file-size=#

- **Scope:** Global

- **Dynamic:** Yes

- **Data Type:**

numeric

- **Default Value:**

4096  
(4KB)

- **Range:**

4096  
(4KB) to  
18446744073709551615  
(16EB)

- **Deprecated:** MariaDB 10.2.6

## innodb\_max\_changed\_pages

- **Description:** Limit to the number of changed page bitmap files (stored in the [Information Schema INNODB\\_CHANGED\\_PAGES table](#)). Zero is unlimited. See [innodb\\_max\\_bitmap\\_file\\_size](#) and [innodb\\_track\\_changed\\_pages](#). Previously named

innodb\_changed\_pages\_limit  
. XtraDB only.

◦ Deprecated and ignored in MariaDB 10.2.6 (which uses InnoDB as default instead of XtraDB) to allow for easier upgrades.

- **Commandline:**

innodb-max-changed-pages=#

- **Scope:** Global

- **Dynamic:** Yes

- **Data Type:**  
numeric

- **Default Value:**  
1000000

- **Range:**  
0  
to  
18446744073709551615

- **Deprecated:** MariaDB 10.2.6
- 

### innodb\_max\_dirty\_pages\_pct

- **Description:** Maximum percentage of unwritten (dirty) pages in the buffer pool.
  - See [InnoDB Page Flushing](#) for more information.

- **Commandline:**  
--innodb-max-dirty-pages-pct=#

- **Scope:** Global
- **Dynamic:** Yes
- **Data Type:**  
numeric

- **Default Value:**
  - 90.000000  
(>= MariaDB 10.5.7 )
  - 75.000000  
(<= MariaDB 10.5.6 )

- **Range:**  
0  
to  
99.999
- 

### innodb\_max\_dirty\_pages\_pct\_lwm

- **Description:** Low water mark percentage of dirty pages that will enable preflushing to lower the dirty page ratio. The value 0 (default) means 'refer to [innodb\\_max\\_dirty\\_pages\\_pct](#)'.
  - See [InnoDB Page Flushing](#) for more information.

- **Commandline:**  
--innodb-max-dirty-pages-pct-lwm=#

- **Scope:** Global
- **Dynamic:** Yes
- **Data Type:**  
numeric

- **Default Value:**  
0  
(>= MariaDB 10.2.2 ),  
0.001000  
(<= MariaDB 10.2.1 )

- **Range:**  
0  
to  
99.999
- 

### innodb\_max\_purge\_lag

- **Description:** When purge operations are lagging on a busy server, setting innodb\_max\_purge\_lag can help. By default set to 0, no lag, the figure is used to calculate a time lag for each INSERT, UPDATE, and DELETE when the system is lagging. XtraDB/InnoDB keeps a list of transactions with delete-marked index records due to UPDATE and DELETE statements. The length of this list is purge\_lag, and the calculation, performed every ten seconds, is as follows: ((purge\_lag/innodb\_max\_purge\_lag)×10)–5 milliseconds.

- **Commandline:**

```
--innodb-max-purge-lag=#
```

- **Scope:** Global

- **Dynamic:** Yes

- **Data Type:**

numeric

- **Default Value:**

0

- **Range:**

0

to

4294967295

## innodb\_max\_purge\_lag\_delay

- **Description:** Maximum delay in milliseconds imposed by the [innodb\\_max\\_purge\\_lag](#) setting. If set to 0, the default, there is no maximum.

- **Commandline:**

```
--innodb-max-purge-lag-delay=#
```

- **Scope:** Global

- **Dynamic:** Yes

- **Data Type:**

numeric

- **Default Value:**

0

## innodb\_max\_purge\_lag\_wait

- **Description:** Wait until History list length is below the specified limit.

- **Commandline:**

```
--innodb-max-purge-wait=#
```

- **Scope:** Global

- **Dynamic:** Yes

- **Data Type:**

numeric

- **Default Value:**

4294967295

- **Range:**

0

to

4294967295

- **Introduced:** [MariaDB 10.5.7](#) , [MariaDB 10.4.16](#) , [MariaDB 10.3.26](#) , [MariaDB 10.2.35](#)

## `innodb_max_undo_log_size`

- **Description:** If an undo tablespace is larger than this, it will be marked for truncation if `innodb_undo_log_truncate` is set.

- **Commandline:**

```
--innodb-max-undo-log-size=#
```

- **Scope:** Global

- **Dynamic:** Yes

- **Data Type:**

numeric

- **Default Value:**

◦

10485760  
( $\geq$  MariaDB 10.2.6 )

◦

1073741824  
( $\leq$  MariaDB 10.2.5 )

- **Range:**

10485760  
to  
18446744073709551615

- **Introduced:** MariaDB 10.2.2
- 

## `innodb_merge_sort_block_size`

- **Description:** Size in bytes of the block used for merge sorting in fast index creation. Replaced in MariaDB 10.0 /XtraDB 5.6 by `innodb_sort_buffer_size`.

- **Commandline:**

```
innodb-merge-sort-block-size=#
```

- **Scope:** Global

- **Dynamic:** Yes

- **Data Type:**

numeric

- **Default Value:**

1048576  
(1M)

- **Range:**

1048576  
(1M) to  
1073741824  
(1G)

- **Removed:** MariaDB 10.0 - replaced by `innodb_sort_buffer_size`
- 

## `innodb_mirrored_log_groups`

- **Description:** Unused. Restored as a deprecated and ignored option in MariaDB 10.2.6 (which uses InnoDB as default instead of XtraDB) to allow for easier upgrades.

- **Deprecated:** MariaDB 10.0

- **Removed:** MariaDB 10.2.2 - MariaDB 10.2.5
- 

## `innodb_mtflush_threads`

- **Description:** Sets the number of threads to use in Multi-Threaded Flush operations. For more information, see [Fusion-io Multi-threaded Flush](#).

◦ InnoDB's multi-thread flush feature was deprecated in MariaDB 10.2.9 and removed from MariaDB 10.3.2. In later versions of MariaDB, us

## `innodb_page_cleaners`

system variable instead.

◦ See [InnoDB Page Flushing: Page Flushing with Multi-threaded Flush Threads](#) for more information.

- **Commandline:**

```
--innodb-mtflush-threads=#
```

- **Scope:** Global

- **Dynamic:** No

- **Data Type:**

```
    numeric
```

- **Default Value:**

```
    8
```

- **Range:**

```
    1
```

```
    to
```

```
    64
```

- **Introduced:** MariaDB 10.1.0

- **Deprecated:** MariaDB 10.2.9

- **Removed:** MariaDB 10.3.2

---

### innodb\_monitor\_disable

- **Description:** Disables the specified counters in the [INFORMATION\\_SCHEMA.INNODB\\_METRICS](#) table.

- **Commandline:**

```
--innodb-monitor-disable=string
```

- **Scope:** Global

- **Dynamic:** Yes

- **Data Type:**

```
    string
```

---

### innodb\_monitor\_enable

- **Description:** Enables the specified counters in the [INFORMATION\\_SCHEMA.INNODB\\_METRICS](#) table.

- **Commandline:**

```
--innodb-monitor-enable=string
```

- **Scope:** Global

- **Dynamic:** Yes

- **Data Type:**

```
    string
```

---

### innodb\_monitor\_reset

- **Description:** Resets the count value of the specified counters in the [INFORMATION\\_SCHEMA.INNODB\\_METRICS](#) table to zero.

- **Commandline:**

```
--innodb-monitor-reset=string
```

- **Scope:** Global

- **Dynamic:** Yes

- **Data Type:**

```
    string
```

---

### innodb\_monitor\_reset\_all

- **Description:** Resets all values for the specified counters in the [INFORMATION\\_SCHEMA.INNODB\\_METRICS](#) table.

- **Commandline:**

```
--innodb-monitor-reset-all=string
```

- **Scope:** Global

- **Dynamic:** Yes

- **Data Type:**

string

---

## innodb\_numa\_interleave

- **Description:** Whether or not to use the NUMA interleave memory policy to allocate the [InnoDB buffer pool](#). Before [MariaDB 10.2.4](#), required that MariaDB be compiled on a NUMA-enabled Linux system.

- **Commandline:**

```
innodb-numa-interleave={0|1}
```

- **Scope:** Global

- **Dynamic:** No

- **Data Type:**

boolean

- **Default Value:**

OFF

- **Removed:** [MariaDB 10.2.23](#), [MariaDB 10.3.14](#), [MariaDB 10.4.4](#)
- 

## innodb\_old\_blocks\_pct

- **Description:** Percentage of the [buffer pool](#) to use for the old block sublist.

- **Commandline:**

```
--innodb-old-blocks-pct=#
```

- **Scope:** Global

- **Dynamic:** Yes

- **Data Type:**

numeric

- **Default Value:**

37

- **Range:**

5

to

95

---

## innodb\_old\_blocks\_time

- **Description:** Time in milliseconds an inserted block must stay in the old sublist after its first access before it can be moved to the new sublist. '0' means "no delay". Setting a non-zero value can help prevent full table scans clogging the [buffer pool](#). See also [innodb\\_old\\_blocks\\_pct](#).

- **Commandline:**

```
--innodb-old-blocks-time=#
```

- **Scope:** Global

- **Dynamic:** Yes

- **Data Type:**

numeric

- **Default Value:**

1000

- **Range:**

0  
to  
2

32

-1

---

## innodb\_online\_alter\_log\_max\_size

- **Description:** The maximum size for temporary log files during online DDL (data and index structure changes). The temporary log file is used for each table being altered, or index being created, to store data changes to the table while the process is underway. The table is extended by [innodb\\_sort\\_buffer\\_size](#) up to the limit set by this variable. If this limit is exceeded, the online DDL operation fails and all uncommitted changes are rolled back. A lower value reduces the time a table could lock at the end of the operation to apply all the log's changes, but also increases the chance of the online DDL changes failing.

- **Commandline:**

--innodb-online-alter-log-max-size=#

- **Scope:** Global

- **Dynamic:** Yes

- **Data Type:**

numeric

- **Default Value:**

134217728

- **Range:**

65536  
to  
2

64

-1

---

## innodb\_open\_files

- **Description:** Maximum .ibd files MariaDB can have open at the same time. Only applies to systems with multiple XtraDB/InnoDB tablespaces, and is separate to the table cache and [open\\_files\\_limit](#). The default, if [innodb\\_file\\_per\\_table](#) is disabled, is 300 or the value of [table\\_open\\_cache](#), whichever is higher. It will also auto-size up to the default value if it is set to a value less than

10

- **Commandline:**

--innodb-open-files=#

- **Scope:** Global

- **Dynamic:** No

- **Data Type:**

numeric

- **Default Value:**

autosized

- **Range:**

10  
to  
4294967295

## innodb\_optimize\_fulltext\_only

- **Description:** When set to

```
1  
(  
0  
is default), OPTIMIZE TABLE will only process InnoDB FULLTEXT index data. Only intended for use during fulltext index maintenance.
```

- **Commandline:**

```
--innodb-optimize-fulltext-only={0|1}
```

- **Scope:** Global

- **Dynamic:** Yes

- **Data Type:**

boolean

- **Default Value:**

OFF

---

## innodb\_page\_cleaners

- **Description:** Number of page cleaner threads. The default is

```
4  
, but the value will be set to the number of innodb\_buffer\_pool\_instances if this is lower. If set to  
1  
, only a single cleaner thread is used, as was the case until MariaDB 10.2.1. Cleaner threads flush dirty pages from the buffer pool,  
performing flush list and least-recently used (LRU) flushing. Deprecated and ignored from MariaDB 10.5.1, as the original reasons for splitting  
the buffer pool have mostly gone away.
```

◦ See [InnoDB Page Flushing: Page Flushing with Multiple InnoDB Page Cleaner Threads](#) for more information.

- **Commandline:**

```
--innodb-page-cleaners=#
```

- **Scope:** Global

- **Dynamic:** Yes (>= [MariaDB 10.3.3](#)), No (<= [MariaDB 10.3.2](#))

- **Data Type:**

numeric

- **Default Value:**

```
4  
(or set to innodb\_buffer\_pool\_instances if lower)
```

- **Range:**

```
1  
to  
64
```

- **Introduced:** [MariaDB 10.2.2](#)

- **Deprecated:** [MariaDB 10.5.1](#)

- **Removed:** [MariaDB 10.6.0](#)

---

## innodb\_page\_size

- **Description:** Specifies the page size in bytes for all InnoDB tablespaces. The default,

```
16k  
, is suitable for most uses.  
◦ A smaller InnoDB page size might work more effectively in a situation with many small writes (OLTP), or with SSD storage, which usually  
has smaller block sizes.  
◦ A larger InnoDB page size can provide a larger maximum row size.  
◦ InnoDB's page size can be as large as
```

```
64k  
for tables using the following row formats : DYNAMIC , COMPACT , and REDUNDANT.
```

◦ InnoDB's page size must still be

```
16k  
or less for tables using the COMPRESSED row format.
```

◦ This system variable's value cannot be changed after the

```
datadir  
has been initialized. InnoDB's page size is set when a MariaDB instance starts, and it remains constant afterwards.
```

- **Commandline:**

```
--innodb-page-size=#
```

- **Scope:** Global

- **Dynamic:** No

- **Data Type:**

```
enumeration
```

- **Default Value:**

```
16384
```

- **Valid Values:**

```
4k  
or  
4096  
,  
8k  
or  
8192  
,  
16k  
or  
16384  
,  
32k  
and  
64k
```

---

## innodb\_pass\_corrupt\_table

- **Removed:** XtraDB 5.5 - renamed [innodb\\_corrupt\\_table\\_action](#).

---

## innodb\_prefix\_index\_cluster\_optimization

- **Description:** Enable prefix optimization to sometimes avoid cluster index lookups.

- **Commandline:**

```
--innodb-prefix-index-cluster-optimization={0|1}
```

- **Scope:** Global

- **Dynamic:** Yes

- **Data Type:**

```
boolean
```

- **Default Value:**

```
OFF
```

- **Introduced:** [MariaDB 10.1.2](#)

---

## innodb\_print\_all\_deadlocks

- **Description:** If set to

```
1
```

```
(
```

```
0
```

```
is default), all XtraDB/InnoDB transaction deadlock information is written to the error log.
```

- **Commandline:**

```
--innodb-print-all-deadlocks={0|1}
```

- **Scope:** Global

- **Dynamic:** Yes
- **Data Type:**  
boolean

- **Default Value:**  
OFF
- 

### innodb\_purge\_batch\_size

- **Description:** Units of [InnoDB redo log](#) records that will trigger a purge operation. Together with [innodb\\_purge\\_threads](#) has a small effect on tuning.
- **Commandline:**

```
--innodb-purge-batch-size=#
```

- **Scope:** Global
- **Dynamic:** No
- **Data Type:**  
numeric

- **Default Value:**  
20

- **Range:**  
1  
to  
5000
- 

### innodb\_purge\_rseg\_truncate\_frequency

- **Description:** Frequency with which undo records are purged. Set by default to every 128 times, reducing this increases the frequency at which rollback segments are freed. See also [innodb\\_undo\\_log\\_truncate](#).
- **Commandline:**

```
-- innodb-purge-rseg-truncate-frequency=#
```

- **Scope:** Global
- **Dynamic:** Yes
- **Data Type:**  
numeric

- **Default Value:**  
128

- **Range:**  
1  
to  
128

- **Introduced:** [MariaDB 10.2.2](#)
- 

### innodb\_purge\_threads

- **Description:** Number of background threads dedicated to InnoDB purge operations. The range is

```
1
```

```
to
```

```
32
```

. At least one background thread is always used from [MariaDB 10.0](#). The default has been increased from

```
1
```

```
to
```

```
4
```

in [MariaDB 10.2.2](#). Setting to a value greater than 1 creates many separate purge threads. This can improve efficiency in some cases, such as when performing DML operations on many tables. In [MariaDB 5.5](#), the options are

0  
and  
1  
. If set to  
0  
, the default, purging is done with the primary thread. If set to  
1  
, purging is done on a separate thread, which could reduce contention. See also [innodb\\_purge\\_batch\\_size](#).

- **Commandline:**

```
--innodb-purge-threads=#
```

- **Scope:** Global

- **Dynamic:** No

- **Data Type:**

numeric

- **Default Value:**

- - 4  
(>= [MariaDB 10.2.2](#))
  - 1  
(>= [MariaDB 10.0](#) to <= [MariaDB 10.2.1](#))

- **Range:**

1  
to  
32

---

## innodb\_random\_read\_ahead

- **Description:** Originally, random read-ahead was always set as an optimization technique, but was removed in [MariaDB 5.5](#).

innodb\_random\_read\_ahead  
permits it to be re-instated if set to  
1  
(  
0  
) is default.

- **Commandline:**

```
--innodb-random-read-ahead={0|1}
```

- **Scope:** Global

- **Dynamic:** Yes

- **Data Type:**

boolean

- **Default Value:**

OFF

---

## innodb\_read\_ahead

- **Description:** If set to

linear  
, the default, XtraDB/InnoDB will automatically fetch remaining pages if there are enough within the same extent that can be accessed sequentially. If set to

none  
, read-ahead is disabled.

random  
has been removed and is now ignored, while

both

sets to both

linear

and

random

. Also see [innodb\\_read\\_ahead\\_threshold](#) for more control on read-aheads. Removed in [MariaDB 10.0](#) /XtraDB 5.6 and replaced by

MySQL 5.6's [innodb\\_random\\_read\\_ahead](#).

- **Commandline:**

```
innodb-read-ahead=value
```

- **Scope:** Global

- **Dynamic:** Yes

- **Data Type:**

```
enumeration
```

- **Default Value:**

```
linear
```

- **Valid Values:**

```
none
```

```
,
```

```
random
```

```
,
```

```
linear
```

```
,
```

```
both
```

- **Removed:** [MariaDB 10.0](#) /XtraDB 5.6 - replaced by MySQL 5.6's [innodb\\_random\\_read\\_ahead](#)

---

## innodb\_read\_ahead\_threshold

• **Description:** Minimum number of pages XtraDB/InnoDB must read from an extent of 64 before initiating an asynchronous read for the following extent.

- **Commandline:**

```
--innodb-read-ahead-threshold=#
```

- **Scope:** Global

- **Dynamic:** Yes

- **Data Type:**

```
numeric
```

- **Default Value:**

```
56
```

- **Range:**

```
0
```

```
to
```

```
64
```

## innodb\_read\_io\_threads

• **Description:** Number of I/O threads for XtraDB/InnoDB reads. You may on rare occasions need to reduce this default on Linux systems running multiple MariaDB servers to avoid exceeding system limits.

- **Commandline:**

```
--innodb-read-io-threads=#
```

- **Scope:** Global

- **Dynamic:** No

- **Data Type:**

```
numeric
```

- **Default Value:**

```
4
```

- **Range:**

```
1
```

```
to
```

```
64
```

## innodb\_read\_only

- **Description:** If set to

1

(

0

is default), the server will be read-only. For use in distributed applications, data warehouses or read-only media.

- **Commandline:**

--innodb-read-only={0|1}

- **Scope:** Global

- **Dynamic:** No

- **Data Type:**

boolean

- **Default Value:**

OFF

## innodb\_read\_only\_compressed

- **Description:** If set (the default before [MariaDB 10.6.6](#)), **ROW\_FORMAT=COMPRESSED** tables will be read-only. This was intended to be the first step towards removing write support and deprecating the feature, but this plan has been abandoned.

- **Commandline:**

--innodb-read-only-compressed  
,  
--skip-innodb-read-only-compressed

- **Scope:**

- **Dynamic:**

- **Data Type:**

boolean

- **Default Value:**

OFF  
(>= [MariaDB 10.6.6](#) ),  
ON  
(<= [MariaDB 10.6.5](#) )

- **Introduced:** [MariaDB 10.6.0](#)
- ## innodb\_recovery\_stats
- **Description:** If set to
- 1
- (
- 0
- is default) and recovery is necessary on startup, the server will write detailed recovery statistics to the error log at the end of the recovery process. This Percona XtraDB variable has not been ported to XtraDB 5.6.
- **Commandline:** No
- **Scope:** Global
- **Dynamic:** No
- **Data Type:**
- boolean
- **Default Value:**
- OFF
- **Removed:** [MariaDB 10.0](#)

## innodb\_recovery\_update\_relay\_log

---

1800/2552

- **Description:** If set to

```
1
(
0
```

is default), the relay log info file will be overwritten on crash recovery if the information differs from the InnoDB record. Should not be used if multiple storage engine types are being replicated. Previously named

```
innodb_overwrite_relay_log_info
. Removed in MariaDB 10.0 /XtraDB 5.6 and replaced by MySQL 5.6's
relay-log-recovery
```

- **Commandline:**

```
innodb-recovery-update-relay-log={0|1}
```

- **Scope:** Global

- **Dynamic:** No

- **Data Type:**

```
boolean
```

- **Default Value:**

```
OFF
```

- **Removed:** MariaDB 10.0 - replaced by MySQL 5.6's

```
relay-log-recovery
```

---

## innodb\_replication\_delay

- **Description:** Time in milliseconds for the replica server to delay the replication thread if [innodb\\_thread\\_concurrency](#) is reached. Deprecated and ignored from [MariaDB 10.5.5](#).

- **Commandline:**

```
--innodb-replication-delay=#
```

- **Scope:** Global

- **Dynamic:** Yes

- **Data Type:**

```
numeric
```

- **Default Value:**

```
0
```

- **Range:**

```
0
to
4294967295
```

- **Deprecated:** MariaDB 10.5.5

- **Removed:** MariaDB 10.6.0
- 

## innodb\_rollback\_on\_timeout

- **Description:** InnoDB usually rolls back the last statement of a transaction that's been timed out (see [innodb\\_lock\\_wait\\_timeout](#)). If [innodb\\_rollback\\_on\\_timeout](#) is set to 1 (0 is default), InnoDB will roll back the entire transaction. Before [MariaDB 5.5](#), rolling back the entire transaction was the default behavior.

- **Commandline:**

```
--innodb-rollback-on-timeout
```

- **Scope:** Global

- **Dynamic:** No

- **Data Type:**

```
boolean
```

- **Default Value:**

```
0
```

---

## innodb\_rollback\_segments

- **Description:** Specifies the number of rollback segments that XtraDB/InnoDB will use within a transaction (see [undo log](#) ). Deprecated and replaced by [innodb\\_undo\\_logs](#) in [MariaDB 10.0](#) .
  - **Commandline:**

```
--innodb-rollback-segments=#
```
  - **Scope:** Global
  - **Dynamic:** Yes
  - **Data Type:**  
numeric
  - **Default Value:**  
128
  - **Range:**  
1  
to  
128
  - **Deprecated:** [MariaDB 10.0](#)
  - **Removed:** [MariaDB 10.5.0](#)
- 

## innodb\_safe\_truncate

- **Description:** Use a backup-safe [TRUNCATE TABLE](#) implementation and crash-safe rename operations inside InnoDB. This is not compatible with hot backup tools other than [Mariabackup](#) . Users who need to use such tools may set this to  
OFF
  - **Commandline:**

```
--innodb-safe-truncate={0|1}
```
  - **Scope:** Global
  - **Dynamic:** No
  - **Data Type:**  
boolean
  - **Default Value:**  
ON
  - **Introduced:** [MariaDB 10.2.19](#)
  - **Removed:** [MariaDB 10.3.0](#)
- 

## innodb\_scrub\_log

- **Description:** Enable [InnoDB redo log](#) scrubbing. See [Data Scrubbing](#) . Deprecated and ignored from [MariaDB 10.5.2](#) , as never really worked ([MDEV-13019](#) and [MDEV-18370](#) ). If old log contents should be kept secret, then enabling [innodb\\_encrypt\\_log](#) or setting a smaller [innodb\\_log\\_file\\_size](#) could help.
  - **Commandline:**

```
--innodb-scrub-log
```
  - **Scope:** Global
  - **Dynamic:** No
  - **Data Type:**  
boolean
  - **Default Value:**  
OFF
  - **Introduced:** [MariaDB 10.1.3](#)
  - **Deprecated:** [MariaDB 10.5.2](#)
  - **Removed:** [MariaDB 10.6.0](#)
-

## `innodb_scrub_log_interval`

- **Description:** Used with [Data Scrubbing](#) in 10.1.3 only - replaced in 10.1.4 by [innodb\\_scrub\\_log\\_speed](#). InnoDB redo log scrubbing interval in milliseconds.
  - **Commandline:**  
    `--innodb-scrub-log-interval=#`
  - **Scope:** Global
  - **Dynamic:** Yes
  - **Data Type:**  
    numeric
  - **Default Value:**  
    56
  - **Range:**  
    0  
    to  
    50000
  - **Introduced:** [MariaDB 10.1.3](#)
  - **Removed:** [MariaDB 10.1.4](#)
- 

## `innodb_scrub_log_speed`

- **Description:** InnoDB redo log scrubbing speed in bytes/sec. See [Data Scrubbing](#). Deprecated and ignored from [MariaDB 10.5.2](#).
  - **Commandline:**  
    `--innodb-scrub-log-speed=#`
  - **Scope:** Global
  - **Dynamic:** Yes
  - **Data Type:**  
    numeric
  - **Default Value:**  
    256
  - **Range:**  
    1  
    to  
    50000
  - **Introduced:** [MariaDB 10.1.4](#)
  - **Deprecated:** [MariaDB 10.5.2](#)
  - **Removed:** [MariaDB 10.6.0](#)
- 

## `innodb_sched_priority_cleaner`

- **Description:** Set a thread scheduling priority for cleaner and least-recently used (LRU) manager threads. The range from 0 to 39 corresponds in reverse order to Linux nice values of -20 to 19. So 0 is the lowest priority (Linux nice value 19) and 39 is the highest priority (Linux nice value -20)

). XtraDB only. Added as a deprecated and ignored option in [MariaDB 10.2.6](#) (which uses InnoDB as default instead of XtraDB) to allow for easier upgrades.

- **Commandline:**

```
innodb-sched-priority-cleaner=#
```

- **Scope:** Global

- **Dynamic:** Yes

- **Data Type:**

numeric

- **Default Value:**

19

- **Range:**

0

to

39

- **Deprecated:** [MariaDB 10.2.6](#)

- **Removed:** [MariaDB 10.3.0](#)

---

## innodb\_show\_locks\_held

- **Description:** Specifies the number of locks held for each InnoDB transaction to be displayed in [SHOW ENGINE INNODB STATUS](#) output. XtraDB only. Added as a deprecated and ignored option in [MariaDB 10.2.6](#) (which uses InnoDB as default instead of XtraDB) to allow for easier upgrades.

- **Commandline:**

```
innodb-show-locks-held=#
```

- **Scope:** Global

- **Dynamic:** Yes

- **Data Type:**

numeric

- **Default Value:**

10

- **Range:**

0

to

1000

- **Deprecated:** [MariaDB 10.2.6](#)

- **Removed:** [MariaDB 10.3.0](#)

---

## innodb\_show\_verbose\_locks

- **Description:** If set to

1

, and [innodb\\_status\\_output\\_locks](#) is also ON, the traditional InnoDB behavior is followed and locked records will be shown in [SHOW ENGINE INNODB STATUS](#) output. If set to

0

, the default, only high-level information about the lock is shown. XtraDB only. Added as a deprecated and ignored option in [MariaDB 10.2.6](#) (which uses InnoDB as default instead of XtraDB) to allow for easier upgrades.

- **Commandline:**

```
innodb-show-verbose-locks=#
```

- **Scope:** Global

- **Dynamic:** Yes

- **Data Type:**

numeric

- **Default Value:**

0

- **Range:**

0  
to  
1

- **Deprecated:** MariaDB 10.2.6
  - **Removed:** MariaDB 10.3.0
- 

### innodb\_simulate\_comp\_failures

- **Description:** Simulate compression failures. Used for testing robustness against random compression failures. XtraDB only.

- **Commandline:** None

- **Scope:** Global

- **Dynamic:** Yes

- **Data Type:**

numeric

- **Default Value:**

0

- **Range:**

0

to

99

### innodb\_sort\_buffer\_size

- **Description:** Size of the sort buffers used for sorting data when an InnoDB index is created, as well as the amount by which the temporary log file is extended during online DDL operations to record concurrent writes. The larger the setting, the fewer merge phases are required between buffers while sorting. When a [CREATE TABLE](#) or [ALTER TABLE](#) creates a new index, three buffers of this size are allocated, as well as pointers for the rows in the buffer.

- **Commandline:**

--innodb-sort-buffer-size=#

- **Scope:** Global

- **Dynamic:** No

- **Data Type:**

numeric

- **Default Value:**

1048576  
(1M)

- **Range:**

65536

to

67108864

### innodb\_spin\_wait\_delay

- **Description:** Maximum delay (not strictly corresponding to a time unit) between spin lock polls. Default changed from

6  
to  
4

in [MariaDB 10.3.5](#), as this was verified to give the best throughput by OLTP update index and read-write benchmarks on Intel Broadwell (2/20/40) and ARM (1/46/46).

- **Commandline:**

--innodb-spin-wait-delay=#

- **Scope:** Global

- **Dynamic:** Yes

- **Data Type:**

numeric

- **Default Value:**

4  
(>= MariaDB 10.3.5 ),  
6  
(<= MariaDB 10.3.4 )

- **Range:**

0  
to  
4294967295

---

## innodb\_stats\_auto\_recalc

- **Description:** If set to

1

(the default), persistent statistics are automatically recalculated when the table changes significantly (more than 10% of the rows). Affects tables created or altered with STATS\_PERSISTENT=1 (see [CREATE TABLE](#)), or when [innodb\\_stats\\_persistent](#) is enabled.

[innodb\\_stats\\_persistent\\_sample\\_pages](#) determines how much data to sample when recalculating. See [InnoDB Persistent Statistics](#).

- **Commandline:**

--innodb-stats-auto-recalc={0|1}

- **Scope:** Global

- **Dynamic:** Yes

- **Data Type:**

boolean

- **Default Value:**

ON

---

## innodb\_stats\_auto\_update

- **Description:** If set to

0

(

1

is default), index statistics will not be automatically calculated except when an [ANALYZE TABLE](#) is run, or the table is first opened.

Replaced by [innodb\\_stats\\_auto\\_recalc](#) in MariaDB 10.0 /XtraDB 5.6.

- **Scope:** Global

- **Dynamic:** Yes

- **Data Type:**

boolean

- **Default Value:**

1

- **Removed:** MariaDB 10.0 - replaced by [innodb\\_stats\\_auto\\_recalc](#).

---

## innodb\_stats\_include\_delete\_marked

- **Description:** Include delete marked records when calculating persistent statistics.

- **Scope:** Global

- **Dynamic:** Yes

- **Data Type:**

boolean

- **Default Value:**

OFF

- **Introduced:** MariaDB 10.2.6

## innodb\_stats\_method

- **Description:** Determines how NULLs are treated for InnoDB index statistics purposes.

- - **nulls\_equal**  
◦ The default, all NULL index values are treated as a single group. This is usually fine, but if you have large numbers of NULLs the average group size is slanted higher, and the optimizer may miss using the index for ref accesses when it would be useful.
  - **nulls\_unequal**  
◦ The opposite approach to **nulls\_equal** is taken, with each NULL forming its own group of one. Conversely, the average group size is slanted lower, and the optimizer may use the index for ref accesses when not suitable.
  - **nulls\_ignored**  
◦ Ignore NULLs altogether from index group calculations.

◦ See also [Index Statistics](#) , [aria\\_stats\\_method](#) and [myisam\\_stats\\_method](#) .

- **Commandline:**

◦ --innodb-stats-method=name

- **Scope:** Global

- **Dynamic:** Yes

- **Data Type:**

◦ enumeration

- **Default Value:**

◦ nulls\_equal

- **Valid Values:**

◦ nulls\_equal  
◦ ,  
◦ nulls\_unequal  
◦ ,  
◦ nulls\_ignored

## innodb\_stats\_modified\_counter

- **Description:** The number of rows modified before we calculate new statistics. If set to

◦ 0  
◦ , the default, current limits are used.

- **Commandline:**

◦ --innodb-stats-modified-counter=#

- **Scope:** Global

- **Dynamic:** Yes

- **Data Type:**

◦ numeric

- **Default Value:**

◦ 0

- **Range:**

◦ 0  
◦ to  
◦ 18446744073709551615

## innodb\_stats\_on\_metadata

- **Description:** If set to

◦ 1

, the default, XtraDB/InnoDB updates statistics when accessing the INFORMATION\_SCHEMA.TABLES or INFORMATION\_SCHEMA.STATISTICS tables, and when running metadata statements such as [SHOW INDEX](#) or [SHOW TABLE STATUS](#). If set to

0

, statistics are not updated at those times, which can reduce the access time for large schemas, as well as make execution plans more stable.

- **Commandline:**

```
--innodb-stats-on-metadata
```

- **Scope:** Global

- **Dynamic:** Yes

- **Data Type:**

boolean

- **Default Value:**

OFF

---

## innodb\_stats\_persistent

- **Description:** [ANALYZE TABLE](#) produces index statistics, and this setting determines whether they will be stored on disk, or be required to be recalculated more frequently, such as when the server restarts. This information is stored for each table, and can be set with the STATS\_PERSISTENT clause when creating or altering tables (see [CREATE TABLE](#)). See [InnoDB Persistent Statistics](#).

- **Commandline:**

```
--innodb-stats-persistent={0|1}
```

- **Scope:** Global

- **Dynamic:** Yes

- **Data Type:**

boolean

- **Default Value:**

ON

---

## innodb\_stats\_persistent\_sample\_pages

- **Description:** Number of index pages sampled when estimating cardinality and statistics for indexed columns. Increasing this value will increase index statistics accuracy, but use more I/O resources when running [ANALYZE TABLE](#). See [InnoDB Persistent Statistics](#).

- **Commandline:**

```
--innodb-stats-persistent-sample-pages=#
```

- **Scope:** Global

- **Dynamic:** Yes

- **Data Type:**

numeric

- **Default Value:**

20

---

## innodb\_stats\_sample\_pages

- **Description:** Gives control over the index distribution statistics by determining the number of index pages to sample. Higher values produce more disk I/O, but, especially for large tables, produce more accurate statistics and therefore make more effective use of the query optimizer. Lower values than the default are not recommended, as the statistics can be quite inaccurate.

- If [innodb\\_stats\\_traditional](#) is enabled, then the exact number of pages configured by this system variable will be sampled for statistics.
- If [innodb\\_stats\\_traditional](#) is disabled, then the number of pages to sample for statistics is calculated using a logarithmic algorithm, so the exact number can change depending on the size of the table. This means that more samples may be used for larger tables.
- If [persistent statistics](#) are enabled, then the [innodb\\_stats\\_persistent\\_sample\\_pages](#) system variable applies instead. [persistent statistics](#) are enabled with the [innodb\\_stats\\_persistent](#) system variable.
- This system variable has been [deprecated](#). The [innodb\\_stats\\_transient\\_sample\\_pages](#) system variable should be used instead.

- **Commandline:**

```
--innodb-stats-sample-pages#
```

- **Scope:** Global

- **Dynamic:** Yes

- **Data Type:**

numeric

- **Default Value:**

8

- **Range:**

1

to

2

64

-1

- **Deprecated:** MariaDB 10.0

- **Removed:** MariaDB 10.5.0

## innodb\_stats\_traditional

- **Description:** This system variable affects how the number of pages to sample for transient statistics is determined, in particular how [innodb\\_stats\\_transient\\_sample\\_pages](#) #is used.

- If [innodb\\_stats\\_traditional](#) is enabled, then the exact number of pages configured by the system variable will be sampled for statistics.
- If [innodb\\_stats\\_traditional](#) is disabled, then the number of pages to sample for statistics is calculated using a logarithmic algorithm, so the exact number can change depending on the size of the table. This means that more samples may be used for larger tables.
- This system variable does not affect the calculation of [persistent statistics](#).

- **Commandline:**

```
--innodb-stats-traditional={0|1}
```

- **Scope:** Global

- **Dynamic:** Yes

- **Data Type:**

boolean

- **Default Value:**

ON

## innodb\_stats\_transient\_sample\_pages

- **Description:** Gives control over the index distribution statistics by determining the number of index pages to sample. Higher values produce more disk I/O, but, especially for large tables, produce more accurate statistics and therefore make more effective use of the query optimizer. Lower values than the default are not recommended, as the statistics can be quite inaccurate.

- If

[innodb\\_stats\\_traditional](#)

is enabled, then the exact number of pages configured by this system variable will be sampled for statistics.

- If

[innodb\\_stats\\_traditional](#)

is disabled, then the number of pages to sample for statistics is calculated using a logarithmic algorithm, so the exact number can change depending on the size of the table. This means that more samples may be used for larger tables.

- If [persistent statistics](#) are enabled, then the

[innodb\\_stats\\_persistent\\_sample\\_pages](#)

system variable applies instead. [persistent statistics](#) are enabled with the

[innodb\\_stats\\_persistent](#)

system variable.

- **Commandline:**

```
--innodb-stats-transient-sample-pages=#
```

- **Scope:** Global

- **Dynamic:** Yes

- **Data Type:**

numeric

- **Default Value:**

8

- **Range:**

1

to

2

64

-1

## innodb\_stats\_update\_need\_lock

- **Description:** Setting to

0

(

1

is default) may help reduce contention of the

&dict\_operation\_lock

, but also disables the *Data\_free* option in [SHOW TABLE STATUS](#). This Percona XtraDB variable has not been ported to XtraDB 5.6.

- **Scope:** Global

- **Dynamic:** Yes

- **Data Type:**

boolean

- **Default Value:**

1

- **Removed:** [MariaDB 10.0](#) /XtraDB 5.6

## innodb\_status\_output

- **Description:** Enable [InnoDB monitor](#) output to the [error log](#).

- **Commandline:**

```
--innodb-status-output={0|1}
```

- **Scope:** Global

- **Dynamic:** Yes

- **Data Type:**

boolean

- **Default Value:**

OFF

## innodb\_status\_output\_locks

- **Description:** Enable [InnoDB lock monitor](#) output to the [error log](#) and [SHOW ENGINE INNODB STATUS](#). Also requires [innodb\\_status\\_output=ON](#) to enable output to the error log.

- **Commandline:**

```
--innodb-status-output-locks={0|1}
```

- **Scope:** Global
- **Dynamic:** Yes
- **Data Type:**  
boolean

- **Default Value:**

OFF

---

## innodb\_strict\_mode

- **Description:** If set to

1

(

0

is the default before [MariaDB 10.2.2](#) ), XtraDB/InnoDB will return errors instead of warnings in certain cases, similar to strict SQL mode.

- **Commandline:**

```
--innodb-strict-mode={0|1}
```

- **Scope:** Global, Session

- **Dynamic:** Yes

- **Data Type:**

boolean

- **Default Value:**

◦

ON

(>= [MariaDB 10.2.2](#) )

◦

OFF

(<= [MariaDB 10.2.1](#) )

---

## innodb\_support\_xa

- **Description:** If set to

1

, the default, [XA transactions](#) are supported. XA support ensures data is written to the [binary log](#) in the same order to the actual database, which is critical for [replication](#) and disaster recovery, but comes at a small performance cost. If your database is set up to only permit one thread to change data (for example, on a replication replica with only the replication thread writing), it is safe to turn this option off. Removed in [MariaDB 10.3](#) , XA transactions are always supported.

- **Commandline:**

```
--innodb-support-xa
```

- **Scope:** Global, Session

- **Dynamic:** Yes

- **Data Type:**

boolean

- **Default Value:**

ON

- **Deprecated:** [MariaDB 10.2](#)

- **Removed:** [MariaDB 10.3.0](#)
- 

## innodb\_sync\_array\_size

- **Description:** By default

1

, can be increased to split internal thread co-ordinating, giving higher concurrency when there are many waiting threads.

- **Commandline:**

```
--innodb-sync-array-size=#
```

- **Scope:** Global
- **Dynamic:** No
- **Data Type:**  
    numeric

- **Default Value:**

```
1
```

- **Range:**

```
1  
to  
1024
```

- **Removed:** MariaDB 10.6.0
- 

## innodb\_sync\_spin\_loops

- **Description:** The number of times a thread waits for an XtraDB/InnoDB mutex to be freed before the thread is suspended.
- **Commandline:**

```
--innodb-sync-spin-loops=#
```

- **Scope:** Global
- **Dynamic:** Yes
- **Data Type:**  
    numeric

- **Default Value:**

```
30
```

- **Range:**

```
0  
to  
4294967295
```

---

## innodb\_table\_locks

- **Description:** If `autocommit` is set to to

```
0  
(  
1  
is default), setting innodb_table_locks to  
1  
, the default, will cause XtraDB/InnoDB to lock a table internally upon a LOCK TABLE .
```

- **Commandline:**

```
--innodb-table-locks
```

- **Scope:** Global, Session
- **Dynamic:** Yes
- **Data Type:**  
    boolean

- **Default Value:**

```
ON
```

---

## innodb\_thread\_concurrency

- **Description:** Once this number of threads is reached (excluding threads waiting for locks), XtraDB/InnoDB will place new threads in a wait state in a first-in, first-out queue for execution, in order to limit the number of threads running concurrently. A setting of

0

, the default, permits as many threads as necessary. A suggested setting is twice the number of CPU's plus the number of disks. Deprecated and ignored from [MariaDB 10.5.5](#).

- **Commandline:**

```
--innodb-thread-concurrency=#
```

- **Scope:** Global

- **Dynamic:** Yes

- **Data Type:**

numeric

- **Default Value:**

0

- **Range:**

0

to

1000

- **Deprecated:** [MariaDB 10.5.5](#)

- **Removed:** [MariaDB 10.6.0](#)

## innodb\_thread\_concurrency\_timer\_based

- **Description:** If set to

1

, thread concurrency will be handled in a lock-free timer-based manner rather than the default mutex-based method. Depends on atomic op builtins being available. This Percona XtraDB variable has not been ported to XtraDB 5.6.

- **Commandline:**

```
innodb-thread-concurrency-timer-based={0|1}
```

- **Scope:** Global

- **Dynamic:** No

- **Data Type:**

boolean

- **Default Value:**

OFF

- **Removed:** [MariaDB 10.0](#) /XtraDB 5.6

## innodb\_thread\_sleep\_delay

- **Description:** Time in microseconds that InnoDB threads sleep before joining the queue. Setting to

0

disables sleep. Deprecated and ignored from [MariaDB 10.5.5](#).

- **Commandline:**

```
--innodb-thread-sleep-delay=#
```

- **Scope:** Global

- **Dynamic:** Yes

- **Data Type:**

numeric

- **Default Value:**

◦

0

(>= [MariaDB 10.5.5](#) .)

◦

10000

(<= [MariaDB 10.5.4](#) )

- **Range:**

0

to

1000000

- **Deprecated:** MariaDB 10.5.5
  - **Removed:** MariaDB 10.6.0
- 

## innodb\_temp\_data\_file\_path

- **Description:**
  - **Commandline:**  
--innodb-temp-data-file-path=path
  - **Scope:** Global
  - **Dynamic:** No
  - **Data Type:**  
string
  - **Default Value:**  
ibtmp1:12M:autoextend
  - **Introduced:** MariaDB 10.2.2
- 

## innodb\_tmpdir

- **Description:** Allows an alternate location to be set for temporary non-tablespace files. If not set (the default), files will be created in the usual tmpdir location.
  - **Commandline:**  
--innodb-tmpdir=path
  - **Scope:** Global
  - **Dynamic:** Yes
  - **Data Type:**  
string
  - **Default Value:** Empty
  - **Introduced:** MariaDB 10.1.14 , MariaDB 10.2.1
- 

## innodb\_track\_changed\_pages

- **Description:** For faster incremental backup with [Xtrabackup](#) , XtraDB tracks pages with changes written to them according to the [XtraDB redo log](#) and writes the information to special changed page bitmap files. This read-only variable is used for controlling this feature. See also [innodb\\_max\\_changed\\_pages](#) and [innodb\\_max\\_bitmap\\_file\\_size](#) . XtraDB only. Added as a deprecated and ignored option in [MariaDB 10.2.6](#) (which uses InnoDB as default instead of XtraDB) to allow for easier upgrades.
  - **Commandline:**  
innodb-track-changed-pages={0|1}
  - **Scope:** Global
  - **Dynamic:** No
  - **Data Type:**  
boolean
  - **Default Value:**  
OFF
  - **Deprecated:** MariaDB 10.2.6
- 

## innodb\_track\_redo\_log\_now

- **Description:** Available on debug builds only. XtraDB only. Added as a deprecated and ignored option in [MariaDB 10.2.6](#) (which uses InnoDB as default instead of XtraDB) to allow for easier upgrades.
- **Commandline:**

innodb-track-redo-log-now={0|1}

- **Scope:** Global
  - **Dynamic:** Yes
  - **Data Type:**  
boolean
  - **Default Value:**  
OFF
  - **Deprecated:** MariaDB 10.2.6
- 

## innodb\_undo\_directory

- **Description:** Path to the directory (relative or absolute) that InnoDB uses to create separate tablespaces for the [undo logs](#).  
(the default value before 10.2.2) leaves the undo logs in the same directory as the other log files. From MariaDB 10.2.2, the default value is NULL, and if no path is specified, undo tablespaces will be created in the directory defined by [datadir](#). Use together with [innodb\\_undo\\_logs](#) and [innodb\\_undo\\_tablespaces](#). Undo logs are most usefully placed on a separate storage device.
  - **Commandline:**  
--innodb-undo-directory=name
  - **Scope:** Global
  - **Dynamic:** No
  - **Data Type:**  
string
  - **Default Value:** NULL (>= MariaDB 10.2.2),  
(<= MariaDB 10.2.1)
- 

## innodb\_undo\_log\_truncate

- **Description:** When enabled, undo tablespaces that are larger than [innodb\\_max\\_undo\\_log\\_size](#) are marked for truncation. See also [innodb\\_purge\\_rseg\\_truncate\\_frequency](#).
  - **Commandline:**  
--innodb-undo-log-truncate[={0|1}]
  - **Scope:** Global
  - **Dynamic:** Yes
  - **Data Type:**  
boolean
  - **Default Value:**  
OFF
  - **Introduced:** MariaDB 10.2.2
- 

## innodb\_undo\_logs

- **Description:** Specifies the number of rollback segments that XtraDB/InnoDB will use within a transaction (or the number of active [undo logs](#)). By default set to the maximum,  
128  
, it can be reduced to avoid allocating unneeded rollback segments. See the [Innodb\\_available\\_undo\\_logs](#) status variable for the number of undo logs available. See also [innodb\\_undo\\_directory](#) and [innodb\\_undo\\_tablespaces](#). Replaced [innodb\\_rollback\\_segments](#) in MariaDB 10.0. The [Information Schema XTRADB\\_RSEG Table](#) contains information about the XtraDB rollback segments. Deprecated and ignored in MariaDB 10.5.0, as it always makes sense to use the maximum number of rollback segments.
- **Commandline:**  
--innodb-undo-logs=#
- **Scope:** Global
- **Dynamic:** Yes

- **Data Type:**

numeric

- **Default Value:**

128

- **Range:**

0  
to  
128

- **Deprecated:** MariaDB 10.5.0

- **Removed:** MariaDB 10.6.0

---

## innodb\_undo\_tablespaces

- **Description:** Number of tablespaces files used for dividing up the [undo logs](#). By default, undo logs are all part of the system tablespace, which contains one undo tablespace more than the

innodb\_undo\_tablespaces

setting. When the undo logs can grow large, splitting them over multiple tablespaces will reduce the size of any single tablespace. Must be set before InnoDB is initialized, or else MariaDB will fail to start, with an error saying that

InnoDB did not find the expected number of undo tablespaces

. The files are created in the directory specified by [innodb\\_undo\\_directory](#), and are named

undo

, N being an integer. The default size of an undo tablespace is 10MB. [innodb\\_undo\\_logs](#) must have a non-zero setting for

innodb\_undo\_tablespaces

to take effect.

- **Commandline:**

--innodb-undo-tablespaces=#

- **Scope:** Global

- **Dynamic:** No

- **Data Type:**

numeric

- **Default Value:**

0

- **Range:**

0  
to  
95  
(>= MariaDB 10.2.2 ),  
0  
to  
126  
(<= MariaDB 10.2.1 )

## innodb\_use\_atomic\_writes

- **Description:** Implement atomic writes on supported SSD devices. See [atomic write support](#) for other variables affected when this is set.

- **Commandline:**

innodb-use-atomic-writes={0|1}

- **Scope:** Global

- **Dynamic:** No

- **Data Type:**

boolean

- **Default Value:**

ON  
(>= MariaDB 10.2.4 ),  
OFF  
(<= MariaDB 10.2.3 )

## `innodb_use_fallocate`

- **Description:** Preallocate files fast, using operating system functionality. On POSIX systems, `posix_fallocate` system call is used.

- Automatically set to

- 1  
when `innodb_use_atomic_writes` is set - see [FusionIO DirectFS atomic write support](#).

- See [InnoDB Page Compression: Saving Storage Space with Sparse Files](#) for more information.

- **Commandline:**

- `--innodb-use-fallocate={0|1}`

- **Scope:** Global

- **Dynamic:** No

- **Data Type:**

- `boolean`

- **Default Value:**

- `OFF`

- **Deprecated:** [MariaDB 10.2.5](#) (treated as if

- `ON`

- `)`

- **Removed:** [MariaDB 10.3.0](#)
- 

## `innodb_use_global_flush_log_at_trx_commit`

- **Description:** Determines whether a user can set the variable `innodb_flush_log_at_trx_commit`. If set to

- `1`  
, a user cannot reset the value with a `SET` command, while if set to

- `1`  
, a user can reset the value of  
`innodb_flush_log_at_trx_commit`

- `XtraDB` only. Added as a deprecated and ignored option in [MariaDB 10.2.6](#) (which uses InnoDB as default instead of XtraDB) to allow for easier upgrades.

- **Commandline:**

- `--innodb-use-global-flush-log-at-trx_commit={0|1}`

- **Scope:** Global

- **Dynamic:** Yes

- **Data Type:**

- `boolean`

- **Default Value:**

- `ON`

- **Deprecated:** [MariaDB 10.2.6](#)

- **Removed:** [MariaDB 10.3.0](#)
- 

## `innodb_use_mtflush`

- **Description:** Whether to enable Multi-Threaded Flush operations. For more information, see [Fusion](#).

- InnoDB's multi-thread flush feature was deprecated in [MariaDB 10.2.9](#) and removed from [MariaDB 10.3.2](#). In later versions of MariaDB, us

### `innodb_page_cleaners`

system variable instead.

- See [InnoDB Page Flushing: Page Flushing with Multi-threaded Flush Threads](#) for more information.

- **Commandline:**

- `--innodb-use-mtflush={0|1}`

- **Scope:** Global

- **Dynamic:** No

- **Data Type:**

- `boolean`

- **Default Value:**

OFF

- **Introduced:** MariaDB 10.1.0
  - **Deprecated:** MariaDB 10.2.9
  - **Removed:** MariaDB 10.3.2
- 

### innodb\_use\_native\_aio

- **Description:** For Linux systems only, specified whether to use Linux's asynchronous I/O subsystem. Set to

ON

by default, it may be changed to

0

at startup if InnoDB detects a problem, or from [MariaDB 10.6.5 / MariaDB 10.7.1](#), if a 5.11 - 5.15 Linux kernel is detected, to avoid an interesting bug/incompatibility ([MDEV-26674](#)). MariaDB-10.6/MariaDB-10.7.2 and later also consider 5.15.3+ as a fixed kernel and default to

ON

. To really benefit from the setting, the files should be opened in O\_DIRECT mode (`innodb_flush_method=O_DIRECT`, default from [MariaDB 10.6](#)), to bypass the file system cache. In this way, the reads and writes can be submitted with DMA, using the InnoDB buffer pool directly, and no processor cycles need to be used for copying data.

- **Commandline:**

`--innodb-use-native-aio={0|1}`

- **Scope:** Global

- **Dynamic:** No

- **Data Type:**

boolean

- **Default Value:**

ON

---

### innodb\_use\_purge\_thread

- **Description:** Usually with InnoDB, data changed by a transaction is written to an undo space to permit read consistency, and freed when the transaction is complete. Many, or large, transactions, can cause the main tablespace to grow dramatically, reducing performance. This option, introduced in XtraDB 5.1 and removed for 5.5, allows multiple threads to perform the purging, resulting in slower, but much more stable performance.

- **Commandline:**

`--innodb-use-purge-thread=#`

- **Scope:** Global

- **Dynamic:** No

- **Data Type:**

numeric

- **Default Value:**

1

- **Range:**

0

to

32

- **Removed:** XtraDB 5.5
- 

### innodb\_use\_stacktrace

- **Description:** If set to

ON

(

OFF

is default), a signal handler for SIGUSR2 is installed when the InnoDB server starts. When a long semaphore wait is detected at sync/sync0array.c, a SIGUSR2 signal is sent to the waiting thread and thread that has acquired the RW-latch. For both threads a full stacktrace is produced as well as if possible. XtraDB only. Added as a deprecated and ignored option in [MariaDB 10.2.6](#) (which uses InnoDB as default instead of XtraDB) to allow for easier upgrades.

- **Commandline:**

```
--innodb-use-stacktrace={0|1}
```

- **Scope:** Global

- **Dynamic:** No

- **Data Type:**

boolean

- **Default Value:**

OFF

- **Deprecated:** [MariaDB 10.2.6](#)

- **Removed:** [MariaDB 10.3.0](#)

---

## innodb\_use\_sys\_malloc

- **Description:** If set the

1

, the default, XtraDB/InnoDB will use the operating system's memory allocator. If set to

0

it will use its own. Deprecated in [MariaDB 10.0](#) and removed in [MariaDB 10.2](#) along with InnoDB's internal memory allocator.

- **Commandline:**

```
--innodb-use-sys-malloc={0|1}
```

- **Scope:** Global

- **Dynamic:** No

- **Data Type:**

boolean

- **Default Value:**

ON

- **Deprecated:** [MariaDB 10.0](#)

- **Removed :** [MariaDB 10.2.2](#)

---

## innodb\_use\_sys\_stats\_table

- **Description:** If set to

1

(

0

is default), XtraDB will use the SYS\_STATS system table for extra table index statistics. When a table is opened for the first time, statistics will then be loaded from SYS\_STATS instead of sampling the index pages. Statistics are designed to be maintained only by running an [ANALYZE TABLE](#) . Replaced by MySQL 5.6's Persistent Optimizer Statistics.

- **Commandline:**

```
innodb-use-sys-stats-table={0|1}
```

- **Scope:** Global

- **Dynamic:** No

- **Data Type:**

boolean

- **Default Value:**

0

- **Removed:** [MariaDB 10.0](#) /XtraDB 5.6

---

## innodb\_use\_trim

- **Description:** Use trim to free up space of compressed blocks.
    - See [InnoDB Page Compression: Saving Storage Space with Sparse Files](#) for more information.
  - **Commandline:**

```
--innodb-use-trim={0|1}
```
  - **Scope:** Global
  - **Dynamic:** No
  - **Data Type:**

```
boolean
```
  - **Default Value:**

```
ON  
(>= MariaDB 10.2.4 ),  
OFF  
(<= MariaDB 10.2.3 )
```
  - **Introduced:** MariaDB 10.1.0
  - **Deprecated:** MariaDB 10.2.4
  - **Removed:** MariaDB 10.3.0
- 

## innodb\_version

- **Description:** InnoDB version number. From [MariaDB 10.3.7](#), as the InnoDB implementation in MariaDB has diverged from MySQL, the MariaDB version is instead reported. For example, the InnoDB version reported in [MariaDB 10.1](#) (which is based on MySQL 5.6) included encryption and variable-size page compression before MySQL 5.7 introduced them. [MariaDB 10.2](#) (based on MySQL 5.7) introduced persistent AUTO\_INCREMENT ([MDEV-6076](#)) in a GA release before MySQL 8.0. [MariaDB 10.3](#) (based on MySQL 5.7) introduced instant ADD COLUMN ([MDEV-11369](#)) before MySQL.
  - **Scope:** Global
  - **Dynamic:** No
  - **Data Type:**

```
string
```
- 

## innodb\_write\_io\_threads

- **Description:** Number of I/O threads for XtraDB/InnoDB writes. You may on rare occasions need to reduce this default on Linux systems running multiple MariaDB servers to avoid exceeding system limits.
  - **Commandline:**

```
--innodb-write-io-threads=#
```
  - **Scope:** Global
  - **Dynamic:** No
  - **Data Type:**

```
numeric
```
  - **Default Value:**

```
4
```
  - **Range:**

```
1  
to  
64
```
- 

## 4.3.2.5 InnoDB Server Status Variables

See [Server Status Variables](#) for a complete list of status variables that can be viewed with `SHOW STATUS`.

Much of the InnoDB/XtraDB information here can also be seen with a `SHOW ENGINE INNODB STATUS` statement.

See also the [Full list of MariaDB options, system and status variables](#).

### Innodb\_adaptive\_hash\_cells

- **Description:** As shown in the INSERT BUFFER AND ADAPTIVE HASH INDEX section of the `SHOW ENGINE INNODB STATUS` output.
    - In [MariaDB 5.5](#), this system variable is present in XtraDB.
    - In [MariaDB 10.1](#) and later, this system variable is not present.
  - **Scope:** Global
  - **Data Type:**  
numeric
  - **Introduced:** [MariaDB 5.5](#)
  - **Removed:** [MariaDB 10.0.0](#)
- 

### Innodb\_adaptive\_hash\_hash\_searches

- **Description:** Hash searches as shown in the INSERT BUFFER AND ADAPTIVE HASH INDEX section of the `SHOW ENGINE INNODB STATUS` output.
    - In [MariaDB 5.5](#), this system variable is present in XtraDB.
    - In [MariaDB 10.1](#), [MariaDB 10.2](#), [MariaDB 10.3](#), and [MariaDB 10.4](#), this system variable is not present. Use the `adaptive_hash_searches` counter in the `information_schema.INNODB_METRICS` table instead.
  - In [MariaDB 10.5](#), this system variable was reintroduced.
  - **Scope:** Global
  - **Data Type:**  
numeric
  - **Introduced:** [MariaDB 5.5](#), [MariaDB 10.5.0](#)
  - **Removed:** [MariaDB 10.0.0](#)
- 

### Innodb\_adaptive\_hash\_heap\_buffers

- **Description:** As shown in the INSERT BUFFER AND ADAPTIVE HASH INDEX section of the `SHOW ENGINE INNODB STATUS` output.
  - In [MariaDB 5.5](#), this system variable is present in XtraDB.
  - In [MariaDB 10.1](#) and later, this system variable is not present.
- **Scope:** Global
- **Data Type:**  
numeric
- **Introduced:** [MariaDB 5.5](#)
- **Removed:** [MariaDB 10.0.0](#)

## Innodb\_adaptive\_hash\_non\_hash\_searches

- **Description:** Non-hash searches as shown in the INSERT BUFFER AND ADAPTIVE HASH INDEX section of the [SHOW ENGINE INNODB STATUS](#) output. From [MariaDB 10.6.2](#), not updated if [innodb\\_adaptive\\_hash\\_index](#) is not enabled (the default).
  - In [MariaDB 10.1](#), [MariaDB 10.2](#), [MariaDB 10.3](#), and [MariaDB 10.4](#), this system variable is not present. Use the `adaptive_hash_searches_btree` counter in the [information\\_schema.INNODB\\_METRICS](#) table instead.
  - From [MariaDB 10.5](#), this status variable is present.
- **Scope:** Global
- **Data Type:**
  - numeric
- **Introduced:** [MariaDB 5.5](#), [MariaDB 10.5.0](#)
- **Removed:** [MariaDB 10.0.0](#)

## Innodb\_available\_undo\_logs

- **Description:** Total number available InnoDB [undo logs](#). Differs from the [innodb\\_undo\\_logs](#) system variable, which specifies the number of *active* undo logs.
- **Scope:** Global
- **Data Type:**
  - numeric

## Innodb\_background\_log\_sync

- **Description:** As shown in the BACKGROUND THREAD section of the [SHOW ENGINE INNODB STATUS](#) output.
  - In [MariaDB 5.5](#), this system variable is present in XtraDB.
  - In [MariaDB 10.1](#), [MariaDB 10.2](#), [MariaDB 10.3](#), and [MariaDB 10.4](#), this system variable is not present.
  - In [MariaDB 10.5](#), this system variable was reintroduced.
- **Scope:** Global
- **Data Type:**
  - numeric
- **Introduced:** [MariaDB 5.5](#) (XtraDB only), [MariaDB 10.5.0](#)

## Innodb\_buffer\_pool\_bytes\_data

- **Description:** Number of bytes contained in the [InnoDB buffer pool](#), both dirty (modified) and clean (unmodified). See also [Innodb\\_buffer\\_pool\\_pages\\_data](#), which can contain pages of different sizes in the case of compression.
- **Scope:** Global
- **Data Type:**
  - numeric

## Innodb\_buffer\_pool\_bytes\_dirty

- **Description:** Number of dirty (modified) bytes contained in the [InnoDB buffer pool](#). See also [Innodb\\_buffer\\_pool\\_pages\\_dirty](#), which can contain pages of different sizes in the case of compression.
- **Scope:** Global
- **Data Type:**
  - numeric

## Innodb\_buffer\_pool\_dump\_status

- **Description:** A text description of the progress or final status of the last Innodb buffer pool dump.
  - **Scope:** Global
  - **Data Type:**  
string
  - **Introduced:** MariaDB 10.0.0
- 

## Innodb\_buffer\_pool\_load\_incomplete

- **Description:** Whether or not the loaded buffer pool is incomplete, for example after a shutdown or abort during innodb buffer pool load from file caused an incomplete save.
  - **Scope:** Global
  - **Data Type:**  
boolean
  - **Introduced:** MariaDB 10.3.5
- 

## Innodb\_buffer\_pool\_load\_status

- **Description:** A text description of the progress or final status of the last Innodb buffer pool load.
  - **Scope:** Global
  - **Data Type:**  
string
  - **Introduced:** MariaDB 10.0.0
- 

## Innodb\_buffer\_pool\_pages\_data

- **Description:** Number of InnoDB buffer pool pages which contain data, both dirty (modified) and clean (unmodified). See also [Innodb\\_buffer\\_pool\\_bytes\\_data](#).
  - **Scope:** Global
  - **Data Type:**  
numeric
- 

## Innodb\_buffer\_pool\_pages\_dirty

- **Description:** Number of InnoDB buffer pool pages which contain dirty (modified) data. See also [Innodb\\_buffer\\_pool\\_bytes\\_dirty](#).
  - **Scope:** Global
  - **Data Type:**  
numeric
- 

## Innodb\_buffer\_pool\_pages\_flushed

- **Description:** Number of InnoDB buffer pool pages which have been flushed.
  - **Scope:** Global
  - **Data Type:**  
numeric
-

## Innodb\_buffer\_pool\_pages\_LRU\_flushed

- **Description:** Flush list as shown in the INSERT BUFFER AND ADAPTIVE HASH INDEX section of the [SHOW ENGINE INNODB STATUS](#) output.
    - In [MariaDB 5.5](#) and [MariaDB 10.1](#) , this system variable is present in XtraDB.
    - In [MariaDB 10.2](#) , [MariaDB 10.3](#) , and [MariaDB 10.4](#) , this system variable is not present.
    - In [MariaDB 10.5](#) , this system variable was reintroduced.
  - **Scope:** Global
  - **Data Type:**  
numeric
  - **Introduced:** [MariaDB 5.5](#) (XtraDB-only), [MariaDB 10.5.0](#)
- 

## Innodb\_buffer\_pool\_pages\_LRU\_freed

- **Description:** Monitor the number of pages that were freed by a buffer pool LRU eviction scan, without flushing.
  - **Scope:** Global
  - **Data Type:**  
numeric
  - **Introduced:** [MariaDB 10.6.0](#)
- 

## Innodb\_buffer\_pool\_pages\_free

- **Description:** Number of free [InnoDB buffer pool](#) pages.
  - **Scope:** Global
  - **Data Type:**  
numeric
- 

## Innodb\_buffer\_pool\_pages\_made\_not\_young

- **Description:** Pages not young as shown in the INSERT BUFFER AND ADAPTIVE HASH INDEX section of the [SHOW ENGINE INNODB STATUS](#) output.
    - In [MariaDB 5.5](#) and [MariaDB 10.1](#) , this system variable is present in XtraDB.
    - In [MariaDB 10.2](#) , [MariaDB 10.3](#) , and [MariaDB 10.4](#) , this system variable is not present.
    - In [MariaDB 10.5](#) , this system variable was reintroduced.
  - **Scope:** Global
  - **Data Type:**  
numeric
  - **Introduced:** [MariaDB 5.5](#) (XtraDB-only), [MariaDB 10.5.0](#)
- 

## Innodb\_buffer\_pool\_pages\_made\_young

- **Description:** Pages made young as shown in the INSERT BUFFER AND ADAPTIVE HASH INDEX section of the [SHOW ENGINE INNODB STATUS](#) output.
    - In [MariaDB 5.5](#) and [MariaDB 10.1](#) , this system variable is present in XtraDB.
    - In [MariaDB 10.2](#) , [MariaDB 10.3](#) , and [MariaDB 10.4](#) , this system variable is not present.
    - In [MariaDB 10.5](#) , this system variable was reintroduced.
  - **Scope:** Global
  - **Data Type:**  
numeric
  - **Introduced:** [MariaDB 5.5](#) (XtraDB-only), [MariaDB 10.5.0](#)
-

## Innodb\_buffer\_pool\_pages\_misc

- **Description:** Number of InnoDB buffer pool pages set aside for internal use.

- **Scope:** Global

- **Data Type:**

numeric

---

## Innodb\_buffer\_pool\_pages\_old

- **Description:** Old database page, as shown in the BUFFER POOL AND MEMORY section of the [SHOW ENGINE INNODB STATUS](#) output.

- In [MariaDB 5.5](#) and [MariaDB 10.1](#), this system variable is present for XtraDB.

- In [MariaDB 10.2](#), [MariaDB 10.3](#), and [MariaDB 10.4](#), this system variable is not present.

- In [MariaDB 10.5](#), this system variable was reintroduced.

- **Scope:** Global

- **Data Type:**

numeric

---

- **Introduced:** [MariaDB 5.5](#) (XtraDB-only), [MariaDB 10.5.0](#)
- 

## Innodb\_buffer\_pool\_pages\_total

- **Description:** Total number of InnoDB buffer pool pages.

- **Scope:** Global

- **Data Type:**

numeric

---

## Innodb\_buffer\_pool\_read\_ahead

- **Description:** Number of pages read into the InnoDB buffer pool by the read-ahead background thread.

- **Scope:** Global

- **Data Type:**

numeric

---

## Innodb\_buffer\_pool\_read\_ahead\_evicted

- **Description:** Number of pages read into the InnoDB buffer pool by the read-ahead background thread that were evicted without having been accessed by queries.

- **Scope:** Global

- **Data Type:**

numeric

---

## Innodb\_buffer\_pool\_read\_ahead\_rnd

- **Description:** Number of random read-aheads.

- **Scope:** Global

- **Data Type:**

numeric

---

## Innodb\_buffer\_pool\_read\_requests

- **Description:** Number of requests to read from the [InnoDB buffer pool](#) .
  - **Scope:** Global
  - **Data Type:**  
    numeric
- 

## Innodb\_buffer\_pool\_reads

- **Description:** Number of reads that could not be satisfied by the [InnoDB buffer pool](#) and had to be read from disk.
  - **Scope:** Global
  - **Data Type:**  
    numeric
- 

## Innodb\_buffer\_pool\_resize\_status

- **Description:** Progress of the dynamic [InnoDB buffer pool](#) resizing operation. See [Setting Innodb Buffer Pool Size Dynamically](#) .
  - **Scope:** Global
  - **Data Type:**  
    numeric
  - **Introduced:** [MariaDB 10.2.2](#)
- 

## Innodb\_buffer\_pool\_wait\_free

- **Description:** Number of times InnoDB waited for a free page before reading or creating a page. Normally, writes to the [InnoDB buffer pool](#) happen in the background. When no clean pages are available, dirty pages are flushed first in order to free some up. This counts the numbers of wait for this operation to finish. If this value is not small, look at increasing [innodb\\_buffer\\_pool\\_size](#) .
  - **Scope:** Global
  - **Data Type:**  
    numeric
- 

## Innodb\_buffer\_pool\_write\_requests

- **Description:** Number of requests to write to the [InnoDB buffer pool](#) .
  - **Scope:** Global
  - **Data Type:**  
    numeric
- 

## Innodb\_buffered\_aio\_submitted

- **Description:**
  - **Scope:** Global
  - **Data Type:**  
    numeric
- **Introduced:** [MariaDB 10.5.0](#)
- 

## Innodb\_checkpoint\_age

- **Description:** The checkpoint age, as shown in the LOG section of the [SHOW ENGINE INNODB STATUS](#) output. (This is equivalent to subtracting "Last checkpoint at" from "Log sequence number".)
    - In [MariaDB 5.5](#) and [MariaDB 10.1](#), this system variable is present in XtraDB.
    - In [MariaDB 10.2](#), [MariaDB 10.3](#), and [MariaDB 10.4](#), this system variable is not present.
    - In [MariaDB 10.5](#), this system variable was reintroduced.
  - **Scope:** Global
  - **Data Type:**  
numeric
  - **Introduced:** [MariaDB 5.5](#) (XtraDB-only), [MariaDB 10.5.0](#)
- 

### Innodb\_checkpoint\_max\_age

- **Description:** Max checkpoint age, as shown in the LOG section of the [SHOW ENGINE INNODB STATUS](#) output.
    - In [MariaDB 5.5](#) and [MariaDB 10.1](#), this system variable is present in XtraDB.
    - In [MariaDB 10.2](#), [MariaDB 10.3](#), and [MariaDB 10.4](#), this system variable is not present.
    - In [MariaDB 10.5](#), this system variable was reintroduced.
  - **Scope:** Global
  - **Data Type:**  
numeric
  - **Introduced:** [MariaDB 5.5](#) (XtraDB-only), [MariaDB 10.5.0](#)
- 

### Innodb\_checkpoint\_target\_age

- **Description:** Checkpoint age target, as shown in the LOG section of the [SHOW ENGINE INNODB STATUS](#) output. XtraDB only. Removed in [MariaDB 10.0](#) and replaced with MySQL 5.6's flushing implementation.
  - **Scope:** Global
  - **Data Type:**  
numeric
  - **Introduced:** [MariaDB 5.5](#)
  - **Removed:** [MariaDB 10.0](#)
- 

### Innodb\_current\_row\_locks

- **Description:** Number of current row locks on InnoDB tables as shown in the TRANSACTIONS section of the [SHOW ENGINE INNODB STATUS](#) output. Renamed from [InnoDB\\_row\\_lock\\_numbers](#) in XtraDB 5.5.8-20.1.
  - **Scope:** Global
  - **Data Type:**  
numeric
  - **Introduced:** [MariaDB 5.5](#)
- 

### Innodb\_data\_fsyncs

- **Description:** Number of InnoDB fsync (sync-to-disk) calls. fsync call frequency can be influenced by the [innodb\\_flush\\_method](#) configuration option.
  - **Scope:** Global
  - **Data Type:**  
numeric
- 

### Innodb\_data\_pending\_fsyncs

- **Description:** Number of pending InnoDB fsync (sync-to-disk) calls. fsync call frequency can be influenced by the [innodb\\_flush\\_method](#) configuration option.
  - **Scope:** Global
  - **Data Type:**  
    numeric
- 

#### `Innodb_data_pending_reads`

- **Description:** Number of pending InnoDB reads.
  - **Scope:** Global
  - **Data Type:**  
    numeric
- 

#### `Innodb_data_pending_writes`

- **Description:** Number of pending InnoDB writes.
  - **Scope:** Global
  - **Data Type:**  
    numeric
- 

#### `Innodb_data_read`

- **Description:** Number of InnoDB bytes read since server startup (not to be confused with [Innodb\\_data\\_reads](#) ).
  - **Scope:** Global
  - **Data Type:**  
    numeric
- 

#### `Innodb_data_reads`

- **Description:** Number of InnoDB read operations (not to be confused with [Innodb\\_data\\_read](#) ).
  - **Scope:** Global
  - **Data Type:**  
    numeric
- 

#### `Innodb_data_writes`

- **Description:** Number of InnoDB write operations.
  - **Scope:** Global
  - **Data Type:**  
    numeric
- 

#### `Innodb_data_written`

- **Description:** Number of InnoDB bytes written since server startup.
- **Scope:** Global
- **Data Type:**  
    numeric

---

### Innodb dblwr\_pages\_written

- **Description:** Number of pages written to the [InnoDB doublewrite buffer](#) .
  - **Scope:** Global
  - **Data Type:**  
    numeric
- 

### Innodb dblwr\_writes

- **Description:** Number of writes to the [InnoDB doublewrite buffer](#) .
  - **Scope:** Global
  - **Data Type:**  
    numeric
- 

### Innodb\_deadlocks

- **Description:** Total number of InnoDB deadlocks. Deadlocks occur when at least two transactions are waiting for the other to finish, creating a circular dependency. InnoDB usually detects these quickly, returning an error.
    - In [MariaDB 5.5](#) and [MariaDB 10.1](#) , this system variable is present in XtraDB.
    - In [MariaDB 10.2](#) , [MariaDB 10.3](#) , and [MariaDB 10.4](#) , this system variable is not present.
    - In [MariaDB 10.5](#) , this system variable was reintroduced.
  - **Scope:** Global
  - **Data Type:**  
    numeric
  - **Introduced:** [MariaDB 5.5](#) (XtraDB-only), [MariaDB 10.5.0](#)
- 

### Innodb\_defragment\_compression\_failures

- **Description:** Number of defragment re-compression failures. See [Defragmenting InnoDB Tablespace](#)s .
  - **Scope:** Global
  - **Data Type:**  
    numeric
  - **Introduced:** [MariaDB 10.1.1](#)
- 

### Innodb\_defragment\_count

- **Description:** Number of defragment operations. See [Defragmenting InnoDB Tablespace](#)s .
  - **Scope:** Global
  - **Data Type:**  
    numeric
  - **Introduced:** [MariaDB 10.1.1](#)
- 

### Innodb\_defragment\_failures

- **Description:** Number of defragment failures. See [Defragmenting InnoDB Tablespace](#)s .
- **Scope:** Global

- **Data Type:**

numeric

- **Introduced:** [MariaDB 10.1.1](#)
- 

#### Innodb\_dict\_tables

- **Description:** Number of entries in the XtraDB data dictionary cache. This Percona XtraDB variable was removed in MariaDB 10/XtraDB 5.6 as it was replaced with MySQL 5.6's [table\\_definition\\_cache](#) implementation.

- **Scope:** Global

- **Data Type:**

numeric

- **Introduced:** [XtraDB 5.0.77-b13](#)

- **Removed:** [MariaDB 10.0](#)
- 

#### Innodb\_encryption\_n\_merge\_blocks\_decrypted

- **Description:**

- **Scope:** Global

- **Data Type:**

numeric

- **Introduced:** [MariaDB 10.1.28](#) , [MariaDB 10.2.9](#) , [MariaDB 10.3.2](#)
- 

#### Innodb\_encryption\_n\_merge\_blocks\_encrypted

- **Description:**

- **Scope:** Global

- **Data Type:**

numeric

- **Introduced:** [MariaDB 10.1.28](#) , [MariaDB 10.2.9](#) , [MariaDB 10.3.2](#)
- 

#### Innodb\_encryption\_n\_rowlog\_blocks\_decrypted

- **Description:**

- **Scope:** Global

- **Data Type:**

numeric

- **Introduced:** [MariaDB 10.1.28](#) , [MariaDB 10.2.9](#) , [MariaDB 10.3.2](#)
- 

#### Innodb\_encryption\_n\_rowlog\_blocks\_encrypted

- **Description:**

- **Scope:** Global

- **Data Type:**

numeric

- **Introduced:** [MariaDB 10.1.28](#) , [MariaDB 10.2.9](#) , [MariaDB 10.3.2](#)
- 

#### Innodb\_encryption\_n\_temp\_blocks\_decrypted

- **Description:**
  - **Scope:** Global
  - **Data Type:**  
    numeric
- **Introduced:** [MariaDB 10.2.26](#) , [MariaDB 10.3.17](#) , [MariaDB 10.4.7](#)
- 

Innodb\_encryption\_n\_temp\_blocks\_encrypted

- **Description:**
  - **Scope:** Global
  - **Data Type:**  
    numeric
- **Introduced:** [MariaDB 10.2.26](#) , [MariaDB 10.3.17](#) , [MariaDB 10.4.7](#)
- 

Innodb\_encryption\_num\_key\_requests

- **Description:** Was not present in [MariaDB 10.5.2](#) .
  - **Scope:** Global
  - **Data Type:**  
    numeric
- **Introduced:** [MariaDB 10.2.4](#)
- 

Innodb\_encryption\_rotation\_estimated\_iops

- **Description:** See [Table and Tablespace Encryption](#) .
  - **Scope:** Global
  - **Data Type:**  
    numeric
- **Removed:** [MariaDB 10.1.3](#)
- 

Innodb\_encryption\_rotation\_pages\_flushed

- **Description:** See [Table and Tablespace Encryption](#) .
  - **Scope:** Global
  - **Data Type:**  
    numeric
- **Removed:** [MariaDB 10.1.3](#)
- 

Innodb\_encryption\_rotation\_pages\_modified

- **Description:** See [Table and Tablespace Encryption](#) .
  - **Scope:** Global
  - **Data Type:**  
    numeric
- **Removed:** [MariaDB 10.1.3](#)
-

## Innodb\_encryption\_rotation\_pages\_read\_from\_cache

- **Description:** See [Table and Tablespace Encryption](#) .
  - **Scope:** Global
  - **Data Type:**  
numeric
  - **Removed:** [MariaDB 10.1.3](#)
- 

## Innodb\_encryption\_rotation\_pages\_read\_from\_disk

- **Description:** See [Table and Tablespace Encryption](#) .
  - **Scope:** Global
  - **Data Type:**  
numeric
  - **Removed:** [MariaDB 10.1.3](#)
- 

## Innodb\_have\_atomic\_builtin

- **Description:** Whether the server has been built with atomic instructions, provided by the CPU ensuring that critical low-level operations can't be interrupted. XtraDB only.
  - **Scope:** Global
  - **Data Type:**  
boolean
- 

## Innodb\_have\_bzip2

- **Description:** Whether the server has the bzip2 compression method available. See [InnoDB/XtraDB Page Compression](#) .
  - **Scope:** Global
  - **Data Type:**  
boolean
  - **Introduced:** [MariaDB 10.1.0](#)
- 

## Innodb\_have\_lz4

- **Description:** Whether the server has the lz4 compression method available. See [InnoDB/XtraDB Page Compression](#) .
  - **Scope:** Global
  - **Data Type:**  
boolean
  - **Introduced:** [MariaDB 10.1.0](#)
- 

## Innodb\_have\_lzma

- **Description:** Whether the server has the lzma compression method available. See [InnoDB/XtraDB Page Compression](#) .
  - **Scope:** Global
  - **Data Type:**  
boolean
  - **Introduced:** [MariaDB 10.1.0](#)
-

## Innodb\_have\_lzo

- **Description:** Whether the server has the lzo compression method available. See [InnoDB/XtraDB Page Compression](#).
  - **Scope:** Global
  - **Data Type:**  
boolean
  - **Introduced:** [MariaDB 10.1.0](#)
- 

## Innodb\_have\_punch\_hole

- **Description:**
  - **Scope:** Global
  - **Data Type:**  
numeric
  - **Introduced:** [MariaDB 10.2.4](#)
- 

## Innodb\_have\_snappy

- **Description:** Whether the server has the snappy compression method available. See [InnoDB/XtraDB Page Compression](#).
  - **Scope:** Global
  - **Data Type:**  
boolean
  - **Introduced:** [MariaDB 10.1.3](#)
- 

## Innodb\_history\_list\_length

- **Description:** History list length as shown in the TRANSACTIONS section of the [SHOW ENGINE INNODB STATUS](#) output. XtraDB only until introduced in [MariaDB 10.5.0](#).
  - **Scope:** Global
  - **Data Type:**  
numeric
  - **Introduced:** [MariaDB 5.5](#) (XtraDB-only), [MariaDB 10.5.0](#)
- 

## Innodb\_ibuf\_discarded\_delete\_marks

- **Description:** As shown in the INSERT BUFFER AND ADAPTIVE HASH INDEX section of the [SHOW ENGINE INNODB STATUS](#) output.
    - In [MariaDB 5.5](#) and [MariaDB 10.1](#), this system variable is present in XtraDB.
    - In [MariaDB 10.2](#), [MariaDB 10.3](#), and [MariaDB 10.4](#), this system variable is not present.
    - In [MariaDB 10.5](#), this system variable was reintroduced.
  - **Scope:** Global
  - **Data Type:**  
numeric
  - **Introduced:** [MariaDB 5.5](#) (XtraDB-only), [MariaDB 10.5.0](#)
- 

## Innodb\_ibuf\_discarded\_deletes

- **Description:** As shown in the INSERT BUFFER AND ADAPTIVE HASH INDEX section of the [SHOW ENGINE INNODB STATUS](#) output.
  - In [MariaDB 5.5](#) and [MariaDB 10.1](#), this system variable is present in XtraDB.
  - In [MariaDB 10.2](#), [MariaDB 10.3](#), and [MariaDB 10.4](#), this system variable is not present.

- In [MariaDB 10.5](#), this system variable was reintroduced.
  - **Scope:** Global
  - **Data Type:**  
numeric
  - **Introduced:** [MariaDB 5.5](#) (XtraDB-only), [MariaDB 10.5.0](#)
- 

#### Innodb\_ibuf\_discarded\_inserts

- **Description:** As shown in the INSERT BUFFER AND ADAPTIVE HASH INDEX section of the [SHOW ENGINE INNODB STATUS](#) output.
    - In [MariaDB 5.5](#) and [MariaDB 10.1](#), this system variable is present in XtraDB.
    - In [MariaDB 10.2](#), [MariaDB 10.3](#), and [MariaDB 10.4](#), this system variable is not present.
    - In [MariaDB 10.5](#), this system variable was reintroduced.
  - **Scope:** Global
  - **Data Type:**  
numeric
  - **Introduced:** [MariaDB 5.5](#) (XtraDB-only), [MariaDB 10.5.0](#)
- 

#### Innodb\_ibuf\_free\_list

- **Description:** As shown in the INSERT BUFFER AND ADAPTIVE HASH INDEX section of the [SHOW ENGINE INNODB STATUS](#) output.
    - In [MariaDB 5.5](#) and [MariaDB 10.1](#), this system variable is present in XtraDB.
    - In [MariaDB 10.2](#), [MariaDB 10.3](#), and [MariaDB 10.4](#), this system variable is not present.
    - In [MariaDB 10.5](#), this system variable was reintroduced.
  - **Scope:** Global
  - **Data Type:**  
numeric
  - **Introduced:** [MariaDB 5.5](#) (XtraDB-only), [MariaDB 10.5.0](#)
- 

#### Innodb\_ibuf\_merged\_delete\_marks

- **Description:** As shown in the INSERT BUFFER AND ADAPTIVE HASH INDEX section of the [SHOW ENGINE INNODB STATUS](#) output.
    - In [MariaDB 5.5](#) and [MariaDB 10.1](#), this system variable is present in XtraDB.
    - In [MariaDB 10.2](#), [MariaDB 10.3](#), and [MariaDB 10.4](#), this system variable is not present.
    - In [MariaDB 10.5](#), this system variable was reintroduced.
  - **Scope:** Global
  - **Data Type:**  
numeric
  - **Introduced:** [MariaDB 5.5](#) (XtraDB-only), [MariaDB 10.5.0](#)
- 

#### Innodb\_ibuf\_merged\_deletes

- **Description:** As shown in the INSERT BUFFER AND ADAPTIVE HASH INDEX section of the [SHOW ENGINE INNODB STATUS](#) output.
    - In [MariaDB 5.5](#) and [MariaDB 10.1](#), this system variable is present in XtraDB.
    - In [MariaDB 10.2](#), [MariaDB 10.3](#), and [MariaDB 10.4](#), this system variable is not present.
    - In [MariaDB 10.5](#), this system variable was reintroduced.
  - **Scope:** Global
  - **Data Type:**  
numeric
  - **Introduced:** [MariaDB 5.5](#) (XtraDB-only), [MariaDB 10.5.0](#)
- 

#### Innodb\_ibuf\_merged\_inserts

- **Description:** As shown in the INSERT BUFFER AND ADAPTIVE HASH INDEX section of the [SHOW ENGINE INNODB STATUS](#) output.

- In [MariaDB 5.5](#) and [MariaDB 10.1](#), this system variable is present in XtraDB.
- In [MariaDB 10.2](#), [MariaDB 10.3](#), and [MariaDB 10.4](#), this system variable is not present.
- In [MariaDB 10.5](#), this system variable was reintroduced.

- **Scope:** Global

- **Data Type:**

numeric

- **Introduced:** [MariaDB 5.5](#) (XtraDB-only), [MariaDB 10.5.0](#)
- 

### Innodb\_ibuf\_merges

- **Description:** As shown in the INSERT BUFFER AND ADAPTIVE HASH INDEX section of the [SHOW ENGINE INNODB STATUS](#) output.

- In [MariaDB 5.5](#) and [MariaDB 10.1](#), this system variable is present in XtraDB.
- In [MariaDB 10.2](#), [MariaDB 10.3](#), and [MariaDB 10.4](#), this system variable is not present.
- In [MariaDB 10.5](#), this system variable was reintroduced.

- **Scope:** Global

- **Data Type:**

numeric

- **Introduced:** [MariaDB 5.5](#) (XtraDB-only), [MariaDB 10.5.0](#)
- 

### Innodb\_ibuf\_segment\_size

- **Description:** As shown in the INSERT BUFFER AND ADAPTIVE HASH INDEX section of the [SHOW ENGINE INNODB STATUS](#) output.

- In [MariaDB 5.5](#) and [MariaDB 10.1](#), this system variable is present in XtraDB.
- In [MariaDB 10.2](#), [MariaDB 10.3](#), and [MariaDB 10.4](#), this system variable is not present.
- In [MariaDB 10.5](#), this system variable was reintroduced.

- **Scope:** Global

- **Data Type:**

numeric

- **Introduced:** [MariaDB 5.5](#) (XtraDB-only), [MariaDB 10.5.0](#)
- 

### Innodb\_ibuf\_size

- **Description:** As shown in the INSERT BUFFER AND ADAPTIVE HASH INDEX section of the [SHOW ENGINE INNODB STATUS](#) output.

- In [MariaDB 5.5](#) and [MariaDB 10.1](#), this system variable is present in XtraDB.
- In [MariaDB 10.2](#), [MariaDB 10.3](#), and [MariaDB 10.4](#), this system variable is not present.
- In [MariaDB 10.5](#), this system variable was reintroduced.

- **Scope:** Global

- **Data Type:**

numeric

- **Introduced:** [MariaDB 5.5](#) (XtraDB-only), [MariaDB 10.5.0](#)
- 

### Innodb\_instant\_alter\_column

- **Description:** See [Instant ADD COLUMN for InnoDB](#).

- **Scope:** Global

- **Data Type:**

numeric

- **Introduced:** [MariaDB 10.3.2](#)
- 

### Innodb\_log\_waits

- **Description:** Number of times InnoDB was forced to wait for log writes to be flushed due to the log buffer being too small.
  - **Scope:** Global
  - **Data Type:**  
numeric
- 

#### Innodb\_log\_write\_requests

- **Description:** Number of requests to write to the InnoDB redo log.
  - **Scope:** Global
  - **Data Type:**  
numeric
- 

#### Innodb\_log\_writes

- **Description:** Number of writes to the InnoDB redo log.
  - **Scope:** Global
  - **Data Type:**  
numeric
- 

#### Innodb\_lsn\_current

- **Description:** Log sequence number as shown in the LOG section of the [SHOW ENGINE INNODB STATUS](#) output.
    - In [MariaDB 5.5](#) and [MariaDB 10.1](#), this system variable is present in XtraDB.
    - In [MariaDB 10.2](#), [MariaDB 10.3](#), and [MariaDB 10.4](#), this system variable is not present.
    - In [MariaDB 10.5](#), this system variable was reintroduced.
  - **Scope:** Global
  - **Data Type:**  
numeric
- 
- **Introduced:** [MariaDB 5.5](#) (XtraDB-only), [MariaDB 10.5.0](#)
- 

#### Innodb\_lsn\_flushed

- **Description:** Flushed up to log sequence number as shown in the LOG section of the [SHOW ENGINE INNODB STATUS](#) output.
    - In [MariaDB 5.5](#) and [MariaDB 10.1](#), this system variable is present in XtraDB.
    - In [MariaDB 10.2](#), [MariaDB 10.3](#), and [MariaDB 10.4](#), this system variable is not present.
    - In [MariaDB 10.5](#), this system variable was reintroduced.
  - **Scope:** Global
  - **Data Type:**  
numeric
- 
- **Introduced:** [MariaDB 5.5](#) (XtraDB-only), [MariaDB 10.5.0](#)
- 

#### Innodb\_lsn\_last\_checkpoint

- **Description:** Log sequence number last checkpoint as shown in the LOG section of the [SHOW ENGINE INNODB STATUS](#) output.
  - In [MariaDB 5.5](#) and [MariaDB 10.1](#), this system variable is present in XtraDB.
  - In [MariaDB 10.2](#), [MariaDB 10.3](#), and [MariaDB 10.4](#), this system variable is not present.
  - In [MariaDB 10.5](#), this system variable was reintroduced.
- **Scope:** Global
- **Data Type:**  
numeric

- **Introduced:** MariaDB 5.5 (XtraDB-only), MariaDB 10.5.0
- 

### Innodb\_master\_thread\_1\_second\_loops

- **Description:** As shown in the BACKGROUND THREAD section of the [SHOW ENGINE INNODB STATUS](#) output.
  - In [MariaDB 5.5](#), this system variable is present in XtraDB.
  - In [MariaDB 10.1](#) and later, this system variable is not present.

- **Scope:** Global

- **Data Type:**

numeric

- **Introduced:** MariaDB 5.5

- **Removed:** MariaDB 10.0
- 

### Innodb\_master\_thread\_10\_second\_loops

- **Description:** As shown in the BACKGROUND THREAD section of the [SHOW ENGINE INNODB STATUS](#) output.
  - In [MariaDB 5.5](#), this system variable is present in XtraDB.
  - In [MariaDB 10.1](#) and later, this system variable is not present

- **Scope:** Global

- **Data Type:**

numeric

- **Introduced:** MariaDB 5.5

- **Removed:** MariaDB 10.0
- 

### Innodb\_master\_thread\_active\_loops

- **Description:** As shown in the BACKGROUND THREAD section of the [SHOW ENGINE INNODB STATUS](#) output.
  - In [MariaDB 10.1](#), this system variable is present in XtraDB.
  - In [MariaDB 10.2](#), [MariaDB 10.3](#), and [MariaDB 10.4](#), this system variable is not present.
  - In [MariaDB 10.5](#), this system variable was reintroduced.

- **Scope:** Global

- **Data Type:**

numeric

- **Introduced:** MariaDB 10.0.9 (XtraDB-only), MariaDB 10.5.0 :
- 

### Innodb\_master\_thread\_background\_loops

- **Description:** As shown in the BACKGROUND THREAD section of the [SHOW ENGINE INNODB STATUS](#) output.
  - In [MariaDB 5.5](#), this system variable is present in XtraDB.
  - In [MariaDB 10.1](#) and later, this system variable is not present

- **Scope:** Global

- **Data Type:**

numeric

- **Introduced:** MariaDB 5.5

- **Removed:** MariaDB 10.0
- 

### Innodb\_master\_thread\_idle\_loops

- **Description:** As shown in the BACKGROUND THREAD section of the [SHOW ENGINE INNODB STATUS](#) output.
  - In [MariaDB 10.1](#), this system variable is present in XtraDB.
  - In [MariaDB 10.2](#), [MariaDB 10.3](#), and [MariaDB 10.4](#), this system variable is not present.
  - In [MariaDB 10.5](#), this system variable was reintroduced.

- **Scope:** Global
  - **Data Type:**  
numeric
- **Introduced:** MariaDB 10.0.9 (XtraDB-only), MariaDB 10.5.0 :
- 

### Innodb\_master\_thread\_main\_flush\_loops

- **Description:** As shown in the BACKGROUND THREAD section of the [SHOW ENGINE INNODB STATUS](#) output.
    - In [MariaDB 5.5](#), this system variable is present in XtraDB.
    - In [MariaDB 10.1](#) and later, this system variable is not present
  - **Scope:** Global
  - **Data Type:**  
numeric
- **Introduced:** MariaDB 5.5
  - **Removed:** MariaDB 10.0
- 

### Innodb\_master\_thread\_sleeps

- **Description:** As shown in the BACKGROUND THREAD section of the [SHOW ENGINE INNODB STATUS](#) output. XtraDB only.
    - In [MariaDB 5.5](#), this system variable is present in XtraDB.
    - In [MariaDB 10.1](#), [MariaDB 10.2](#), [MariaDB 10.3](#), and [MariaDB 10.4](#), this system variable is not present. Use the `innodb_master_thread_sleeps` counter in the `information_schema.INNODB_METRICS` table instead.
    - In [MariaDB 10.5](#), this system variable was reintroduced.
  - **Scope:** Global
  - **Data Type:**  
numeric
- **Introduced:** MariaDB 5.5
  - **Removed:** MariaDB 10.0
- 

### Innodb\_max\_trx\_id

- **Description:** As shown in the TRANSACTIONS section of the [SHOW ENGINE INNODB STATUS](#) output.
    - In [MariaDB 5.5](#) and [MariaDB 10.1](#), this system variable is present in XtraDB.
    - In [MariaDB 10.2](#), [MariaDB 10.3](#), and [MariaDB 10.4](#), this system variable is not present.
    - In [MariaDB 10.5](#), this system variable was reintroduced.
  - **Scope:** Global
  - **Data Type:**  
numeric
- **Introduced:** MariaDB 5.5 (XtraDB-only), MariaDB 10.5.0
- 

### Innodb\_mem\_adaptive\_hash

- **Description:** As shown in the BUFFER POOL AND MEMORY section of the [SHOW ENGINE INNODB STATUS](#) output.
  - In [MariaDB 5.5](#) and [MariaDB 10.1](#), this system variable is present in XtraDB.
  - In [MariaDB 10.2](#), [MariaDB 10.3](#), and [MariaDB 10.4](#), this system variable is not present.
  - In [MariaDB 10.5](#), this system variable was reintroduced.
- **Scope:** Global
- **Data Type:**  
numeric

- **Introduced:** [MariaDB 5.5](#) (XtraDB-only), [MariaDB 10.5.0](#)
- 

### Innodb\_mem\_dictionary

- **Description:** As shown in the BUFFER POOL AND MEMORY section of the [SHOW ENGINE INNODB STATUS](#) output.

- In [MariaDB 5.5](#) and [MariaDB 10.1](#), this system variable is present in XtraDB.
- In [MariaDB 10.2](#), [MariaDB 10.3](#), and [MariaDB 10.4](#), this system variable is not present.
- In [MariaDB 10.5](#), this system variable was reintroduced.

- **Scope:** Global

- **Data Type:**

numeric

- **Introduced:** [MariaDB 5.5](#) (XtraDB-only), [MariaDB 10.5.0](#)
- 

### Innodb\_mem\_total

- **Description:** As shown in the BUFFER POOL AND MEMORY section of the [SHOW ENGINE INNODB STATUS](#) output.

- In [MariaDB 5.5](#) and [MariaDB 10.1](#), this system variable is present in XtraDB.
- In [MariaDB 10.2](#) and later, this system variable is not present.

- **Scope:** Global

- **Data Type:**

numeric

- **Introduced:** [MariaDB 5.5](#)
- 

### Innodb\_mutex\_os\_waits

- **Description:** Mutex OS waits as shown in the SEMAPHORES section of the [SHOW ENGINE INNODB STATUS](#) output.

- In [MariaDB 5.5](#) and [MariaDB 10.1](#), this system variable is present in XtraDB.
- In [MariaDB 10.2](#) and later, this system variable is not present.

- **Scope:** Global

- **Data Type:**

numeric

- **Introduced:** [MariaDB 5.5](#)
- 

### Innodb\_mutex\_spin\_rounds

- **Description:** Mutex spin rounds as shown in the SEMAPHORES section of the [SHOW ENGINE INNODB STATUS](#) output.

- In [MariaDB 5.5](#) and [MariaDB 10.1](#), this system variable is present in XtraDB.
- In [MariaDB 10.2](#) and later, this system variable is not present.

- **Scope:** Global

- **Data Type:**

numeric

- **Introduced:** [MariaDB 5.5](#)
- 

### Innodb\_mutex\_spin\_waits

- **Description:** Mutex spin waits as shown in the SEMAPHORES section of the [SHOW ENGINE INNODB STATUS](#) output.

- In [MariaDB 5.5](#) and [MariaDB 10.1](#), this system variable is present in XtraDB.
- In [MariaDB 10.2](#) and later, this system variable is not present.

- **Scope:** Global

- **Data Type:**

numeric

- **Introduced:** MariaDB 5.5
- 

Innodb\_num\_index\_pages\_written

- **Description:**
  - **Scope:**
  - **Data Type:**  
    numeric
- **Introduced:** MariaDB 10.1.0
- 

Innodb\_num\_non\_index\_pages\_written

- **Description:**
  - **Scope:**
  - **Data Type:**  
    numeric
- **Introduced:** MariaDB 10.1.0
- 

Innodb\_num\_open\_files

- **Description:** Number of open files held by InnoDB. InnoDB only.
  - **Scope:** Global
  - **Data Type:**  
    numeric
- **Introduced:** MariaDB 10.0.0
- 

Innodb\_num\_page\_compressed\_trim\_op

- **Description:** Number of trim operations performed.
  - **Scope:** Global
  - **Data Type:**  
    numeric
- **Introduced:** MariaDB 10.1.0
- 

Innodb\_num\_page\_compressed\_trim\_op\_saved

- **Description:** Number of trim operations not done because of an earlier trim.
  - **Scope:** Global
  - **Data Type:**  
    numeric
- **Introduced:** MariaDB 10.1.0
- 

Innodb\_num\_pages\_decrypted

- **Description:** Number of pages page decrypted. See [Table and Tablespace Encryption](#). Was originally named  
    Innodb\_num\_pages\_page\_decrypted  
    in [MariaDB 10.1.3](#), renamed to its current name in [MariaDB 10.1.4](#).
- **Scope:** Global

- **Data Type:**

numeric

- **Introduced:** MariaDB 10.1.3
- 

### Innodb\_num\_pages\_encrypted

- **Description:** Number of pages page encrypted. See [Table and Tablespace Encryption](#). Was originally named

Innodb\_num\_pages\_page\_encrypted  
in MariaDB 10.1.3 , renamed to its current name in MariaDB 10.1.4 .

- **Scope:** Global

- **Data Type:**

numeric

- **Introduced:** MariaDB 10.1.3
- 

### Innodb\_num\_pages\_page\_compressed

- **Description:** Number of pages that are page compressed.

- **Scope:** Global

- **Data Type:**

numeric

- **Introduced:** MariaDB 10.1.0
- 

### Innodb\_num\_pages\_page\_compression\_error

- **Description:** Number of compression errors.

- **Scope:** Global

- **Data Type:**

numeric

- **Introduced:** MariaDB 10.1
- 

### Innodb\_num\_pages\_page\_decompressed

- **Description:** Number of pages compressed with page compression that are decompressed.

- **Scope:** Global

- **Data Type:**

numeric

- **Introduced:** MariaDB 10.1.0
- 

### Innodb\_num\_pages\_page\_encryption\_error

- **Description:** Number of page encryption errors. See [Table and Tablespace Encryption](#).

- **Scope:** Global

- **Data Type:**

numeric

- **Introduced:** MariaDB 10.1.3

- **Removed:** MariaDB 10.1.4
-

## Innodb\_oldest\_view\_low\_limit\_trx\_id

- **Description:** As shown in the TRANSACTIONS section of the [SHOW ENGINE INNODB STATUS](#) output.
    - In [MariaDB 5.5](#) and [MariaDB 10.1](#), this system variable is present in XtraDB.
    - In [MariaDB 10.2](#) and later, this system variable is not present.
  - **Scope:** Global
  - **Data Type:**  
numeric
  - **Introduced:** [MariaDB 5.5](#)
- 

## Innodb\_onlineddl\_pct\_progress

- **Description:** Shows the progress of in-place alter table. It might be not so accurate because in-place alter is highly dependent on disk and buffer pool status. See [Monitoring progress and temporal memory usage of Online DDL in InnoDB](#).
  - **Scope:** Global
  - **Data Type:**  
numeric
  - **Introduced:** [MariaDB 10.1.1](#)
- 

## Innodb\_onlineddl\_rowlog\_pct\_used

- **Description:** Shows row log buffer usage in 5-digit integer (10000 means 100.00%). See [Monitoring progress and temporal memory usage of Online DDL in InnoDB](#).
  - **Scope:** Global
  - **Data Type:**  
numeric
  - **Introduced:** [MariaDB 10.1.1](#)
- 

## Innodb\_onlineddl\_rowlog\_rows

- **Description:** Number of rows stored in the row log buffer. See [Monitoring progress and temporal memory usage of Online DDL in InnoDB](#).
  - **Scope:** Global
  - **Data Type:**  
numeric
  - **Introduced:** [MariaDB 10.1.1](#)
- 

## Innodb\_os\_log\_fsyncs

- **Description:** Number of InnoDB log fsync (sync-to-disk) requests.
  - **Scope:** Global
  - **Data Type:**  
numeric
- 

## Innodb\_os\_log\_pending\_fsyncs

- **Description:** Number of pending InnoDB log fsync (sync-to-disk) requests.
- **Scope:** Global
- **Data Type:**  
numeric

---

### Innodb\_os\_log\_pending\_writes

- **Description:** Number of pending InnoDB log writes.
- **Scope:** Global
- **Data Type:**

numeric

---

### Innodb\_os\_log\_written

- **Description:** Number of bytes written to the InnoDB log.
- **Scope:** Global
- **Data Type:**

numeric

---

### Innodb\_page\_compression\_saved

- **Description:** Number of bytes saved by page compression.
- **Scope:**
- **Data Type:**
- **Introduced:** [MariaDB 10.1.0](#) , [MariaDB 10.0.15](#) Fusion-io

---

### Innodb\_page\_compression\_trim\_sect512

- **Description:** Number of TRIM operations performed for the page-compression/NVM Compression workload for the 512 byte block-size.
  - **Scope:**
  - **Data Type:**
  - **Introduced:** [MariaDB 10.1.0](#) , [MariaDB 10.0.15](#) Fusion-io
  - **Removed:** [MariaDB 10.2.4](#)
- 

### Innodb\_page\_compression\_trim\_sect1024

- **Description:** Number of TRIM operations performed for the page-compression/NVM Compression workload for the 1K block-size.
  - **Scope:**
  - **Data Type:**
  - **Introduced:** [MariaDB 10.1.2](#) , [MariaDB 10.0.15](#) Fusion-io
  - **Removed:** [MariaDB 10.2.4](#)
- 

### Innodb\_page\_compression\_trim\_sect2048

- **Description:** Number of TRIM operations performed for the page-compression/NVM Compression workload for the 2K block-size.
- **Scope:**
- **Data Type:**
- **Introduced:** [MariaDB 10.1.2](#) , [MariaDB 10.0.15](#) Fusion-io
- **Removed:** [MariaDB 10.2.4](#)

## Innodb\_page\_compression\_trim\_sect4096

- **Description:** Number of TRIM operations performed for the page-compression/NVM Compression workload for the 4K block-size.
  - **Scope:**
  - **Data Type:**  
    numeric
- **Introduced:** [MariaDB 10.1.0](#) , [MariaDB 10.0.15](#) Fusion-io  
• **Removed:** [MariaDB 10.2.4](#)
- 

## Innodb\_page\_compression\_trim\_sect8192

- **Description:** Number of TRIM operations performed for the page-compression/NVM Compression workload for the 8K block-size.
  - **Scope:**
  - **Data Type:**  
    numeric
- **Introduced:** [MariaDB 10.1.2](#) , [MariaDB 10.0.15](#) Fusion-io  
• **Removed:** [MariaDB 10.2.4](#)
- 

## Innodb\_page\_compression\_trim\_sect16384

- **Description:** Number of TRIM operations performed for the page-compression/NVM Compression workload for the 16K block-size.
  - **Scope:**
  - **Data Type:**  
    numeric
- **Introduced:** [MariaDB 10.1.2](#) , [MariaDB 10.0.15](#) Fusion-io  
• **Removed:** [MariaDB 10.2.4](#)
- 

## Innodb\_page\_compression\_trim\_sect32768

- **Description:** Number of TRIM operations performed for the page-compression/NVM Compression workload for the 32K block-size.
  - **Scope:**
  - **Data Type:**  
    numeric
- **Introduced:** [MariaDB 10.1.2](#) , [MariaDB 10.0.15](#) Fusion-io  
• **Removed:** [MariaDB 10.2.4](#)
- 

## Innodb\_page\_size

- **Description:** Page size used by InnoDB. Defaults to 16KB, can be compiled with a different value.
  - **Scope:** Global
  - **Data Type:**  
    numeric
- 

## Innodb\_pages\_created

- **Description:** Number of InnoDB pages created.
- **Scope:** Global
- **Data Type:**  
    numeric

---

### Innodb\_pages\_read

- **Description:** Number of InnoDB pages read.
  - **Scope:** Global
  - **Data Type:**  
    numeric
- 

### Innodb\_pages0\_read

- **Description:** Counter for keeping track of reads of the first page of InnoDB data files, because the original implementation of data-at-rest-encryption for InnoDB introduced new code paths for reading the pages. Removed in [MariaDB 10.4.0](#) as the extra reads of the first page were removed, and the encryption subsystem will be initialized whenever we first read the first page of each data file, in `fil_node_open_file()`.
  - **Scope:** Global
  - **Data Type:**  
    numeric
  - **Introduced:** [MariaDB 10.2.4](#) , [MariaDB 10.1.21](#)
  - **Removed:** [MariaDB 10.4.0](#)
- 

### Innodb\_pages\_written

- **Description:** Number of InnoDB pages written.
  - **Scope:** Global
  - **Data Type:**  
    numeric
- 

### Innodb\_purge\_trx\_id

- **Description:** Purge transaction id as shown in the TRANSACTIONS section of the [SHOW ENGINE INNODB STATUS](#) output.
    - In [MariaDB 5.5](#) and [MariaDB 10.1](#) , this system variable is present in XtraDB.
    - In [MariaDB 10.2](#) and later, this system variable is not present.
  - **Scope:** Global
  - **Data Type:**  
    numeric
  - **Introduced:** [MariaDB 5.5](#)
- 

### Innodb\_purge\_undo\_no

- **Description:** As shown in the TRANSACTIONS section of the [SHOW ENGINE INNODB STATUS](#) output.
    - In [MariaDB 5.5](#) and [MariaDB 10.1](#) , this system variable is present in XtraDB.
    - In [MariaDB 10.2](#) and later, this system variable is not present.
  - **Scope:** Global
  - **Data Type:**  
    numeric
  - **Introduced:** [MariaDB 5.5](#)
- 

### Innodb\_read\_views\_memory

- **Description:** As shown in the BUFFER POOL AND MEMORY section of the [SHOW ENGINE INNODB STATUS](#) output. Shows the total of memory in bytes allocated for the InnoDB read view.
    - In [MariaDB 5.5](#) and [MariaDB 10.1](#), this system variable is present in XtraDB.
    - In [MariaDB 10.2](#) and later, this system variable is not present.
  - **Scope:** Global
  - **Data Type:**  
numeric
  - **Introduced:** [MariaDB 5.5.32](#)
- 

#### Innodb\_row\_lock\_current\_waits

- **Description:** Number of pending row lock waits on InnoDB tables.
  - **Scope:** Global
  - **Data Type:**  
numeric
- 

#### Innodb\_row\_lock\_numbers

- **Description:** Number of current row locks on InnoDB tables as shown in the TRANSACTIONS section of the [SHOW ENGINE INNODB STATUS](#) output. Renamed to [InnoDB\\_current\\_row\\_locks](#) in XtraDB 5.5.10-20.1.
  - **Scope:** Global
  - **Data Type:**  
numeric
  - **Introduced:** [MariaDB 5.5](#) / XtraDB 5.5.8-20
  - **Removed:** [MariaDB 5.5](#) / XtraDB 5.5.10-20.1
- 

#### Innodb\_row\_lock\_time

- **Description:** Total time in milliseconds spent getting InnoDB row locks.
  - **Scope:** Global
  - **Data Type:**  
numeric
- 

#### Innodb\_row\_lock\_time\_avg

- **Description:** Average time in milliseconds spent getting an InnoDB row lock.
  - **Scope:** Global
  - **Data Type:**  
numeric
- 

#### Innodb\_row\_lock\_time\_max

- **Description:** Maximum time in milliseconds spent getting an InnoDB row lock.
  - **Scope:** Global
  - **Data Type:**  
numeric
-

### Innodb\_row\_lock\_waits

- **Description:** Number of times InnoDB had to wait before getting a row lock.
  - **Scope:** Global
  - **Data Type:**  
    numeric
- 

### Innodb\_rows\_deleted

- **Description:** Number of rows deleted from InnoDB tables.
  - **Scope:** Global
  - **Data Type:**  
    numeric
- 

### Innodb\_rows\_inserted

- **Description:** Number of rows inserted into InnoDB tables.
  - **Scope:** Global
  - **Data Type:**  
    numeric
- 

### Innodb\_rows\_read

- **Description:** Number of rows read from InnoDB tables.
  - **Scope:** Global
  - **Data Type:**  
    numeric
- 

### Innodb\_rows\_updated

- **Description:** Number of rows updated in InnoDB tables.
  - **Scope:** Global
  - **Data Type:**  
    numeric
- 

### Innodb\_s\_lock\_os\_waits

- **Description:** As shown in the SEMAPHORES section of the [SHOW ENGINE INNODB STATUS](#) output.
    - In [MariaDB 5.5](#) and [MariaDB 10.1](#), this system variable is present in XtraDB.
    - In [MariaDB 10.2](#) and later, this system variable is not present.
  - **Scope:** Global
  - **Data Type:**  
    numeric
  - **Introduced:** [MariaDB 5.5](#)
- 

### Innodb\_s\_lock\_spin\_rounds

- **Description:** As shown in the SEMAPHORES section of the [SHOW ENGINE INNODB STATUS](#) output.
    - In [MariaDB 5.5](#) and [MariaDB 10.1](#) , this system variable is present in XtraDB.
    - In [MariaDB 10.2](#) and later, this system variable is not present.
  - **Scope:** Global
  - **Data Type:**
    - numeric
  - **Introduced:** [MariaDB 5.5](#)
- 

#### Innodb\_s\_lock\_spin\_waits

- **Description:** As shown in the SEMAPHORES section of the [SHOW ENGINE INNODB STATUS](#) output.
    - In [MariaDB 5.5](#) and [MariaDB 10.1](#) , this system variable is present in XtraDB.
    - In [MariaDB 10.2](#) and later, this system variable is not present.
  - **Scope:** Global
  - **Data Type:**
    - numeric
  - **Introduced:** [MariaDB 5.5](#)
- 

#### Innodb\_scrub\_background\_page\_reorganizations

- **Description:** See [Table and Tablespace Encryption](#) .
  - **Scope:** Global
  - **Data Type:**
    - numeric
  - **Introduced:** [MariaDB 10.1.3](#)
  - **Removed:** [MariaDB 10.5.2](#)
- 

#### Innodb\_scrub\_background\_page\_split\_failures\_missing\_index

- **Description:** See [Table and Tablespace Encryption](#) .
  - **Scope:** Global
  - **Data Type:**
    - numeric
  - **Introduced:** [MariaDB 10.1.3](#)
  - **Removed:** [MariaDB 10.5.2](#)
- 

#### Innodb\_scrub\_background\_page\_split\_failures\_out\_of\_filespace

- **Description:** See [Table and Tablespace Encryption](#) .
  - **Scope:** Global
  - **Data Type:**
    - numeric
  - **Introduced:** [MariaDB 10.1.3](#)
  - **Removed:** [MariaDB 10.5.2](#)
- 

#### Innodb\_scrub\_background\_page\_split\_failures\_underflow

- **Description:** See [Table and Tablespace Encryption](#) .
- **Scope:** Global
- **Data Type:**
  - numeric

- **Introduced:** MariaDB 10.1.3
  - **Removed:** MariaDB 10.5.2
- 

### Innodb\_scrub\_background\_page\_split\_failures\_unknown

- **Description:** See [Table and Tablespace Encryption](#) .
- **Scope:** Global
- **Data Type:**

numeric

- **Introduced:** MariaDB 10.2.5 , MariaDB 10.1.3
  - **Removed:** MariaDB 10.5.2
- 

### Innodb\_scrub\_background\_page\_splits

- **Description:** See [Table and Tablespace Encryption](#) .
- **Scope:** Global
- **Data Type:**

numeric

- **Introduced:** MariaDB 10.1
  - **Removed:** MariaDB 10.5.2
- 

### Innodb\_scrub\_log

- **Description:**
- **Scope:** Global
- **Data Type:**

numeric

- **Introduced:** MariaDB 10.2.4
  - **Removed:** MariaDB 10.5.2
- 

### Innodb\_secondary\_index\_triggered\_cluster\_reads

- **Description:** Used to track the effectiveness of the Prefix Index Queries Optimization ( [MDEV-6929](#) )
- **Scope:** Global
- **Data Type:**

numeric

- **Introduced:** MariaDB 10.1.2
- 

### Innodb\_secondary\_index\_triggered\_cluster\_reads\_avoided

- **Description:** Used to track the effectiveness of the Prefix Index Queries Optimization ( [MDEV-6929](#) )
- **Scope:** Global
- **Data Type:**

numeric

- **Introduced:** MariaDB 10.1.2
- 

### Innodb\_system\_rows\_deleted

- **Description:**
  - **Scope:**
  - **Data Type:**  
    numeric
- **Introduced:** [MariaDB 10.0.15](#)
- 

#### Innodb\_system\_rows\_inserted

- **Description:**
  - **Scope:**
  - **Data Type:**  
    numeric
- **Introduced:** [MariaDB 10.0.15](#)
- 

#### Innodb\_system\_rows\_read

- **Description:**

## 4.3.2.6 AUTO\_INCREMENT Handling in InnoDB

### Contents

1. [AUTO\\_INCREMENT Lock Modes](#)
  1. [Traditional Lock Mode](#)
  2. [Consecutive Lock Mode](#)
  3. [Interleaved Lock Mode](#)
2. [Setting AUTO\\_INCREMENT Values](#)
3. [See Also](#)

## AUTO\_INCREMENT Lock Modes

The `innodb_autoinc_lock_mode` system variable determines the lock mode when generating `AUTO_INCREMENT` values for InnoDB tables. These modes allow InnoDB to make significant performance optimizations in certain circumstances.

The `innodb_autoinc_lock_mode` system variable may be removed in a future release. See [MDEV-19577](#) for more information.

### Traditional Lock Mode

When `innodb_autoinc_lock_mode` is set to

0

, InnoDB uses the traditional lock mode.

In this mode, InnoDB holds a table-level lock for all `INSERT` statements until the statement completes.

### Consecutive Lock Mode

When `innodb_autoinc_lock_mode` is set to

1

, InnoDB uses the consecutive lock mode.

In this mode, InnoDB holds a table-level lock for all bulk `INSERT` statements (such as `LOAD DATA` or `INSERT ... SELECT`) until the end of the statement. For simple `INSERT` statements, no table-level lock is held. Instead, a lightweight mutex is used which scales significantly better. This is the default setting.

## Interleaved Lock Mode

When `innodb_autoinc_lock_mode` is set to

2

, InnoDB uses the interleaved lock mode.

In this mode, InnoDB does not hold any table-level locks at all. This is the fastest and most scalable mode, but is not safe for `statement-based` replication.

## Setting AUTO\_INCREMENT Values

The `AUTO_INCREMENT` value for an InnoDB table can be set for a table by executing the `ALTER TABLE` statement and specifying the `AUTO_INCREMENT` table option. For example:

```
ALTER TABLE tab AUTO_INCREMENT=100;
```

However, in MariaDB 10.2.3 and before, InnoDB stores the table's `AUTO_INCREMENT` counter in memory. In these versions, when the server restarts, the counter is re-initialized to the highest value found in the table. This means that the above operation can be undone if the server is restarted before any rows are written to the table.

In MariaDB 10.2.4 and later, the `AUTO_INCREMENT` counter is persistent, so this restriction is no longer present. Persistent, however, does not mean transactional. Gaps may still occur in some cases, such as if a `INSERT IGNORE` statement fails, or if a user executes `ROLLBACK` or `ROLLBACK TO SAVEPOINT`.

For example:

```
CREATE TABLE t1 (pk INT AUTO_INCREMENT PRIMARY KEY, i INT, UNIQUE (i)) ENGINE=InnoDB;

INSERT INTO t1 (i) VALUES (1),(2),(3);
INSERT IGNORE INTO t1 (pk, i) VALUES (100,1);
Query OK, 0 rows affected, 1 warning (0.099 sec)

SELECT * FROM t1;
+---+---+
| pk | i   |
+---+---+
| 1  | 1   |
| 2  | 2   |
| 3  | 3   |
+---+---+

SHOW CREATE TABLE t1\G
***** 1. row *****
    Table: t1
Create Table: CREATE TABLE `t1` (
  `pk` int(11) NOT NULL AUTO_INCREMENT,
  `i` int(11) DEFAULT NULL,
  PRIMARY KEY (`pk`),
  UNIQUE KEY `i` (`i`)
) ENGINE=InnoDB AUTO_INCREMENT=4 DEFAULT CHARSET=latin1
```

If the server is restarted at this point, then the `AUTO_INCREMENT` counter will revert to

101

, which is the persistent value set as part of the failed `INSERT IGNORE`.

```
# Restart server
SHOW CREATE TABLE t1\G
***** 1. row *****
    Table: t1
Create Table: CREATE TABLE `t1` (
  `pk` int(11) NOT NULL AUTO_INCREMENT,
  `i` int(11) DEFAULT NULL,
  PRIMARY KEY (`pk`),
  UNIQUE KEY `i` (`i`)
) ENGINE=InnoDB AUTO_INCREMENT=101 DEFAULT CHARSET=latin1
```

## 4.3.2.7 InnoDB Buffer Pool

### Contents

1. [How the Buffer Pool Works](#)
2. [innodb\\_buffer\\_pool\\_size](#)
3. [innodb\\_buffer\\_pool\\_instances](#)
4. [innodb\\_old\\_blocks\\_pct](#) and [innodb\\_old\\_blocks\\_time](#)
5. [Dumping and Restoring the Buffer Pool](#)
6. [See Also](#)

The InnoDB buffer pool is a key component for optimizing MariaDB. It stores data and indexes, and you usually want it as large as possible so as to keep as much of the data and indexes in memory, reducing disk IO, as main bottleneck.

### How the Buffer Pool Works

The buffer pool attempts to keep frequently-used blocks in the buffer, and so essentially works as two sublists, a *new* sublist of recently-used information, and an *old* sublist of older information. By default, 37% of the list is reserved for the old list.

When new information is accessed that doesn't appear in the list, it is placed at the top of the old list, the oldest item in the old list is removed, and everything else bumps back one position in the list.

When information is accessed that appears in the *old* list, it is moved to the top the new list, and everything above moves back one position.

### innodb\_buffer\_pool\_size

The most important [server system variable](#) is [innodb\\_buffer\\_pool\\_size](#). This size should contain most of the active data set of your server so that SQL request can work directly with information in the buffer pool cache. Starting at several gigabytes of memory is a good starting point if you have that RAM available. Once warmed up to its normal load there should be very few [innodb\\_buffer\\_pool\\_reads](#) compared to [innodb\\_buffer\\_pool\\_read\\_requests](#). Look how these values change over a minute. If the change in [innodb\\_buffer\\_pool\\_reads](#) is less than 1% of the change in [innodb\\_buffer\\_pool\\_read\\_requests](#) then you have a good amount of usage. If you are getting the status variable [innodb\\_buffer\\_pool\\_wait\\_free](#) increasing then you don't have enough buffer pool (or your flushing isn't occurring frequently enough).

Be aware that before [MariaDB 10.4.4](#) the total memory allocated is about 10% more than the specified size as extra space is also reserved for control structures and buffers.

The larger the size, the longer it will take to initialize. On a modern 64-bit server with a 10GB memory pool, this can take five seconds or more. Increasing [innodb\\_buffer\\_pool\\_chunk\\_size](#) by several factors will reduce this significantly.

Make sure that the size is not too large, causing swapping. The benefit of a larger buffer pool size is more than undone if your operating system is regularly swapping.

Since [MariaDB 10.2.2](#), the buffer pool can be set dynamically, and new variables are introduced that may affect the size and performance. See [Setting Innodb Buffer Pool Size Dynamically](#).

### innodb\_buffer\_pool\_instances

The functionality described below was disabled in [MariaDB 10.5](#), and removed in [MariaDB 10.6](#), as the original reasons for splitting the buffer pool have mostly gone away.

If [innodb\\_buffer\\_pool\\_size](#) is set to more than 1GB, [innodb\\_buffer\\_pool\\_instances](#) divides the InnoDB buffer pool into a specific number of instances. The default was 1 in [MariaDB 5.5](#), but for large systems with buffer pools of many gigabytes, many instances can help reduce contention concurrency. The default is 8 in [MariaDB 10.0](#), with the exception of 32-bit Windows, where it depends on the value of [innodb\\_buffer\\_pool\\_size](#). Each instance manages its own data structures and takes an equal portion of the total buffer pool size, so for example if [innodb\\_buffer\\_pool\\_size](#) is 4GB and [innodb\\_buffer\\_pool\\_instances](#) is set to 4, each instance will be 1GB. Each instance should ideally be at least 1GB in size.

### innodb\_old\_blocks\_pct and innodb\_old\_blocks\_time

The default 37% reserved for the old list can be adjusted by changing the value of [innodb\\_old\\_blocks\\_pct](#). It can accept anything between 5% and 95%.

The [innodb\\_old\\_blocks\\_time](#) variable specifies the delay before a block can be moved from the old to the new sublist.

0

means no delay, while the default has been set to

1000

Before changing either of these values from their defaults, make sure you understand the impact and how your system currently uses the buffer. Their

main reason for existence is to reduce the impact of full table scans, which are usually infrequent, but large, and previously could clear everything from the buffer. Setting a non-zero delay could help in situations where full table scans are performed in quick succession.

Temporarily changing these values can also be useful to avoid the negative impact of a full table scan, as explained in [InnoDB logical backups](#).

## Dumping and Restoring the Buffer Pool

When the server starts, the buffer pool is empty. As it starts to access data, the buffer pool will slowly be populated. As more data will be accessed, the most frequently accessed data will be put into the buffer pool, and old data may be evicted. This means that a certain period of time is necessary before the buffer pool is really useful. This period of time is called the warmup.

Since [MariaDB 10.0](#), InnoDB can dump the buffer pool before the server shuts down, and restore it when it starts again. If this feature is used (default since [MariaDB 10.2](#)), no warmup is necessary. Use the `innodb_buffer_pool_dump_at_shutdown` and `innodb_buffer_pool_load_at_startup` system variables to enable or disable the buffer pool dump at shutdown and the restore at startup respectively.

It is also possible to dump the InnoDB buffer pool at any moment while the server is running, and it is possible to restore the last buffer pool dump at any moment. To do this, the special `innodb_buffer_pool_dump_now` and `innodb_buffer_pool_load_now` system variables can be set to ON. When selected, their value is always OFF.

A buffer pool restore, both at startup or at any other moment, can be aborted by setting `innodb_buffer_pool_load_abort` to ON.

The file which contains the buffer pool dump is specified via the `innodb_buffer_pool_filename` system variable.

### 4.3.2.8 InnoDB Change Buffering

Benchmarks attached to [MDEV-19514](#) show that the change buffer sometimes reduces performance, and in the best case seem to bring a few per cent improvement to throughput. However, such improvement could come with a price: If the buffered changes are never merged ([MDEV-19514](#), motivated by the reduction of random crashes and the removal of an `innodb_force_recovery` option that can inflict further corruption), then the InnoDB system tablespace can grow out of control ([MDEV-21952](#)).

Because of all this, the change buffer has been disabled by default from [MariaDB 10.5.15](#), [MariaDB 10.6.7](#), [MariaDB 10.7.3](#) and [MariaDB 10.8.2](#) ([MDEV-27734](#)) and the feature is deprecated and ignored from [MariaDB 10.9.0](#) ([MDEV-27735](#)).

## Contents

1. [Change Buffer Related Status Variables](#)
2. [See Also](#)

INSERT, UPDATE and DELETE statements can be particularly heavy operations to perform, as all indexes need to be updated after each change. For this reason these changes are often buffered.

Pages are modified in the `buffer pool`, and not immediately on disk. When rows are deleted, a flag is set, thus rows are not immediately deleted on disk. Later the changes will be written to disk ("flushed") by InnoDB background threads. Pages that have been modified in memory and not yet flushed are called dirty pages. The buffering of data changes is called Change Buffer.

Before [MariaDB 5.5](#), only inserted rows could be buffered, so this buffer was called Insert Buffer. The old name still appears in several places, for example in the output of `SHOW ENGINE INNODB STATUS`.

The change buffer only contains changes to the indexes. Inserts to UNIQUE secondary indexes cannot be buffered unless `unique_checks=0` is used. Delete-mark and purge buffering of UNIQUE secondary indexes is allowed.

The Change Buffer is an optimization because:

- A page can be modified several times in memory and be flushed to disk only once.
- Dirty pages are flushed together, so the number of IO operations is lower.

If the server crashes, usually the Change Buffer is not empty. However, changes are not lost because they are written to the transaction logs, so they can be applied at server restart.

The main server system variable here is `innodb_change_buffering`, which determines which form of change buffering, if any, to use.

The following settings are available:

- inserts
  - Only buffer insert operations
- deletes
  - Only buffer delete operations
- changes
  - Buffer both insert and delete operations
- purges
  - Buffer the actual physical deletes that occur in the background

- all
  - Buffer inserts, deletes and purges. Default setting from [MariaDB 5.5](#) until [MariaDB 10.5.14](#) , [MariaDB 10.6.6](#) , [MariaDB 10.7.2](#) and [MariaDB 10.8.1](#) .
- none
  - Don't buffer any operations. Default from [MariaDB 10.5.15](#) , [MariaDB 10.6.7](#) , [MariaDB 10.7.3](#) and [MariaDB 10.8.2](#) .

Modifying the value of this variable only affects the buffering of new operations. The merging of already buffered changes is not affected.

The `innodb_change_buffer_max_size` server system variable, determines the maximum size of the change buffer, expressed as a percentage of the buffer pool.

## Change Buffer Related Status Variables

- `Innodb_buffer_pool_pages_dirty` : Number of dirty pages in the Change Buffer.
- `innodb_buffer_pool_bytes_dirty` : Total size of the dirty pages, in bytes.
- `innodb_buffer_pool_wait_free` : How many times InnoDB was forced to flush dirty pages to write new data, because the buffer pool had no more free pages.

## See Also

- [InnoDB Buffer Pool](#)

### 4.3.2.9 InnoDB Doublewrite Buffer

The [InnoDB](#) doublewrite buffer was implemented to recover from half-written pages. This can happen when there's a power failure while InnoDB is writing a page to disk. On reading that page, InnoDB can discover the corruption from the mismatch of the page checksum. However, in order to recover, an intact copy of the page would be needed.

The double write buffer provides such a copy.

Whenever InnoDB flushes a page to disk, it is first written to the double write buffer. Only when the buffer is safely flushed to disk will InnoDB write the page to the final destination. When recovering, InnoDB scans the double write buffer and for each valid page in the buffer checks if the page in the data file is valid too.

## Doublewrite Buffer Settings

To turn off the doublewrite buffer, set the `innodb_doublewrite` system variable to

`0`

. This is safe on filesystems that write pages atomically - that is, a page write fully succeeds or fails. But with other filesystems, it is not recommended for production systems. An alternative option is atomic writes. See [atomic write support](#) for more details.

### 4.3.2.10 InnoDB Tablespaces

#### 4.3.2.10.1 InnoDB System Tablespaces

##### Contents

1. [Changing Sizes](#)
  1. [Increasing the Size](#)
  2. [Decreasing the Size](#)
2. [Using Raw Disk Partitions](#)
  1. [Raw Disk Partitions on Windows](#)
3. [System Tables within the InnoDB System Tablespace](#)

When InnoDB needs to store general information relating to the system as a whole, rather than a specific table, the specific file it writes to is the system tablespace. By default, this is the

`ibdata1`

file located in the data directory, (as defined by either the

`datadir`

or

`innodb_data_home_dir`

system variables). InnoDB uses the system tablespace to store the data dictionary, change buffer, and undo logs.

You can define the system tablespace filename or filenames, size and other options by setting the

`innodb_data_file_path`

system variable. This system variable can be specified as a command-line argument to

```
mysqld
```

or it can be specified in a relevant server [option group](#) in an [option file](#). For example:

```
[mariadb]
...
innodb_data_file_path=ibdata1:50M:autoextend
```

This system variable defaults to the file

```
ibdata1
, and it defaults to a minimum size of
12M
, and it defaults with the
autoextend
attribute enabled.
```

## Changing Sizes

InnoDB defaults to allocating 12M to the

```
ibdata1
file for the system tablespace. While this is sufficient for most use cases, it may not be for all. You may find after using MariaDB for a while that the allocation is too small for the system tablespace or it grows too large for your disk. Fortunately, you can adjust this size as need later.
```

### Increasing the Size

When setting the

```
innodb_data_file_path
```

system variable, you can define a size for each file given. In cases where you need a larger system tablespace, add the `autoextend` option to the last value.

```
[mariadb]
...
innodb_data_file_path=ibdata1:12M;ibdata2:50M:autoextend
```

Under this configuration, when the last system tablespace grows beyond the size allocation, InnoDB increases the size of the file by increments. To control the allocation increment, set the

```
innodb_autoextend_increment
```

system variable.

### Decreasing the Size

In cases where the InnoDB system tablespace has grown too large, the process to reduce it in size is a little more complicated than increasing the size. MariaDB does not allow you to remove data from the tablespace file itself. Instead you need to delete the tablespace files themselves, then restore the database from backups.

The backup utility mysqldump produces backup files containing the SQL statements needed to recreate the database. As a result, it restores a database with the bare minimum data rather than any additional information that might have built up in the tablespace file.

Use mysqldump to backup all of your InnoDB database tables, including the system tables in the

```
mysql
database that use InnoDB. You can find out what they are using the Information Schema.
```

```
SELECT TABLE_NAME FROM information_schema.TABLES
WHERE TABLE_SCHEMA = 'mysql' AND ENGINE = 'InnoDB';
```

If you only use InnoDB, you may find it easier to back up all databases and tables.

```
$ mysqldump -u root -p --all-databases > full-backup.sql
```

Then stop the MariaDB Server and remove the InnoDB tablespace files. In the data directory or the InnoDB data home directory, delete all the `ibdata` and

```
ib_log  
files as well as any file with an  
.ibd  
or  
.frm  
extension.
```

Once this is done, restart the server and import the dump file:

```
$ mysql -u root -p < full-backup.sql
```

## Using Raw Disk Partitions

Instead of having InnoDB write to the file system, you can set it to use raw disk partitions. On Windows and some Linux distributions, this allows you to perform non-buffered I/O without the file system overhead. Note that in many use cases this may not actually improve performance. Run tests to verify if there are any real gains for your application usage.

To enable a raw disk partition, first start MariaDB with the

```
newraw  
option set on the tablespace. For example:
```

```
[mariadb]  
...  
innodb_data_file_path=/dev/sdc:10Gnewraw
```

When the MariaDB Server starts, it initializes the partition. Don't create or change any data, (any data written to InnoDB at this stage will be lost on restart). Once the server has successfully started, stop it then edit the configuration file again, changing the

```
newraw  
keyword to  
raw
```

```
[mariadb]  
...  
innodb_data_file_path=/dev/sdc:10Graw
```

When you start MariaDB again, it'll read and write InnoDB data to the given disk partition instead of the file system.

## Raw Disk Partitions on Windows

When defining a raw disk partition for InnoDB on the Windows operating system, use the same procedure as defined above, but when defining the path for the

```
innodb_data_file_path
```

system variable, use

```
./
```

at the start. For example:

```
[mariadb]  
...  
innodb_data_file_path=//./E::10Graw
```

The given path is synonymous with the Windows syntax for accessing the physical drive.

## System Tables within the InnoDB System Tablespace

InnoDB creates some system tables within the InnoDB System Tablespace:

- `SYS_DATAFILES`
- `SYS_FOREIGN`
- `SYS_FOREIGN_COLS`

- SYS\_TABLESPACES
- SYS\_VIRTUAL
- SYS\_ZIP\_DICT
- SYS\_ZIP\_DICT\_COLS

These tables cannot be queried. However, you might see references to them in some places, such as in the

[INNODB\\_SYS\\_TABLES](#)

table in the

[information\\_schema](#)

database.

## 4.3.2.10.2 InnoDB File-Per-Table Tablespaces

### Contents

1. [File-Per-Table Tablespace Locations](#)

    2. [Differing ROW\\_FORMAT Values](#)
    3. [Foreign Key Constraints](#)
  3. [Tablespace Encryption](#)
  4. [See Also](#)

When you create a table using the [InnoDB storage engine](#), data written to that table is stored on the file system in a data file called a tablespace. Tablespace files contain both the data and indexes.

When

[innodb\\_file\\_per\\_table=ON](#)

is set, InnoDB uses one tablespace file per InnoDB table. These tablespace files have the [.ibd](#) extension. When

[innodb\\_file\\_per\\_table=OFF](#)

is set, InnoDB stores all tables in the [InnoDB system tablespace](#).

InnoDB versions in MySQL 5.7 and above also support an additional type of tablespace called [general tablespaces](#) that are created with

[CREATE TABLESPACE](#)

. However, InnoDB versions in MariaDB Server do not currently support general tablespaces or

## File-Per-Table Tablespace Locations

By default, InnoDB's file-per-table tablespaces are created in the system's data directory, which is defined by the

`datadir`

system variable. The system variable

`innodb_data_home_dir`

will not change the location of file-per-table tablespaces.

In the event that you have a specific tablespace that you need stored in a dedicated path, you can set the location using the

`DATA DIRECTORY`

table option when you create the table.

For instance,

```
CREATE TABLE test.t1 (
    id INT PRIMARY KEY AUTO_INCREMENT,
    name VARCHAR(50)
) ENGINE=InnoDB
DATA DIRECTORY = "/data/contact";
```

MariaDB then creates a database directory on the configured path and the file-per-table tablespace will be created inside that directory. On Unix-like operating systems, you can see the file using the `ls` command:

```
# ls -al /data/contact/test
drwxrwx--- 2 mysql mysql 4096 Dec 8 18:46 .
drwxr-xr-x 3 mysql mysql 4096 Dec 8 18:46 ..
-rw-rw---- 1 mysql mysql 98304 Dec 8 20:41 t1.ibd
```

Note, the system user that runs the MariaDB Server process (which is usually  
`mysql`) must have write permissions on the given path.

## Copying Transportable Tablespaces

InnoDB's file-per-table tablespaces are transportable, which means that you can copy a file-per-table tablespace from one MariaDB Server to another server. You may find this useful in cases where you need to transport full tables between servers and don't want to use backup tools like

`mariabackup`

or

`mysqldump`

. In fact, this process can even be used with

`mariabackup`

in some cases, such as when `restoring partial backups` or when `restoring individual tables or partitions from a backup`.

## Copying Transportable Tablespaces for Non-partitioned Tables

You can copy the transportable tablespace of a non-partitioned table from one server to another by exporting the tablespace file from the original server, and then importing the tablespace file into the new server.

### Exporting Transportable Tablespaces for Non-partitioned Tables

You can export a non-partitioned table by locking the table and copying the table's  
`.ibd`

and

.cfg

files from the relevant [tablespace location](#) for the table to a backup location. For example, the process would go like this:

- First, use the

```
FLUSH TABLES ... FOR EXPORT
```

statement on the target table:

```
FLUSH TABLES test.t1 FOR EXPORT;
```

This forces the server to close the table and provides your connection with a read lock on the table.

- Then, while your connection still holds the lock on the table, copy the tablespace file and the metadata file to a safe directory:

```
# cp /data/contacts/test/t1.ibd /data/saved-tablespaces/
# cp /data/contacts/test/t1.cfg /data/saved-tablespaces/
```

- Then, once you've copied the files, you can release the lock with

```
UNLOCK TABLES
```

:

```
UNLOCK TABLES;
```

## Importing Transportable Tablespaces for Non-partitioned Tables

You can import a non-partitioned table by discarding the table's original tablespace, copying the table's

.ibd

and

.cfg

files from the backup location to the relevant [tablespace location](#) for the table, and then telling the server to import the tablespace. For example, the process would go like this:

- First, on the destination server, you need to create a copy of the table. Use the same

```
CREATE TABLE
```

statement that was used to create the table on the original server:

```
CREATE TABLE test.t1 (
    id INT PRIMARY KEY AUTO_INCREMENT,
    name VARCHAR(50)
) ENGINE=InnoDB;
```

- Then, use

```
ALTER TABLE ... DISCARD TABLESPACE
```

to discard the new table's tablespace:

```
ALTER TABLE test.t1 DISCARD TABLESPACE;
```

- Then, copy the

.ibd

and

.cfg

files from the original server to the relevant directory on the target MariaDB Server:

```
# scp /data/tablespaces/t1.ibd target-server.com:/var/lib/mysql/test/
# scp /data/tablespaces/t1.cfg target-server.com:/var/lib/mysql/test/
```

File-per-table tablespaces can be imported with just the

.ibd

file in many cases. If you do not have the tablespace's

.cfg

file for whatever reason, then it is usually worth trying to import the tablespace with just the

.ibd

file.

- Then, once the files are in the proper directory on the target server, use

```
ALTER TABLE ... IMPORT TABLESPACE
```

to import the new table's tablespace:

```
ALTER TABLE test.t1 IMPORT TABLESPACE;
```

## Copying Transportable Tablespaces for Partitioned Tables

Currently, MariaDB does not directly support the transport of tablespaces from partitioned tables. See [MDEV-10568](#) for more information about that. It is still possible to transport partitioned tables if we use a workaround. You can copy the transportable tablespaces of a partitioned table from one server to another by exporting the tablespace file of each partition from the original server, and then importing the tablespace file of each partition into the new server.

### Exporting Transportable Tablespaces for Partitioned Tables

You can export a partitioned table by locking the table and copying the

.ibd

and

.cfg

files of each partition from the relevant [tablespace location](#) for the partition to a backup location. For example, the process would go like this:

- First, let's create a test table with some data on the original server:

```
CREATE TABLE test.t2 (
    employee_id INT,
    name VARCHAR(50),
) ENGINE=InnoDB
PARTITION BY RANGE (employee_id) (
    PARTITION p0 VALUES LESS THAN (6),
    PARTITION p1 VALUES LESS THAN (11),
    PARTITION p2 VALUES LESS THAN (16),
    PARTITION p3 VALUES LESS THAN MAXVALUE
);

INSERT INTO test.t2 (name, employee_id) VALUES
    ('Geoff Montee', 1),
    ('Chris Calendar', 6),
    ('Kyle Joiner', 11),
    ('Will Fong', 16);
```

- Then, we need to export the partitioned tablespace from the original server, which follows the same process as exporting non-partitioned tablespaces. That means that we need to use the

```
FLUSH TABLES ... FOR EXPORT
```

statement on the target table:

```
FLUSH TABLES test.t2 FOR EXPORT;
```

This forces the server to close the table and provides your connection with a read lock on the table.

- Then, if we grep the database directory in the data directory for the newly created

t2

table, we can see a number of

.ibd

and

.cfg

files for the table:

```
# ls -l /var/lib/mysql/test/ | grep t2
total 428
-rw-rw--- 1 mysql mysql 827 Dec 5 16:08 t2frm
-rw-rw--- 1 mysql mysql 48 Dec 5 16:08 t2.par
-rw-rw--- 1 mysql mysql 579 Dec 5 18:47 t2#P#p0.cfg
-rw-r----- 1 mysql mysql 98304 Dec 5 16:43 t2#P#p0.ibd
-rw-rw--- 1 mysql mysql 579 Dec 5 18:47 t2#P#p1.cfg
-rw-rw--- 1 mysql mysql 98304 Dec 5 16:08 t2#P#p1.ibd
-rw-rw--- 1 mysql mysql 579 Dec 5 18:47 t2#P#p2.cfg
-rw-rw--- 1 mysql mysql 98304 Dec 5 16:08 t2#P#p2.ibd
-rw-rw--- 1 mysql mysql 579 Dec 5 18:47 t2#P#p3.cfg
-rw-rw--- 1 mysql mysql 98304 Dec 5 16:08 t2#P#p3.ibd
```

- Then, while our connection still holds the lock on the table, we need to copy the tablespace files and the metadata files to a safe directory:

```
$ mkdir /tmp/backup
$ sudo cp /var/lib/mysql/test/*.*ibd /tmp/backup
$ sudo cp /var/lib/mysql/test/*.*cfg /tmp/backup
```

- Then, once we've copied the files, we can release the lock with

UNLOCK TABLES

:

```
UNLOCK TABLES;
```

## Importing Transportable Tablespaces for Partitioned Tables

You can import a partitioned table by creating a placeholder table, discarding the placeholder table's original tablespace, copying the partition's

.ibd

and

.cfg

files from the backup location to the relevant [tablespace location](#) for the placeholder table, and then telling the server to import the tablespace. At that point, the server can exchange the tablespace for the placeholder table with the one for the partition. For example, the process would go like this:

- First, we need to copy the saved tablespace files from the original server to the target server:

```
$ scp /tmp/backup/t2* user@target-host:/tmp/backup
```

- Then, we need to import the partitioned tablespaces onto the target server. The import process for partitioned tables is more complicated than the import process for non-partitioned tables. To start with, if it doesn't already exist, then we need to create a partitioned table on the target server that matches the partitioned table on the original server:

```
CREATE TABLE test.t2 (
    id INT PRIMARY KEY AUTO_INCREMENT,
    name VARCHAR(50),
    employee_id INT
) ENGINE=InnoDB
PARTITION BY RANGE (employee_id) (
    PARTITION p0 VALUES LESS THAN (6),
    PARTITION p1 VALUES LESS THAN (11),
    PARTITION p2 VALUES LESS THAN (16),
    PARTITION p3 VALUES LESS THAN MAXVALUE
);
```

- Then, using this table as a model, we need to create a placeholder of this table with the same structure that does not use partitioning. This can be done with a

CREATE TABLE... AS SELECT

statement:

```
CREATE TABLE test.t2_placeholder AS
SELECT * FROM test.t2 WHERE NULL;
```

This statement will create a new table called

t2\_placeholder

that has the same schema structure as

t2

, but it does not use partitioning and it contains no rows.

## For Each Partition

From this point forward, the rest of our steps need to happen for each individual partition. For each partition, we need to do the following process:

- First, we need to use

```
ALTER TABLE ... DISCARD TABLESPACE
```

to discard the placeholder table's tablespace:

```
ALTER TABLE test.t2_placeholder DISCARD TABLESPACE;
```

- Then, copy the  
.ibd  
and  
.cfg  
files for the next partition to the relevant directory for the  
t2\_placeholder  
table on the target MariaDB Server:

```
# cp /tmp/backup/t2#p0.cfg /var/lib/mysql/test/t2_placeholder.cfg
# cp /tmp/backup/t2#p0.ibd /var/lib/mysql/test/t2_placeholder.ibd
# chown mysql:mysql /var/lib/mysql/test/t2_placeholder*
```

File-per-table tablespaces can be imported with just the  
.ibd  
file in many cases. If you do not have the tablespace's  
.cfg  
file for whatever reason, then it is usually worth trying to import the tablespace with just the  
.ibd  
file.

- Then, once the files are in the proper directory on the target server, we need to use

```
ALTER TABLE ... IMPORT TABLESPACE
```

to import the new table's tablespace:

```
ALTER TABLE test.t2_placeholder IMPORT TABLESPACE;
```

The placeholder table now contains data from the  
p0  
partition on the source server.

```
SELECT * FROM test.t2_placeholder;
```

employee_id	name
1	Geoff Montee

- Then, it's time to transfer the partition from the placeholder to the target table. This can be done with an

```
ALTER TABLE... EXCHANGE PARTITION
```

statement:

```
ALTER TABLE test.t2 EXCHANGE PARTITION p0 WITH TABLE test.t2_placeholder;
```

The target table now contains the first partition from the source table.

```
SELECT * FROM test.t2;
```

employee_id	name
1	Geoff Montee

- Repeat this procedure for each partition you want to import. For each partition, we need to discard the placeholder table's tablespace, and then import the partitioned table's tablespace into the placeholder table, and then exchange the tablespaces between the placeholder table and the partition of our target table.

When this process is complete for all partitions, the target table will contain the imported data:

```
SELECT * FROM test.t2;
```

employee_id	name
1	Geoff Montee
6	Chris Calendar
11	Kyle Joiner
16	Will Fong

- Then, we can remove the placeholder table from the database:

```
DROP TABLE test.t2_placeholder;
```

## Known Problems with Copying Transportable Tablespaces

### Differing Storage Formats for Temporal Columns

MariaDB 10.1.2 added the

`mysql56_temporal_format`

system variable, which enables a new MySQL 5.6-compatible storage format for the

`TIME`

,

`DATETIME`

and

`TIMESTAMP`

data types.

If a file-per-tablespace file contains columns that use one or more of these temporal data types and if the tablespace file's original table was created with a certain storage format for these columns, then the tablespace file can only be imported into tables that were also created with the same storage format for these columns as the original table. Otherwise, you will see errors like the following:

```
ALTER TABLE dt_test IMPORT TABLESPACE;
ERROR 1808 (HY000): Schema mismatch (Column dt precise type mismatch.)
```

See [MDEV-15225](#) for more information.

See the pages for the

`TIME`

,

`DATETIME`

and

`TIMESTAMP`

data types to determine how to update the storage format for temporal columns in tables that were created before MariaDB 10.1.2 or that were created with

`mysql56_temporal_format=OFF`

## Differing ROW\_FORMAT Values

InnoDB file-per-table tablespaces can use different [row formats](#). A specific row format can be specified when creating a table either by setting the

`ROW_FORMAT`

table option or by the setting the

`innodb_default_row_format`

system variable. See [Setting a Table's Row Format](#) for more information on how to set an InnoDB table's row format.

If a file-per-tablespace file was created with a certain row format, then the tablespace file can only be imported into tables that were created with the same row format as the original table. Otherwise, you will see errors like the following:

```
ALTER TABLE t0 IMPORT TABLESPACE;
ERROR 1808 (HY000): Schema mismatch (Expected FSP_SPACE_FLAGS=0x21, .ibd file contains 0x0.)
```

The error message will be a bit more descriptive in [MariaDB 10.2.17](#) and later:

```
ALTER TABLE t0 IMPORT TABLESPACE;
ERROR 1808 (HY000): Schema mismatch (Table flags don't match, server table has 0x1 and the meta-data file has 0x0; .cfg file use
```

Be sure to check a tablespace's row format before moving it from one server to another. Keep in mind that the default row format can change between major versions of MySQL or MariaDB. See [Checking a Table's Row Format](#) for information on how to check an InnoDB table's row format.

See [MDEV-15049](#) and [MDEV-16851](#) for more information.

## Foreign Key Constraints

DISCARD on a table with foreign key constraints is only possible after disabling [foreign\\_key\\_checks](#):

```
SET SESSION foreign_key_checks=0;
ALTER TABLE t0 DISCARD TABLESPACE;
```

IMPORT on the other hand does not enforce foreign key constraints. So when importing tablespaces, referential integrity can only be guaranteed to import all tables bound by foreign key constraint at the same time, from an EXPORT of those tables taken with the same transactional state.

## Tablespace Encryption

MariaDB supports data-at-rest encryption for the InnoDB storage engine. When enabled, the Server encrypts data before writing it to the tablespace and decrypts reads from the tablespace before returning result-sets. This means that a malicious user attempting to exfiltrate sensitive data won't be able to import the tablespace onto a different server as shown above without the encryption key.

For more information on data encryption, see [Encrypting Data for InnoDB](#).

### 4.3.2.10.3 InnoDB Temporary Tablespaces

MariaDB starting with 10.2

The use of the temporary tablespaces in InnoDB was introduced in [MariaDB 10.2](#). In earlier versions, temporary tablespaces exist as part of the InnoDB `system` tablespace or were file-per-table depending on the configuration of the `innodb_file_per_table` system variable.

When the user creates a temporary table using the `CREATE TEMPORARY TABLE` statement and the engine is set as InnoDB, MariaDB creates a temporary tablespace file. When the table is not compressed, MariaDB writes to a shared temporary tablespace as defined by the `innodb_temp_data_file_path` system variable. MariaDB does not allow the creation of `ROW_FORMAT=COMPRESSED` temporary tables. All temporary tables will be uncompressed. MariaDB deletes temporary tablespaces when the server shuts down gracefully and is recreated when it starts again. It cannot be placed on a raw device.

Internal temporary tablespaces, (that is, temporary tables that cannot be kept in memory) use either Aria or MyISAM, depending on the `aria_used_for_temp_tables` system variable. You can set the default storage engine for user-created temporary tables using the `default_tmp_storage_engine` system variable.

## Sizing Temporary Tablespaces

In order to size temporary tablespaces, use the `innodb_temp_data_file_path` system variable. This system variable can be specified as a command-line

argument to `mysqld` or it can be specified in a relevant server option group in an [option file](#). For example:

```
[mariadb]
...
innodb_temp_data_file_path=ibtmp1:32M:autoextend
```

This system variable's syntax is the same as the `innodb_data_file_path` system variable. That is, a file name, size and option. By default, it writes a 12MB autoextending file to

ibtmp1  
in the data directory.

To see the current size of the temporary tablespace from MariaDB, query the Information Schema:

```
SELECT FILE_NAME AS "File Name",
       INITIAL_SIZE AS "Initial Size",
       DATA_FREE AS "Free Space",
       TOTAL_EXTENTS * EXTENT_SIZE AS "Total Size",
       MAXIMUM_SIZE AS "Max"
  FROM information_Schema.FILES
 WHERE TABLESPACE_NAME = "innodb_temporary";

+-----+-----+-----+-----+
| File Name | Initial Size | Free Space | Total Size | Max   |
+-----+-----+-----+-----+
| ./ibtmp1 |      12582912 |     621456 |    12592912 | NULL |
+-----+-----+-----+-----+
```

To increase the size of the temporary tablespace, you can add a path to an additional tablespace file to the value of the the `innodb_temp_data_file_path` system variable. Providing additional paths allows you to spread the temporary tablespace between multiple tablespace files. The last file can have the `autoextend` attribute, which ensures that you won't run out of space. For example:

```
[mariadb]
...
innodb_temp_data_file_path=ibtmp1:32M;ibtmp2:32M:autoextend
```

Unlike normal tablespaces, temporary tablespaces are deleted when you stop MariaDB. To shrink temporary tablespaces to their minimum sizes, restart the server.

### 4.3.2.11 InnoDB File Format

#### Contents

- 1. [Setting a Table's File Format](#)
- 2. [Supported File Formats](#)
  - 1. [Antelope](#)
  - 2. [Barracuda](#)
  - 3. [Future Formats](#)
- 3. [Checking a Table's File Format](#).
- 4. [Compatibility](#)
- 5. [See Also](#)

Prior to [MariaDB 10.3](#), the XtraDB/InnoDB storage engine supports two different file formats.

## Setting a Table's File Format

In [MariaDB 10.2](#) and before, the default file format for InnoDB tables can be chosen by setting the `innodb_file_format`.

In [MariaDB 10.2.1](#) and before, the default file format is

Antelope  
. In [MariaDB 10.2.2](#) and later, the default file format is  
Barracuda  
and  
Antelope  
is deprecated.

A table's tablespace is tagged with the lowest InnoDB file format that supports the table's [row format](#). So, even if the Barracuda file format is enabled, tables that use the COMPACT or REDUNDANT

row formats will be tagged with the  
Antelope  
file format in the `information_schema.INNODB_SYS_TABLES` table.

## Supported File Formats

The `InnoDB` storage engine supports two different file formats:

- Antelope
- Barracuda

### Antelope

In `MariaDB 10.2.1` and before, the default file format is

Antelope  
. In `MariaDB 10.2.2` and later, the  
Antelope  
file format is deprecated.

Antelope  
is the original InnoDB file format. It supports the  
COMPACT  
and  
REDUNDANT  
row formats, but not the  
DYNAMIC  
or  
COMPRESSED  
row formats.

### Barracuda

In `MariaDB 10.1` and before, the

Barracuda  
file format is only supported if the `innodb_file_per_table` system variable is set to  
ON  
. In `MariaDB 10.2.2` and later, the default file format is  
Barracuda  
and  
Antelope  
is deprecated.

Barracuda  
is a newer InnoDB file format. It supports the  
COMPACT  
,  
REDUNDANT  
,  
DYNAMIC  
and  
COMPRESSED  
row formats. Tables with large BLOB or TEXT columns in particular could benefit from the dynamic row format.

## Future Formats

InnoDB might use new file formats in the future. Each format will have an identifier from 0 to 25, and a name. The names have already been decided, and are animal names listed in an alphabetical order: Antelope, Barracuda, Cheetah, Dragon, Elk, Fox, Gazelle, Hornet, Impala, Jaguar, Kangaroo, Leopard, Moose, Nautilus, Ocelot, Porpoise, Quail, Rabbit, Shark, Tiger, Urchin, Viper, Whale, Xenops, Yak and Zebra.

## Checking a Table's File Format.

In `MariaDB 10.0` and later, the `information_schema.INNODB_SYS_TABLES` table can be queried to see the file format used by a table.

A table's tablespace is tagged with the lowest InnoDB file format that supports the table's `row format`. So, even if the Barracuda file format is enabled, tables that use the COMPACT or REDUNDANT row formats will be tagged with the Antelope file format in the `information_schema.INNODB_SYS_TABLES` table.

## Compatibility

Each tablespace is tagged with the id of the most recent file format used by one of its tables. All versions of XtraDB/InnoDB can read tables that use an older file format. However, it can not read from more recent formats. For this reason, each time XtraDB/InnoDB opens a table it checks the tablespace's format, and returns an error if a newer format is used.

This check can be skipped via the `innodb_file_format_check` variable. Beware that, if XtraDB/InnoDB tries to repair a table in an unknown format, the table will be corrupted! This happens on restart if `innodb_file_format_check` is disabled and the server crashed, or it was closed with fast shutdown.

To downgrade a table from the Barracuda format to Antelope, the table's

`ROW_FORMAT` can be set to a value supported by Antelope, via an `ALTER TABLE` statement. This recreates the indexes.

The Antelope format can be used to make sure that tables work on MariaDB and MySQL servers which are older than 5.5.

### 4.3.2.12

#### 4.3.2.12.1 InnoDB Row Formats Overview

##### Contents

1. Default Row Format
2. Setting a Table's Row Format
3. Checking a Table's Row Format
4. Row Formats
  1. REDUNDANT Row Format
  2. COMPACT Row Format
  3. DYNAMIC Row Format
  4. COMPRESSED Row Format
5. Maximum Row Size
6. Known Issues
  1. Upgrading Causes Row Size Too Large Errors

The InnoDB storage engine supports four different row formats:

- REDUNDANT
- COMPACT
- DYNAMIC
- COMPRESSED

In MariaDB 10.1 and before, the latter two row formats are only supported if the InnoDB file format is

Barracuda.  
Therefore, the `innodb_file_format` system variable must be set to  
Barracuda  
to use these row formats in those versions.

In MariaDB 10.1 and before, the latter two row formats are also only supported if the table is in a file per-table tablespace. Therefore, the `innodb_file_per_table` system variable must be set to

ON  
to use these row formats in those versions.

## Default Row Format

MariaDB starting with 10.2.2

In MariaDB 10.2.2 and later, the `innodb_default_row_format` system variable can be used to set the default row format for InnoDB tables. The possible values are:

- redundant
- compact
- dynamic

This system variable's default value is

dynamic  
, which means that the default row format is  
DYNAMIC

This system variable cannot be set to

compressed  
, which means that the default row format cannot be  
COMPRESSED

For example, the following statements would create a table with the

DYNAMIC  
row format:

```
SET SESSION innodb_strict_mode=ON;  
  
SET GLOBAL innodb_default_row_format='dynamic';  
  
CREATE TABLE tab (  
    id int,  
    str varchar(50)  
) ENGINE=InnoDB;
```

#### MariaDB until 10.2.1

In MariaDB 10.2.1 and before, the default row format is

COMPACT

For example, the following statements would create a table with the

COMPACT  
row format:

```
SET SESSION innodb_strict_mode=ON;  
  
CREATE TABLE tab (  
    id int,  
    str varchar(50)  
) ENGINE=InnoDB;
```

## Setting a Table's Row Format

One way to specify an InnoDB table's row format is by setting the `ROW_FORMAT` table option to the relevant row format in a `CREATE TABLE` or `ALTER TABLE` statement. For example:

```
SET SESSION innodb_strict_mode=ON;  
  
SET GLOBAL innodb_file_per_table=ON;  
  
SET GLOBAL innodb_file_format='Barracuda';  
  
CREATE TABLE tab (  
    id int,  
    str varchar(50)  
) ENGINE=InnoDB ROW_FORMAT=DYNAMIC;
```

In MariaDB 10.1 and before, InnoDB can silently ignore and override some row format choices if you do not have the `innodb_file_format` system

variable set to  
Barracuda  
and the `innodb_file_per_table` system variable set to  
ON

## Checking a Table's Row Format

The `SHOW TABLE STATUS` statement can be used to see the row format used by a table. For example:

```
SHOW TABLE STATUS FROM db1 WHERE Name='tab' \G
***** 1. row *****
      Name: tab
      Engine: InnoDB
      Version: 10
      Row_format: Dynamic
      Rows: 0
      Avg_row_length: 0
      Data_length: 16384
      Max_data_length: 0
      Index_length: 0
      Data_free: 0
      Auto_increment: NULL
      Create_time: 2019-04-18 20:24:04
      Update_time: NULL
      Check_time: NULL
      Collation: latin1_swedish_ci
      Checksum: NULL
      Create_options: row_format=DYNAMIC
      Comment:
```

The `information_schema.INNODB_SYS_TABLES` table can also be queried to see the row format used by a table. For example:

```
SELECT * FROM information_schema.INNODB_SYS_TABLES WHERE name='db1/tab' \G
***** 1. row *****
      TABLE_ID: 42
      NAME: db1/tab
      FLAG: 33
      N_COLS: 4
      SPACE: 27
      FILE_FORMAT: Barracuda
      ROW_FORMAT: Dynamic
      ZIP_PAGE_SIZE: 0
      SPACE_TYPE: Single
```

A table's tablespace is tagged with the lowest InnoDB file format that supports the table's row format. So, even if the Barracuda file format is enabled, tables that use the COMPACT or REDUNDANT row formats will be tagged with the Antelope file format in the `information_schema.INNODB_SYS_TABLES` table.

## Row Formats

### REDUNDANT Row Format

The REDUNDANT row format is the original non-compacted row format.

The REDUNDANT row format was the only available row format before MySQL 5.0.3. In that release, this row format was retroactively named the

#### REDUNDANT

row format. In the same release, the

#### COMPACT

row format was introduced as the new default row format.

See [InnoDB REDUNDANT Row Format](#) for more information.

## COMPACT Row Format

MariaDB until [10.2.1](#)

In [MariaDB 10.2.1](#) and before, the default row format is

#### COMPACT

.

The

#### COMPACT

row format is similar to the

#### REDUNDANT

row format, but it stores data in a more compact manner that requires about 20% less storage.

This row format was originally introduced in MySQL 5.0.3.

See [InnoDB COMPACT Row Format](#) for more information.

## DYNAMIC Row Format

MariaDB starting with [10.2.2](#)

In [MariaDB 10.2.2](#) and later, the default row format is

#### DYNAMIC

.

The

#### DYNAMIC

row format is similar to the

#### COMPACT

row format, but tables using the

#### DYNAMIC

row format can store even more data on overflow pages than tables using the

#### COMPACT

row format. This results in more efficient data storage than tables using the

#### COMPACT

row format, especially for tables containing columns using the [VARBINARY](#) , [VARCHAR](#) , [BLOB](#) and [TEXT](#) data types. However, InnoDB tables using the

#### COMPRESSED

row format are more efficient.

See [InnoDB DYNAMIC Row Format](#) for more information.

## COMPRESSED Row Format

From [MariaDB 10.1](#) , an alternative way to compress InnoDB tables is by using [InnoDB Page Compression](#) .

The

#### COMPRESSED

row format is similar to the

#### COMPACT

row format, but tables using the

#### COMPRESSED

row format can store even more data on overflow pages than tables using the

#### COMPACT

row format. This results in more efficient data storage than tables using the

COMPACT

row format, especially for tables containing columns using the `VARBINARY`, `VARCHAR`, `BLOB` and `TEXT` data types.

The

COMPRESSED

row format also supports compression of all data and index pages.

See [InnoDB COMPRESSED Row Format](#) for more information.

## Maximum Row Size

Several factors help determine the maximum row size of an InnoDB table.

First, MariaDB enforces a 65,535 byte limit on a table's maximum row size. The total size of a table's `BLOB` and `TEXT` columns do not count towards this limit. Only the pointers for a table's `BLOB` and `TEXT` columns count towards this limit. MariaDB enforces this limit for all storage engines, so this limit also applies to InnoDB tables. Therefore, this limit is the absolute maximum row size for an InnoDB table.

If you try to create a table that exceeds MariaDB's global limit on a table's maximum row size, then you will see an error like this:

```
ERROR 1118 (42000): Row size too large. The maximum row size for the used table type,
not counting BLOBS, is 65535. This includes storage overhead, check the manual. You
have to change some columns to TEXT or BLOBS
```

However, InnoDB also has its own limits on the maximum row size, so an InnoDB table's maximum row size could be smaller than MariaDB's global limit.

Second, the maximum amount of data that an InnoDB table can store in a row's main data page depends on the value of the `innodb_page_size` system variable. At most, the data that a single row can consume on the row's main data page is half of the value of the `innodb_page_size` system variable. With the default value of

16k

, that would mean that a single row can consume at most around 8 KB on the row's main data page. However, the limit on the row's main data page is not the absolute limit on the row's size.

Third, all InnoDB row formats can store certain kinds of data in overflow pages, so the maximum row size of an InnoDB table can be larger than the maximum amount of data that can be stored in the row's main data page.

Some row formats can store more data in overflow pages than others. For example, the

DYNAMIC

and

COMPRESSED

row formats can store the most data in overflow pages. To see how to determine the how the various InnoDB row formats can use overflow pages, see the following sections:

- [InnoDB REDUNDANT Row Format: Overflow Pages with the REDUNDANT Row Format](#)
- [InnoDB COMPACT Row Format: Overflow Pages with the COMPACT Row Format](#)
- [InnoDB DYNAMIC Row Format: Overflow Pages with the DYNAMIC Row Format](#)
- [InnoDB COMPRESSED Row Format: Overflow Pages with the COMPRESSED Row Format](#)

If a table's definition can allow rows that the table's InnoDB row format can't actually store, then InnoDB will raise errors or warnings in certain scenarios.

If the table were using the

REDUNDANT

or

COMPACT

row formats, then the error or warning would be the following:

```
ERROR 1118 (42000): Row size too large (> 8126). Changing some columns to
TEXT or BLOB or using ROW_FORMAT=DYNAMIC or ROW_FORMAT=COMPRESSED
may help. In current row format, BLOB prefix of 768 bytes is stored inline.
```

And if the table were using the

DYNAMIC

or

COMPRESSED

row formats, then the error or warning would be the following:

```
ERROR 1118 (42000): Row size too large (> 8126). Changing some columns to
TEXT or BLOB may help. In current row format, BLOB prefix of 0 bytes is stored inline.
```

These messages are raised in the following cases:

- If `InnoDB strict mode` is **enabled** and if a `DDL` statement is executed that touches the table, such as `CREATE TABLE` or `ALTER TABLE`, then InnoDB will raise an `error` with this message
- If `InnoDB strict mode` is **disabled** and if a `DDL` statement is executed that touches the table, such as `CREATE TABLE`  
or

## ALTER TABLE

- , then InnoDB will raise a **warning** with this message.
- Regardless of whether **InnoDB strict mode** is enabled, if a **DML** statement is executed that attempts to write a row that the table's InnoDB row format can't store, then InnoDB will raise an **error** with this message.

For information on how to solve the problem, see [Troubleshooting Row Size Too Large Errors with InnoDB](#).

## Known Issues

### Upgrading Causes Row Size Too Large Errors

Prior to [MariaDB 10.2.26](#), [MariaDB 10.3.17](#), and [MariaDB 10.4.7](#), MariaDB doesn't properly calculate the row sizes while executing DDL. In these versions, *unsafe* tables can be created, even if **InnoDB strict mode** is enabled. The calculations were fixed by [MDEV-19292](#) in [MariaDB 10.2.26](#), [MariaDB 10.3.17](#), and [MariaDB 10.4.7](#).

As a side effect, some tables that could be created or altered in previous versions may get rejected with the following error in these releases and any later releases.

```
ERROR 1118 (42000): Row size too large (> 8126). Changing some columns to  
TEXT or BLOB may help. In current row format, BLOB prefix of 0 bytes is stored inline.
```

And users could also see the following message as an error or warning in the [error log](#):

```
[Warning] InnoDB: Cannot add field col in table db1.tab because after adding it, the row size is 8478 which is greater than maxi
```

InnoDB used the wrong calculations to determine row sizes for quite a long time, so a lot of users may unknowingly have *unsafe* tables that the InnoDB row format can't actually store.

InnoDB does not currently have an easy way to check which existing tables have this problem. See [MDEV-20400](#) for more information.

For information on how to solve the problem, see [Troubleshooting Row Size Too Large Errors with InnoDB](#).

### 4.3.2.12.2 InnoDB REDUNDANT Row Format

#### Contents

1. [Using the REDUNDANT Row Format](#)
2. [Index Prefixes with the REDUNDANT Row Format](#)
3. [Overflow Pages with the REDUNDANT Row Format](#)

The

REDUNDANT  
row format is the original non-compacted row format.

The

REDUNDANT  
row format was the only available row format before MySQL 5.0.3. In that release, this row format was retroactively named the  
REDUNDANT  
row format. In the same release, the  
COMPACT  
row format was introduced as the new default row format.

## Using the

### REDUNDANT Row Format

The easiest way to create an InnoDB table that uses the

REDUNDANT  
row format is by setting the **ROW\_FORMAT** table option to  
REDUNDANT  
in a **CREATE TABLE** or **ALTER TABLE** statement.

It is recommended to set the **innodb\_strict\_mode** system variable to  
ON  
when using this format.

The

REDUNDANT

row format is supported by both the Antelope and the Barracuda file formats, so tables with this row format can be created regardless of the value of the `innodb_file_format` system variable.

For example:

```
SET SESSION innodb_strict_mode=ON;

CREATE TABLE tab (
    id int,
    str varchar(50)
) ENGINE=InnoDB ROW_FORMAT=REDUNDANT;
```

## Index Prefixes with the REDUNDANT Row Format

The REDUNDANT row format supports index prefixes up to 767 bytes.

## Overflow Pages with the REDUNDANT Row Format

All InnoDB row formats can store certain kinds of data in overflow pages. This allows for the maximum row size of an InnoDB table to be larger than the maximum amount of data that can be stored in the row's main data page. See [Maximum Row Size](#) for more information about the other factors that can contribute to the maximum row size for InnoDB tables.

In the REDUNDANT row format variable-length columns, such as columns using the `VARBINARY`, `VARCHAR`, `BLOB` and `TEXT` data types, can be partially stored in overflow pages.

InnoDB only considers using overflow pages if the table's row size is greater than half of `innodb_page_size`. If the row size is greater than this, then InnoDB chooses variable-length columns to be stored on overflow pages until the row size is less than half of `innodb_page_size`.

For `VARBINARY`, `VARCHAR`, `BLOB` and `TEXT` columns, only values longer than 767 bytes are considered for storage on overflow pages. Bytes that are stored to track a value's length do not count towards this limit. This limit is only based on the length of the actual column's data.

Fixed-length columns greater than 767 bytes are encoded as variable-length columns, so they can also be stored in overflow pages if the table's row size is greater than half of `innodb_page_size`. Even though a column using the `CHAR` data type can hold at most 255 characters, a `CHAR` column can still exceed 767 bytes in some cases. For example, a

```
char(255)  
column can exceed 767 bytes if the character set is  
utf8mb4
```

If a column is chosen to be stored on overflow pages, then the first 767 bytes of the column's value and a 20-byte pointer to the column's first overflow page are stored on the main page. Each overflow page is the size of `[innodb-system-variables#innodb_page_size] * innodb_page_size]`. If a column is too large to be stored on a single overflow page, then it is stored on multiple overflow pages. Each overflow page contains part of the data and a 20-byte pointer to the next overflow page, if a next page exists.

### 4.3.2.12.3 InnoDB COMPACT Row Format

MariaDB until 10.2.1

In MariaDB 10.2.1 and before, the default row format is

COMPACT

## Contents

1. Using the COMPACT Row Format
2. Index Prefixes with the COMPACT Row Format
3. Overflow Pages with the COMPACT Row Format

The

COMPACT  
row format is similar to the  
REDUNDANT  
row format, but it stores data in a more compact manner that requires about 20% less storage.

## Using the COMPACT Row Format

MariaDB starting with 10.2.2

In MariaDB 10.2.2 and later, the easiest way to create an InnoDB table that uses the

COMPACT  
row format is by setting the `ROW_FORMAT` table option to to  
COMPACT  
in a `CREATE TABLE` or `ALTER TABLE` statement.

It is recommended to set the `innodb_strict_mode` system variable to  
ON  
when using this row format.

The

COMPACT  
row format is supported by both the  
Antelope  
and the  
Barracuda  
`file formats`, so tables with this row format can be created regardless of the value of the `innodb_file_format` system variable.

For example:

```
SET SESSION innodb_strict_mode=ON;

CREATE TABLE tab (
    id int,
    str varchar(50)
) ENGINE=InnoDB ROW_FORMAT=COMPACT;
```

MariaDB until 10.2.1

In MariaDB 10.2.1 and before, the default row format is

COMPACT  
. Therefore, in these versions, the easiest way to create an InnoDB table that uses the  
COMPACT  
row format is by **not** setting the `ROW_FORMAT` table option at all in the `CREATE TABLE` or `ALTER TABLE` statement.

It is recommended to set the `innodb_strict_mode` system variable to  
ON  
when using this row format.

The

COMPACT  
row format is supported by both the  
Antelope  
and the  
Barracuda  
`file formats`, so tables with this row format can be created regardless of the value of the `innodb_file_format` system variable.

For example:

```
SET SESSION innodb_strict_mode=ON;

CREATE TABLE tab (
    id int,
    str varchar(50)
) ENGINE=InnoDB;
```

## Index Prefixes with the COMPACT Row Format

The

COMPACT

row format supports index prefixes up to 767 bytes.

## Overflow Pages with the COMPACT Row Format

All InnoDB row formats can store certain kinds of data in overflow pages. This allows for the maximum row size of an InnoDB table to be larger than the maximum amount of data that can be stored in the row's main data page. See [Maximum Row Size](#) for more information about the other factors that can contribute to the maximum row size for InnoDB tables.

In the

COMPACT

row format variable-length columns, such as columns using the `VARBINARY`, `VARCHAR`, `BLOB` and `TEXT` data types, can be partially stored in overflow pages.

InnoDB only considers using overflow pages if the table's row size is greater than half of `innodb_page_size`. If the row size is greater than this, then InnoDB chooses variable-length columns to be stored on overflow pages until the row size is less than half of `innodb_page_size`.

For `VARBINARY`, `VARCHAR`, `BLOB` and `TEXT` columns, only values longer than 767 bytes are considered for storage on overflow pages. Bytes that are stored to track a value's length do not count towards this limit. This limit is only based on the length of the actual column's data.

Fixed-length columns greater than 767 bytes are encoded as variable-length columns, so they can also be stored in overflow pages if the table's row size is greater than half of `innodb_page_size`. Even though a column using the `CHAR` data type can hold at most 255 characters, a `CHAR` column can still exceed 767 bytes in some cases. For example, a

`char(255)`

column can exceed 767 bytes if the `character set` is

`utf8mb4`

If a column is chosen to be stored on overflow pages, then the first 767 bytes of the column's value and a 20-byte pointer to the column's first overflow page are stored on the main page. Each overflow page is the size of `innodb_page_size`. If a column is too large to be stored on a single overflow page, then it is stored on multiple overflow pages. Each overflow page contains part of the data and a 20-byte pointer to the next overflow page, if a next page exists.

### 4.3.2.12.4 InnoDB DYNAMIC Row Format

MariaDB starting with 10.2.2

In MariaDB 10.2.2 and later, the default row format is

DYNAMIC

#### Contents

1. [Using the DYNAMIC Row Format](#)
2. [Index Prefixes with the DYNAMIC Row Format](#)
3. [Overflow Pages with the DYNAMIC Row Format](#)

The

DYNAMIC

row format is similar to the

COMPACT

row format, but tables using the DYNAMIC row format can store even more data on overflow pages than tables using the COMPACT row format. This results in more efficient data storage than tables using the COMPACT row format, especially for tables containing columns using the `VARBINARY`, `VARCHAR`, `BLOB` and `TEXT` data types. However, InnoDB tables using the COMPRESSED row format are more efficient.

The

DYNAMIC row format was originally introduced in [MariaDB 5.5](#).

## Using the DYNAMIC Row Format

MariaDB starting with [10.2.2](#)

In [MariaDB 10.2.2](#) and later, the default row format is

DYNAMIC

, as long as the `innodb_default_row_format` system variable has not been modified. Therefore, in these versions, the easiest way to create an InnoDB table that uses the

DYNAMIC

row format is by **not** setting the `ROW_FORMAT` table option at all in a `CREATE TABLE` or `ALTER TABLE` statement.

It is recommended to set the `innodb_strict_mode` system variable to

ON

when using this row format.

For example:

```
SET SESSION innodb_strict_mode=ON;

SET GLOBAL innodb_default_row_format='dynamic';

CREATE TABLE tab (
    id int,
    str varchar(50)
) ENGINE=InnoDB;
```

MariaDB until [10.2.1](#)

In [MariaDB 10.2.1](#) and before, the easiest way to create an InnoDB table that uses the

DYNAMIC

row format is by setting the `ROW_FORMAT` table option to to

DYNAMIC

in a `CREATE TABLE` or `ALTER TABLE` statement.

It is recommended to set the `innodb_strict_mode` system variable to

ON

when using this row format.

The

DYNAMIC

row format is only supported by the

Barracuda

`file format`. As a side effect, in [MariaDB 10.1](#) and before, the

DYNAMIC

row format is only supported if the `InnoDB file format` is

Barracuda

. Therefore, the `innodb_file_format` system variable must be set to

Barracuda

to use these row formats in those versions.

In [MariaDB 10.1](#) and before, the

DYNAMIC

row format is also only supported if the table is in a `file per-table` tablespace. Therefore, the `innodb_file_per_table` system variable must be set to

ON

to use this row format in those versions.

For example:

```

SET SESSION innodb_strict_mode=ON;

SET GLOBAL innodb_file_per_table=ON;

SET GLOBAL innodb_file_format='Barracuda';

CREATE TABLE tab (
    id int,
    str varchar(50)
) ENGINE=InnoDB ROW_FORMAT=DYNAMIC;

```

## Index Prefixes with the DYNAMIC Row Format

The

DYNAMIC

row format supports index prefixes up to 3072 bytes. In MariaDB 10.2 and before, the `innodb_large_prefix` system variable is used to configure the maximum index prefix length. In these versions, if `innodb_large_prefix` is set to

ON

, then the maximum prefix length is 3072 bytes, and if it is set to

OFF

, then the maximum prefix length is 767 bytes.

## Overflow Pages with the DYNAMIC Row Format

All InnoDB row formats can store certain kinds of data in overflow pages. This allows for the maximum row size of an InnoDB table to be larger than the maximum amount of data that can be stored in the row's main data page. See [Maximum Row Size](#) for more information about the other factors that can contribute to the maximum row size for InnoDB tables.

In the

DYNAMIC

row format variable-length columns, such as columns using the `VARBINARY`, `VARCHAR`, `BLOB` and `TEXT` data types, can be completely stored in overflow pages.

InnoDB only considers using overflow pages if the table's row size is greater than half of `innodb_page_size`. If the row size is greater than this, then InnoDB chooses variable-length columns to be stored on overflow pages until the row size is less than half of `innodb_page_size`.

For `BLOB` and `TEXT` columns, only values longer than 40 bytes are considered for storage on overflow pages. For `VARBINARY` and `VARCHAR` columns, only values longer than 255 bytes are considered for storage on overflow pages. Bytes that are stored to track a value's length do not count towards these limits. These limits are only based on the length of the actual column's data.

These limits differ from the limits for the

COMPACT

row format, where the limit is 767 bytes for all types.

Fixed-length columns greater than 767 bytes are encoded as variable-length columns, so they can also be stored in overflow pages if the table's row size is greater than half of `innodb_page_size`. Even though a column using the `CHAR` data type can hold at most 255 characters, a `CHAR` column can still exceed 767 bytes in some cases. For example, a

`char(255)`

column can exceed 767 bytes if the `character set` is

`utf8mb4`

If a column is chosen to be stored on overflow pages, then the entire value of the column is stored on overflow pages, and only a 20-byte pointer to the column's first overflow page is stored on the main page. Each overflow page is the size of `innodb_page_size`. If a column is too large to be stored on a single overflow page, then it is stored on multiple overflow pages. Each overflow page contains part of the data and a 20-byte pointer to the next overflow page, if a next page exists.

This behavior differs from the behavior of the

COMPACT

row format, which always stores the column prefix on the main page. This allows tables using the

DYNAMIC

row format to contain a high number of columns using the `VARBINARY`, `VARCHAR`, `BLOB` and `TEXT` data types.

## 4.3.2.12.5 InnoDB COMPRESSED Row Format

## Contents

1. Using the COMPRESSED Row Format
2. Compression with the COMPRESSED Row Format
3. Monitoring Performance of the COMPRESSED Row Format
4. Index Prefixes with the COMPRESSED Row Format
5. Overflow Pages with the COMPRESSED Row Format
6. Read-Only
7. See Also

In MariaDB 10.1 and later, an alternative (and usually superior) way to compress InnoDB tables is by using [InnoDB Page Compression](#). See [Comparison with the COMPRESSED Row Format](#).

The

COMPRESSED row format is similar to the COMPACT row format, but tables using the COMPRESSED row format can store even more data on overflow pages than tables using the COMPACT row format. This results in more efficient data storage than tables using the COMPACT row format, especially for tables containing columns using the [VARBINARY](#), [VARCHAR](#), [BLOB](#) and [TEXT](#) data types.

The

COMPRESSED row format also supports compression of all data and index pages.

## Using the COMPRESSED Row Format

An InnoDB table that uses the

COMPRESSED row format can be created by setting the [ROW\\_FORMAT](#) table option to COMPRESSED

and by setting the [KEY\\_BLOCK\\_SIZE](#) table option to one of the following values in a [CREATE TABLE](#) or [ALTER TABLE](#) statement, where the units are in

KB

:

•

1

•

2

•

4

•

8

•

16

16k

is the default value of the [innodb\\_page\\_size](#) system variable, so using

16

will usually result in minimal compression unless one of the following is true:

- The table has many columns that can be stored in overflow pages, such as columns that use the [VARBINARY](#), [VARCHAR](#), [BLOB](#) and [TEXT](#) data types.

- The server is using a non-default `innodb_page_size` value that is greater than 16k

In MariaDB 10.1 and later, the value of the `innodb_page_size` system variable can be set to

32k  
and  
64k

. This is especially useful because the larger page size permits more columns using the `VARBINARY`, `VARCHAR`, `BLOB` and `TEXT` data types.

Regardless, even when the value of the `innodb_page_size` system variable is set to some value higher than

16k

,

16

is still the maximum value for the `KEY_BLOCK_SIZE` table option for InnoDB tables using the `COMPRESSED` row format.

The

`COMPRESSED` row format cannot be set as the default row format with the `innodb_default_row_format` system variable.

The

`COMPRESSED` row format is only supported by the `Barracuda` file format . As a side effect, in MariaDB 10.1 and before, the `COMPRESSED` row format is only supported if the `InnoDB file format` is `Barracuda` . Therefore, the `innodb_file_format` system variable must be set to `Barracuda` to use these row formats in those versions.

In MariaDB 10.1 and before, the

`COMPRESSED` row format is also only supported if the table is in a `file per-table` tablespace. Therefore, the `innodb_file_per_table` system variable must be set to `ON` to use this row format in those versions.

It is also recommended to set the `innodb_strict_mode` system variable to

`ON` when using this row format.

InnoDB automatically uses the

`COMPRESSED` row format for a table if the `KEY_BLOCK_SIZE` table option is set to some value in a `CREATE TABLE` or `ALTER TABLE` statement. For example:

```
SET SESSION innodb_strict_mode=ON;
SET GLOBAL innodb_file_per_table=ON;
SET GLOBAL innodb_file_format='Barracuda';

CREATE TABLE tab (
    id int,
    str varchar(50)
) ENGINE=InnoDB KEY_BLOCK_SIZE=4;
```

If the `KEY_BLOCK_SIZE` table option is **not** set to some value, but the `ROW_FORMAT` table option is set to

`COMPRESSED` in a `CREATE TABLE` or `ALTER TABLE` statement, then InnoDB uses a default value of 8 for the `KEY_BLOCK_SIZE` table option. For example:

```

SET SESSION innodb_strict_mode=ON;

SET GLOBAL innodb_file_per_table=ON;

SET GLOBAL innodb_file_format='Barracuda';

CREATE TABLE tab (
    id int,
    str varchar(50)
) ENGINE=InnoDB ROW_FORMAT=COMPRESSED;

```

## Compression with the COMPRESSED Row Format

The

COMPRESSED  
row format supports compression of all data and index pages.

To avoid compressing and uncompressing pages too many times, InnoDB tries to keep both compressed and uncompressed pages in the [buffer pool](#) when there is enough room. This results in a bigger cache. When there is not enough room, an adaptive LRU algorithm is used to decide whether compressed or uncompressed pages should be evicted from the buffer: for CPU-bound workloads, the compressed pages are evicted first; for I/O-bound workloads, the uncompressed pages are evicted first. Of course, when necessary, both the compressed and uncompressed version of the same data can be evicted from the buffer.

Each compressed page has an uncompressed *modification log*, stored within the page itself. InnoDB writes small changes into it. When the space in the modification log runs out, the page is uncompressed, changes are applied, and the page is recompressed again. This is done to avoid some unnecessary decompression and compression operations.

Sometimes a *compression failure* might happen, because the data has grown too much to fit the page. When this happens, the page (and the index node) is split into two different pages. This process can be repeated recursively until the data fit the pages. This can be CPU-consuming on some busy servers which perform many write operations.

Before writing a compressed page into a data file, InnoDB writes it into the [redo log](#). This ensures that the [redo log](#) can always be used to recover tables after a crash, even if the compression library is updated and some incompatibilities are introduced. But this also means that the [redo log](#) will grow faster and might need more space, or the frequency of checkpoints might need to increase.

## Monitoring Performance of the COMPRESSED Row Format

The following

[INFORMATION\\_SCHEMA](#)  
tables can be used to monitor the performances of InnoDB compressed tables:

- [INNODB\\_CMP](#) and [INNODB\\_CMP\\_RESET](#)
- [INNODB\\_CMP\\_PER\\_INDEX](#) and [INNODB\\_CMP\\_PER\\_INDEX\\_RESET](#)
- [INNODB\\_CMPPMEM](#) and [INNODB\\_CMPPMEM\\_RESET](#)

## Index Prefixes with the COMPRESSED Row Format

The

COMPRESSED  
row format supports index prefixes up to 3072 bytes. In [MariaDB 10.2](#) and before, the [innodb\\_large\\_prefix](#) system variable is used to configure the maximum index prefix length. In these versions, if [innodb\\_large\\_prefix](#) is set to

ON  
, then the maximum prefix length is 3072 bytes, and if it is set to  
OFF  
, then the maximum prefix length is 767 bytes.

## Overflow Pages with the COMPRESSED Row Format

All InnoDB row formats can store certain kinds of data in overflow pages. This allows for the maximum row size of an InnoDB table to be larger than the maximum amount of data that can be stored in the row's main data page. See [Maximum Row Size](#) for more information about the other factors that can contribute to the maximum row size for InnoDB tables.

In the

COMPRESSED

row format variable-length columns, such as columns using the `VARBINARY`, `VARCHAR`, `BLOB` and `TEXT` data types, can be completely stored in overflow pages.

InnoDB only considers using overflow pages if the table's row size is greater than half of `innodb_page_size`. If the row size is greater than this, then InnoDB chooses variable-length columns to be stored on overflow pages until the row size is less than half of `innodb_page_size`.

For `BLOB` and `TEXT` columns, only values longer than 40 bytes are considered for storage on overflow pages. For `VARBINARY` and `VARCHAR` columns, only values longer than 255 bytes are considered for storage on overflow pages. Bytes that are stored to track a value's length do not count towards these limits. These limits are only based on the length of the actual column's data.

These limits differ from the limits for the

COMPACT

row format, where the limit is 767 bytes for all types.

Fixed-length columns greater than 767 bytes are encoded as variable-length columns, so they can also be stored in overflow pages if the table's row size is greater than half of `innodb_page_size`. Even though a column using the `CHAR` data type can hold at most 255 characters, a `CHAR` column can still exceed 767 bytes in some cases. For example, a

`char(255)`

column can exceed 767 bytes if the `character set` is

`utf8mb4`

If a column is chosen to be stored on overflow pages, then the entire value of the column is stored on overflow pages, and only a 20-byte pointer to the column's first overflow page is stored on the main page. Each overflow page is the size of `innodb_page_size`. If a column is too large to be stored on a single overflow page, then it is stored on multiple overflow pages. Each overflow page contains part of the data and a 20-byte pointer to the next overflow page, if a next page exists.

This behavior differs from the behavior of the

COMPACT

row format, which always stores the column prefix on the main page. This allows tables using the

COMPRESSED

row format to contain a high number of columns using the `VARBINARY`, `VARCHAR`, `BLOB` and `TEXT` data types.

## Read-Only

MariaDB starting with [10.6](#)

From [MariaDB 10.6.0](#) until [MariaDB 10.6.5](#), tables that are of the

COMPRESSED

row format are read-only by default. This was intended to be the first step towards removing write support and deprecating the feature.

This plan has been scrapped, and from [MariaDB 10.6.6](#),

COMPRESSED

tables are no longer read-only by default.

From [MariaDB 10.6.0](#) to [MariaDB 10.6.5](#), set the `innodb_read_only_compressed` variable to

OFF

to make the tables writable.

## 4.3.2.12.6 Troubleshooting Row Size Too Large Errors with InnoDB

## 4.3.2.13 InnoDB Strict Mode

## Contents

1. Configuring InnoDB Strict Mode
2. InnoDB Strict Mode Errors
  1. Wrong Create Options
  2. COMPRESSED Row Format
  3. Row Size Too Large

InnoDB strict mode is similar to [SQL strict mode](#). When it is enabled, certain InnoDB warnings become errors instead.

## Configuring InnoDB Strict Mode

MariaDB starting with [10.2.2](#)

In [MariaDB 10.2.2](#) and later, InnoDB strict mode is enabled by default.

InnoDB strict mode can be enabled or disabled by configuring the

`innodb_strict_mode`

server system variable.

Its global value can be changed dynamically with

`SET GLOBAL`

. For example:

```
SET GLOBAL innodb_strict_mode=ON;
```

Its value for the current session can also be changed dynamically with

`SET SESSION`

. For example:

```
SET SESSION innodb_strict_mode=ON;
```

It can also be set in a server [option group](#) in an [option file](#) prior to starting up the server. For example:

```
[mariadb]
...
innodb_strict_mode=ON
```

## InnoDB Strict Mode Errors

### Wrong Create Options

If InnoDB strict mode is enabled, and if a DDL statement is executed and invalid or conflicting [table options](#) are specified, then an error is raised. The error will only be a generic error that says the following:

```
ERROR 1005 (HY000): Can't create table `db1`.`tab` (errno: 140 "Wrong create options")
```

However, more details about the error can be found by executing

`SHOW WARNINGS`

For example, the error is raised in the following cases:

- The

`KEY_BLOCK_SIZE`

table option is set to a non-zero value, but the

`ROW_FORMAT`

table option is set to some row format other than the

[COMPRESSED](#)

row format. For example:

```
SET SESSION innodb_strict_mode=ON;

CREATE OR REPLACE TABLE tab (
    id int PRIMARY KEY,
    str varchar(50)

| Warning | 1030 | Got error 140 "Wrong create options" from storage engine InnoDB
+-----+-----+
3 rows in set (0.00 sec)

```

## COMPRESSED Row Format

If InnoDB strict mode is enabled, and if a table uses the

`COMPRESSED`

row format, and if the table's

`KEY_BLOCK_SIZE`

is too small to contain a row, then an error is returned by the statement.

## Row Size Too Large

If InnoDB strict mode is enabled, and if a table exceeds its row format's `maximum row size`, then InnoDB will return an error.

```

ERROR 1118 (42000): Row size too large (> 8126). Changing some columns to
TEXT or BLOB may help. In current row format, BLOB prefix of 0 bytes is stored inline.

```

See [Troubleshooting Row Size Too Large Errors with InnoDB](#) for more information.

### 4.3.2.14 InnoDB Redo Log

#### Contents

1. [Overview](#)
2. [Flushing Effects on Performance and Consistency](#)
  1. [Binary Log Group Commit and Redo Log Flushing](#)
3. [Redo Log Group Capacity](#)
  1. [Changing the Redo Log Group Capacity](#)
4. [Log Sequence Number \(LSN\)](#)
5. [Checkpoints](#)
  1. [Determining the Checkpoint Age](#)
    1. [Determining the Checkpoint Age in InnoDB](#)
    2. [Determining the Checkpoint Age in XtraDB](#)
  6. [Determining the Redo Log Occupancy](#)

## Overview

The redo log is used by [InnoDB](#) during crash recovery. The redo log files have names like

`ib_logfileN`  
, where  
N

is an integer. From [MariaDB 10.5](#), there is only one redo log, so the file will always be named `ib_logfile0`.  
If the `innodb_log_group_home_dir` system variable is configured, then the redo log files will be created in that directory. Otherwise, they will be created in the directory defined by the `datadir` system variable.

## Flushing Effects on Performance and Consistency

The `innodb_flush_log_at_trx_commit` system variable determines how often the transactions are flushed to the redo log, and it is important to achieve a good balance between speed and reliability.

## Binary Log Group Commit and Redo Log Flushing

In [MariaDB 10.0](#) and above, when both `innodb_flush_log_at_trx_commit=1` (the default) is set and the [binary log](#) is enabled, there is now one less sync to disk inside InnoDB during commit (2 syncs shared between a group of transactions instead of 3). See [Binary Log Group Commit and InnoDB Flushing Performance](#) for more information.

## Redo Log Group Capacity

The redo log group capacity is the total combined size of all InnoDB redo logs. The relevant factors are:

- From [MariaDB 10.5](#), there is 1 redo log. For [MariaDB 10.4](#) and before, the number of redo log files is configured by the `innodb_log_files_in_group` system variable.
- The size of each redo log file is configured by the `innodb_log_file_size` system variable.

Therefore, redo log group capacity is determined by the following calculation:

```
innodb_log_group_capacity  
=  
  
  innodb_log_file_size  
  
  *  
  
  innodb_log_files_in_group
```

For example, if `innodb_log_file_size` is set to

2G

and `innodb_log_files_in_group` is set to

2

, then we would have the following:

- ```
  innodb_log_group_capacity  
  =  
  
    innodb_log_file_size  
  
    *  
  
    innodb_log_files_in_group
```
- =  
2G  
\*  
2
- =  
4G

## Changing the Redo Log Group Capacity

The number (until [MariaDB 10.4](#) only - from [MariaDB 10.5](#) there is only 1 redo log) or size of redo log files can be changed with the following process:

- Stop the server.
- To change the log file size, configure `innodb_log_file_size`. To increase the number of log files (until [MariaDB 10.4](#) only), configure `innodb_log_files_in_group`.
- Start the server.

# Log Sequence Number (LSN)

Records within the InnoDB redo log are identified via a log sequence number (LSN).

## Checkpoints

When InnoDB performs a checkpoint, it writes the LSN of the oldest dirty page in the [InnoDB buffer pool](#) to the InnoDB redo log. If a page is the oldest dirty page in the [InnoDB buffer pool](#), then that means that all pages with lower LSNs have been flushed to the physical InnoDB tablespace files. If the server were to crash, then InnoDB would perform crash recovery by only applying log records with LSNs that are greater than or equal to the LSN of the oldest dirty page written in the last checkpoint.

Checkpoints are one of the tasks performed by the InnoDB master background thread. This thread schedules checkpoints 7 seconds apart when the server is very active, but checkpoints can happen more frequently when the server is less active.

Dirty pages are not actually flushed from the buffer pool to the physical InnoDB tablespace files during a checkpoint. That process happens asynchronously on a continuous basis by InnoDB's write I/O background threads configured by the [innodb\\_write\\_io\\_threads](#) system variable. If you want to make this process more aggressive, then you can decrease the value of the [innodb\\_max\\_dirty\\_pages\\_pct](#) system variable. You may also need to better tune InnoDB's I/O capacity on your system by setting the [innodb\\_io\\_capacity](#) system variable.

## Determining the Checkpoint Age

The checkpoint age is the amount of data written to the InnoDB redo log since the last checkpoint.

### Determining the Checkpoint Age in InnoDB

MariaDB starting with 10.2

In [MariaDB 10.2](#) and later, MariaDB uses InnoDB. In those versions, the checkpoint age can be determined by the process shown below.

To determine the InnoDB checkpoint age, do the following:

- Query [SHOW ENGINE INNODB STATUS](#).
- Find the

LOG  
section. For example:

```
---  
LOG  
---  
Log sequence number 252794398789379  
Log flushed up to 252794398789379  
Pages flushed up to 252792767756840  
Last checkpoint at 252792767756840  
0 pending log flushes, 0 pending chkp writes  
23930412 log i/o's done, 2.03 log i/o's/second
```

- Perform the following calculation:

```
innodb_checkpoint_age  
=  
Log sequence number  
-  
Last checkpoint at
```

In the example above, that would be:

- innodb\_checkpoint\_age  
=  
Log sequence number  
-  
Last checkpoint at
- = 252794398789379 - 252792767756840
- = 1631032539 bytes
- = 1631032539 bytes / (1024 \* 1024 \* 1024) (GB/bytes)
- = 1.5 GB of redo log written since last checkpoint

### Determining the Checkpoint Age in XtraDB

MariaDB until 10.1

In MariaDB 10.1 and before, MariaDB uses XtraDB by default. In those versions, the checkpoint age can be determined by the [Innodb\\_checkpoint\\_age](#) status variable.

## Determining the Redo Log Occupancy

The redo log occupancy is the percentage of the InnoDB redo log capacity that is taken up by dirty pages that have not yet been flushed to the physical InnoDB tablespace files in a checkpoint. Therefore, it's determined by the following calculation:

```
innodb_log_occupancy
=
innodb_checkpoint_age
/
innodb_log_group_capacity
```

For example, if

```
innodb_checkpoint_age
is
1.5G
and
innodb_log_group_capacity
is
4G
```

, then we would have the following:

- innodb\_log\_occupancy  
=
- innodb\_checkpoint\_age  
/  
innodb\_log\_group\_capacity
- =  
1.5G  
/  
4G
- =  
0.375

If the calculated value for redo log occupancy is too close to

1.0  
, then the InnoDB redo log capacity may be too small for the current workload.

### 4.3.2.15 InnoDB Undo Log

#### Contents

1. [Overview](#)
2. [Implementation Details](#)
3. [Effects of Long-Running Transactions](#)
4. [Configuration](#)

## Overview

When a [transaction](#) writes data, it always inserts them in the table indexes or data (in the buffer pool or in physical files). No private copies are created.

The old versions of data being modified by active XtraDB/InnoDB transactions are stored in the undo log. The original data can then be restored, or viewed by a consistent read.

## Implementation Details

Before a row is modified, it is copied into the undo log. Each normal row contains a pointer to the most recent version of the same row in the undo log. Each row in the undo log contains a pointer to previous version, if any. So, each modified row has an history chain.

Rows are never physically deleted until a transaction ends. If they were deleted, the restore would be impossible. Thus, rows are simply marked for deletion.

Each transaction uses a view of the records. The [transaction level](#) determines how this view is created. For example, READ UNCOMMITTED usually uses the current version of rows, even if they are not committed (*dirty reads*). Other isolation levels require that the most recent committed version of rows is searched in the undo log. READ COMMITTED uses a different view for each table, while REPEATABLE READ and SERIALIZABLE use the same view for all tables.

There is also a global history list of the data. When a transaction is committed, its history is added to this history list. The order of the list is the chronological order of the commits.

The purge thread deletes the rows in the undo log which are not needed by any existing view. The rows for which a most recent version exists are deleted, as well as the delete-marked rows.

If InnoDB needs to restore an old version, it will simply replace the newer version with the older one. When a transaction inserts a new row, there is no older version. However, in that case, the restore can be done by deleting the inserted rows.

## Effects of Long-Running Transactions

Understanding how the undo log works helps with understanding the negative effects long transactions.

- Long transactions generate several old versions of the rows in the undo log. Those rows will probably be needed for a longer time, because other long transactions will need them. Since those transactions will generate more modified rows, a sort of combinatory explosion can be observed. Thus, the undo log requires more space.
- Transaction may need to read very old versions of the rows in the history list, thus their performance will degrade.

Of course read-only transactions do not write more entries in the undo log; however, they delay the purging of existing entries.

Also, long transactions can more likely result in deadlocks, but this problem is not related to the undo log.

## Configuration

The undo log is not a log file that can be viewed on disk in the usual sense, such as the [error log](#) or [slow query log](#), rather an area of storage.

The undo log is usually part of the physical system tablespace, but from [MariaDB 10.0](#), the [innodb\\_undo\\_directory](#) and [innodb\\_undo\\_tablespaces](#) system variables can be used to split into different tablespaces and store in a different location (perhaps on a different storage device).

Each insert or update portion of the undo log is known as a rollback segment. The [innodb\\_undo\\_logs](#) system variable specifies the number of rollback segments to be used per transaction.

The related [innodb\\_available\\_undo\\_logs](#) status variable stores the total number of available InnoDB undo logs.

### 4.3.2.16 InnoDB Page Flushing

#### Contents

1. [Page Flushing with InnoDB Page Cleaner Threads](#)
1. [Page Flushing with Multiple InnoDB Page Cleaner Threads](#)
2. [Page Flushing with a Single InnoDB Page Cleaner Thread](#)
2. [Page Flushing with Multi-threaded Flush Threads](#)
3. [Configuring the InnoDB I/O Capacity](#)
4. [See Also](#)

## Page Flushing with InnoDB Page Cleaner Threads

InnoDB page cleaner threads flush dirty pages from the [InnoDB buffer pool](#). These dirty pages are flushed using a least-recently used (LRU) algorithm.

### Page Flushing with Multiple InnoDB Page Cleaner Threads

MariaDB 10.2.2 - 10.5.1

The [innodb\\_page\\_cleaners](#) system variable was added in [MariaDB 10.2.2](#), and makes it possible to use multiple InnoDB page cleaner threads. It is deprecated and ignored from [MariaDB 10.5.1](#), as the original reasons for splitting the buffer pool have mostly gone away.

The number of InnoDB page cleaner threads can be configured by setting the [innodb\\_page\\_cleaners](#) system variable. This system variable can be set in a server [option group](#) in an [option file](#) prior to starting up the server. For example:

```
[mariadb]
...
innodb_page_cleaners=8
```

In [MariaDB 10.3.3](#) and later, this system variable can also be changed dynamically with [SET GLOBAL](#). For example:

```
SET GLOBAL innodb_page_cleaners=8;
```

This system variable's default value is either

4

or the configured value of the [innodb\\_buffer\\_pool\\_instances](#) system variable, whichever is lower.

## Page Flushing with a Single InnoDB Page Cleaner Thread

In [MariaDB 10.2.1](#) and before, and from [MariaDB 10.5.1](#), when the original reasons for splitting the buffer pool have mostly gone away, only a single InnoDB page cleaner thread is supported.

## Page Flushing with Multi-threaded Flush Threads

**MariaDB 10.1.0 - 10.3.2**

InnoDB's multi-thread flush feature was first added in [MariaDB 10.1.0](#). It was deprecated in [MariaDB 10.2.9](#) and removed in [MariaDB 10.3.2](#).

In [MariaDB 10.3.1](#) and before, InnoDB's multi-thread flush feature can be used. This is especially useful in [MariaDB 10.1](#), which only supports a single page cleaner thread.

InnoDB's multi-thread flush feature can be enabled by setting the [innodb\\_use\\_mtflush](#) system variable. The number of threads can be configured by setting the [innodb\\_mtflush\\_threads](#) system variable. This system variable can be set in a server [option group](#) in an [option file](#) prior to starting up the server. For example:

```
[mariadb]
...
innodb_use_mtflush = ON
innodb_mtflush_threads = 8
```

The [innodb\\_mtflush\\_threads](#) system variable's default value is

8

. The maximum value is

64

. In multi-core systems, it is recommended to set its value close to the configured value of the [innodb\\_buffer\\_pool\\_instances](#) system variable.

However, it is also recommended to use your own benchmarks to find a suitable value for your particular application.

InnoDB's multi-thread flush feature was deprecated in [MariaDB 10.2.9](#) and removed from [MariaDB 10.3.2](#). In later versions of MariaDB, use multiple InnoDB page cleaner threads instead.

## Configuring the InnoDB I/O Capacity

Increasing the amount of I/O capacity available to InnoDB can also help increase the performance of page flushing.

The amount of I/O capacity available to InnoDB can be configured by setting the [innodb\\_io\\_capacity](#) system variable. This system variable can be changed dynamically with [SET GLOBAL](#). For example:

```
SET GLOBAL innodb_io_capacity=20000;
```

This system variable can also be set in a server [option group](#) in an [option file](#) prior to starting up the server. For example:

```
[mariadb]
...
innodb_io_capacity=20000
```

The maximum amount of I/O capacity available to InnoDB in an emergency defaults to either

2000

or twice [innodb\\_io\\_capacity](#), whichever is higher, or can be directly configured by setting the [innodb\\_io\\_capacity\\_max](#) system variable. This system variable can be changed dynamically with [SET GLOBAL](#). For example:

```
SET GLOBAL innodb_io_capacity_max=20000;
```

This system variable can also be set in a server [option group](#) in an [option file](#) prior to starting up the server. For example:

```
[mariadb]
...
innodb_io_capacity_max=20000
```

### 4.3.2.17 InnoDB Purge

#### Contents

1. [Optimizing Purge Performance](#)
  1. [Configuring the Purge Threads](#)
  2. [Configuring the Purge Batch Size](#)
  3. [Configuring the Max Purge Lag](#)
  4. [Configuring the Purge Rollback Segment Truncation Frequency](#)
  5. [Configuring the Purge Undo Log Truncation](#)
2. [Purge's Effect on Row Metadata](#)

When a transaction updates a row in an InnoDB table, InnoDB's MVCC implementation keeps old versions of the row in the [InnoDB undo log](#). The old versions are kept at least until all transactions older than the transaction that updated the row are no longer open. At that point, the old versions can be deleted. InnoDB has purge process that is used to delete these old versions.

## Optimizing Purge Performance

### Configuring the Purge Threads

The number of purge threads can be set by configuring the

```
innodb_purge_threads
```

system variable. This system variable can be specified as a command-line argument to

```
mysqld
```

or it can be specified in a relevant server [option group](#) in an [option file](#). For example:

```
[mariadb]
...
innodb_purge_threads = 6
```

### Configuring the Purge Batch Size

The purge batch size is defined as the number of [InnoDB redo log](#) records that must be written before triggering purge. The purge batch size can be set by configuring the

```
innodb_purge_batch_size
```

system variable. This system variable can be specified as a command-line argument to

```
mysqld
```

or it can be specified in a relevant server [option group](#) in an [option file](#). For example:

```
[mariadb]
...
innodb_purge_batch_size = 50
```

### Configuring the Max Purge Lag

If purge operations are lagging on a busy server, then this can be a tough situation to recover from. As a solution, InnoDB allows you to set the max purge lag. The max purge lag is defined as the maximum number of [InnoDB undo log](#) that can be waiting to be purged from the history until InnoDB begins delaying DML statements.

The max purge lag can be set by configuring the

```
innodb_max_purge_lag
```

system variable. This system variable can be changed dynamically with

```
SET GLOBAL
```

. For example:

```
SET GLOBAL innodb_max_purge_lag=1000;
```

This system variable can also be specified as a command-line argument to

```
mysqld
```

or it can be specified in a relevant server [option group](#) in an [option file](#). For example:

```
[mariadb]
...
innodb_max_purge_lag = 1000
```

The maximum delay can be set by configuring the

```
innodb_max_purge_lag_delay
```

system variable. This system variable can be changed dynamically with

```
SET GLOBAL
```

. For example:

```
SET GLOBAL innodb_max_purge_lag_delay=100;
```

This system variable can also be specified as a command-line argument to

```
mysqld
```

or it can be specified in a relevant server [option group](#) in an [option file](#). For example:

```
[mariadb]
...
innodb_max_purge_lag_delay = 100
```

## Configuring the Purge Rollback Segment Truncation Frequency

MariaDB starting with [10.2.2](#)

The

```
innodb_purge_rseg_truncate_frequency
```

system variable was first added in [MariaDB 10.2.2](#).

The purge rollback segment truncation frequency is defined as the number of purge loops that are run before unnecessary rollback segments are truncated. The purge rollback segment truncation frequency can be set by configuring the

```
innodb_purge_rseg_truncate_frequency
```

system variable. This system variable can be changed dynamically with

```
SET GLOBAL
```

. For example:

```
SET GLOBAL innodb_purge_rseg_truncate_frequency=64;
```

This system variable can also be specified as a command-line argument to

`mysqld`

or it can be specified in a relevant server [option group](#) in an [option file](#). For example:

```
[mariadb]
...
innodb_purge_rseg_truncate_frequency = 64
```

## Configuring the Purge Undo Log Truncation

MariaDB starting with [10.2.2](#)

The

`innodb_undo_log_truncate`

and

`innodb_max_undo_log_size`

system variables were first added in [MariaDB 10.2.2](#).

Purge undo log truncation occurs when InnoDB truncates an entire [InnoDB undo log](#) tablespace, rather than deleting individual [InnoDB undo log](#) records.

Purge undo log truncation can be enabled by configuring the

`innodb_undo_log_truncate`

system variable. This system variable can be changed dynamically with

`SET GLOBAL`

. For example:

```
SET GLOBAL innodb_undo_log_truncate=ON;
```

This system variable can also be specified as a command-line argument to

`mysqld`

or it can be specified in a relevant server [option group](#) in an [option file](#). For example:

```
[mariadb]
...
innodb_undo_log_truncate = ON
```

An [InnoDB undo log](#) tablespace is truncated when it exceeds the maximum size that is configured for [InnoDB undo log](#) tablespaces. The maximum size can be set by configuring the

`innodb_max_undo_log_size`

system variable. This system variable can be changed dynamically with

`SET GLOBAL`

. For example:

```
SET GLOBAL innodb_max_undo_log_size='64M';
```

This system variable can also be specified as a command-line argument to

`mysqld`

or it can be specified in a relevant server [option group](#) in an [option file](#). For example:

```
[mariadb]
...
innodb_max_undo_log_size = 64M
```

## Purge's Effect on Row Metadata

An InnoDB table's clustered index has three hidden system columns that are automatically generated. These hidden system columns are:

- - DB\_ROW\_ID
    - If the table has no other PRIMARY KEY or no other UNIQUE KEY defined as NOT NULL that can be promoted to the table's PRIMARY KEY, then InnoDB will use a hidden system column called DB\_ROW\_ID
      - . InnoDB will automatically generate the value for the column from a global InnoDB-wide 48-bit sequence (instead of being table-local).
- - DB\_TRX\_ID
    - The transaction ID of either the transaction that last changed the row or the transaction that currently has the row locked.
- - DB\_ROLL\_PTR
    - A pointer to the [InnoDB undo log](#) that contains the row's previous record. The value of DB\_ROLL\_PTR is only valid if DB\_TRX\_ID belongs to the current read view. The oldest valid read view is the purge view.

If a row's last [InnoDB undo log](#) record is purged, this can obviously affect the value of the row's

DB\_ROLL\_PTR column, because there would no longer be any [InnoDB undo log](#) record for the pointer to reference.

In [MariaDB 10.2](#) and before, the purge process wouldn't touch the value of the row's

DB\_TRX\_ID column.

However, in [MariaDB 10.3](#) and later, the purge process will set a row's

DB\_TRX\_ID column to 0

after all of the row's associated [InnoDB undo log](#) records have been deleted. This change allows InnoDB to perform an optimization: if a query wants to read a row, and if the row's

DB\_TRX\_ID column is set to 0

, then it knows that no other transaction has the row locked. Usually, InnoDB needs to lock the transaction system's mutex in order to safely check whether a row is locked, but this optimization allows InnoDB to confirm that the row can be safely read without any heavy internal locking.

This optimization can speed up reads, but it comes at a noticeable cost at other times. For example, it can cause the purge process to use more I/O after inserting a lot of rows, since the value of each row's

DB\_TRX\_ID column will have to be reset.

  - 1. DEFAULT Locking Strategy
  - 2. NONE Locking Strategy
  - 3. SHARED Locking Strategy
  - 4. EXCLUSIVE Locking Strategy

InnoDB tables support online DDL, which permits concurrent DML and uses optimizations to avoid unnecessary table copying.

The `ALTER TABLE` statement supports two clauses that are used to implement online DDL:

- `ALGORITHM` - This clause controls how the DDL operation is performed.
- `LOCK` - This clause controls how much concurrency is allowed while the DDL operation is being performed.

## Alter Algorithms

InnoDB supports multiple algorithms for performing DDL operations. This offers a significant performance improvement over previous versions. The supported algorithms are:

- - DEFAULT
    - This implies the default behavior for the specific operation.
- - COPY
- - INPLACE
- - NOCOPY
    - This was added in [MariaDB 10.3.7](#).
- - INSTANT
    - This was added in [MariaDB 10.3.7](#).

## Specifying an Alter Algorithm

The set of alter algorithms can be considered as a hierarchy. The hierarchy is ranked in the following order, with *least efficient* algorithm at the top, and *most efficient* algorithm at the bottom:

- - COPY
-

INPLACE

•

NOCOPY

•

INSTANT

When a user specifies an alter algorithm for a DDL operation, MariaDB does not necessarily use that specific algorithm for the operation. It interprets the choice in the following way:

- If the user specifies

COPY

, then InnoDB uses the

COPY

algorithm.

- If the user specifies any other algorithm, then InnoDB interprets that choice as the *least efficient* algorithm that the user is willing to accept. This means that if the user specifies

INPLACE

, then InnoDB will use the *most efficient* algorithm supported by the specific operation from the set (

INPLACE

,

NOCOPY

,

INSTANT

). Likewise, if the user specifies

NOCOPY

, then InnoDB will use the *most efficient* algorithm supported by the specific operation from the set (

NOCOPY

,

INSTANT

).

There is also a special value that can be specified:

- If the user specifies

DEFAULT

, then InnoDB uses its default choice for the operation. The default choice is to use the most efficient algorithm supported by the operation. The default choice will also be used if no algorithm is specified. Therefore, if you want InnoDB to use the most efficient algorithm supported by an operation, then you usually do not have to explicitly specify any algorithm at all.

## Specifying an Alter Algorithm Using the

ALGORITHM

Clause

InnoDB supports the

ALGORITHM

clause.

The ALGORITHM clause can be used to specify the *least efficient* algorithm that the user is willing to accept. It is supported by the ALTER TABLE and CREATE INDEX statements.

For example, if a user wanted to add a column to a table, but only if the operation used an algorithm that is at least as efficient as the

INPLACE

, then they could execute the following:

```
CREATE OR REPLACE TABLE tab (
    a int PRIMARY KEY,
    b varchar(50)
);

ALTER TABLE tab ADD COLUMN c varchar(50), ALGORITHM=INPLACE;
```

In MariaDB 10.3 and later, the above operation would actually use the

INSTANT

algorithm, because the

ADD COLUMN

operation supports the

INSTANT

algorithm, and the

INSTANT  
algorithm is more efficient than the  
INPLACE  
algorithm.

## Specifying an Alter Algorithm Using System Variables

MariaDB starting with 10.3

In MariaDB 10.3 and later, the `alter_algorithm` system variable can be used to pick the *least efficient* algorithm that the user is willing to accept.

For example, if a user wanted to add a column to a table, but only if the operation used an algorithm that is at least as efficient as the

INPLACE

, then they could execute the following:

```
CREATE OR REPLACE TABLE tab (
    a int PRIMARY KEY,
    b varchar(50)
);

SET SESSION alter_algorithm='INPLACE';
ALTER TABLE tab ADD COLUMN c varchar(50);
```

In MariaDB 10.3 and later, the above operation would actually use the

INSTANT

algorithm, because the

ADD COLUMN

operation supports the

INSTANT

algorithm, and the

INSTANT

algorithm is more efficient than the

INPLACE

algorithm.

MariaDB until 10.2

In MariaDB 10.2 and before, the `old_alter_table` system variable can be used to specify whether the

COPY

algorithm should be used.

For example, if a user wanted to add a column to a table, but they wanted to use the

COPY

algorithm instead of the default algorithm for the operation, then they could execute the following:

```
CREATE OR REPLACE TABLE tab (
    a int PRIMARY KEY,
    b varchar(50)
);

SET SESSION old_alter_table=1;
ALTER TABLE tab ADD COLUMN c varchar(50);
```

## Supported Alter Algorithms

The supported algorithms are described in more details below.

### DEFAULT Algorithm

The default behavior, which occurs if

`ALGORITHM=DEFAULT`

is specified, or if

`ALGORITHM`

is not specified at all, usually only makes a copy if the operation doesn't support being done in-place at all. In this case, the *most efficient* available algorithm will usually be used.

This means that, if an operation supports the

INSTANT  
algorithm, then it will use that algorithm by default. If an operation does not support the  
INSTANT  
algorithm, but it does support the  
NOCOPY  
algorithm, then it will use that algorithm by default. If an operation does not support the  
NOCOPY  
algorithm, but it does support the  
INPLACE  
algorithm, then it will use that algorithm by default.

## COPY Algorithm

The

COPY  
algorithm refers to the original [ALTER TABLE](#) algorithm.

When the

COPY  
algorithm is used, MariaDB essentially does the following operations:

```
-- Create a temporary table with the new definition
CREATE TEMPORARY TABLE tmp_tab (
...
);

-- Copy the data from the original table
INSERT INTO tmp_tab
    SELECT * FROM original_tab;

-- Drop the original table
DROP TABLE original_tab;

-- Rename the temporary table, so that it replaces the original one
RENAME TABLE tmp_tab TO original_tab;
```

This algorithm is very inefficient, but it is generic, so it works for all storage engines.

If the

COPY  
algorithm is specified with the

[ALGORITHM](#)

clause or with the

[alter\\_algorithm](#)

system variable, then the

COPY  
algorithm will be used even if it is not necessary. This can result in a lengthy table copy. If multiple

[ALTER TABLE](#)

operations are required that each require the table to be rebuilt, then it is best to specify all operations in a single

[ALTER TABLE](#)

statement, so that the table is only rebuilt once.

Using the

COPY  
Algorithm with InnoDB

If the

COPY  
algorithm is used with an [InnoDB](#) table, then the following statements apply:

- The table will be rebuilt using the current values of the [innodb\\_file\\_per\\_table](#), [innodb\\_file\\_format](#), and [innodb\\_default\\_row\\_format](#) system variables.

- The operation will have to create a temporary table to perform the table copy. This temporary table will be in the same directory as the original table, and its file name will be in the format

```
#  
  
sql${PID}_${THREAD_ID}_${TMP_TABLE_COUNT}  
, where  
 ${PID}  
is the process ID of  
mysqld  
,  
 ${THREAD_ID}  
is the connection ID, and  
 ${TMP_TABLE_COUNT}  
is the number of temporary tables that the connection has open. Therefore, the
```

`datadir`

may contain files with file names like

```
#  
  
sql1234_12_1.ibd
```

- The operation inserts one record at a time into each index, which is very inefficient.
- InnoDB does not use a sort buffer.
- In MariaDB 10.2.13 , MariaDB 10.3.5 and later, the table copy operation creates a lot fewer InnoDB undo log writes. See MDEV-11415 for more information.
- The table copy operation creates a lot of InnoDB redo log writes.

## INPLACE Algorithm

The

`COPY`  
algorithm can be incredibly slow, because the whole table has to be copied and rebuilt. The  
`INPLACE`  
algorithm was introduced as a way to avoid this by performing operations in-place and avoiding the table copy and rebuild, when possible.

When the

`INPLACE`  
algorithm is used, the underlying storage engine uses optimizations to perform the operation while avoiding the table copy and rebuild. However,

`INPLACE`  
is a bit of a misnomer, since some operations may still require the table to be rebuilt for some storage engines. Regardless, several operations can be performed without a full copy of the table for some storage engines.

A more accurate name for the algorithm would have been the

`ENGINE`  
algorithm, since the `storage engine` decides how to implement the algorithm.

If an `ALTER TABLE` operation supports the

`INPLACE`  
algorithm, then it can be performed using optimizations by the underlying storage engine, but it may rebuilt.

If the

`INPLACE`  
algorithm is specified with the `ALGORITHM` clause or with the `alter_algorithm` system variable and if the `ALTER TABLE` operation does not support the  
`INPLACE`  
algorithm, then an error will be raised. For example:

```
SET SESSION alter_algorithm='INPLACE';  
  
ALTER TABLE tab MODIFY COLUMN c int;  
ERROR 1846 (0A000): ALGORITHM=INPLACE is not supported. Reason: Cannot change column type INPLACE. Try ALGORITHM=COPY
```

In this case, raising an error is preferable, if the alternative is for the operation to make a copy of the table, and perform unexpectedly slowly.

## Using the

### INPLACE Algorithm with InnoDB

If the

INPLACE

algorithm is used with an [InnoDB](#) table, then the following statements apply:

- The operation might have to write sort files in the directory defined by the `innodb_tmpdir` system variable.
- The operation might also have to write a temporary log file to track data changes by [DML queries](#) executed during the operation. The maximum size for this log file is configured by the `innodb_online_alter_log_max_size` system variable.
- Some operations require the table to be rebuilt, even though the algorithm is inaccurately called "in-place". This includes operations such as adding or dropping columns, adding a primary key, changing a column to `NULL`, etc.
- If the operation requires the table to be rebuilt, then the operation might have to create temporary tables.
  - It may have to create a temporary intermediate table for the actual table rebuild operation.
    - In [MariaDB 10.2.19](#) and later, this temporary table will be in the same directory as the original table, and its file name will be in the format

```
#  
  
sql${PID}_${THREAD_ID}_${TMP_TABLE_COUNT}  
, where  
${PID}  
is the process ID of  
mysqld  
,  
${THREAD_ID}  
is the connection ID, and  
${TMP_TABLE_COUNT}  
is the number of temporary tables that the connection has open. Therefore, the
```

`datadir`

may contain files with file names like

```
#  
  
sql1234_12_1.ibd
```

- In [MariaDB 10.2.18](#) and before, this temporary table will be in the same directory as the original table, and its file name will be in the format

```
#  
  
sql-ib${TABLESPACE_ID}-${RAND}  
, where  
${TABLESPACE_ID}  
is the table's tablespace ID within InnoDB and  
${RAND}  
is a randomly initialized number. Therefore, the datadir may contain files with file names like
```

```
#  
  
sql-ib230291-1363966925.ibd
```

- When it replaces the original table with the rebuilt table, it may also have to rename the original table using a temporary table name.

- If the server is [MariaDB 10.3](#) or later or if it is running [MariaDB 10.2](#) and the `innodb_safe_truncate` system variable is set to `OFF`, then the format will actually be

```
#  
  
sql-ib${TABLESPACE_ID}-${RAND}  
, where  
${TABLESPACE_ID}  
is the table's tablespace ID within InnoDB and  
${RAND}  
is a randomly initialized number. Therefore, the datadir may contain files with file names like
```

#

sql\_ib230291-1363966925.ibd

- If the server is running [MariaDB 10.1](#) or before or if it is running [MariaDB 10.2](#) and the `innodb_safe_truncate` system variable is set to `ON`, then the renamed table will have a temporary table name in the format  
#  
`sql-ib${TABLESPACE_ID}`  
, where  
`${TABLESPACE_ID}`  
is the table's tablespace ID within InnoDB. Therefore, the `datadir` may contain files with file names like  
#  
`sql-ib230291.ibd`

- The storage needed for the above items can add up to the size of the original table, or more in some cases.
- Some operations are instantaneous, if they only require the table's metadata to be changed. This includes operations such as renaming a column, changing a column's `DEFAULT` value, etc.

## Operations Supported by InnoDB with the INPLACE Algorithm

With respect to the allowed operations, the

`INPLACE`  
algorithm supports a subset of the operations supported by the  
`COPY`  
algorithm, and it supports a superset of the operations supported by the  
`NOCOPY`  
algorithm.

See [InnoDB Online DDL Operations with ALGORITHM=INPLACE](#) for more information.

## NOCOPY Algorithm

MariaDB starting with [10.3](#)

In [MariaDB 10.3](#) and later, the  
`NOCOPY`  
algorithm is supported.

The

`INPLACE`  
algorithm can sometimes be surprisingly slow in instances where it has to rebuild the clustered index, because when the clustered index has to be rebuilt, the whole table has to be rebuilt. The  
`NOCOPY`  
algorithm was introduced as a way to avoid this.

If an `ALTER TABLE` operation supports the

`NOCOPY`  
algorithm, then it can be performed without rebuilding the clustered index.

If the

`NOCOPY`  
algorithm is specified with the `ALGORITHM` clause or with the `alter_algorithm` system variable and if the `ALTER TABLE` operation does not support the  
`NOCOPY`  
algorithm, then an error will be raised. For example:

```
SET SESSION alter_algorithm='NOCOPY';

ALTER TABLE tab MODIFY COLUMN c int;
ERROR 1846 (0A000): ALGORITHM=NOCOPY is not supported. Reason: Cannot change column type INPLACE. Try ALGORITHM=COPY
```

In this case, raising an error is preferable, if the alternative is for the operation to rebuild the clustered index, and perform unexpectedly slowly.

## Operations Supported by InnoDB with the NOCOPY Algorithm

With respect to the allowed operations, the

NOCOPY algorithm supports a subset of the operations supported by the INPLACE algorithm, and it supports a superset of the operations supported by the INSTANT algorithm.

See [InnoDB Online DDL Operations with ALGORITHM=NOCOPY](#) for more information.

## INSTANT Algorithm

MariaDB starting with 10.3

In MariaDB 10.3 and later, the INSTANT algorithm is supported.

The

INPLACE algorithm can sometimes be surprisingly slow in instances where it has to modify data files. The INSTANT algorithm was introduced as a way to avoid this.

If an [ALTER TABLE](#) operation supports the

INSTANT algorithm, then it can be performed without modifying any data files.

If the

INSTANT algorithm is specified with the [ALGORITHM](#) clause or with the [alter\\_algorithm](#) system variable and if the [ALTER TABLE](#) operation does not support the INSTANT algorithm, then an error will be raised. For example:

```
SET SESSION alter_algorithm='INSTANT';

ALTER TABLE tab MODIFY COLUMN c int;
ERROR 1846 (0A000): ALGORITHM=INSTANT is not supported. Reason: Cannot change column type INPLACE. Try ALGORITHM=COPY
```

In this case, raising an error is preferable, if the alternative is for the operation to modify data files, and perform unexpectedly slowly.

## Operations Supported by InnoDB with the INSTANT Algorithm

With respect to the allowed operations, the

INSTANT algorithm supports a subset of the operations supported by the NOCOPY algorithm.

See [InnoDB Online DDL Operations with ALGORITHM=INSTANT](#) for more information.

# Alter Locking Strategies

InnoDB supports multiple locking strategies for performing DDL operations. This offers a significant performance improvement over previous versions. The supported locking strategies are:

- DEFAULT
  - This implies the default behavior for the specific operation.
- NONE

- SHARED

- EXCLUSIVE

Regardless of which locking strategy is used to perform a DDL operation, InnoDB will have to exclusively lock the table for a short time at the start and end of the operation's execution. This means that any active transactions that may have accessed the table must be committed or aborted for the operation to continue. This applies to most DDL statements, such as [ALTER TABLE](#), [CREATE INDEX](#), [DROP INDEX](#), [OPTIMIZE TABLE](#), [RENAME TABLE](#), etc.

## Specifying an Alter Locking Strategy

### Specifying an Alter Locking Strategy Using the LOCK Clause

The [ALTER TABLE](#) statement supports the [LOCK](#) clause.

The [LOCK](#) clause can be used to specify the locking strategy that the user is willing to accept. It is supported by the [ALTER TABLE](#) and [CREATE INDEX](#) statements.

For example, if a user wanted to add a column to a table, but only if the operation is non-locking, then they could execute the following:

```
CREATE OR REPLACE TABLE tab (
    a int PRIMARY KEY,
    b varchar(50)
);

ALTER TABLE tab ADD COLUMN c varchar(50), ALGORITHM=INPLACE, LOCK=NONE;
```

If the [LOCK](#) clause is not explicitly set, then the operation uses

LOCK=DEFAULT

### Specifying an Alter Locking Strategy Using ALTER ONLINE TABLE

[ALTER ONLINE TABLE](#) is equivalent to

LOCK=NONE

. Therefore, the [ALTER ONLINE TABLE](#) statement can be used to ensure that your [ALTER TABLE](#) operation allows all concurrent DML.

## Supported Alter Locking Strategies

The supported algorithms are described in more details below.

To see which locking strategies InnoDB supports for each operation, see the pages that describe which operations are supported for each algorithm:

- [InnoDB Online DDL Operations with ALGORITHM=INPLACE](#)
- [InnoDB Online DDL Operations with ALGORITHM=NOCOPY](#)
- [InnoDB Online DDL Operations with ALGORITHM=INSTANT](#)

### DEFAULT Locking Strategy

The default behavior, which occurs if

LOCK=DEFAULT

is specified, or if

LOCK

is not specified at all, acquire the least restrictive lock on the table that is supported for the specific operation. This permits the maximum amount of concurrency that is supported for the specific operation.

### NONE Locking Strategy

The

NONE

locking strategy performs the operation without acquiring any lock on the table. This permits **all** concurrent DML.

If this locking strategy is not permitted for an operation, then an error is raised.

## SHARED Locking Strategy

The

SHARED

locking strategy performs the operation after acquiring a read lock on the table. This permit **read-only** concurrent DML.

If this locking strategy is not permitted for an operation, then an error is raised.

## EXCLUSIVE Locking Strategy

The

EXCLUSIVE

locking strategy performs the operation after acquiring a write lock on the table. This does **not** permit concurrent DML.

  - 3. [Limitations Related to Generated \(Virtual and Persistent/Stored\) Columns](#)

## Supported Operations by Inheritance

When the [ALGORITHM](#) clause is set to

[INPLACE](#)

, the supported operations are a superset of the operations that are supported when the [ALGORITHM](#) clause is set to [NOCOPY](#)

. Similarly, when the [ALGORITHM](#) clause is set to

[NOCOPY](#)

, the supported operations are a superset of the operations that are supported when the [ALGORITHM](#) clause is set to [INSTANT](#)

Therefore, when the [ALGORITHM](#) clause is set to

INPLACE

, some operations are supported by inheritance. See the following additional pages for more information about these supported operations:

- [InnoDB Online DDL Operations with ALGORITHM=NOCOPY](#)
- [InnoDB Online DDL Operations with ALGORITHM=INSTANT](#)

## Column Operations

### ALTER TABLE ... ADD COLUMN

InnoDB supports adding columns to a table with [ALGORITHM](#) set to

INPLACE

The table is rebuilt, which means that all of the data is reorganized substantially, and the indexes are rebuilt. As a result, the operation is quite expensive.

With the exception of adding an [auto-increment](#) column, this operation supports the non-locking strategy. This strategy can be explicitly chosen by setting the [LOCK](#) clause to

NONE

. When this strategy is used, all concurrent DML is permitted.

For example:

```
CREATE OR REPLACE TABLE tab (
  a int PRIMARY KEY,
  b varchar(50)
);

SET SESSION alter_algorithm='INPLACE';
ALTER TABLE tab ADD COLUMN c varchar(50);
Query OK, 0 rows affected (0.006 sec)
```

This applies to [ALTER TABLE ... ADD COLUMN](#) for InnoDB tables.

### ALTER TABLE ... DROP COLUMN

InnoDB supports dropping columns from a table with [ALGORITHM](#) set to

INPLACE

The table is rebuilt, which means that all of the data is reorganized substantially, and the indexes are rebuilt. As a result, the operation is quite expensive.

This operation supports the non-locking strategy. This strategy can be explicitly chosen by setting the [LOCK](#) clause to

NONE

. When this strategy is used, all concurrent DML is permitted.

For example:

```
CREATE OR REPLACE TABLE tab (
  a int PRIMARY KEY,
  b varchar(50),
  c varchar(50)
);

SET SESSION alter_algorithm='INPLACE';
ALTER TABLE tab DROP COLUMN c;
Query OK, 0 rows affected (0.021 sec)
```

This applies to [ALTER TABLE ... DROP COLUMN](#) for InnoDB tables.

### ALTER TABLE ... MODIFY COLUMN

This applies to [ALTER TABLE ... MODIFY COLUMN](#) for InnoDB tables.

## Reordering Columns

InnoDB supports reordering columns within a table with `ALGORITHM` set to `INPLACE`.

The table is rebuilt, which means that all of the data is reorganized substantially, and the indexes are rebuilt. As a result, the operation is quite expensive.

This operation supports the non-locking strategy. This strategy can be explicitly chosen by setting the `LOCK` clause to `NONE`.

. When this strategy is used, all concurrent DML is permitted.

For example:

```
CREATE OR REPLACE TABLE tab (
    a int PRIMARY KEY,
    b varchar(50),
    c varchar(50)
);

SET SESSION alter_algorithm='INPLACE';
ALTER TABLE tab MODIFY COLUMN c varchar(50) AFTER a;
Query OK, 0 rows affected (0.022 sec)
```

## Changing the Data Type of a Column

InnoDB does **not** support modifying a column's data type with `ALGORITHM` set to

`INPLACE`

in most cases. There are some exceptions:

- In [MariaDB 10.2.2](#) and later, InnoDB supports increasing the length of  
VARCHAR  
columns with `ALGORITHM` set to  
`INPLACE`, unless it would require changing the number of bytes required to represent the column's length. A  
VARCHAR  
column that is between 0 and 255 bytes in size requires 1 byte to represent its length, while a  
VARCHAR  
column that is 256 bytes or longer requires 2 bytes to represent its length. This means that the length of a column cannot be increased with `ALGORITHM` set to  
`INPLACE`  
if the original length was less than 256 bytes, and the new length is 256 bytes or more.
- In [MariaDB 10.4.3](#) and later, InnoDB supports increasing the length of  
VARCHAR  
columns with `ALGORITHM` set to  
`INPLACE` in the cases where the operation supports having the `ALGORITHM` clause set to  
`INSTANT`.

See [InnoDB Online DDL Operations with ALGORITHM=INSTANT: Changing the Data Type of a Column](#) for more information.

For example, this fails:

```
CREATE OR REPLACE TABLE tab (
    a int PRIMARY KEY,
    b varchar(50),
    c varchar(50)
);

SET SESSION alter_algorithm='INPLACE';
ALTER TABLE tab MODIFY COLUMN c int;
ERROR 1846 (0A000): ALGORITHM=INPLACE is not supported. Reason: Cannot change column type INPLACE. Try ALGORITHM=COPY
```

But this succeeds in [MariaDB 10.2.2](#) and later, because the original length of the column is less than 256 bytes, and the new length is still less than 256 bytes:

```

CREATE OR REPLACE TABLE tab (
  a int PRIMARY KEY,
  b varchar(50),
  c varchar(50)
) CHARACTER SET=latin1;

SET SESSION alter_algorithm='INPLACE';
ALTER TABLE tab MODIFY COLUMN c varchar(100);
Query OK, 0 rows affected (0.005 sec)

```

But this fails in [MariaDB 10.2.2](#) and later, because the original length of the column is less than 256 bytes, and the new length is greater than 256 bytes:

```

CREATE OR REPLACE TABLE tab (
  a int PRIMARY KEY,
  b varchar(50),
  c varchar(255)
) CHARACTER SET=latin1;

SET SESSION alter_algorithm='INPLACE';
ALTER TABLE tab MODIFY COLUMN c varchar(256);
ERROR 1846 (0A000): ALGORITHM=INPLACE is not supported. Reason: Cannot change column type INPLACE. Try ALGORITHM=COPY

```

## Changing a Column to NULL

InnoDB supports modifying a column to allow `NULL` values with `ALGORITHM` set to `INPLACE`

The table is rebuilt, which means that all of the data is reorganized substantially, and the indexes are rebuilt. As a result, the operation is quite expensive.

This operation supports the non-locking strategy. This strategy can be explicitly chosen by setting the `LOCK` clause to `NONE`

- . When this strategy is used, all concurrent DML is permitted.

For example:

```

CREATE OR REPLACE TABLE tab (
  a int PRIMARY KEY,
  b varchar(50),
  c varchar(50) NOT NULL
);

SET SESSION alter_algorithm='INPLACE';
ALTER TABLE tab MODIFY COLUMN c varchar(50) NULL;
Query OK, 0 rows affected (0.021 sec)

```

## Changing a Column to NOT NULL

InnoDB supports modifying a column to **not** allow `NULL` values with `ALGORITHM` set to

- `INPLACE`
- . It is required for `strict mode` to be enabled in `SQL_MODE`. The operation will fail if the column contains any `NULL` values. Changes that would interfere with referential integrity are also not permitted.

The table is rebuilt, which means that all of the data is reorganized substantially, and the indexes are rebuilt. As a result, the operation is quite expensive.

This operation supports the non-locking strategy. This strategy can be explicitly chosen by setting the `LOCK` clause to `NONE`

- . When this strategy is used, all concurrent DML is permitted.

For example:

```

CREATE OR REPLACE TABLE tab (
  a int PRIMARY KEY,
  b varchar(50),
  c varchar(50)
);

SET SESSION alter_algorithm='INPLACE';
ALTER TABLE tab MODIFY COLUMN c varchar(50) NOT NULL;
Query OK, 0 rows affected (0.021 sec)

```

## Adding a New ENUM

## Option

InnoDB supports adding a new **ENUM** option to a column with **ALGORITHM** set to

INPLACE  
. In order to add a new **ENUM** option with **ALGORITHM** set to  
INPLACE  
, the following requirements must be met:

- It must be added to the end of the list.
- The storage requirements must not change.

This operation only changes the table's metadata, so the table does not have to be rebuilt..

This operation supports the non-locking strategy. This strategy can be explicitly chosen by setting the **LOCK** clause to

NONE  
. When this strategy is used, all concurrent DML is permitted.

For example, this succeeds:

```
CREATE OR REPLACE TABLE tab (
    a int PRIMARY KEY,
    b varchar(50),
    c ENUM('red', 'green')
);

SET SESSION alter_algorithm='INPLACE';
ALTER TABLE tab MODIFY COLUMN c ENUM('red', 'green', 'blue');
Query OK, 0 rows affected (0.004 sec)
```

But this fails:

```
CREATE OR REPLACE TABLE tab (
    a int PRIMARY KEY,
    b varchar(50),
    c ENUM('red', 'green')
);

SET SESSION alter_algorithm='INPLACE';
ALTER TABLE tab MODIFY COLUMN c ENUM('red', 'blue', 'green');
ERROR 1846 (0A000): ALGORITHM=INPLACE is not supported. Reason: Cannot change column type INPLACE. Try ALGORITHM=COPY
```

## Adding a New

SET  
Option

InnoDB supports adding a new **SET** option to a column with **ALGORITHM** set to

INPLACE  
. In order to add a new **SET** option with **ALGORITHM** set to  
INPLACE  
, the following requirements must be met:

- It must be added to the end of the list.
- The storage requirements must not change.

This operation only changes the table's metadata, so the table does not have to be rebuilt..

This operation supports the non-locking strategy. This strategy can be explicitly chosen by setting the **LOCK** clause to

NONE  
. When this strategy is used, all concurrent DML is permitted.

For example, this succeeds:

```
CREATE OR REPLACE TABLE tab (
    a int PRIMARY KEY,
    b varchar(50),
    c SET('red', 'green')
);

SET SESSION alter_algorithm='INPLACE';
ALTER TABLE tab MODIFY COLUMN c SET('red', 'green', 'blue');
Query OK, 0 rows affected (0.004 sec)
```

But this fails:

```

CREATE OR REPLACE TABLE tab (
  a int PRIMARY KEY,
  b varchar(50),
  c SET('red', 'green')
);

SET SESSION alter_algorithm='INPLACE';
ALTER TABLE tab MODIFY COLUMN c SET('red', 'blue', 'green');
ERROR 1846 (0A000): ALGORITHM=INPLACE is not supported. Reason: Cannot change column type INPLACE. Try ALGORITHM=COPY

```

## Removing System Versioning from a Column

In MariaDB 10.3.8 and later, InnoDB supports removing system versioning from a column with `ALGORITHM` set to

- INPLACE
  - . In order for this to work, the `system_versioning_alter_history` system variable must be set to `KEEP`
  - . See [MDEV-16330](#) for more information.

This operation supports the non-locking strategy. This strategy can be explicitly chosen by setting the `LOCK` clause to

- NONE
  - . When this strategy is used, all concurrent DML is permitted.

For example:

```

CREATE OR REPLACE TABLE tab (
  a int PRIMARY KEY,
  b varchar(50),
  c varchar(50) WITH SYSTEM VERSIONING
);

SET SESSION system_versioning_alter_history='KEEP';
SET SESSION alter_algorithm='INPLACE';
ALTER TABLE tab MODIFY COLUMN c varchar(50) WITHOUT SYSTEM VERSIONING;
Query OK, 0 rows affected (0.005 sec)

```

## ALTER TABLE ... ALTER COLUMN

This applies to `ALTER TABLE ... ALTER COLUMN` for InnoDB tables.

### Setting a Column's Default Value

InnoDB supports modifying a column's `DEFAULT` value with `ALGORITHM` set to

- INPLACE
  - .

This operation only changes the table's metadata, so the table does not have to be rebuilt.

This operation supports the non-locking strategy. This strategy can be explicitly chosen by setting the `LOCK` clause to

- NONE
  - . When this strategy is used, all concurrent DML is permitted. For example:

```

CREATE OR REPLACE TABLE tab (
  a int PRIMARY KEY,
  b varchar(50),
  c varchar(50)
);

SET SESSION alter_algorithm='INPLACE';
ALTER TABLE tab ALTER COLUMN c SET DEFAULT 'No value explicitly provided.';
Query OK, 0 rows affected (0.005 sec)

```

### Removing a Column's Default Value

InnoDB supports removing a column's `DEFAULT` value with `ALGORITHM` set to

- INPLACE
  - .

This operation only changes the table's metadata, so the table does not have to be rebuilt.

This operation supports the non-locking strategy. This strategy can be explicitly chosen by setting the `LOCK` clause to

- NONE
  - .

. When this strategy is used, all concurrent DML is permitted.

For example:

```
CREATE OR REPLACE TABLE tab (
  a int PRIMARY KEY,
  b varchar(50),
  c varchar(50) DEFAULT 'No value explicitly provided.'
);

SET SESSION alter_algorithm='INPLACE';
ALTER TABLE tab ALTER COLUMN c DROP DEFAULT;
Query OK, 0 rows affected (0.005 sec)
```

## ALTER TABLE ... CHANGE COLUMN

InnoDB supports renaming a column with [ALGORITHM](#) set to

INPLACE

, unless the column's data type or attributes changed in addition to the name.

This operation only changes the table's metadata, so the table does not have to be rebuilt.

This operation supports the non-locking strategy. This strategy can be explicitly chosen by setting the [LOCK](#) clause to

NONE

. When this strategy is used, all concurrent DML is permitted.

For example, this succeeds:

```
CREATE OR REPLACE TABLE tab (
  a int PRIMARY KEY,
  b varchar(50),
  c varchar(50)
);

SET SESSION alter_algorithm='INPLACE';
ALTER TABLE tab CHANGE COLUMN c str varchar(50);
Query OK, 0 rows affected (0.006 sec)
```

But this fails:

```
CREATE OR REPLACE TABLE tab (
  a int PRIMARY KEY,
  b varchar(50),
  c varchar(50)
);

SET SESSION alter_algorithm='INPLACE';
ALTER TABLE tab CHANGE COLUMN c num int;
ERROR 1846 (0A000): ALGORITHM=INPLACE is not supported. Reason: Cannot change column type INPLACE. Try ALGORITHM=COPY
```

This applies to [ALTER TABLE ... CHANGE COLUMN](#) for InnoDB tables.

## Index Operations

### ALTER TABLE ... ADD PRIMARY KEY

InnoDB supports adding a primary key to a table with [ALGORITHM](#) set to

INPLACE

If the new primary key column is not defined as [NOT NULL](#), then it is highly recommended for [strict mode](#) to be enabled in [SQL\\_MODE](#). Otherwise, [NULL](#) values will be silently converted to the default value for the given data type, which is probably not the desired behavior in this scenario.

The table is rebuilt, which means that all of the data is reorganized substantially, and the indexes are rebuilt. As a result, the operation is quite expensive.

This operation supports the non-locking strategy. This strategy can be explicitly chosen by setting the [LOCK](#) clause to

NONE

. When this strategy is used, all concurrent DML is permitted.

For example, this succeeds:

```
CREATE OR REPLACE TABLE tab (
    a int,
    b varchar(50),
    c varchar(50)
);

SET SESSION sql_mode='STRICT_TRANS_TABLES';
SET SESSION alter_algorithm='INPLACE';
ALTER TABLE tab ADD PRIMARY KEY (a);
Query OK, 0 rows affected (0.021 sec)
```

But this fails:

```
CREATE OR REPLACE TABLE tab (
    a int,
    b varchar(50),
    c varchar(50)
);

INSERT INTO tab VALUES (NULL, NULL, NULL);

SET SESSION sql_mode='STRICT_TRANS_TABLES';
SET SESSION alter_algorithm='INPLACE';
ALTER TABLE tab ADD PRIMARY KEY (a);
ERROR 1265 (01000): Data truncated for column 'a' at row 1
```

And this fails:

```
CREATE OR REPLACE TABLE tab (
    a int,
    b varchar(50),
    c varchar(50)
);

INSERT INTO tab VALUES (1, NULL, NULL);
INSERT INTO tab VALUES (1, NULL, NULL);

SET SESSION sql_mode='STRICT_TRANS_TABLES';
SET SESSION alter_algorithm='INPLACE';
ALTER TABLE tab ADD PRIMARY KEY (a);
ERROR 1062 (23000): Duplicate entry '1' for key 'PRIMARY'
```

This applies to [ALTER TABLE ... ADD PRIMARY KEY](#) for InnoDB tables.

## ALTER TABLE ... DROP PRIMARY KEY

InnoDB does **not** support dropping a primary key with [ALGORITHM](#) set to

INPLACE  
in most cases.

If you try to do so, then you will see an error. InnoDB only supports this operation with [ALGORITHM](#) set to

COPY  
. Concurrent DML is \*not\* permitted.

However, there is an exception. If you are dropping a primary key, and adding a new one at the same time, then that operation can be performed with [ALGORITHM](#) set to

INPLACE  
. This operation supports the non-locking strategy. This strategy can be explicitly chosen by setting the [LOCK](#) clause to  
NONE  
. When this strategy is used, all concurrent DML is permitted.

For example, this fails:

```

CREATE OR REPLACE TABLE tab (
  a int PRIMARY KEY,
  b varchar(50),
  c varchar(50)
);

SET SESSION alter_algorithm='INPLACE';
ALTER TABLE tab DROP PRIMARY KEY;
ERROR 1846 (0A000): ALGORITHM=INPLACE is not supported. Reason: Dropping a primary key is not allowed without also adding a new

```

But this succeeds:

```

CREATE OR REPLACE TABLE tab (
  a int PRIMARY KEY,
  b varchar(50),
  c varchar(50)
);

SET SESSION sql_mode='STRICT_TRANS_TABLES';
SET SESSION alter_algorithm='INPLACE';
ALTER TABLE tab DROP PRIMARY KEY, ADD PRIMARY KEY (b);
Query OK, 0 rows affected (0.020 sec)

```

This applies to [ALTER TABLE ... DROP PRIMARY KEY](#) for InnoDB tables.

ALTER TABLE ... ADD INDEX  
and  
CREATE INDEX

This applies to [ALTER TABLE ... ADD INDEX](#) and [CREATE INDEX](#) for InnoDB tables.

### Adding a Plain Index

InnoDB supports adding a plain index to a table with [ALGORITHM](#) set to

- . INPLACE
- . The table is not rebuilt.

This operation supports the non-locking strategy. This strategy can be explicitly chosen by setting the [LOCK](#) clause to

- . NONE
- . When this strategy is used, all concurrent DML is permitted.

For example, this succeeds:

```

CREATE OR REPLACE TABLE tab (
  a int PRIMARY KEY,
  b varchar(50),
  c varchar(50)
);

SET SESSION alter_algorithm='INPLACE';
ALTER TABLE tab ADD INDEX b_index (b);
Query OK, 0 rows affected (0.010 sec)

```

And this succeeds:

```

CREATE OR REPLACE TABLE tab (
  a int PRIMARY KEY,
  b varchar(50),
  c varchar(50)
);

SET SESSION alter_algorithm='INPLACE';
CREATE INDEX b_index ON tab (b);
Query OK, 0 rows affected (0.011 sec)

```

### Adding a Fulltext Index

InnoDB supports adding a [FULLTEXT](#) index to a table with [ALGORITHM](#) set to

INPLACE

. The table is not rebuilt in some cases.

However, there are some limitations, such as:

- Adding a **FULLTEXT** index to a table that does not have a user-defined **FTS\_DOC\_ID** column will require the table to be rebuilt once. When the table is rebuilt, the system adds a hidden **FTS\_DOC\_ID** column. From that point forward, adding additional **FULLTEXT** indexes to the same table will not require the table to be rebuilt when **ALGORITHM** is set to **INPLACE**.
- Only one **FULLTEXT** index may be added at a time when **ALGORITHM** is set to **INPLACE**.
- If a table has more than one **FULLTEXT** index, then it cannot be rebuilt by any **ALTER TABLE** operations when **ALGORITHM** is set to **INPLACE**.
- If a table has a **FULLTEXT** index, then it cannot be rebuilt by any **ALTER TABLE** operations when the **LOCK** clause is set to **NONE**.

This operation supports a read-only locking strategy. This strategy can be explicitly chosen by setting the **LOCK** clause to **SHARED**.

. When this strategy is used, read-only concurrent DML is permitted.

For example, this succeeds, but requires the table to be rebuilt, so that the hidden **FTS\_DOC\_ID** column can be added:

```
CREATE OR REPLACE TABLE tab (
    a int PRIMARY KEY,
    b varchar(50),
    c varchar(50)
);

SET SESSION alter_algorithm='INPLACE';
ALTER TABLE tab ADD FULLTEXT INDEX b_index (b);
Query OK, 0 rows affected (0.055 sec)
```

And this succeeds in the same way as above:

```
CREATE OR REPLACE TABLE tab (
    a int PRIMARY KEY,
    b varchar(50),
    c varchar(50)
);

SET SESSION alter_algorithm='INPLACE';
CREATE FULLTEXT INDEX b_index ON tab (b);
Query OK, 0 rows affected (0.041 sec)
```

And this succeeds, and the second command does not require the table to be rebuilt:

```
CREATE OR REPLACE TABLE tab (
    a int PRIMARY KEY,
    b varchar(50),
    c varchar(50)
);

SET SESSION alter_algorithm='INPLACE';
ALTER TABLE tab ADD FULLTEXT INDEX b_index (b);
Query OK, 0 rows affected (0.043 sec)

ALTER TABLE tab ADD FULLTEXT INDEX c_index (c);
Query OK, 0 rows affected (0.017 sec)
```

But this second command fails, because only one **FULLTEXT** index can be added at a time:

```

CREATE OR REPLACE TABLE tab (
    a int PRIMARY KEY,
    b varchar(50),
    c varchar(50),
    d varchar(50)
);

SET SESSION alter_algorithm='INPLACE';
ALTER TABLE tab ADD FULLTEXT INDEX b_index (b);
Query OK, 0 rows affected (0.041 sec)

ALTER TABLE tab ADD FULLTEXT INDEX c_index (c), ADD FULLTEXT INDEX d_index (d);
ERROR 1846 (0A000): ALGORITHM=INPLACE is not supported. Reason: InnoDB presently supports one FULLTEXT index creation at a time.

```

And this third command fails, because a table cannot be rebuilt when it has more than one [FULLTEXT](#) index:

```

CREATE OR REPLACE TABLE tab (
    a int PRIMARY KEY,
    b varchar(50),
    c varchar(50)
);

SET SESSION alter_algorithm='INPLACE';
ALTER TABLE tab ADD FULLTEXT INDEX b_index (b);
Query OK, 0 rows affected (0.040 sec)

ALTER TABLE tab ADD FULLTEXT INDEX c_index (c);
Query OK, 0 rows affected (0.015 sec)

ALTER TABLE tab FORCE;
ERROR 1846 (0A000): ALGORITHM=INPLACE is not supported. Reason: InnoDB presently supports one FULLTEXT index creation at a time.

```

## Adding a Spatial Index

InnoDB supports adding a [SPATIAL](#) index to a table with [ALGORITHM](#) set to  
INPLACE

However, there are some limitations, such as:

- If a table has a [SPATIAL](#) index, then it cannot be rebuilt by any [ALTER TABLE](#) operations when the [LOCK](#) clause is set to  
NONE

This operation supports a read-only locking strategy. This strategy can be explicitly chosen by setting the [LOCK](#) clause to  
SHARED  
. When this strategy is used, read-only concurrent DML is permitted.

For example, this succeeds:

```

CREATE OR REPLACE TABLE tab (
    a int PRIMARY KEY,
    b varchar(50),
    c GEOMETRY NOT NULL
);

SET SESSION alter_algorithm='INPLACE';
ALTER TABLE tab ADD SPATIAL INDEX c_index (c);
Query OK, 0 rows affected (0.006 sec)

```

And this succeeds in the same way as above:

```

CREATE OR REPLACE TABLE tab (
    a int PRIMARY KEY,
    b varchar(50),
    c GEOMETRY NOT NULL
);

SET SESSION alter_algorithm='INPLACE';
CREATE SPATIAL INDEX c_index ON tab (c);
Query OK, 0 rows affected (0.006 sec)

```

## ALTER TABLE ... DROP INDEX and DROP INDEX

InnoDB supports dropping indexes from a table with [ALGORITHM](#) set to  
INPLACE

This operation only changes the table's metadata, so the table does not have to be rebuilt.

This operation supports the non-locking strategy. This strategy can be explicitly chosen by setting the [LOCK](#) clause to  
NONE  
. When this strategy is used, all concurrent DML is permitted.

For example, this succeeds:

```
CREATE OR REPLACE TABLE tab (
    a int PRIMARY KEY,
    b varchar(50),
    c varchar(50),
    INDEX b_index (b)
);

SET SESSION alter_algorithm='INPLACE';
ALTER TABLE tab DROP INDEX b_index;
```

And this succeeds:

```
CREATE OR REPLACE TABLE tab (
    a int PRIMARY KEY,
    b varchar(50),
    c varchar(50),
    INDEX b_index (b)
);

SET SESSION alter_algorithm='INPLACE';
DROP INDEX b_index ON tab;
```

This applies to [ALTER TABLE ... DROP INDEX](#) and [DROP INDEX](#) for InnoDB tables.

## ALTER TABLE ... ADD FOREIGN KEY

InnoDB supports adding foreign key constraints to a table with [ALGORITHM](#) set to  
INPLACE  
. In order to add a new foreign key constraint to a table with [ALGORITHM](#) set to  
INPLACE  
, the [foreign\\_key\\_checks](#) system variable needs to be set to  
OFF  
. If it is set to  
ON  
, then  
[ALGORITHM=COPY](#)  
is required.

This operation only changes the table's metadata, so the table does not have to be rebuilt.

This operation supports the non-locking strategy. This strategy can be explicitly chosen by setting the [LOCK](#) clause to  
NONE  
. When this strategy is used, all concurrent DML is permitted.

For example, this fails:

```

CREATE OR REPLACE TABLE tab1 (
  a int PRIMARY KEY,
  b varchar(50),
  c varchar(50),
  d int
);

CREATE OR REPLACE TABLE tab2 (
  a int PRIMARY KEY,
  b varchar(50)
);

SET SESSION alter_algorithm='INPLACE';
ALTER TABLE tab1 ADD FOREIGN KEY tab2_fk (d) REFERENCES tab2 (a);
ERROR 1846 (0A000): ALGORITHM=INPLACE is not supported. Reason: Adding foreign keys needs foreign_key_checks=OFF. Try ALGORITHM=

```

But this succeeds:

```

CREATE OR REPLACE TABLE tab1 (
  a int PRIMARY KEY,
  b varchar(50),
  c varchar(50),
  d int
);

CREATE OR REPLACE TABLE tab2 (
  a int PRIMARY KEY,
  b varchar(50)
);

SET SESSION foreign_key_checks=OFF;
SET SESSION alter_algorithm='INPLACE';
ALTER TABLE tab1 ADD FOREIGN KEY tab2_fk (d) REFERENCES tab2 (a);
Query OK, 0 rows affected (0.011 sec)

```

This applies to [ALTER TABLE ... ADD FOREIGN KEY](#) for InnoDB tables.

## ALTER TABLE ... DROP FOREIGN KEY

InnoDB supports dropping foreign key constraints from a table with [ALGORITHM](#) set to [INPLACE](#).

This operation only changes the table's metadata, so the table does not have to be rebuilt.

This operation supports the non-locking strategy. This strategy can be explicitly chosen by setting the [LOCK](#) clause to [NONE](#). When this strategy is used, all concurrent DML is permitted.

For example:

```

CREATE OR REPLACE TABLE tab2 (
  a int PRIMARY KEY,
  b varchar(50)
);

CREATE OR REPLACE TABLE tab1 (
  a int PRIMARY KEY,
  b varchar(50),
  c varchar(50),
  d int,
  FOREIGN KEY tab2_fk (d) REFERENCES tab2 (a)
);

SET SESSION alter_algorithm='INPLACE';
ALTER TABLE tab1 DROP FOREIGN KEY tab2_fk;
Query OK, 0 rows affected (0.005 sec)

```

This applies to [ALTER TABLE ... DROP FOREIGN KEY](#) for InnoDB tables.

# Table Operations

## ALTER TABLE ... AUTO\_INCREMENT=...

InnoDB supports changing a table's `AUTO_INCREMENT` value with `ALGORITHM` set to

`INPLACE`

. This operation should finish instantly. The table is not rebuilt.

This operation supports the non-locking strategy. This strategy can be explicitly chosen by setting the `LOCK` clause to

`NONE`

. When this strategy is used, all concurrent DML is permitted.

For example:

```
CREATE OR REPLACE TABLE tab (
    a int PRIMARY KEY,
    b varchar(50),
    c varchar(50)
);

SET SESSION alter_algorithm='INPLACE';
ALTER TABLE tab AUTO_INCREMENT=100;
Query OK, 0 rows affected (0.004 sec)
```

This applies to `ALTER TABLE ... AUTO_INCREMENT=...` for InnoDB tables.

## ALTER TABLE ... ROW\_FORMAT=...

InnoDB supports changing a table's `row format` with `ALGORITHM` set to

`INPLACE`

The table is rebuilt, which means that all of the data is reorganized substantially, and the indexes are rebuilt. As a result, the operation is quite expensive.

This operation supports the non-locking strategy. This strategy can be explicitly chosen by setting the `LOCK` clause to

`NONE`

. When this strategy is used, all concurrent DML is permitted.

For example:

```
CREATE OR REPLACE TABLE tab (
    a int PRIMARY KEY,
    b varchar(50),
    c varchar(50)
) ROW_FORMAT=DYNAMIC;

SET SESSION alter_algorithm='INPLACE';
ALTER TABLE tab ROW_FORMAT=COMPRESSED;
Query OK, 0 rows affected (0.025 sec)
```

This applies to `ALTER TABLE ... ROW_FORMAT=...` for InnoDB tables.

## ALTER TABLE ... KEY\_BLOCK\_SIZE=...

InnoDB supports changing a table's `KEY_BLOCK_SIZE` with `ALGORITHM` set to

`INPLACE`

The table is rebuilt, which means that all of the data is reorganized substantially, and the indexes are rebuilt. As a result, the operation is quite expensive.

This operation supports the non-locking strategy. This strategy can be explicitly chosen by setting the `LOCK` clause to

`NONE`

. When this strategy is used, all concurrent DML is permitted.

For example:

```

CREATE OR REPLACE TABLE tab (
  a int PRIMARY KEY,
  b varchar(50),
  c varchar(50)
) ROW_FORMAT=COMPRESSED
KEY_BLOCK_SIZE=4;

SET SESSION alter_algorithm='INPLACE';
ALTER TABLE tab KEY_BLOCK_SIZE=2;
Query OK, 0 rows affected (0.021 sec)

```

This applies to [KEY\\_BLOCK\\_SIZE=...](#) for InnoDB tables.

ALTER TABLE ... PAGE\_COMPRESSED=...  
 and  
 ALTER TABLE ... PAGE\_COMPRESSION\_LEVEL=...

In MariaDB 10.3.10 and later, InnoDB supports setting a table's [PAGE\\_COMPRESSED](#) value to

```

1
with ALGORITHM set to
INPLACE
. InnoDB also supports changing a table's PAGE\_COMPRESSED value from
1
to
0
with ALGORITHM set to
INPLACE
.

```

In these versions, InnoDB also supports changing a table's [PAGE\\_COMPRESSION\\_LEVEL](#) value with [ALGORITHM](#) set to  
 INPLACE

This operation supports the non-locking strategy. This strategy can be explicitly chosen by setting the [LOCK](#) clause to

```

NONE
. When this strategy is used, all concurrent DML is permitted.

```

See [MDEV-16328](#) for more information.

For example, this succeeds:

```

CREATE OR REPLACE TABLE tab (
  a int PRIMARY KEY,
  b varchar(50),
  c varchar(50)
);

SET SESSION alter_algorithm='INPLACE';
ALTER TABLE tab PAGE_COMPRESSED=1;
Query OK, 0 rows affected (0.006 sec)

```

And this succeeds:

```

CREATE OR REPLACE TABLE tab (
  a int PRIMARY KEY,
  b varchar(50),
  c varchar(50)
) PAGE_COMPRESSED=1;

SET SESSION alter_algorithm='INPLACE';
ALTER TABLE tab PAGE_COMPRESSED=0;
Query OK, 0 rows affected (0.020 sec)

```

And this succeeds:

```

CREATE OR REPLACE TABLE tab (
  a int PRIMARY KEY,
  b varchar(50),
  c varchar(50)
) PAGE_COMPRESSED=1
PAGE_COMPRESSION_LEVEL=5;

SET SESSION alter_algorithm='INPLACE';
ALTER TABLE tab PAGE_COMPRESSION_LEVEL=4;
Query OK, 0 rows affected (0.006 sec)

```

This applies to [PAGE\\_COMPRESSED=...](#) and [PAGE\\_COMPRESSION\\_LEVEL=...](#) for InnoDB tables.

## ALTER TABLE ... DROP SYSTEM VERSIONING

InnoDB supports dropping [system versioning](#) from a table with [ALGORITHM](#) set to [INPLACE](#)

This operation supports the read-only locking strategy. This strategy can be explicitly chosen by setting the [LOCK](#) clause to [SHARED](#). When this strategy is used, read-only concurrent DML is permitted.

For example:

```

CREATE OR REPLACE TABLE tab (
  a int PRIMARY KEY,
  b varchar(50),
  c varchar(50)
) WITH SYSTEM VERSIONING;

SET SESSION alter_algorithm='INPLACE';
ALTER TABLE tab DROP SYSTEM VERSIONING;

```

This applies to [ALTER TABLE ... DROP SYSTEM VERSIONING](#) for InnoDB tables.

## ALTER TABLE ... DROP CONSTRAINT

In MariaDB 10.3.6 and later, InnoDB supports dropping a [CHECK](#) constraint from a table with [ALGORITHM](#) set to [INPLACE](#). See [MDEV-16331](#) for more information.

This operation supports the non-locking strategy. This strategy can be explicitly chosen by setting the [LOCK](#) clause to [NONE](#). When this strategy is used, all concurrent DML is permitted.

For example:

```

CREATE OR REPLACE TABLE tab (
  a int PRIMARY KEY,
  b varchar(50),
  c varchar(50),
  CONSTRAINT b_not_empty CHECK (b != '')
);

SET SESSION alter_algorithm='INPLACE';
ALTER TABLE tab DROP CONSTRAINT b_not_empty;
Query OK, 0 rows affected (0.004 sec)

```

This applies to [ALTER TABLE ... DROP CONSTRAINT](#) for InnoDB tables.

## ALTER TABLE ... FORCE

InnoDB supports forcing a table rebuild with [ALGORITHM](#) set to

INPLACE

The table is rebuilt, which means that all of the data is reorganized substantially, and the indexes are rebuilt. As a result, the operation is quite expensive.

This operation supports the non-locking strategy. This strategy can be explicitly chosen by setting the [LOCK](#) clause to  
NONE  
. When this strategy is used, all concurrent DML is permitted.

For example:

```
CREATE OR REPLACE TABLE tab (
    a int PRIMARY KEY,
    b varchar(50),
    c varchar(50)
);

SET SESSION alter_algorithm='INPLACE';
ALTER TABLE tab FORCE;
Query OK, 0 rows affected (0.022 sec)
```

This applies to [ALTER TABLE ... FORCE](#) for InnoDB tables.

## ALTER TABLE ... ENGINE=InnoDB

InnoDB supports forcing a table rebuild with [ALGORITHM](#) set to

INPLACE

The table is rebuilt, which means that all of the data is reorganized substantially, and the indexes are rebuilt. As a result, the operation is quite expensive.

This operation supports the non-locking strategy. This strategy can be explicitly chosen by setting the [LOCK](#) clause to  
NONE  
. When this strategy is used, all concurrent DML is permitted.

For example:

```
CREATE OR REPLACE TABLE tab (
    a int PRIMARY KEY,
    b varchar(50),
    c varchar(50)
);

SET SESSION alter_algorithm='INPLACE';
ALTER TABLE tab ENGINE=InnoDB;
Query OK, 0 rows affected (0.022 sec)
```

This applies to [ALTER TABLE ... ENGINE=InnoDB](#) for InnoDB tables.

## OPTIMIZE TABLE ...

InnoDB supports optimizing a table with [ALGORITHM](#) set to

INPLACE

If the [innodb\\_defragment](#) system variable is set to

OFF

, and if the [innodb\\_optimize\\_fulltext\\_only](#) system variable is also set to

OFF

, then

[OPTIMIZE TABLE](#)

will be equivalent to

[ALTER TABLE ... FORCE](#)

The table is rebuilt, which means that all of the data is reorganized substantially, and the indexes are rebuilt. As a result, the operation is quite expensive.

If either of the previously mentioned system variables is set to

ON

, then

```
OPTIMIZE TABLE
```

will optimize some data without rebuilding the table. However, the file size will not be reduced.

For example, this succeeds:

```
CREATE OR REPLACE TABLE tab (
    a int PRIMARY KEY,
    b varchar(50),
    c varchar(50)
);

SHOW GLOBAL VARIABLES WHERE Variable_name IN('innodb_defragment', 'innodb_optimize_fulltext_only');
+-----+-----+
| Variable_name          | Value   |
+-----+-----+
| innodb_defragment      | OFF     |
| innodb_optimize_fulltext_only | OFF     |
+-----+-----+

SET SESSION alter_algorithm='INPLACE';
OPTIMIZE TABLE tab;
+-----+-----+-----+
| Table  | Op       | Msg_type | Msg_text           |
+-----+-----+-----+
| db1.tab | optimize | note      | Table does not support optimize, doing recreate + analyze instead |
| db1.tab | optimize | status     | OK                |
+-----+-----+-----+
2 rows in set (0.026 sec)
```

And this succeeds, but the table is not rebuilt:

```
CREATE OR REPLACE TABLE tab (
    a int PRIMARY KEY,
    b varchar(50),
    c varchar(50)
);

SET GLOBAL innodb_defragment=ON;
SHOW GLOBAL VARIABLES WHERE Variable_name IN('innodb_defragment', 'innodb_optimize_fulltext_only');
+-----+-----+
| Variable_name          | Value   |
+-----+-----+
| innodb_defragment      | ON      |
| innodb_optimize_fulltext_only | OFF     |
+-----+-----+

SET SESSION alter_algorithm='INPLACE';
OPTIMIZE TABLE tab;
+-----+-----+-----+
| Table  | Op       | Msg_type | Msg_text           |
+-----+-----+-----+
| db1.tab | optimize | status    | OK                |
+-----+-----+-----+
1 row in set (0.004 sec)
```

This applies to [OPTIMIZE TABLE](#) for InnoDB tables.

ALTER TABLE ... RENAME TO  
and  
RENAME TABLE ...

InnoDB supports renaming a table with [ALGORITHM](#) set to

INPLACE

This operation only changes the table's metadata, so the table does not have to be rebuilt.

This operation supports the exclusive locking strategy. This strategy can be explicitly chosen by setting the [LOCK](#) clause to EXCLUSIVE . When this strategy is used, concurrent DML is **not** permitted.

For example, this succeeds:

```
CREATE OR REPLACE TABLE tab (
  a int PRIMARY KEY,
  b varchar(50),
  c varchar(50)
);

SET SESSION alter_algorithm='INPLACE';
ALTER TABLE tab RENAME TO old_tab;
Query OK, 0 rows affected (0.011 sec)
```

And this succeeds:

```
CREATE OR REPLACE TABLE tab (
  a int PRIMARY KEY,
  b varchar(50),
  c varchar(50)
);

SET SESSION alter_algorithm='INPLACE';
RENAME TABLE tab TO old_tab;
```

This applies to [ALTER TABLE ... RENAME TO](#) and [RENAME TABLE](#) for InnoDB tables.

## Limitations

### Limitations Related to Fulltext Indexes

- If a table has more than one [FULLTEXT](#) index, then it cannot be rebuilt by any [ALTER TABLE](#) operations when [ALGORITHM](#) is set to [INPLACE](#)
- If a table has a [FULLTEXT](#) index, then it cannot be rebuilt by any [ALTER TABLE](#) operations when the [LOCK](#) clause is set to [NONE](#)

### Limitations Related to Spatial Indexes

- If a table has a [SPATIAL](#) index, then it cannot be rebuilt by any [ALTER TABLE](#) operations when the [LOCK](#) clause is set to [NONE](#)

### Limitations Related to Generated (Virtual and Persistent/Stored) Columns

[Generated columns](#) do not currently support online DDL for all of the same operations that are supported for "real" columns.

See [Generated \(Virtual and Persistent/Stored\) Columns: Statement Support](#) for more information on the limitations.

## 4.3.2.19.3 InnoDB Online DDL Operations with the NOCOPY Alter Algorithm

  1. Limitations Related to Generated (Virtual and Persistent/Stored) Columns

## Supported Operations by Inheritance

When the `ALGORITHM` clause is set to

`NOCOPY`

, the supported operations are a superset of the operations that are supported when the `ALGORITHM` clause is set to `INSTANT`

Therefore, when the `ALGORITHM` clause is set to

`NOCOPY`

, some operations are supported by inheritance. See the following additional pages for more information about these supported operations:

- [InnoDB Online DDL Operations with `ALGORITHM=INSTANT`](#)

# Column Operations

## ALTER TABLE ... ADD COLUMN

In MariaDB 10.3.2 and later, InnoDB supports adding columns to a table with `ALGORITHM` set to  
NOCOPY  
in the cases where the operation supports having the `ALGORITHM` clause set to  
INSTANT

See [InnoDB Online DDL Operations with ALGORITHM=INSTANT: ALTER TABLE ... ADD COLUMN](#) for more information.

This applies to `ALTER TABLE ... ADD COLUMN` for InnoDB tables.

## ALTER TABLE ... DROP COLUMN

In MariaDB 10.4 and later, InnoDB supports dropping columns from a table with `ALGORITHM` set to  
NOCOPY  
in the cases where the operation supports having the `ALGORITHM` clause set to  
INSTANT

See [InnoDB Online DDL Operations with ALGORITHM=INSTANT: ALTER TABLE ... DROP COLUMN](#) for more information.

This applies to `ALTER TABLE ... DROP COLUMN` for InnoDB tables.

## ALTER TABLE ... MODIFY COLUMN

This applies to `ALTER TABLE ... MODIFY COLUMN` for InnoDB tables.

### Reordering Columns

In MariaDB 10.4 and later, InnoDB supports reordering columns within a table with `ALGORITHM` set to  
NOCOPY  
in the cases where the operation supports having the `ALGORITHM` clause set to  
INSTANT

See [InnoDB Online DDL Operations with ALGORITHM=INSTANT: Reordering Columns](#) for more information.

### Changing the Data Type of a Column

InnoDB does **not** support modifying a column's data type with `ALGORITHM` set to  
NOCOPY  
in most cases. There are a few exceptions in the cases where the operation supports having the `ALGORITHM` clause set to  
INSTANT

See [InnoDB Online DDL Operations with ALGORITHM=INSTANT: Changing the Data Type of a Column](#) for more information.

### Changing a Column to NULL

In MariaDB 10.4.3 and later, InnoDB supports modifying a column to allow `NULL` values with `ALGORITHM` set to  
NOCOPY  
in the cases where the operation supports having the `ALGORITHM` clause set to  
INSTANT

See [InnoDB Online DDL Operations with ALGORITHM=INSTANT: Changing a Column to NULL](#) for more information.

### Changing a Column to NOT NULL

InnoDB does **not** support modifying a column to **not** allow `NULL` values with `ALGORITHM` set to  
NOCOPY

For example:

```
CREATE OR REPLACE TABLE tab (
  a int PRIMARY KEY,
  b varchar(50),
  c varchar(50)
) ROW_FORMAT=REDUNDANT;

SET SESSION alter_algorithm='NOCOPY';
ALTER TABLE tab MODIFY COLUMN c varchar(50) NOT NULL;
ERROR 1845 (0A000): ALGORITHM=NOCOPY is not supported for this operation. Try ALGORITHM=INPLACE
```

## Adding a New ENUM Option

InnoDB supports adding a new [ENUM](#) option to a column with [ALGORITHM](#) set to

NOCOPY

in the cases where the operation supports having the [ALGORITHM](#) clause set to

INSTANT

See [InnoDB Online DDL Operations with ALGORITHM=INSTANT: Adding a New ENUM Option](#) for more information.

## Adding a New SET Option

InnoDB supports adding a new [SET](#) option to a column with [ALGORITHM](#) set to

NOCOPY

in the cases where the operation supports having the [ALGORITHM](#) clause set to

INSTANT

See [InnoDB Online DDL Operations with ALGORITHM=INSTANT: Adding a New SET Option](#) for more information.

## Removing System Versioning from a Column

In [MariaDB 10.3.8](#) and later, InnoDB supports removing [system](#) versioning from a column with [ALGORITHM](#) set to

NOCOPY

in the cases where the operation supports having the [ALGORITHM](#) clause set to

INSTANT

See [InnoDB Online DDL Operations with ALGORITHM=INSTANT: Removing System Versioning from a Column](#) for more information.

## ALTER TABLE ... ALTER COLUMN

This applies to [ALTER TABLE ... ALTER COLUMN](#) for InnoDB tables.

### Setting a Column's Default Value

InnoDB supports modifying a column's [DEFAULT](#) value with [ALGORITHM](#) set to

NOCOPY

in the cases where the operation supports having the [ALGORITHM](#) clause set to

INSTANT

See [InnoDB Online DDL Operations with ALGORITHM=INSTANT: Setting a Column's Default Value](#) for more information.

### Removing a Column's Default Value

InnoDB supports removing a column's [DEFAULT](#) value with [ALGORITHM](#) set to

NOCOPY

in the cases where the operation supports having the [ALGORITHM](#) clause set to

INSTANT

See [InnoDB Online DDL Operations with ALGORITHM=INSTANT: Removing a Column's Default Value](#) for more information.

## ALTER TABLE ... CHANGE COLUMN

InnoDB supports renaming a column with `ALGORITHM` set to

`NOCOPY`

in the cases where the operation supports having the `ALGORITHM` clause set to

`INSTANT`

See [InnoDB Online DDL Operations with ALGORITHM=INSTANT: ALTER TABLE ... CHANGE COLUMN](#) for more information.

This applies to `ALTER TABLE ... CHANGE COLUMN` for InnoDB tables.

## Index Operations

### ALTER TABLE ... ADD PRIMARY KEY

InnoDB does **not** support adding a primary key to a table with `ALGORITHM` set to

`NOCOPY`

For example:

```
CREATE OR REPLACE TABLE tab (
    a int,
    b varchar(50),
    c varchar(50)
);

SET SESSION sql_mode='STRICT_TRANS_TABLES';
SET SESSION alter_algorithm='NOCOPY';
ALTER TABLE tab ADD PRIMARY KEY (a);
ERROR 1845 (0A000): ALGORITHM=NOCOPY is not supported for this operation. Try ALGORITHM=INPLACE
```

This applies to `ALTER TABLE ... ADD PRIMARY KEY` for InnoDB tables.

### ALTER TABLE ... DROP PRIMARY KEY

InnoDB does **not** support dropping a primary key with `ALGORITHM` set to

`NOCOPY`

For example:

```
CREATE OR REPLACE TABLE tab (
    a int PRIMARY KEY,
    b varchar(50),
    c varchar(50)
);

SET SESSION alter_algorithm='NOCOPY';
ALTER TABLE tab DROP PRIMARY KEY;
ERROR 1846 (0A000): ALGORITHM=NOCOPY is not supported. Reason: Dropping a primary key is not allowed without also adding a new p
```

This applies to `ALTER TABLE ... DROP PRIMARY KEY` for InnoDB tables.

### ALTER TABLE ... ADD INDEX and CREATE INDEX

This applies to `ALTER TABLE ... ADD INDEX` and `CREATE INDEX` for InnoDB tables.

## Adding a Plain Index

InnoDB supports adding a plain index to a table with `ALGORITHM` set to  
`NOCOPY`

This operation supports the non-locking strategy. This strategy can be explicitly chosen by setting the `LOCK` clause to  
`NONE`. When this strategy is used, all concurrent DML is permitted.

For example, this succeeds:

```
CREATE OR REPLACE TABLE tab (
    a int PRIMARY KEY,
    b varchar(50),
    c varchar(50)
);

SET SESSION alter_algorithm='NOCOPY';
ALTER TABLE tab ADD INDEX b_index (b);
Query OK, 0 rows affected (0.009 sec)
```

And this succeeds:

```
CREATE OR REPLACE TABLE tab (
    a int PRIMARY KEY,
    b varchar(50),
    c varchar(50)
);

SET SESSION alter_algorithm='NOCOPY';
CREATE INDEX b_index ON tab (b);
Query OK, 0 rows affected (0.009 sec)
```

## Adding a Fulltext Index

InnoDB supports adding a `FULLTEXT` index to a table with `ALGORITHM` set to  
`NOCOPY`

However, there are some limitations, such as:

- Adding a `FULLTEXT` index to a table that does not have a user-defined  
`FTS_DOC_ID` column will require the table to be rebuilt once. When the table is rebuilt, the system adds a hidden  
`FTS_DOC_ID` column. This initial operation will have to be performed with `ALGORITHM` set to  
`INPLACE`. From that point forward, adding additional `FULLTEXT` indexes to the same table will not require the table to be rebuilt, and `ALGORITHM` can be set to  
`NOCOPY`
- Only one `FULLTEXT` index may be added at a time when `ALGORITHM` is set to  
`NOCOPY`

This operation supports a read-only locking strategy. This strategy can be explicitly chosen by setting the `LOCK` clause to  
`SHARED`. When this strategy is used, read-only concurrent DML is permitted.

For example, this succeeds, but the first operation requires the table to be rebuilt `ALGORITHM` set to  
`INPLACE`, so that the hidden  
`FTS_DOC_ID` column can be added:

```

CREATE OR REPLACE TABLE tab (
  a int PRIMARY KEY,
  b varchar(50),
  c varchar(50)
);

SET SESSION alter_algorithm='INPLACE';
ALTER TABLE tab ADD FULLTEXT INDEX b_index (b);
Query OK, 0 rows affected (0.043 sec)

SET SESSION alter_algorithm='NOCOPY';
ALTER TABLE tab ADD FULLTEXT INDEX c_index (c);
Query OK, 0 rows affected (0.017 sec)

```

And this succeeds in the same way as above:

```

CREATE OR REPLACE TABLE tab (
  a int PRIMARY KEY,
  b varchar(50),
  c varchar(50)
);

SET SESSION alter_algorithm='INPLACE';
CREATE FULLTEXT INDEX b_index ON tab (b);
Query OK, 0 rows affected (0.048 sec)

SET SESSION alter_algorithm='NOCOPY';
CREATE FULLTEXT INDEX c_index ON tab (c);
Query OK, 0 rows affected (0.016 sec)

```

But this second command fails, because only one **FULLTEXT** index can be added at a time:

```

CREATE OR REPLACE TABLE tab (
  a int PRIMARY KEY,
  b varchar(50),
  c varchar(50),
  d varchar(50)
);

SET SESSION alter_algorithm='INPLACE';
ALTER TABLE tab ADD FULLTEXT INDEX b_index (b);
Query OK, 0 rows affected (0.041 sec)

SET SESSION alter_algorithm='NOCOPY';
ALTER TABLE tab ADD FULLTEXT INDEX c_index (c), ADD FULLTEXT INDEX d_index (d);
ERROR 1846 (0A000): ALGORITHM=NOCOPY is not supported. Reason: InnoDB presently supports one FULLTEXT index creation at a time.

```

## Adding a Spatial Index

InnoDB supports adding a **SPATIAL** index to a table with **ALGORITHM** set to  
NOCOPY

This operation supports a read-only locking strategy. This strategy can be explicitly chosen by setting the **LOCK** clause to  
SHARED  
. When this strategy is used, read-only concurrent DML is permitted.

For example, this succeeds:

```

CREATE OR REPLACE TABLE tab (
  a int PRIMARY KEY,
  b varchar(50),
  c GEOMETRY NOT NULL
);

SET SESSION alter_algorithm='NOCOPY';
ALTER TABLE tab ADD SPATIAL INDEX c_index (c);
Query OK, 0 rows affected (0.005 sec)

```

And this succeeds in the same way as above:

```

CREATE OR REPLACE TABLE tab (
  a int PRIMARY KEY,
  b varchar(50),
  c GEOMETRY NOT NULL
);

SET SESSION alter_algorithm='NOCOPY';
CREATE SPATIAL INDEX c_index ON tab (c);
Query OK, 0 rows affected (0.005 sec)

```

## ALTER TABLE ... DROP INDEX and DROP INDEX

InnoDB supports dropping indexes from a table with [ALGORITHM](#) set to

- NOCOPY
- in the cases where the operation supports having the [ALGORITHM](#) clause set to
- INSTANT

See [InnoDB Online DDL Operations with ALGORITHM=INSTANT: ALTER TABLE ... DROP INDEX and DROP INDEX](#) for more information.

This applies to [ALTER TABLE ... DROP INDEX](#) and [DROP INDEX](#) for InnoDB tables.

## ALTER TABLE ... ADD FOREIGN KEY

InnoDB does supports adding foreign key constraints to a table with [ALGORITHM](#) set to

- NOCOPY
- . In order to add a new foreign key constraint to a table with [ALGORITHM](#) set to
- NOCOPY
- , the [foreign\\_key\\_checks](#) system variable needs to be set to
- OFF
- . If it is set to
- ON
- , then
- [ALGORITHM=COPY](#)
- is required.

This operation supports the non-locking strategy. This strategy can be explicitly chosen by setting the [LOCK](#) clause to

- NONE
- . When this strategy is used, all concurrent DML is permitted.

For example, this fails:

```

CREATE OR REPLACE TABLE tab1 (
  a int PRIMARY KEY,
  b varchar(50),
  c varchar(50),
  d int
);

CREATE OR REPLACE TABLE tab2 (
  a int PRIMARY KEY,
  b varchar(50)
);

SET SESSION alter_algorithm='NOCOPY';
ALTER TABLE tab1 ADD FOREIGN KEY tab2_fk (d) REFERENCES tab2 (a);
ERROR 1846 (0A000): ALGORITHM=NOCOPY is not supported. Reason: Adding foreign keys needs foreign_key_checks=OFF. Try ALGORITHM=C

```

But this succeeds:

```

CREATE OR REPLACE TABLE tab1 (
  a int PRIMARY KEY,
  b varchar(50),
  c varchar(50),
  d int
);

CREATE OR REPLACE TABLE tab2 (
  a int PRIMARY KEY,
  b varchar(50)
);

SET SESSION foreign_key_checks=OFF;
SET SESSION alter_algorithm='NOCOPY';
ALTER TABLE tab1 ADD FOREIGN KEY tab2_fk (d) REFERENCES tab2 (a);
Query OK, 0 rows affected (0.011 sec)

```

This applies to [ALTER TABLE ... ADD FOREIGN KEY](#) for InnoDB tables.

## ALTER TABLE ... DROP FOREIGN KEY

InnoDB supports dropping foreign key constraints from a table with [ALGORITHM](#) set to  
 NOCOPY  
 in the cases where the operation supports having the [ALGORITHM](#) clause set to  
 INSTANT

See [InnoDB Online DDL Operations with ALGORITHM=INSTANT: ALTER TABLE ... DROP FOREIGN KEY](#) for more information.

This applies to [ALTER TABLE ... DROP FOREIGN KEY](#) for InnoDB tables.

## Table Operations

### ALTER TABLE ... AUTO\_INCREMENT=...

InnoDB supports changing a table's [AUTO\\_INCREMENT](#) value with [ALGORITHM](#) set to  
 NOCOPY  
 in the cases where the operation supports having the [ALGORITHM](#) clause set to  
 INSTANT

See [InnoDB Online DDL Operations with ALGORITHM=INSTANT: ALTER TABLE ... AUTO\\_INCREMENT=...](#) for more information.

This applies to [ALTER TABLE ... AUTO\\_INCREMENT=...](#) for InnoDB tables.

### ALTER TABLE ... ROW\_FORMAT=...

InnoDB does **not** support changing a table's [row format](#) with [ALGORITHM](#) set to  
 NOCOPY

For example:

```

CREATE OR REPLACE TABLE tab (
  a int PRIMARY KEY,
  b varchar(50),
  c varchar(50)
) ROW_FORMAT=DYNAMIC;

SET SESSION alter_algorithm='NOCOPY';
ALTER TABLE tab ROW_FORMAT=COMPRESSED;
ERROR 1846 (0A000): ALGORITHM=NOCOPY is not supported. Reason: Changing table options requires the table to be rebuilt. Try ALGO

```

This applies to [ALTER TABLE ... ROW\\_FORMAT=...](#) for InnoDB tables.

## ALTER TABLE ... KEY\_BLOCK\_SIZE=...

InnoDB does **not** support changing a table's `KEY_BLOCK_SIZE` with `ALGORITHM` set to  
NOCOPY

For example:

```
CREATE OR REPLACE TABLE tab (
    a int PRIMARY KEY,
    b varchar(50),
    c varchar(50)
) ROW_FORMAT=COMPRESSED
KEY_BLOCK_SIZE=4;

SET SESSION alter_algorithm='NOCOPY';
ALTER TABLE tab KEY_BLOCK_SIZE=2;
ERROR 1846 (0A000): ALGORITHM=NOCOPY is not supported. Reason: Changing table options requires the table to be rebuilt. Try ALGO
```

This applies to `KEY_BLOCK_SIZE=...` for InnoDB tables.

## ALTER TABLE ... PAGE\_COMPRESSED=1

and

## ALTER TABLE ... PAGE\_COMPRESSION\_LEVEL=...

In MariaDB 10.3.10 and later, InnoDB supports setting a table's `PAGE_COMPRESSED` value to

1  
with `ALGORITHM` set to  
NOCOPY

in the cases where the operation supports having the `ALGORITHM` clause set to  
INSTANT

InnoDB does **not** support changing a table's `PAGE_COMPRESSED` value from

1  
to  
0  
with `ALGORITHM` set to  
NOCOPY

In these versions, InnoDB also supports changing a table's `PAGE_COMPRESSION_LEVEL` value with `ALGORITHM` set to

NOCOPY  
in the cases where the operation supports having the `ALGORITHM` clause is set to  
INSTANT

See [InnoDB Online DDL Operations with ALGORITHM=INSTANT: ALTER TABLE ... PAGE\\_COMPRESSED=1 and ALTER TABLE ... PAGE\\_COMPRESSION\\_LEVEL=...](#) for more information.

This applies to `ALTER TABLE ... PAGE_COMPRESSED=...` and `ALTER TABLE ... PAGE_COMPRESSION_LEVEL=...` for InnoDB tables.

## ALTER TABLE ... DROP SYSTEM VERSIONING

InnoDB does **not** support dropping `system versioning` from a table with `ALGORITHM` set to  
NOCOPY

For example:

```

CREATE OR REPLACE TABLE tab (
  a int PRIMARY KEY,
  b varchar(50),
  c varchar(50)
) WITH SYSTEM VERSIONING;

SET SESSION alter_algorithm='NOCOPY';
ALTER TABLE tab DROP SYSTEM VERSIONING;
ERROR 1845 (0A000): ALGORITHM=NOCOPY is not supported for this operation. Try ALGORITHM=INPLACE

```

This applies to [ALTER TABLE ... DROP SYSTEM VERSIONING](#) for InnoDB tables.

## ALTER TABLE ... DROP CONSTRAINT

In MariaDB 10.3.6 and later, InnoDB supports dropping a [CHECK](#) constraint from a table with [ALGORITHM](#) set to  
NOCOPY  
in the cases where the operation supports having the [ALGORITHM](#) clause set to  
INSTANT

See [InnoDB Online DDL Operations with ALGORITHM=INSTANT: ALTER TABLE ... DROP CONSTRAINT](#) for more information.

This applies to [ALTER TABLE ... DROP CONSTRAINT](#) for InnoDB tables.

## ALTER TABLE ... FORCE

InnoDB does **not** support forcing a table rebuild with [ALGORITHM](#) set to  
NOCOPY

For example:

```

CREATE OR REPLACE TABLE tab (
  a int PRIMARY KEY,
  b varchar(50),
  c varchar(50)
);

SET SESSION alter_algorithm='NOCOPY';
ALTER TABLE tab FORCE;
ERROR 1845 (0A000): ALGORITHM=NOCOPY is not supported for this operation. Try ALGORITHM=INPLACE

```

This applies to [ALTER TABLE ... FORCE](#) for InnoDB tables.

## ALTER TABLE ... ENGINE=InnoDB

InnoDB does **not** support forcing a table rebuild with [ALGORITHM](#) set to  
NOCOPY

For example:

```

CREATE OR REPLACE TABLE tab (
  a int PRIMARY KEY,
  b varchar(50),
  c varchar(50)
);

SET SESSION alter_algorithm='NOCOPY';
ALTER TABLE tab ENGINE=InnoDB;
ERROR 1845 (0A000): ALGORITHM=NOCOPY is not supported for this operation. Try ALGORITHM=INPLACE

```

This applies to [ALTER TABLE ... ENGINE=InnoDB](#) for InnoDB tables.

## OPTIMIZE TABLE ...

InnoDB does **not** support optimizing a table with with [ALGORITHM](#) set to  
NOCOPY

For example:

```
CREATE OR REPLACE TABLE tab (
  a int PRIMARY KEY,
  b varchar(50),
  c varchar(50)
);

SHOW GLOBAL VARIABLES WHERE Variable_name IN('innodb_defragment', 'innodb_optimize_fulltext_only');
+-----+-----+
| Variable_name      | Value |
+-----+-----+
| innodb_defragment | OFF   |
| innodb_optimize_fulltext_only | OFF   |
+-----+-----+
2 rows in set (0.001 sec)

SET SESSION alter_algorithm='NOCOPY';
OPTIMIZE TABLE tab;
+-----+-----+-----+
| Table  | Op       | Msg_type | Msg_text
+-----+-----+-----+
| db1.tab | optimize | note     | Table does not support optimize, doing recreate + analyze instead
| db1.tab | optimize | error    | ALGORITHM=NOCOPY is not supported for this operation. Try ALGORITHM=INPLACE
| db1.tab | optimize | status   | Operation failed
+-----+-----+-----+
3 rows in set, 1 warning (0.002 sec)
```

This applies to [OPTIMIZE TABLE](#) for InnoDB tables.

ALTER TABLE ... RENAME TO  
and  
RENAME TABLE ...

InnoDB supports renaming a table with [ALGORITHM](#) set to  
NOCOPY  
in the cases where the operation supports having the [ALGORITHM](#) clause set to  
INSTANT

See [InnoDB Online DDL Operations with ALGORITHM=INSTANT: ALTER TABLE ... RENAME TO and RENAME TABLE ...](#) for more information.

This applies to [ALTER TABLE ... RENAME TO](#) and [RENAME TABLE](#) for InnoDB tables.

## Limitations

### Limitations Related to Generated (Virtual and Persistent/Stored) Columns

[Generated columns](#) do not currently support online DDL for all of the same operations that are supported for "real" columns.

See [Generated \(Virtual and Persistent/Stored\) Columns: Statement Support](#) for more information on the limitations.

    - 2. [Open Bugs](#)

## Column Operations

### ALTER TABLE ... ADD COLUMN

In MariaDB 10.3.2 and later, InnoDB supports adding columns to a table with [ALGORITHM](#) set to

INSTANT

if the new column is the last column in the table. See [MDEV-11369](#) for more information. If the table has a hidden

`FTS_DOC_ID`  
column is present, then this is not supported.

In MariaDB 10.4 and later, InnoDB supports adding columns to a table with `ALGORITHM` set to

`INSTANT`  
, regardless of where in the column list the new column is added.

When this operation is performed with `ALGORITHM` set to

`INSTANT`  
, the tablespace file will have a non-canonical storage format. See [Non-canonical Storage Format Caused by Some Operations](#) for more information.

With the exception of adding an `auto-increment` column, this operation supports the non-locking strategy. This strategy can be explicitly chosen by setting the `LOCK` clause to

`NONE`  
. When this strategy is used, all concurrent DML is permitted.

For example, this succeeds:

```
CREATE OR REPLACE TABLE tab (
    a int PRIMARY KEY,
    b varchar(50)
);

SET SESSION alter_algorithm='INSTANT';
ALTER TABLE tab ADD COLUMN c varchar(50);
Query OK, 0 rows affected (0.004 sec)
```

And this succeeds in MariaDB 10.4 and later:

```
CREATE OR REPLACE TABLE tab (
    a int PRIMARY KEY,
    b varchar(50)
);

SET SESSION alter_algorithm='INSTANT';
ALTER TABLE tab ADD COLUMN c varchar(50) AFTER a;
Query OK, 0 rows affected (0.004 sec)
```

This applies to [ALTER TABLE ... ADD COLUMN](#) for InnoDB tables.

See [Instant ADD COLUMN](#) for InnoDB for more information.

## ALTER TABLE ... DROP COLUMN

In MariaDB 10.4 and later, InnoDB supports dropping columns from a table with `ALGORITHM` set to

`INSTANT`  
. See [MDEV-15562](#) for more information.

When this operation is performed with `ALGORITHM` set to

`INSTANT`  
, the tablespace file will have a non-canonical storage format. See [Non-canonical Storage Format Caused by Some Operations](#) for more information.

This operation supports the non-locking strategy. This strategy can be explicitly chosen by setting the `LOCK` clause to

`NONE`  
. When this strategy is used, all concurrent DML is permitted.

For example:

```
CREATE OR REPLACE TABLE tab (
    a int PRIMARY KEY,
    b varchar(50),
    c varchar(50)
);

SET SESSION alter_algorithm='INSTANT';
ALTER TABLE tab DROP COLUMN c;
Query OK, 0 rows affected (0.004 sec)
```

This applies to [ALTER TABLE ... DROP COLUMN](#) for InnoDB tables.

## ALTER TABLE ... MODIFY COLUMN

This applies to [ALTER TABLE ... MODIFY COLUMN](#) for InnoDB tables.

### Reordering Columns

In MariaDB 10.4 and later, InnoDB supports reordering columns within a table with [ALGORITHM](#) set to

INSTANT

. See [MDEV-15562](#) for more information.

When this operation is performed with [ALGORITHM](#) set to

INSTANT

, the tablespace file will have a non-canonical storage format. See [Non-canonical Storage Format Caused by Some Operations](#) for more information.

This operation supports the non-locking strategy. This strategy can be explicitly chosen by setting the [LOCK](#) clause to

NONE

. When this strategy is used, all concurrent DML is permitted.

For example:

```
CREATE OR REPLACE TABLE tab (
    a int PRIMARY KEY,
    b varchar(50),
    c varchar(50)
);

SET SESSION alter_algorithm='INSTANT';
ALTER TABLE tab MODIFY COLUMN c varchar(50) AFTER a;
Query OK, 0 rows affected (0.004 sec)
```

### Changing the Data Type of a Column

InnoDB does **not** support modifying a column's data type with [ALGORITHM](#) set to

INSTANT

in most cases. There are some exceptions:

- InnoDB supports increasing the length of

VARCHAR

columns with [ALGORITHM](#) set to

INSTANT

, unless it would require changing the number of bytes required to represent the column's length. A

VARCHAR

column that is between 0 and 255 bytes in size requires 1 byte to represent its length, while a

VARCHAR

column that is 256 bytes or longer requires 2 bytes to represent its length. This means that the length of a column cannot be increased with [ALGORITHM](#) set to

INSTANT

if the original length was less than 256 bytes, and the new length is 256 bytes or more.

- In MariaDB 10.4.3 and later, InnoDB supports increasing the length of

VARCHAR

columns with [ALGORITHM](#) set to

INSTANT

with no restrictions if the [ROW\\_FORMAT](#) table option is set to [REDUNDANT](#). See [MDEV-15563](#) for more information.

- In MariaDB 10.4.3 and later, InnoDB also supports increasing the length of

VARCHAR

columns with [ALGORITHM](#) set to

INSTANT

in a more limited manner if the [ROW\\_FORMAT](#) table option is set to [COMPACT](#), [DYNAMIC](#), or [COMPRESSED](#). In this scenario, the following limitations apply:

- The length can be increased with [ALGORITHM](#) set to

INSTANT

if the original length of the column is 127 bytes or less, and the new length of the column is 256 bytes or more.

- The length can be increased with [ALGORITHM](#) set to

INSTANT

if the original length of the column is 255 bytes or less, and the new length of the column is still 255 bytes or less.

- The length can be increased with [ALGORITHM](#) set to

INSTANT

if the original length of the column is 256 bytes or more, and the new length of the column is still 256 bytes or more.

- The length can **not** be increased with [ALGORITHM](#) set to

INSTANT  
if the original length was between 128 bytes and 255 bytes, and the new length is 256 bytes or more.  
o See [MDEV-15563](#) for more information.

The supported operations in this category support the non-locking strategy. This strategy can be explicitly chosen by setting the `LOCK` clause to `NONE`. When this strategy is used, all concurrent DML is permitted.

For example, this fails:

```
CREATE OR REPLACE TABLE tab (
    a int PRIMARY KEY,
    b varchar(50),
    c varchar(50)
);

SET SESSION alter_algorithm='INSTANT';
ALTER TABLE tab MODIFY COLUMN c int;
ERROR 1846 (0A000): ALGORITHM=INSTANT is not supported. Reason: Cannot change column type INPLACE. Try ALGORITHM=COPY
```

But this succeeds because the original length of the column is less than 256 bytes, and the new length is still less than 256 bytes:

```
CREATE OR REPLACE TABLE tab (
    a int PRIMARY KEY,
    b varchar(50),
    c varchar(50)
) CHARACTER SET=latin1;

SET SESSION alter_algorithm='INSTANT';
ALTER TABLE tab MODIFY COLUMN c varchar(100);
Query OK, 0 rows affected (0.005 sec)
```

But this fails because the original length of the column is between 128 bytes and 255 bytes, and the new length is greater than 256 bytes:

```
CREATE OR REPLACE TABLE tab (
    a int PRIMARY KEY,
    b varchar(50),
    c varchar(255)
) CHARACTER SET=latin1;

SET SESSION alter_algorithm='INSTANT';
ALTER TABLE tab MODIFY COLUMN c varchar(256);
ERROR 1846 (0A000): ALGORITHM=INSTANT is not supported. Reason: Cannot change column type INPLACE. Try ALGORITHM=COPY
```

But this succeeds in [MariaDB 10.4.3](#) and later because the table has

```
ROW_FORMAT=REDUNDANT
:
```

```
CREATE OR REPLACE TABLE tab (
    a int PRIMARY KEY,
    b varchar(50),
    c varchar(200)
) ROW_FORMAT=REDUNDANT;

SET SESSION alter_algorithm='INSTANT';
ALTER TABLE tab MODIFY COLUMN c varchar(300);
Query OK, 0 rows affected (0.004 sec)
```

And this succeeds in [MariaDB 10.4.3](#) and later because the table has

```
ROW_FORMAT=DYNAMIC
```

and the column's original length is 127 bytes or less:

```
CREATE OR REPLACE TABLE tab (
    a int PRIMARY KEY,
    b varchar(50),
    c varchar(127)
) ROW_FORMAT=DYNAMIC
CHARACTER SET=latin1;

SET SESSION alter_algorithm='INSTANT';
ALTER TABLE tab MODIFY COLUMN c varchar(300);
Query OK, 0 rows affected (0.003 sec)
```

And this succeeds in [MariaDB 10.4.3](#) and later because the table has

ROW\_FORMAT=COMPRESSED

and the column's original length is 127 bytes or less:

```
CREATE OR REPLACE TABLE tab (
    a int PRIMARY KEY,
    b varchar(50),
    c varchar(127)
) ROW_FORMAT=COMPRESSED
CHARACTER SET=latin1;

SET SESSION alter_algorithm='INSTANT';
ALTER TABLE tab MODIFY COLUMN c varchar(300);
Query OK, 0 rows affected (0.003 sec)
```

But this fails even in [MariaDB 10.4.3](#) and later because the table has

ROW\_FORMAT=DYNAMIC

and the column's original length is between 128 bytes and 255 bytes:

```
CREATE OR REPLACE TABLE tab (
    a int PRIMARY KEY,
    b varchar(50),
    c varchar(128)
) ROW_FORMAT=DYNAMIC
CHARACTER SET=latin1;

SET SESSION alter_algorithm='INSTANT';
ALTER TABLE tab MODIFY COLUMN c varchar(300);
ERROR 1846 (0A000): ALGORITHM=INSTANT is not supported. Reason: Cannot change column type INPLACE. Try ALGORITHM=COPY
```

## Changing a Column to NULL

In [MariaDB 10.4.3](#) and later, InnoDB supports modifying a column to allow **NULL** values with **ALGORITHM** set to

INSTANT

if the **ROW\_FORMAT** table option is set to **REDUNDANT**. See [MDEV-15563](#) for more information.

This operation supports the non-locking strategy. This strategy can be explicitly chosen by setting the **LOCK** clause to

NONE

. When this strategy is used, all concurrent DML is permitted.

For example:

```
CREATE OR REPLACE TABLE tab (
    a int PRIMARY KEY,
    b varchar(50),
    c varchar(50) NOT NULL
) ROW_FORMAT=REDUNDANT;

SET SESSION alter_algorithm='INSTANT';
ALTER TABLE tab MODIFY COLUMN c varchar(50) NULL;
Query OK, 0 rows affected (0.004 sec)
```

## Changing a Column to NOT NULL

InnoDB does **not** support modifying a column to **not** allow **NULL** values with **ALGORITHM** set to

INSTANT

For example:

```
CREATE OR REPLACE TABLE tab (
    a int PRIMARY KEY,
    b varchar(50),
    c varchar(50)
) ROW_FORMAT=REDUNDANT;

SET SESSION alter_algorithm='INSTANT';
ALTER TABLE tab MODIFY COLUMN c varchar(50) NOT NULL;
ERROR 1845 (0A000): ALGORITHM=INSTANT is not supported for this operation. Try ALGORITHM=INPLACE
```

## Adding a New ENUM Option

InnoDB supports adding a new **ENUM** option to a column with **ALGORITHM** set to

INSTANT

. In order to add a new **ENUM** option with **ALGORITHM** set to

INSTANT

, the following requirements must be met:

- It must be added to the end of the list.
- The storage requirements must not change.

This operation supports the non-locking strategy. This strategy can be explicitly chosen by setting the **LOCK** clause to

NONE

. When this strategy is used, all concurrent DML is permitted.

For example, this succeeds:

```
CREATE OR REPLACE TABLE tab (
    a int PRIMARY KEY,
    b varchar(50),
    c ENUM('red', 'green')
);

SET SESSION alter_algorithm='INSTANT';
ALTER TABLE tab MODIFY COLUMN c ENUM('red', 'green', 'blue');
Query OK, 0 rows affected (0.002 sec)
```

But this fails:

```
CREATE OR REPLACE TABLE tab (
    a int PRIMARY KEY,
    b varchar(50),
    c ENUM('red', 'green')
);

SET SESSION alter_algorithm='INSTANT';
ALTER TABLE tab MODIFY COLUMN c ENUM('red', 'blue', 'green');
ERROR 1846 (0A000): ALGORITHM=INSTANT is not supported. Reason: Cannot change column type INPLACE. Try ALGORITHM=COPY
```

## Adding a New

SET

Option

InnoDB supports adding a new **SET** option to a column with **ALGORITHM** set to

INSTANT

. In order to add a new **SET** option with **ALGORITHM** set to

INSTANT

, the following requirements must be met:

- It must be added to the end of the list.
- The storage requirements must not change.

This operation supports the non-locking strategy. This strategy can be explicitly chosen by setting the **LOCK** clause to

NONE

. When this strategy is used, all concurrent DML is permitted.

For example, this succeeds:

```
CREATE OR REPLACE TABLE tab (
    a int PRIMARY KEY,
    b varchar(50),
    c SET('red', 'green')
);

SET SESSION alter_algorithm='INSTANT';
ALTER TABLE tab MODIFY COLUMN c SET('red', 'green', 'blue');
Query OK, 0 rows affected (0.002 sec)
```

But this fails:

```

CREATE OR REPLACE TABLE tab (
  a int PRIMARY KEY,
  b varchar(50),
  c SET('red', 'green')
);

SET SESSION alter_algorithm='INSTANT';
ALTER TABLE tab MODIFY COLUMN c SET('red', 'blue', 'green');
ERROR 1846 (0A000): ALGORITHM=INSTANT is not supported. Reason: Cannot change column type INPLACE. Try ALGORITHM=COPY

```

## Removing System Versioning from a Column

In MariaDB 10.3.8 and later, InnoDB supports removing system versioning from a column with `ALGORITHM` set to

- INSTANT
  - . In order for this to work, the `system_versioning_alter_history` system variable must be set to `KEEP`
  - . See [MDEV-16330](#) for more information.

This operation supports the non-locking strategy. This strategy can be explicitly chosen by setting the `LOCK` clause to

- NONE
  - . When this strategy is used, all concurrent DML is permitted.

For example:

```

CREATE OR REPLACE TABLE tab (
  a int PRIMARY KEY,
  b varchar(50),
  c varchar(50) WITH SYSTEM VERSIONING
);

SET SESSION system_versioning_alter_history='KEEP';
SET SESSION alter_algorithm='INSTANT';
ALTER TABLE tab MODIFY COLUMN c varchar(50) WITHOUT SYSTEM VERSIONING;
Query OK, 0 rows affected (0.004 sec)

```

## ALTER TABLE ... ALTER COLUMN

This applies to `ALTER TABLE ... ALTER COLUMN` for InnoDB tables.

### Setting a Column's Default Value

InnoDB supports modifying a column's `DEFAULT` value with `ALGORITHM` set to

- INSTANT
  - .

This operation supports the non-locking strategy. This strategy can be explicitly chosen by setting the `LOCK` clause to

- NONE
  - . When this strategy is used, all concurrent DML is permitted.

For example:

```

CREATE OR REPLACE TABLE tab (
  a int PRIMARY KEY,
  b varchar(50),
  c varchar(50)
);

SET SESSION alter_algorithm='INSTANT';
ALTER TABLE tab ALTER COLUMN c SET DEFAULT 'No value explicitly provided.';
Query OK, 0 rows affected (0.003 sec)

```

### Removing a Column's Default Value

InnoDB supports removing a column's `DEFAULT` value with `ALGORITHM` set to

- INSTANT
  - .

This operation supports the non-locking strategy. This strategy can be explicitly chosen by setting the `LOCK` clause to

- NONE
  - . When this strategy is used, all concurrent DML is permitted.

```

CREATE OR REPLACE TABLE tab (
  a int PRIMARY KEY,
  b varchar(50),
  c varchar(50) DEFAULT 'No value explicitly provided.'
);

SET SESSION alter_algorithm='INSTANT';
ALTER TABLE tab ALTER COLUMN c DROP DEFAULT;
Query OK, 0 rows affected (0.002 sec)

```

## ALTER TABLE ... CHANGE COLUMN

InnoDB supports renaming a column with [ALGORITHM](#) set to

INSTANT  
, unless the column's data type or attributes changed in addition to the name.

This operation supports the non-locking strategy. This strategy can be explicitly chosen by setting the [LOCK](#) clause to

NONE  
. When this strategy is used, all concurrent DML is permitted.

For example, this succeeds:

```

CREATE OR REPLACE TABLE tab (
  a int PRIMARY KEY,
  b varchar(50),
  c varchar(50)
);

SET SESSION alter_algorithm='INSTANT';
ALTER TABLE tab CHANGE COLUMN c str varchar(50);
Query OK, 0 rows affected (0.004 sec)

```

But this fails:

```

CREATE OR REPLACE TABLE tab (
  a int PRIMARY KEY,
  b varchar(50),
  c varchar(50)
);

SET SESSION alter_algorithm='INSTANT';
ALTER TABLE tab CHANGE COLUMN c num int;
ERROR 1846 (0A000): ALGORITHM=INSTANT is not supported. Reason: Cannot change column type INPLACE. Try ALGORITHM=COPY

```

This applies to [ALTER TABLE ... CHANGE COLUMN](#) for InnoDB tables.

## Index Operations

### ALTER TABLE ... ADD PRIMARY KEY

InnoDB does **not** support adding a primary key to a table with [ALGORITHM](#) set to

INSTANT

For example:

```

CREATE OR REPLACE TABLE tab (
  a int,
  b varchar(50),
  c varchar(50)
);

SET SESSION sql_mode='STRICT_TRANS_TABLES';
SET SESSION alter_algorithm='INSTANT';
ALTER TABLE tab ADD PRIMARY KEY (a);
ERROR 1845 (0A000): ALGORITHM=INSTANT is not supported for this operation. Try ALGORITHM=INPLACE

```

This applies to [ALTER TABLE ... ADD PRIMARY KEY](#) for InnoDB tables.

## ALTER TABLE ... DROP PRIMARY KEY

InnoDB does **not** support dropping a primary key with [ALGORITHM](#) set to  
INSTANT

For example:

```
CREATE OR REPLACE TABLE tab (
    a int PRIMARY KEY,
    b varchar(50),
    c varchar(50)
);

SET SESSION alter_algorithm='INSTANT';
ALTER TABLE tab DROP PRIMARY KEY;
ERROR 1846 (0A000): ALGORITHM=INSTANT is not supported. Reason: Dropping a primary key is not allowed without also adding a new
```

This applies to [ALTER TABLE ... DROP PRIMARY KEY](#) for InnoDB tables.

## ALTER TABLE ... ADD INDEX and CREATE INDEX

This applies to [ALTER TABLE ... ADD INDEX](#) and [CREATE INDEX](#) for InnoDB tables.

### Adding a Plain Index

InnoDB does **not** support adding a plain index to a table with [ALGORITHM](#) set to  
INSTANT

For example, this fails:

```
CREATE OR REPLACE TABLE tab (
    a int PRIMARY KEY,
    b varchar(50),
    c varchar(50)
);

SET SESSION alter_algorithm='INSTANT';
ALTER TABLE tab ADD INDEX b_index (b);
ERROR 1846 (0A000): ALGORITHM=INSTANT is not supported. Reason: ADD INDEX. Try ALGORITHM=NOCOPY
```

And this fails:

```
CREATE OR REPLACE TABLE tab (
    a int PRIMARY KEY,
    b varchar(50),
    c varchar(50)
);

SET SESSION alter_algorithm='INSTANT';
CREATE INDEX b_index ON tab (b);
ERROR 1846 (0A000): ALGORITHM=INSTANT is not supported. Reason: ADD INDEX. Try ALGORITHM=NOCOPY
```

### Adding a Fulltext Index

InnoDB does **not** support adding a [FULLTEXT](#) index to a table with [ALGORITHM](#) set to  
INSTANT

For example, this fails:

```

CREATE OR REPLACE TABLE tab (
  a int PRIMARY KEY,
  b varchar(50),
  c varchar(50)
);

SET SESSION alter_algorithm='INPLACE';
ALTER TABLE tab ADD FULLTEXT INDEX b_index (b);
Query OK, 0 rows affected (0.042 sec)

SET SESSION alter_algorithm='INSTANT';
ALTER TABLE tab ADD FULLTEXT INDEX c_index (c);
ERROR 1846 (0A000): ALGORITHM=INSTANT is not supported. Reason: ADD INDEX. Try ALGORITHM=NOCOPY

```

And this fails:

```

CREATE OR REPLACE TABLE tab (
  a int PRIMARY KEY,
  b varchar(50),
  c varchar(50)
);

SET SESSION alter_algorithm='INPLACE';
CREATE FULLTEXT INDEX b_index ON tab (b);
Query OK, 0 rows affected (0.040 sec)

SET SESSION alter_algorithm='INSTANT';
CREATE FULLTEXT INDEX c_index ON tab (c);
ERROR 1846 (0A000): ALGORITHM=INSTANT is not supported. Reason: ADD INDEX. Try ALGORITHM=NOCOPY

```

## Adding a Spatial Index

InnoDB does **not** support adding a **Spatial** index to a table with **ALGORITHM** set to  
INSTANT

For example, this fails:

```

CREATE OR REPLACE TABLE tab (
  a int PRIMARY KEY,
  b varchar(50),
  c GEOMETRY NOT NULL
);

SET SESSION alter_algorithm='INSTANT';
ALTER TABLE tab ADD SPATIAL INDEX c_index (c);
ERROR 1846 (0A000): ALGORITHM=INSTANT is not supported. Reason: ADD INDEX. Try ALGORITHM=NOCOPY

```

And this fails:

```

CREATE OR REPLACE TABLE tab (
  a int PRIMARY KEY,
  b varchar(50),
  c GEOMETRY NOT NULL
);

SET SESSION alter_algorithm='INSTANT';
CREATE SPATIAL INDEX c_index ON tab (c);
ERROR 1846 (0A000): ALGORITHM=INSTANT is not supported. Reason: ADD INDEX. Try ALGORITHM=NOCOPY

```

ALTER TABLE ... DROP INDEX  
and  
DROP INDEX

InnoDB supports dropping indexes from a table with **ALGORITHM** set to  
INSTANT

This operation supports the non-locking strategy. This strategy can be explicitly chosen by setting the **LOCK** clause to

NONE

. When this strategy is used, all concurrent DML is permitted.

For example, this succeeds:

```
CREATE OR REPLACE TABLE tab (
    a int PRIMARY KEY,
    b varchar(50),
    c varchar(50),
    INDEX b_index (b)
);

SET SESSION alter_algorithm='INSTANT';
ALTER TABLE tab DROP INDEX b_index;
Query OK, 0 rows affected (0.008 sec)
```

And this succeeds:

```
CREATE OR REPLACE TABLE tab (
    a int PRIMARY KEY,
    b varchar(50),
    c varchar(50),
    INDEX b_index (b)
);

SET SESSION alter_algorithm='INSTANT';
DROP INDEX b_index ON tab;
Query OK, 0 rows affected (0.007 sec)
```

This applies to [ALTER TABLE ... DROP INDEX](#) and [DROP INDEX](#) for InnoDB tables.

## ALTER TABLE ... ADD FOREIGN KEY

InnoDB does **not** support adding foreign key constraints to a table with [ALGORITHM](#) set to INSTANT.

For example:

```
CREATE OR REPLACE TABLE tab1 (
    a int PRIMARY KEY,
    b varchar(50),
    c varchar(50),
    d int
);

CREATE OR REPLACE TABLE tab2 (
    a int PRIMARY KEY,
    b varchar(50)
);

SET SESSION foreign_key_checks=OFF;
SET SESSION alter_algorithm='INSTANT';
ALTER TABLE tab1 ADD FOREIGN KEY tab2_fk (d) REFERENCES tab2 (a);
ERROR 1846 (0A000): ALGORITHM=INSTANT is not supported. Reason: ADD INDEX. Try ALGORITHM=NOCOPY
```

This applies to [ALTER TABLE ... ADD FOREIGN KEY](#) for InnoDB tables.

## ALTER TABLE ... DROP FOREIGN KEY

InnoDB supports dropping foreign key constraints from a table with [ALGORITHM](#) set to INSTANT.

This operation supports the non-locking strategy. This strategy can be explicitly chosen by setting the [LOCK](#) clause to

NONE

. When this strategy is used, all concurrent DML is permitted.

For example:

```

CREATE OR REPLACE TABLE tab2 (
  a int PRIMARY KEY,
  b varchar(50)
);

CREATE OR REPLACE TABLE tab1 (
  a int PRIMARY KEY,
  b varchar(50),
  c varchar(50),
  d int,
  FOREIGN KEY tab2_fk (d) REFERENCES tab2 (a)
);
;

SET SESSION alter_algorithm='INSTANT';
ALTER TABLE tab1 DROP FOREIGN KEY tab2_fk;
Query OK, 0 rows affected (0.004 sec)

```

This applies to [ALTER TABLE ... DROP FOREIGN KEY](#) for InnoDB tables.

## Table Operations

### ALTER TABLE ... AUTO\_INCREMENT=...

InnoDB supports changing a table's `AUTO_INCREMENT` value with `ALGORITHM` set to `INSTANT`

This operation supports the non-locking strategy. This strategy can be explicitly chosen by setting the `LOCK` clause to `NONE`. When this strategy is used, all concurrent DML is permitted.

For example:

```

CREATE OR REPLACE TABLE tab (
  a int PRIMARY KEY,
  b varchar(50),
  c varchar(50)
);

SET SESSION alter_algorithm='INSTANT';
ALTER TABLE tab AUTO_INCREMENT=100;
Query OK, 0 rows affected (0.002 sec)

```

This applies to [ALTER TABLE ... AUTO\\_INCREMENT=...](#) for InnoDB tables.

### ALTER TABLE ... ROW\_FORMAT=...

InnoDB does **not** support changing a table's `row format` with `ALGORITHM` set to `INSTANT`

For example:

```

CREATE OR REPLACE TABLE tab (
  a int PRIMARY KEY,
  b varchar(50),
  c varchar(50)
) ROW_FORMAT=DYNAMIC;

SET SESSION alter_algorithm='INSTANT';
ALTER TABLE tab ROW_FORMAT=COMPRESSED;
ERROR 1846 (0A000): ALGORITHM=INSTANT is not supported. Reason: Changing table options requires the table to be rebuilt. Try ALG

```

This applies to [ALTER TABLE ... ROW\\_FORMAT=...](#) for InnoDB tables.

`ALTER TABLE ... KEY_BLOCK_SIZE=...`

InnoDB does **not** support changing a table's `KEY_BLOCK_SIZE` with `ALGORITHM` set to  
`INSTANT`

For example:

```
CREATE OR REPLACE TABLE tab (
    a int PRIMARY KEY,
    b varchar(50),
    c varchar(50)
) ROW_FORMAT=COMPRESSED
KEY_BLOCK_SIZE=4;

SET SESSION alter_algorithm='INSTANT';
ALTER TABLE tab KEY_BLOCK_SIZE=2;
ERROR 1846 (0A000): ALGORITHM=INSTANT is not supported. Reason: Changing table options requires the table to be rebuilt. Try ALG
```

This applies to `KEY_BLOCK_SIZE=...` for InnoDB tables.

`ALTER TABLE ... PAGE_COMPRESSED=1`

and

`ALTER TABLE ... PAGE_COMPRESSION_LEVEL=...`

In MariaDB 10.3.10 and later, InnoDB supports setting a table's `PAGE_COMPRESSED` value to

```
1
with ALGORITHM set to
INSTANT
. InnoDB does not support changing a table's PAGE_COMPRESSED value from
1
to
0
with ALGORITHM set to
INSTANT
```

In these versions, InnoDB also supports changing a table's `PAGE_COMPRESSION_LEVEL` value with `ALGORITHM` set to  
`INSTANT`

This operation supports the non-locking strategy. This strategy can be explicitly chosen by setting the `LOCK` clause to

```
NONE
. When this strategy is used, all concurrent DML is permitted.
```

See [MDEV-16328](#) for more information.

For example, this succeeds:

```
CREATE OR REPLACE TABLE tab (
    a int PRIMARY KEY,
    b varchar(50),
    c varchar(50)
);

SET SESSION alter_algorithm='INSTANT';
ALTER TABLE tab PAGE_COMPRESSED=1;
Query OK, 0 rows affected (0.004 sec)
```

And this succeeds:

```

CREATE OR REPLACE TABLE tab (
  a int PRIMARY KEY,
  b varchar(50),
  c varchar(50)
) PAGE_COMPRESSED=1
PAGE_COMPRESSION_LEVEL=5;

SET SESSION alter_algorithm='INSTANT';
ALTER TABLE tab PAGE_COMPRESSION_LEVEL=4;
Query OK, 0 rows affected (0.004 sec)

```

But this fails:

```

CREATE OR REPLACE TABLE tab (
  a int PRIMARY KEY,
  b varchar(50),
  c varchar(50)
) PAGE_COMPRESSED=1;

SET SESSION alter_algorithm='INSTANT';
ALTER TABLE tab PAGE_COMPRESSED=0;
ERROR 1846 (0A000): ALGORITHM=INSTANT is not supported. Reason: Changing table options requires the table to be rebuilt. Try ALG

```

This applies to [ALTER TABLE ... PAGE\\_COMPRESSED=...](#) and [ALTER TABLE ... PAGE\\_COMPRESSION\\_LEVEL=...](#) for InnoDB tables.

## ALTER TABLE ... DROP SYSTEM VERSIONING

InnoDB does **not** support dropping [system versioning](#) from a table with [ALGORITHM](#) set to  
INSTANT

For example:

```

CREATE OR REPLACE TABLE tab (
  a int PRIMARY KEY,
  b varchar(50),
  c varchar(50)
) WITH SYSTEM VERSIONING;

SET SESSION alter_algorithm='INSTANT';
ALTER TABLE tab DROP SYSTEM VERSIONING;
ERROR 1845 (0A000): ALGORITHM=INSTANT is not supported for this operation. Try ALGORITHM=INPLACE

```

This applies to [ALTER TABLE ... DROP SYSTEM VERSIONING](#) for InnoDB tables.

## ALTER TABLE ... DROP CONSTRAINT

In MariaDB 10.3.6 and later, InnoDB supports dropping a [CHECK](#) constraint from a table with [ALGORITHM](#) set to  
INSTANT  
. See [MDEV-16331](#) for more information.

This operation supports the non-locking strategy. This strategy can be explicitly chosen by setting the [LOCK](#) clause to  
NONE  
. When this strategy is used, all concurrent DML is permitted.

For example:

```

CREATE OR REPLACE TABLE tab (
  a int PRIMARY KEY,
  b varchar(50),
  c varchar(50),
  CONSTRAINT b_not_empty CHECK (b != '')
);

SET SESSION alter_algorithm='INSTANT';
ALTER TABLE tab DROP CONSTRAINT b_not_empty;
Query OK, 0 rows affected (0.002 sec)

```

This applies to [ALTER TABLE ... DROP CONSTRAINT](#) for InnoDB tables.

## ALTER TABLE ... FORCE

InnoDB does **not** support forcing a table rebuild with [ALGORITHM](#) set to  
INSTANT

For example:

```
CREATE OR REPLACE TABLE tab (
    a int PRIMARY KEY,
    b varchar(50),
    c varchar(50)
);

SET SESSION alter_algorithm='INSTANT';
ALTER TABLE tab FORCE;
ERROR 1845 (0A000): ALGORITHM=INSTANT is not supported for this operation. Try ALGORITHM=INPLACE
```

This applies to [ALTER TABLE ... FORCE](#) for InnoDB tables.

## ALTER TABLE ... ENGINE=InnoDB

InnoDB does **not** support forcing a table rebuild with [ALGORITHM](#) set to  
INSTANT

For example:

```
CREATE OR REPLACE TABLE tab (
    a int PRIMARY KEY,
    b varchar(50),
    c varchar(50)
);

SET SESSION alter_algorithm='INSTANT';
ALTER TABLE tab ENGINE=InnoDB;
ERROR 1845 (0A000): ALGORITHM=INSTANT is not supported for this operation. Try ALGORITHM=INPLACE
```

This applies to [ALTER TABLE ... ENGINE=InnoDB](#) for InnoDB tables.

## OPTIMIZE TABLE ...

InnoDB does **not** support optimizing a table with with [ALGORITHM](#) set to  
INSTANT

For example:

```

CREATE OR REPLACE TABLE tab (
  a int PRIMARY KEY,
  b varchar(50),
  c varchar(50)
);

SHOW GLOBAL VARIABLES WHERE Variable_name IN('innodb_defragment', 'innodb_optimize_fulltext_only');
+-----+-----+
| Variable_name | Value |
+-----+-----+
| innodb_defragment | OFF |
| innodb_optimize_fulltext_only | OFF |
+-----+-----+
2 rows in set (0.001 sec)

SET SESSION alter_algorithm='INSTANT';
OPTIMIZE TABLE tab;
+-----+-----+-----+
| Table | Op      | Msg_type | Msg_text
+-----+-----+-----+
| db1.tab | optimize | note    | Table does not support optimize, doing recreate + analyze instead |
| db1.tab | optimize | error   | ALGORITHM=INSTANT is not supported for this operation. Try ALGORITHM=INPLACE |
| db1.tab | optimize | status  | Operation failed
+-----+-----+-----+
3 rows in set, 1 warning (0.002 sec)

```

This applies to [OPTIMIZE TABLE](#) for InnoDB tables.

ALTER TABLE ... RENAME TO  
and  
RENAME TABLE ...

InnoDB supports renaming a table with [ALGORITHM](#) set to  
INSTANT

This operation supports the exclusive locking strategy. This strategy can be explicitly chosen by setting the [LOCK](#) clause to EXCLUSIVE.  
. When this strategy is used, concurrent DML is **not** permitted.

For example, this succeeds:

```

CREATE OR REPLACE TABLE tab (
  a int PRIMARY KEY,
  b varchar(50),
  c varchar(50)
);

SET SESSION alter_algorithm='INSTANT';
ALTER TABLE tab RENAME TO old_tab;
Query OK, 0 rows affected (0.008 sec)

```

And this succeeds:

```

CREATE OR REPLACE TABLE tab (
  a int PRIMARY KEY,
  b varchar(50),
  c varchar(50)
);

SET SESSION alter_algorithm='INSTANT';
RENAME TABLE tab TO old_tab;
Query OK, 0 rows affected (0.008 sec)

```

This applies to [ALTER TABLE ... RENAME TO](#) and [RENAME TABLE](#) for InnoDB tables.

## Limitations

## Limitations Related to Generated (Virtual and Persistent/Stored) Columns

Generated columns do not currently support online DDL for all of the same operations that are supported for "real" columns.

See [Generated \(Virtual and Persistent/Stored\) Columns: Statement Support](#) for more information on the limitations.

## Non-canonical Storage Format Caused by Some Operations

Some operations cause a table's tablespace file to use a non-canonical storage format when the

INSTANT

algorithm is used. The affected operations include:

- [Adding a column](#).
- [Dropping a column](#).
- [Reordering columns](#).

These operations require the following non-canonical changes to the storage format:

- A hidden metadata record at the start of the clustered index is used to store each column's **DEFAULT** value. This makes it possible to add new columns that have default values without rebuilding the table.
- A **BLOB** in the hidden metadata record is used to store column mappings. This makes it possible to drop or reorder columns without rebuilding the table. This also makes it possible to add columns to any position or drop columns from any position in the table without rebuilding the table.
- If a column is dropped, old records will contain garbage in that column's former position, and new records will be written with **NULL** values, empty strings, or dummy values.

This non-canonical storage format has the potential to incur some performance or storage overhead for all subsequent DML operations. If you notice some issues like this and you want to normalize a table's storage format to avoid this problem, then you can do so by forcing a table rebuild by executing **ALTER TABLE ... FORCE** with **ALGORITHM** set to

INPLACE

. For example:

```
SET SESSION alter_algorithm='INPLACE';
ALTER TABLE tab FORCE;
Query OK, 0 rows affected (0.008 sec)
```

However, keep in mind that there are certain scenarios where you may not be able to rebuild the table with **ALGORITHM** set to

INPLACE

. See [InnoDB Online DDL Operations with ALGORITHM=INPLACE: Limitations](#) for more information on those cases. If you hit one of those scenarios, but you still want to rebuild the table, then you would have to do so with **ALGORITHM** set to

COPY

## Known Bugs

There are some known bugs that could lead to issues when an InnoDB DDL operation is performed using the **INSTANT** algorithm. This algorithm will usually be chosen by default if the operation supports the algorithm.

The effect of many of these bugs is that the table seems to *forget* that its tablespace file is in the [non-canonical storage format](#).

If you are concerned that a table may be affected by one of these bugs, then your best option would be to normalize the table structure. This can be done by rebuilding the table. For example:

```
SET SESSION alter_algorithm='INPLACE';
ALTER TABLE tab FORCE;
Query OK, 0 rows affected (0.008 sec)
```

If you are concerned about these bugs, and you want to perform an operation that supports the **INSTANT** algorithm, but you want to avoid using that algorithm, then you can set the algorithm to **INPLACE** and add the

FORCE

keyword to the **ALTER TABLE** statement:

```
SET SESSION alter_algorithm='INPLACE';
ALTER TABLE tab ADD COLUMN c varchar(50), FORCE;
```

## Closed Bugs

- [MDEV-20066](#) : This bug could cause a table to become corrupt if a column was added instantly. It is fixed in [MariaDB 10.3.18](#) and [MariaDB 10.4.8](#).
- [MDEV-20117](#) : This bug could cause a table to become corrupt if a column was dropped instantly. It is fixed in [MariaDB 10.4.9](#).

## Open Bugs

- [MDEV-18519](#) : This bug could cause a table to become corrupt if a column was added instantly.
- [MDEV-19743](#) : This bug could cause a table to become corrupt during page reorganization if a column was added instantly.

- [MDEV-19783](#) : This bug could cause a table to become corrupt if a column was added instantly.
- [MDEV-20090](#) : This bug could cause a table to become corrupt if columns were added, dropped, or reordered instantly.

## 4.3.2.19.5 Instant ADD COLUMN for InnoDB

MariaDB starting with [10.3.2](#)

Instant [ALTER TABLE ... ADD COLUMN](#) for InnoDB was introduced in [MariaDB 10.3.2](#). The [INSTANT](#) option for the [ALGORITHM](#) clause was introduced in [MariaDB 10.3.7](#).

### Contents

1. [Limitations](#)
2. [Example](#)

Normally, adding a column to a table requires the full table to be rebuilt. The complexity of the operation is proportional to the size of the table, or  $O(n \cdot m)$  where n is the number of rows in the table and m is the number of indexes.

In [MariaDB 10.0](#) and later, the [ALTER TABLE](#) statement supports [online DDL](#) for storage engines that have implemented the relevant online DDL [algorithms](#) and [locking strategies](#).

The [InnoDB](#) storage engine has implemented online DDL for many operations. These online DDL optimizations allow concurrent DML to the table in many cases, even if the table needs to be rebuilt.

See [InnoDB Online DDL Overview](#) for more information about online DDL with InnoDB.

Allowing concurrent DML during the operation does not solve all problems. When a column was added to a table with the older in-place optimization, the resulting table rebuild could still significantly increase the I/O and memory consumption and cause replication lag.

In contrast, with the new instant [ALTER TABLE ... ADD COLUMN](#), all that is needed is an  $O(\log n)$  operation to insert a special hidden record into the table, and an update of the data dictionary. For a large table, instead of taking several hours, the operation would be completed in the blink of an eye. The [ALTER TABLE ... ADD COLUMN](#) operation is only slightly more expensive than a regular [INSERT](#), due to locking constraints.

In the past, some developers may have implemented a kind of "instant add column" in the application by encoding multiple columns in a single [TEXT](#) or [BLOB](#) column. MariaDB [Dynamic Columns](#) was an early example of that. A more recent example is [JSON](#) and related string manipulation functions.

Adding real columns has the following advantages over encoding columns into a single "expandable" column:

- Efficient storage in a native binary format
- Data type safety
- Indexes can be built natively
- Constraints are available: UNIQUE, CHECK, FOREIGN KEY
- DEFAULT values can be specified
- Triggers can be written more easily

With instant [ALTER TABLE ... ADD COLUMN](#), you can enjoy all the benefits of structured storage without the drawback of having to rebuild the table.

Instant [ALTER TABLE ... ADD COLUMN](#) is available for both old and new InnoDB tables. Basically you can just upgrade from MySQL 5.x or MariaDB and start adding columns instantly.

Columns instantly added to a table exist in a separate data structure from the main table definition, similar to how InnoDB separates

[BLOB](#) columns. If the table ever becomes empty, (such as from [TRUNCATE](#) or [DELETE](#) statements), InnoDB incorporates the instantly added columns into the main table definition. See [InnoDB Online DDL Operations with ALGORITHM=INSTANT: Non-canonical Storage Format Caused by Some Operations](#) for more information.

The operation is also crash safe. If the server is killed while executing an instant [ALTER TABLE ... ADD COLUMN](#), when the table is restored InnoDB integrates the new column, flattening the table definition.

## Limitations

- In [MariaDB 10.3](#), instant [ALTER TABLE ... ADD COLUMN](#) only applies when the added columns appear last in the table. The place specifier [LAST](#) is the default. If [AFTER](#) col is specified, then col must be the last column, or the operation will require the table to be rebuilt. In [MariaDB 10.4](#), this restriction has been lifted.
- If the table contains a hidden [FTS\\_DOC\\_ID](#) column due to a [FULLTEXT INDEX](#), then instant [ALTER TABLE ... ADD COLUMN](#) will not be possible.
- InnoDB data files after instant [ALTER TABLE ... ADD COLUMN](#) cannot be imported to older versions of MariaDB or MySQL without first being rebuilt.
- After using Instant [ALTER TABLE ... ADD COLUMN](#), any table-rebuilding operation such as [ALTER TABLE ... FORCE](#) will incorporate instantaneously added columns into the main table body.

- Instant ALTER TABLE ... ADD COLUMN is not available for ROW\_FORMAT=COMPRESSED .
- In MariaDB 10.3 , ALTER TABLE ... DROP COLUMN requires the table to be rebuilt. In MariaDB 10.4 , this restriction has been lifted.

## Example

```

CREATE TABLE t(id INT PRIMARY KEY, u INT UNSIGNED NOT NULL UNIQUE)
ENGINE=InnoDB;

INSERT INTO t(id,u) VALUES(1,1),(2,2),(3,3);

ALTER TABLE t ADD COLUMN
(d DATETIME DEFAULT current_timestamp(),
 p POINT NOT NULL DEFAULT ST_GeomFromText('POINT(0 0)'),
 t TEXT CHARSET utf8 DEFAULT 'The quick brown fox jumps over the lazy dog');

UPDATE t SET t=NULL WHERE id=3;

SELECT id,u,d,ST_AsText(p),t FROM t;

SELECT variable_value FROM information_schema.global_status
WHERE variable_name = 'innodb_instant_alter_column';

```

The above example illustrates that when the added columns are declared NOT NULL, a DEFAULT value must be available, either implied by the data type or set explicitly by the user. The expression need not be constant, but it must not refer to the columns of the table, such as DEFAULT u+1 (a MariaDB extension). The DEFAULT current\_timestamp() would be evaluated at the time of the ALTER TABLE and apply to each row, like it does for non-instant ALTER TABLE. If a subsequent ALTER TABLE changes the DEFAULT value for subsequent INSERT, the values of the columns in existing records will naturally be unaffected.

The design was brainstormed in April by engineers from MariaDB Corporation, Alibaba and Tencent. A prototype was developed by Vin Chen (陈福荣) from the Tencent Game DBA Team.

## 4.3.2.20 Binary Log Group Commit and InnoDB Flushing Performance

### Contents

1. Overview
2. Switching to Old Flushing Behavior
  1. Non-durable Binary Log Settings
  2. Recent Transactions Missing from Backups

MariaDB 10.0 introduced a performance improvement related to [group commit](#) that affects the performance of flushing InnoDB transactions when the [binary log](#) is enabled.

## Overview

In MariaDB 10.0 and above, when both [innodb\\_flush\\_log\\_at\\_trx\\_commit=1](#) (the default) is set and the [binary log](#) is enabled, there is now one less sync to disk inside InnoDB during commit (2 syncs shared between a group of transactions instead of 3).

Durability of commits is not decreased — this is because even if the server crashes before the commit is written to disk by InnoDB, it will be recovered from the binary log at next server startup (and it is guaranteed that sufficient information is synced to disk so that such a recovery is always possible).

## Switching to Old Flushing Behavior

The old behavior, with 3 syncs to disk per (group) commit (and consequently lower performance), can be selected with the new [innodb\\_flush\\_log\\_at\\_trx\\_commit=3](#) option. There is normally no benefit to doing this, however there are a couple of edge cases to be aware of.

## Non-durable Binary Log Settings

If [innodb\\_flush\\_log\\_at\\_trx\\_commit=1](#) is set and the [binary log](#) is enabled, but [sync\\_binlog=0](#) is set, then commits are not guaranteed durable inside InnoDB after commit. This is because if [sync\\_binlog=0](#) is set and if the server crashes, then transactions that were not flushed to the binary log prior to the crash will be missing from the binary log.

In this specific scenario, [innodb\\_flush\\_log\\_at\\_trx\\_commit=3](#) can be set to ensure that transactions will be durable in InnoDB, even if they are not necessarily durable from the perspective of the binary log.

One should be aware that if [sync\\_binlog=0](#) is set, then a crash is nevertheless likely to cause transactions to be missing from the binary log. This will cause the binary log and InnoDB to be inconsistent with each other. This is also likely to cause any [replication slaves](#) to become inconsistent, since transactions are replicated through the [binary log](#) . Thus it is recommended to set [sync\\_binlog=1](#) . With the [group commit](#) improvements introduced in

## Recent Transactions Missing from Backups

Mariabackup and Percona XtraBackup only see transactions that have been flushed to the [redo log](#) . With the [group commit](#) improvements, there may be a small delay (defined by the [binlog\\_commit\\_wait\\_usecs](#) system variable) between when a commit happens and when the commit will be included in a backup.

Note that the backup will still be fully consistent with itself and the [binary log](#) . This problem is normally not an issue in practice. A backup usually takes a long time to complete (relative to the 1 second or so that [binlog\\_commit\\_wait\\_usecs](#) is normally set to), and a backup usually includes a lot of transactions that were committed during the backup. With this in mind, it is not generally noticeable if the backup does not include transactions that were committed during the last 1 second or so of the backup process. It is just mentioned here for completeness.

## 4.3.3 MariaDB ColumnStore

MariaDB ColumnStore is a columnar storage engine that utilizes a massively parallel distributed data architecture. It's a columnar storage system built by porting InfiniDB 4.6.7 to MariaDB, and released under the GPL license.

From [MariaDB 10.5.4](#) , it is available as a storage engine for MariaDB Server. Before then, it is only available as a separate download.

MariaDB ColumnStore is designed for big data scaling to process petabytes of data, linear scalability and exceptional performance with real-time response to analytical queries. It leverages the I/O benefits of columnar storage, compression, just-in-time projection, and horizontal and vertical partitioning to deliver tremendous performance when analyzing large data sets.

Documentation for the latest release of Columnstore is not available on the Knowledge Base. Instead, see:

## 4.3.4 Aria

### 4.3.4.1 Aria Storage Engine

#### Contents

1. [mysqld Startup Options for Aria](#)
2. [See Also](#)

The **Aria** storage engine is compiled in by default from [MariaDB 5.1](#) and it is required to be 'in use' when mysqld is started.

From [MariaDB 10.4](#), all [system tables](#) are Aria.

Additionally, internal on-disk tables are in the Aria table format instead of the [MyISAM](#) table format. This should speed up some [GROUP BY](#) and [DISTINCT](#) queries because Aria has better caching than MyISAM.

Note: The **Aria** storage engine was previously called **Maria** (see [The Aria Name](#) for details on the rename) and in previous versions of [MariaDB](#) the engine was still called Maria.

The following table options to Aria tables in

[CREATE TABLE](#)

and

[ALTER TABLE](#)

#:

• **TRANSACTIONAL= 0**

|

1  
: If the  
TRANSACTIONAL

table option is set for an Aria table, then the table will be crash-safe. This is implemented by logging any changes to the table to Aria's transaction log, and syncing those writes at the end of the statement. This will marginally slow down writes and updates. However, the benefit is that if the server dies before the statement ends, all non-durable changes will roll back to the state at the beginning of the statement. This also needs up to 6 bytes more for each row and key to store the transaction id (to allow concurrent insert's and selects).

◦

TRANSACTIONAL=1  
is not supported for partitioned tables.

◦ An Aria table's default value for the

TRANSACTIONAL  
table option depends on the table's value for the  
ROW\_FORMAT  
table option. See below for more details.

◦ If the

TRANSACTIONAL  
table option is set for an Aria table, the table does not actually support transactions. See [MDEV-21364](#) for more information. In this context, *transactional* just means *crash-safe*.

• **PAGE\_CHECKSUM= 0**

|

1  
: If index and data should use page checksums for extra safety.

- TABLE\_CHECKSUM= 0
  - |
  - 1 : Same as CHECKSUM in MySQL 5.1
- ROW\_FORMAT=PAGE
  - |
  - FIXED
  - |
  - DYNAMIC : The table's [row format](#) .
    - The default value is PAGE
    - . To emulate MyISAM, set ROW\_FORMAT=FIXED or ROW\_FORMAT=DYNAMIC

The

TRANSACTIONAL  
and  
ROW\_FORMAT  
table options interact as follows:

- If TRANSACTIONAL=1  
is set, then the only supported row format is PAGE
  - . If ROW\_FORMAT is set to some other value, then Aria issues a warning, but still forces the row format to be PAGE
- If TRANSACTIONAL=0  
is set, then the table will be not be crash-safe, and any row format is supported.
- If TRANSACTIONAL  
is not set to any value, then any row format is supported. If ROW\_FORMAT is set, then the table will use that row format. Otherwise, the table will use the default PAGE row format. In this case, if the table uses the PAGE row format, then it will be crash-safe. If it uses some other row format, then it will not be crash-safe.

Some other improvements are:

- - CHECKSUM\_TABLE
    - now ignores values in NULL fields. This makes CHECKSUM\_TABLE faster and fixes some cases where same table definition could give different checksum values depending on [row format](#) . The disadvantage is that the value is now different compared to other MySQL installations. The new checksum calculation is fixed for all table engines that uses the default way to calculate and MyISAM which does the calculation internally. Note: Old MyISAM tables with internal checksum will return the same checksum as before. To fix them to calculate according to new rules you have to do an ALTER TABLE
      - . You can use the old ways to calculate checksums by using the option --old

```
to mysqld or set the system variable '  
@@old  
' to  
1  
when you do  
CHECKSUM TABLE ... EXTENDED;
```

- At startup Aria will check the Aria logs and automatically recover the tables from the last checkpoint if mysqld was not taken down correctly.

## mysqld Startup Options for Aria

For a full list, see [Aria System Variables](#).

In normal operations, the only variables you have to consider are:

- [aria-pagelcache-buffer-size](#)
  - This is where all index and data pages are cached. The bigger this is, the faster Aria will work.
- [aria-block-size](#)
  - The default value 8192, should be ok for most cases. The only problem with a higher value is that it takes longer to find a packed key in the block as one has to search roughly 8192/2 to find each key. We plan to fix this by adding a dictionary at the end of the page to be able to do a binary search within the block before starting a scan. Until this is done and key lookups takes too long time even if you are not hitting disk, then you should consider making this smaller.
  - Possible values to try are
    - 2048
    - ,
    - 4096
    - or
    - 8192
- Note that you can't change this without dumping, deleting old tables and deleting all log files and then restoring your Aria tables. (This is the only option that requires a dump and load)
- [aria-log-purge-type](#)
  - Set this to "[at\\_flush](#)" if you want to keep a copy of the transaction logs (good as an extra backup). The logs will stay around until you execute [FLUSH ENGINE LOGS](#).

### 4.3.4.2 Aria Clients and Utilities

#### 4.3.4.2.1 aria\_chk

##### Contents

1. [Options and Variables](#)
  1. [Global Options](#)
  2. [Main Arguments](#)
  3. [Check Options \(--check is the Default Action for aria\\_chk\):](#)
  4. [Recover \(Repair\) Options \(When Using '--recover' or '--safe-recover'\):](#)
  5. [Other Options](#)
  6. [Variables](#)
2. [Usage](#)

`aria_chk`  
is used to check, repair, optimize, sort and get information about [Aria](#) tables.

With the MariaDB server you can use [CHECK TABLE](#), [REPAIR TABLE](#) and [OPTIMIZE TABLE](#) to do similar things.

##### Note:

`aria_chk`  
should not be used when MariaDB is running. MariaDB assumes that no one is changing the tables it's using!

Usage:

```
aria_chk [OPTIONS] aria_tables[.MAI]
```

Aria table information is stored in 2 files: the

.MAI  
file contains base table information and the index and the  
.MAD  
file contains the data.  
aria\_chk  
takes one or more  
.MAI  
files as arguments.

The following groups are read from the my.cnf files:

- [maria\_chk]
- [aria\_chk]

## Options and Variables

### Global Options

The following options to handle option files may be given as the first argument:

| Option                      | Description                                      |
|-----------------------------|--------------------------------------------------|
| --<br>print-defaults        | Print the program argument list and exit.        |
| --<br>no-defaults           | Don't read default options from any option file. |
| --<br>defaults-file=#       | Only read default options from the given file #. |
| --<br>defaults-extra-file=# | Read this file after the global files are read.  |

### Main Arguments

| Option | Description |
|--------|-------------|
|--------|-------------|

|                                |                                                                                                       |
|--------------------------------|-------------------------------------------------------------------------------------------------------|
| -<br>#<br>,                    | Output debug log. Often this is 'd:o,filename'.                                                       |
| --<br>debug=...                |                                                                                                       |
| -H<br>,                        | Display this help and exit.                                                                           |
| --<br>HELP                     |                                                                                                       |
| -?<br>,                        | Display this help and exit.                                                                           |
| --<br>help                     |                                                                                                       |
| --<br>datadir=path             | Path for control file (and logs if<br>--logdir<br>not used).                                          |
| --<br>ignore-<br>control-file  | Don't open the control file. Only use this if you are sure the tables are not used by another program |
| --<br>logdir=path              | Path for log files.                                                                                   |
| --<br>require-<br>control-file | Abort if we can't find/read the maria_log_control file                                                |
| -s<br>,                        | Only print errors. One can use two -s to make aria_chk very silent.                                   |
| --<br>silent                   |                                                                                                       |

|                       |                                                                                                                                                                    |
|-----------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| -t<br>,               | Path for temporary files. Multiple paths can be specified, separated by colon (:) on Unix or semicolon (;) on Windows. They will be used in a round-robin fashion. |
| --<br><br>tmpdir=path |                                                                                                                                                                    |
| -v<br>,               | Print more information. This can be used with<br>--description<br>and<br>--check<br>. Use many -v for more verbosity.                                              |
| --<br><br>verbose     |                                                                                                                                                                    |
| -V<br>,               | Print version and exit.                                                                                                                                            |
| --<br><br>version     |                                                                                                                                                                    |
| -w<br>,               | Wait if table is locked.                                                                                                                                           |
| --<br><br>wait        |                                                                                                                                                                    |

### Check Options (--check is the Default Action for aria\_chk):

| Option                 | Description                                                                                                                                                  |
|------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------|
| -c<br>,                | Check table for errors.                                                                                                                                      |
| --<br><br>check        |                                                                                                                                                              |
| -e<br>,                | Check the table VERY thoroughly. Only use this in extreme cases as aria_chk should normally be able to find out if the table is ok even without this switch. |
| --<br><br>extend-check |                                                                                                                                                              |

|                              |                                                                                                                          |
|------------------------------|--------------------------------------------------------------------------------------------------------------------------|
| -F<br>,                      | Check only tables that haven't been closed properly.                                                                     |
| --<br>fast                   |                                                                                                                          |
| -C<br>,                      | Check only tables that have changed since last check.                                                                    |
| --<br>check-only-<br>changed |                                                                                                                          |
| -f<br>,                      | Restart with '<br>-r<br>' if there are any errors in the table. States will be updated as with '<br>--update-state<br>'. |
| --<br>force                  |                                                                                                                          |
| -i<br>,                      | Print statistics information about table that is checked.                                                                |
| --<br>information            |                                                                                                                          |
| -m<br>,                      | Faster than extend-check, and finds 99.99% of all errors. Should be good enough for most cases.                          |
| --<br>medium-check           |                                                                                                                          |

|         |                                                                                                                                                                                                                                                                                                                                                                     |
|---------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| -U<br>, | Mark tables as crashed if any errors were found and clean if check didn't find any errors but table was marked as 'not clean' before. This allows one to get rid of warnings like 'table not properly closed'. If table was updated, update also the timestamp for when the check was made. This option is on by default! Use<br>--skip-update-state<br>to disable. |
| -T<br>, | Don't mark table as checked.                                                                                                                                                                                                                                                                                                                                        |

### Recover (Repair) Options (When Using '--recover' or '--safe-recover'):

| Option                           | Description                                                                                                                                                       |
|----------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| -B<br>,                          |                                                                                                                                                                   |
| --<br>backup                     | Make a backup of the .MAD file as 'filename-time.BAK'.                                                                                                            |
| --<br>correct-<br>checksum       | Correct checksum information for table.                                                                                                                           |
| -D<br>,                          |                                                                                                                                                                   |
| --<br>data-file-<br>length=<br># | Max length of data file (when recreating data file when it's full).                                                                                               |
| -e<br>,                          |                                                                                                                                                                   |
| --<br>extend-check               | Try to recover every possible row from the data file. Normally this will also find a lot of garbage rows; Don't use this option if you are not totally desperate. |

|         |                                                  |                                                                                                                                 |
|---------|--------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------|
|         | <code>-f</code><br>,--<br><b>force</b>           | Overwrite old temporary files.                                                                                                  |
|         | <code>-k</code><br>,--<br><b>keys-used=</b><br># | Tell MARIA to update only some specific keys. # is a bit mask of which keys to use. This can be used to get faster inserts.     |
| length= | --<br><b>max-record-</b><br>#                    | Skip rows bigger than this if aria_chk can't allocate memory to hold it.                                                        |
|         | <code>-r</code><br>,--<br><b>recover</b>         | Can fix almost anything except unique keys that aren't unique.                                                                  |
|         | <code>-n</code><br>,--<br><b>sort-recover</b>    | Forces recovering with sorting even if the temporary file would be very big.                                                    |
| recover | <code>-p</code><br>,--<br><b>parallel-</b>       | Uses the same technique as '-r' and '-n', but creates all the keys in parallel, in different threads.                           |
|         | <code>-o</code><br>,--<br><b>safe-recover</b>    | Uses old recovery method; Slower than '-r' but can handle a couple of cases where '-r' reports that it can't fix the data file. |

|                                  |                                                                                                                                                                                                                                              |
|----------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| --<br>transaction-<br>log        | Log repair command to transaction log. This is needed if one wants to use the maria_read_log to repeat the repair.                                                                                                                           |
| --<br>character-<br>sets-dir=... | Directory where character sets are.                                                                                                                                                                                                          |
| --<br>set-<br>collation=name     | Change the collation used by the index.                                                                                                                                                                                                      |
| -q<br>,<br>--<br>quick           | Faster repair by not modifying the data file. One can give a second '<br>-q<br>' to force aria_chk to modify the original datafile in case of duplicate keys. NOTE: Tables where the data file is corrupted can't be fixed with this option. |
| -u<br>,<br>--<br>unpack          | Unpack file packed with <a href="#">aria_pack</a> .                                                                                                                                                                                          |

## Other Options

| Option                       | Description                                                                                                                                                                             |
|------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| -a<br>,<br>--<br>analyze     | Analyze distribution of keys. Will make some joins in MariaDB faster. You can check the calculated distribution by using '<br>--description --verbose table_name<br>'                   |
| --<br>stats_method=name      | Specifies how index statistics collection code should treat NULLs. Possible values of name are "nulls_unequal" (default for 4.1/5.0), "nulls_equal" (emulate 4.0), and "nulls_ignored". |
| -d<br>,<br>--<br>description | Prints some information about table.                                                                                                                                                    |

|                                  |                                                                                                                                                                                                                                                                                                                                      |
|----------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| -A<br>,                          |                                                                                                                                                                                                                                                                                                                                      |
| --set-<br>auto-increment[=value] | Force auto_increment to start at this or higher value If no value is given, then sets the next auto_increment value to the highest used value for the auto key + 1.                                                                                                                                                                  |
| -S<br>,                          |                                                                                                                                                                                                                                                                                                                                      |
| --sort-index                     | Sort index blocks. This speeds up 'read-next' in applications.                                                                                                                                                                                                                                                                       |
| -R<br>,                          |                                                                                                                                                                                                                                                                                                                                      |
| --sort-<br>records=              | Sort records according to an index. This makes your data much more localized and may speed up things (It may be VERY slow to do a sort the first time!).                                                                                                                                                                             |
| #                                |                                                                                                                                                                                                                                                                                                                                      |
| -b<br>,                          |                                                                                                                                                                                                                                                                                                                                      |
| --block-search=                  | Find a record, a block at given offset belongs to.                                                                                                                                                                                                                                                                                   |
| #                                |                                                                                                                                                                                                                                                                                                                                      |
| -z<br>,                          |                                                                                                                                                                                                                                                                                                                                      |
| --zerofill                       | Remove transaction id's from the data and index files and fills empty space in the data and index files with zeroes. Zerofilling makes it possible to move the table from one system to another without the server having to do an automatic zerofill. It also allows one to compress the tables better if one want to archive them. |
| --zerofill-keep-lsn              | Like<br>--zerofill<br>but does not zero out LSN of data/index pages.                                                                                                                                                                                                                                                                 |

## Variables

| Option           | Description                                   |
|------------------|-----------------------------------------------|
| page_buffer_size | Size of page buffer. Used by<br>--safe-repair |

|                   |                                                                                          |
|-------------------|------------------------------------------------------------------------------------------|
| read_buffer_size  | Read buffer size for sequential reads during scanning                                    |
| write_buffer_size | Write buffer size for sequential writes during repair of fixed size or dynamic size rows |
| sort_buffer_size  | Size of sort buffer. Used by<br>--recover                                                |
| sort_key_blocks   | Internal buffer for sorting keys; Don't touch :)                                         |

## Usage

One main usage of

`aria_chk`

is when you want to do a fast check of all Aria tables in your system. This is faster than doing it in MariaDB as you can allocate all free memory to the buffers.

Assuming you have a bit more than 2G free memory.

The following commands, run in the MariaDB data directory, check all your tables and repairs only those that have an error:

```
aria_chk --check --sort_order --force --sort_buffer_size=1G */*.MAI
```

If you want to optimize all your tables: (The

`--zerofill`

is used here to fill up empty space with

`\0`

which can speed up compressed backups).

```
aria_chk --analyze --sort-index --page_buffer_size=1G --zerofill */*.MAI
```

In case you have a serious problem and have to use

`--safe-recover`

:

```
aria_chk --safe-recover --zerofill --page_buffer_size=2G */*.MAI
```

## 4.3.4.2.2 aria\_pack

### Contents

1. [Options](#)
2. [Unpacking](#)
3. [Example](#)
4. [See Also](#)

`aria_pack` is a tool for compressing [Aria](#) tables. The resulting table are read-only, and usually about 40% to 70% smaller.

`aria_pack` is run as follows

```
aria_pack [options] file_name [file_name2...]
```

The file name is the .MAI index file. The extension can be omitted, although keeping it permits wildcards, such as

```
aria_pack *.MAI
```

to compress all the files.

`aria_pack` compresses each column separately, and, when the resulting data is read, only the individual rows and columns required need to be decompressed, allowing for quicker reading.

Once a table has been packed, use `aria_chk -rq` (the quick and recover options) to rebuild its indexes.

## Options

The following variables can be set while passed as commandline options to aria\_pack, or set in the [ariapack] section in your [my.cnf](#) file.

| Option                    | Description                                                                                      |
|---------------------------|--------------------------------------------------------------------------------------------------|
| -b, --backup              | Make a backup of the table as table_name.OLD.                                                    |
| --character-sets-dir=name | Directory where character sets are.                                                              |
| -h, --datadir             | Path for control file (and logs if<br>--logdir<br>not used). From <a href="#">MariaDB 10.5.3</a> |
| -#, --debug[=name]        | Output debug log. Often this is 'd:t:o,filename'.                                                |
| -?, --help                | Display help and exit.                                                                           |
| -f, --force               | Force packing of table even if it gets bigger or if tempfile exists.                             |
| --ignore-control-file     | Ignore the control file. From <a href="#">MariaDB 10.5.3</a> .                                   |
| -j, --join=name           | Join all given tables into 'new_table_name'. All tables MUST have identical layouts.             |
| --require-control-file    | Abort if cannot find control file. From <a href="#">MariaDB 10.5.3</a> .                         |
| -s, --silent              | Only write output when an error occurs.                                                          |
| -t, --test                | Don't pack table, only test packing it.                                                          |
| -T, --tmpdir=name         | Use temporary directory to store temporary table.                                                |
| -v, --verbose             | Write info about progress and packing result. Use many -v for more verbosity!                    |
| -V, --version             | Output version information and exit.                                                             |
| -w, --wait                | Wait and retry if table is in use.                                                               |

## Unpacking

To unpack a table compressed with aria\_pack, use the [aria\\_chk -u](#) option.

## Example

```
> aria_pack /my/data/test/posts
Compressing /my/data/test/posts.MAD: (1690 records)
- Calculating statistics
- Compressing file
37.71%
> aria_chk -rq --ignore-control-file /my/data/test/posts
- check record delete-chain
- recovering (with keycache) Aria-table '/my/data/test/posts'
Data records: 1690
State updated
```

## See Also

- [FLUSH TABLES FOR EXPORT](#)
- [myisamchk](#)

### 4.3.4.2.3 aria\_read\_log

[aria\\_read\\_log](#) is a tool for displaying and applying log records from an [Aria](#) transaction log.

Note: Aria is compiled without -DIDENTICAL\_PAGES\_AFTER\_RECOVERY which means that the table files are not byte-to-byte identical to files created during normal execution. This should be ok, except for test scripts that try to compare files before and after recovery.

Usage:

```
aria_read_log OPTIONS
```

You need to use one of

-d  
or  
-a  
.

# Options

The following variables can be set while passed as commandline options to aria\_read\_log, or set in the

[aria\_read\_log]  
section in your [my.cnf](#) file.

| Option                       | Description                                                                                                                   |
|------------------------------|-------------------------------------------------------------------------------------------------------------------------------|
| -a, --apply                  | Apply log to tables: modifies tables! you should make a backup first! Displays a lot of information if not run with --silent. |
| --character-sets-dir=name    | Directory where character sets are.                                                                                           |
| -c, --check                  | if --display-only, check if record is fully readable (for debugging).                                                         |
| -?, --help                   | Display help and exit.                                                                                                        |
| -d, --display-only           | Display brief info read from records' header.                                                                                 |
| -e, --end-lsn=#              | Stop applying at this lsn. If end-lsn is used, UNDO:s will not be applied                                                     |
| -h, --aria-log-dir-path=name | Path to the directory where to store transactional log                                                                        |
| -P, --page-buffer-size=#     | The size of the buffer used for index blocks for Aria tables.                                                                 |
| -l, --print-log-control-file | Print the content of the aria_log_control_file. From <a href="#">MariaDB 10.4.1</a> .                                         |
| -o, --start-from-lsn=#       | Start reading log from this lsn.                                                                                              |
| -C, --start-from-checkpoint  | Start applying from last checkpoint.                                                                                          |
| -s, --silent                 | Print less information during apply/undo phase.                                                                               |
| -T, --tables-to-redo=name    | List of comma-separated tables that we should apply REDO on. Use this if you only want to recover some tables.                |
| -t, --tmpdir=name            | Path for temporary files. Multiple paths can be specified, separated by colon (:)                                             |
| --translog-buffer-size=#     | The size of the buffer used for transaction log for Aria tables.                                                              |
| -u, --undo                   | Apply UNDO records to tables. (disable with --disable-undo) (Defaults to on; use --skip-undo to disable.)                     |
| -v, --verbose                | Print more information during apply/undo phase.                                                                               |
| -V, --version                | Print version and exit.                                                                                                       |

## 4.3.4.2.4 aria\_s3\_copy

MariaDB starting with [10.5](#)

The [S3 storage engine](#) has been available since [MariaDB 10.5.4](#).

`aria_s3_copy`  
is a tool for copying an [Aria](#) table to and from [S3](#).

The Aria table must be non transactional and have [ROW\\_FORMAT=PAGE](#).

For

`aria_s3_copy`

to work reliably, the table should not be changed by the MariaDB server during the copy, and one should have first performed [FLUSH TABLES](#) to ensure that the table is properly closed.

Example of properly created Aria table:

```
create table test1 (a int) transactional=0 row_format=PAGE engine=aria;
```

Note that [ALTER TABLE table\\_name ENGINE=S3](#) will work for any kind of table. This internally converts the table to an Aria table and then moves it to S3 storage.

## Main Arguments

| Option                   | Description                 |
|--------------------------|-----------------------------|
| -?, --help               | Display this help and exit. |
| -k, --s3-access-key=name | AWS access key ID           |
| -r, --s3-region=name     | AWS region                  |
| -K, --s3-secret-key=name | AWS secret access key ID    |

|                                |                                                                                                  |
|--------------------------------|--------------------------------------------------------------------------------------------------|
| -b, --s3-bucket=name           | AWS prefix for tables                                                                            |
| -h, --s3-host-name=name        | Host name to S3 provider                                                                         |
| -c, --compress                 | Use compression                                                                                  |
| -o, --op=name                  | Operation to execute. One of 'from_s3', 'to_s3' or 'delete_from_s3'                              |
| -d, --database=name            | Database for copied table (second prefix). If not given, the directory of the table file is used |
| -B, --s3-block-size=#          | Block size for data/index blocks in s3                                                           |
| -L, --s3-protocol-version=name | Protocol used to communication with S3. One of "Amazon" or "Original".                           |
| -f, --force                    | Force copy even if target exists                                                                 |
| -v, --verbose                  | Write more information                                                                           |
| -V, --version                  | Print version and exit.                                                                          |
| #, --debug[=name]              | Output debug log. Often this is 'd:to,filename'.                                                 |
| --s3-debug                     | Output debug log from marias3 to stdout                                                          |

## Typical Configuration in a my.cnf File

```
[aria_s3_copy]
s3-bucket=mariadb
s3-access-key=xxxx
s3-secret-key=xxx
s3-region=eu-north-1
#s3-host-name=s3.amazonaws.com
#s3-protocol-version=Amazon
verbose=1
op=to
```

## Example Usage

The following code will copy an existing Aria table named

```
test1
to S3. If the
--database
option is not given, then the directory name where the table files exist will be used as the database.
```

```
shell> aria_s3_copy --force --op=to --database=foo --compress --verbose --s3_block_size=4M test1
Delete of aria table: foo.test1
Delete of index information foo/test1/index
Delete of data information foo/test1/data
Delete of base information and frm
Copying frm file test1.frm
Copying aria table: foo.test1 to s3
Creating aria table information foo/test1/aria
Copying index information foo/test1/index
.
Copying data information foo/test1/data
```

When using

```
--verbose
,
aria_s3_copy
will write a dot for each #/79 part of the file copied.
```

## See Also

[Using the S3 storage engine](#) . This pages has examples of .my.cnf entries for using

```
aria_s3_copy
```

## 4.3.4.3 Aria FAQ

This FAQ provides information on the [Aria](#) storage engine.

The **Aria** storage engine was previously known as **Maria** , (see, the [Aria Name](#) ). In current releases of **MariaDB** , you can refer to the engine as Maria or Aria. As this will change in future releases, please update references in your scripts and automation to use the correct name.

## What is Aria?

Aria is a storage engine for MySQL ® and MariaDB. It was originally developed with the goal of becoming the default transactional **and** non-transactional storage engine for MariaDB and MySQL.

It has been in development since 2007 and was first announced on Monty's [blog](#) . The same core MySQL engineers who developed the MySQL server and the [MyISAM](#) , [MERGE](#) , and [MEMORY](#) storage engines are also working on Aria.

## Why is the engine called Aria?

Originally, the storage engine was called **Maria** , after Monty's younger daughter. Monty named MySQL after his first child, **My** and his second child **Max** gave his name to MaxDB and the MySQL-Max distributions.

In practice, having both *MariaDB* the database server and *Maria* the storage engine with such similar names proved confusing. To mitigate this, the decision was made to change the name. A Rename Maria contest was held during the first half of 2010 and names were submitted from around the world. Monty picked the name **Aria** from a short list of finalist. Chris Tooley, who suggested it, received the prize of a Linux-powered [System 76 Meerkat NetTop](#) from Monty Program.

For more information, see the [Aria Name](#) .

## What's the goal for the current version?

The current version of Aria is 1.5. The goal of this release is to develop a crash-safe alternative to MyISAM. That is, when MariaDB restarts after a crash, Aria recovers all tables to the state as of the start of a statement or at the start of the last

LOCK TABLES  
statement.

The current goal is to keep the code stable and fix all bugs.

# What's the goal for the next version?

The next version of Aria is 2.0. The goal for this release is to develop a fully transactional storage engine with at least all the major features of InnoDB.

Currently, Aria 2.0 is on hold as its developers are focusing on improving MariaDB. However, they are interested in working with interested customers and partners to add more features to Aria and eventually release 2.0.

These are some of the goals for Aria 2.0:

- ACID compliant
- Commit/Rollback
- Concurrent updates/deletes
- Row locking
- Group commit (Already in [MariaDB 5.2](#) )
- Faster lookup in index pages (Page directory)

Beginning in Aria 2.5, the plan is to focus on improving performance.

# What is the ultimate goal of Aria?

Long term, we have the following goals for Aria:

- To create a new, ACID and Multi-Version Concurrency Control (MVCC), transactional storage engine that can function as both the default non-transactional and transactional storage engine for MariaDB and MySQL ® .
- To be a MyISAM replacement. This is possible because Aria can also be run in non-transactional mode, supports the same row formats as MyISAM, and supports or will support all major features of MyISAM.
- To be the default non-transactional engine in MariaDB (instead of MyISAM).

# What are the design goals in Aria?

- Multi-Version Concurrency Control (MVCC) and ACID storage engine.
- Optionally non-transactional tables that should be 'as fast and as compact' as MyISAM tables.
- Be able to use Aria for internal temporary tables in MariaDB (instead of MyISAM).
- All indexes should have equal speed (clustered index is not on our current road map for Aria. If you need clustered index, you should use XtraDB).
- Allow 'any' length transactions to work (Having long running transactions will cause more log space to be used).
- Allow log shipping; that is, you can do incremental backups of Aria tables just by copying the Aria logs.
- Allow copying of Aria tables between different Aria servers (under some well-defined constraints).
- Better blob handling (than is currently offered in MyISAM, at a minimum).
- No memory copying or extra memory used for blobs on insert/update.
- Blobs allocated in big sequential blocks - Less fragmentation over time.
- Blobs are stored so that Aria can easily be extended to have access to any part of a blob with a single fetch in the future.
- Efficient storage on disk (that is, low row data overhead, low page data overhead and little lost space on pages). Note: There is still some more work to succeed with this goal. The disk layout is fine, but we need more in-memory caches to ensure that we get a higher fill factor on the pages.
- Small footprint, to make MariaDB + Aria suitable for desktop and embedded applications.
- Flexible memory allocation and scalable algorithms to utilize large amounts of memory efficiently, when it is available.

# Where can I find documentation and help about Aria?

Documentation is available at [Aria](#) and related topics. The project is maintained on [GitHub](#) .

If you want to know what happens or be part of developing Aria, you can subscribe to the [maria-developers](#) , [maria-docs](#) , or [maria-discuss](#) groups on Launchpad.

To report and check bugs in Aria, see [Reporting Bugs](#) .

You can usually find some of the Maria developers on our Zulip instance at <https://mariadb.zulipchat.com> or on the IRC channel #maria at <https://libera.chat/> .

# Who develops Aria?

The Core Team who develop Aria are:

## Technical lead

- Michael "Monty" Widenius - Creator of MySQL and MyISAM

## Core Developers (in alphabetical order)

- Guilhem Bichot - Replication expert, on line backup for MyISAM, etc.
- Kristian Nielsen - MySQL build tools, NDB, MySQL server
- Oleksandr Byelkin - Query cache, sub-queries, views.
- Sergei Golubchik - Server Architect, Full text search, keys for MyISAM-Merge, Plugin architecture, etc.

All except Guilhem Bichot are working for [MariaDB Corporation Ab](#) .

# What is the release policy/schedule of Aria?

Aria follows the same [release criteria](#) as for [MariaDB](#). Some clarifications, unique for the Aria storage engine:

- Aria index and data file formats should be backwards and forwards compatible to ensure easy upgrades and downgrades.
- The log file format should also be compatible, but we don't make any guarantees yet. In some cases when upgrading, you must remove the old `aria_log.%`  
and  
`maria_log.%`  
files before restarting MariaDB. (So far, this has only occurred in the upgrade from [MariaDB 5.1](#) and [MariaDB 5.2](#)).

## Extended commitment for Beta 1.5

- Aria is now feature complete according to specification.

## How does Aria 1.5 Compare to MyISAM?

Aria 1.0 was basically a crash-safe non-transactional version of MyISAM. Aria 1.5 added more concurrency (multiple inserter) and some optimizations.

Aria supports all aspects of MyISAM, except as noted below. This includes external and internal check/repair/compressing of rows, different row formats, different index compress formats,

`aria_chk`

etc. After a normal shutdown you can copy Aria files between servers.

## Advantages of Aria compared to MyISAM

- Data and indexes are crash safe.
- On a crash, changes will be rolled back to state of the start of a statement or a last `LOCK TABLES`  
statement.
- Aria can replay almost everything from the log. (Including

`CREATE`

,

`DROP`

,

`RENAME`

,

`TRUNCATE`

tables). Therefore, you make a backup of Aria by just copying the log. The things that can't be replayed (yet) are:

- Batch

`INSERT`

into an empty table (This includes  
`LOAD DATA INFILE`

,

`SELECT... INSERT`  
and

`INSERT`

(many rows)).

- 

`ALTER TABLE`

. Note that  
.frm

tables are NOT recreated!

- 

`LOAD INDEX`

can skip index blocks for unwanted indexes.

- Supports all MyISAM

`ROW`

formats and new

`PAGE`

format where data is stored in pages. (default size is 8K).

- Multiple concurrent inserters into the same table.

- When using

`PAGE`

format (default) row data is cached by page cache.

- Aria has unit tests of most parts.

- Supports both crash-safe (soon to be transactional) and not transactional tables. (Non-transactional tables are not logged and rows uses less space):

- CREATE TABLE foo (...) TRANSACTIONAL=0|1 ENGINE=Aria
- PAGE  
is the only crash-safe/transactional row format.
- PAGE  
format should give a notable speed improvement on systems which have bad data caching. (For example Windows).
- From MariaDB 10.5, max key length is 2000 bytes, compared to 1000 bytes in MyISAM.

## Differences between Aria and MyISAM

- Aria uses BIG (1G by default) log files.
- Aria has a log control file (
 

```
aria_log_control
```

 ) and log files (
 

```
aria_log.%
```

 ). The log files can be automatically purged when not needed or purged on demand (after backup).
- Aria uses 8K pages by default (MyISAM uses 1K). This makes Aria a bit faster when using keys of fixed size, but slower when using variable-length packed keys (until we add a directory to index pages).

## Disadvantages of Aria compared to MyISAM

- Aria doesn't support
 

```
INSERT DELAYED
```
- Aria does not support multiple key caches.
- Storage of very small rows (< 25 bytes) are not efficient for
 

```
PAGE
```

 format.
- MERGE  
tables don't support Aria (should be very easy to add later).
- Aria data pages in block format have an overhead of 10 bytes/page and 5 bytes/row. Transaction and multiple concurrent-writer support will use an extra overhead of 7 bytes for new rows, 14 bytes for deleted rows and 0 bytes for old compacted rows.
- No external locking (MyISAM has external locking, but this is a rarely used feature).
- Aria has one page size for both index and data (defined when Aria is used the first time). MyISAM supports different page sizes per index.
- Small overhead (15 bytes) per index page.
- Aria doesn't support MySQL internal RAID (disabled in MyISAM too, it's a deprecated feature).
- Minimum data file size for PAGE format is 16K (with 8K pages).
- Aria doesn't support indexes on virtual fields.

## Differences between MariaDB 5.1 release and the normal MySQL-5.1 release?

See:

- [Aria storage engine](#)
- [MariaDB versus MySQL](#)

## Why do you use the TRANSACTIONAL keyword now when Aria is not yet transactional?

In the current development phase Aria tables created with

```
TRANSACTIONAL=1
are crash safe and atomic but not transactional because changes in Aria tables can't be rolled back with the
ROLLBACK
command. As we planned to make Aria tables fully transactional, we decided it was better to use the
TRANSACTIONAL
keyword from the start so that applications don't need to be changed later.
```

## What are the known problems with the MySQL-5.1-Maria release?

- See
 

```
KNOWN_BUGS.txt
```

 for open/design bugs.

- See jira.mariadb.org for newly reported bugs. Please report anything you can't find here!
- If there is a bug in the Aria recovery code or in the code that generates the logs, or if the logs become corrupted, then mysqld may fail to start because Aria can't execute the logs at start up.
- Query cache and concurrent insert using page row format have a bug, please disable query cache while using page row format and [MDEV-6817](#) isn't complete

If Aria doesn't start or you have an unrecoverable table (shouldn't happen):

- Remove the `aria_log.%` files from the data directory.

- Restart `mysqld` and run

[CHECK TABLE](#)

,

[REPAIR TABLE](#)

or

`mysqlcheck`

on your Aria tables.

Alternatively,

- Remove logs and run

`aria_chk`

on your `*.MAI` files.

## What is going to change in later Aria main releases?

The

`LOCK TABLES`  
statement will not start a crash-safe segment. You should use

`BEGIN`

and

`COMMIT`

instead.

To make things future safe, you could do this:

```
BEGIN;
LOCK TABLES ....
UNLOCK TABLES;
COMMIT;
```

And later you can just remove the

`LOCK TABLES`  
and  
`UNLOCK TABLES`  
statements.

## How can I create a MyISAM-like (non-transactional) table in Aria?

Example:

```
CREATE TABLE t1 (a int) ROW_FORMAT=FIXED TRANSACTIONAL=0 PAGE_CHECKSUM=0;
CREATE TABLE t2 (a int) ROW_FORMAT=DYNAMIC TRANSACTIONAL=0 PAGE_CHECKSUM=0;
SHOW CREATE TABLE t1;
SHOW CREATE TABLE t2;
```

Note that the rows are not cached in the page cache for

FIXED

or

DYNAMIC

format. If you want to have the data cached (something MyISAM doesn't support) you should use

ROW\_FORMAT=PAGE

:

```
CREATE TABLE t3 (a int) ROW_FORMAT=PAGE TRANSACTIONAL=0 PAGE_CHECKSUM=0;
SHOW CREATE TABLE t3;
```

You can use

PAGE\_CHECKSUM=1

also for non-transactional tables; This puts a page checksums on all index pages. It also puts a checksum on data pages if you use  
ROW\_FORMAT=PAGE

You may still have a speed difference (may be slightly positive or negative) between MyISAM and Aria because of different page sizes. You can change the page size for MariaDB with

```
--aria-block-size=\n#, where\n\\# is 1024, 2048, 4096, 8192, 16384 or 32768.
```

Note that if you change the page size you have to dump all your old tables into text (with

mysqldump

) and remove the old Aria log and files:

```
# rm datadir/aria_log*
```

## What are the advantages/disadvantages of the new PAGE format compared to the old MyISAM-like row formats ( DYNAMIC and FIXED )

The MyISAM-like

DYNAMIC

and

FIXED

format are extremely simple and have very little space overhead, so it's hard to beat them for when it comes to simple scanning of unmodified data. The

DYNAMIC

format does however get notably worse over time if you update the row a lot in a manner that increases the size of the row.

The advantages of the

PAGE

format (compared to

DYNAMIC

or

FIXED

) for non-transactional tables are:

- It's cached by the Page Cache, which gives better random performance (as it uses less system calls).
- Does not fragment as easily as the

DYNAMIC

format during

UPDATE

statements. The maximum number of fragments are very low.

- Code can easily be extended to only read the accessed columns (for example to skip reading blobs).
- Faster updates (compared to

DYNAMIC

).

The disadvantages are:

- Slight storage overhead (should only be notable for very small row sizes)
- Slower full table scan time.
- When using

```
row_format=PAGE
, (the default), Aria first writes the row, then the keys, at which point the check for duplicate keys happens. This makes
PAGE
format slower than
DYNAMIC
(or MyISAM) if there is a lot of duplicated keys because of the overhead of writing and removing the row. If this is a problem, you can use
row_format=DYNAMIC
to get same behavior as MyISAM.
```

## What's the proper way to copy a Aria table from one place to another?

An Aria table consists of 3 files:

```
XXX.frm : The definition for the table, used by MySQL.
XXX.MYI : Aria internal information about the structure of the data and index and data for all indexes.
XXX.MAD : The data.
```

It's safe to copy all the Aria files to another directory or MariaDB instance if any of the following holds:

- If you shutdown the MariaDB Server properly with

```
mysqladmin shutdown
```

, so that there is nothing for Aria to recover when it starts.

or

- If you have run a

```
FLUSH TABLES
```

statement and not accessed the table using SQL from that time until the tables have been copied.

In addition, you must adhere the following rule for transactional tables:

You can't copy the table to a location within the same MariaDB server if the new table has existed before and the new table is still active in the Aria recovery log (that is, Aria may need to access the old data during recovery). If you are unsure whether the old name existed, run

```
aria_chk --zerofill
```

on the table before you use it.

After copying a transactional table and before you use the table, we recommend that you run the command:

```
$ aria_chk --zerofill table_name
```

This will overwrite all references to the logs (LSN), all transactional references (TRN) and all unused space with 0. It also marks the table as 'movable'. An additional benefit of zerofill is that the Aria files will compress better. No real data is ever removed as part of zerofill.

Aria will automatically notice if you have copied a table from another system and do 'zerofill' for the first access of the table if it was not marked as 'movable'. The reason for using

```
aria_chk --zerofill
```

is that you avoid a delay in the MariaDB server for the first access of the table.

Note that this automatic detection doesn't work if you copy tables within the same MariaDB server!

## When is it safe to remove old log files?

If you want to remove the Aria log files (

```
aria_log.%
) with
rm
or delete, then you must first shut down MariaDB cleanly (for example, with
```

```
mysqladmin shutdown
```

) before deleting the old files.

The same rules apply when upgrading MariaDB; When upgrading, first take down MariaDB in a clean way and then upgrade. This will allow you to remove the old log files if there are incompatible problems between releases.

Don't remove the

`aria_log_control`

file! This is not a log file, but a file that contains information about the Aria setup (current transaction id, unique id, next log file number etc.).

If you do, Aria will generate a new

`aria_log_control`

file at startup and will regard all old Aria files as files moved from another system. This means that they have to be 'zerofilled' before they can be used. This will happen automatically at next access of the Aria files, which can take some time if the files are big.

If this happens, you will see things like this in your mysqld.err file:

```
[Note] Zerofilling moved table: '.\database\xxxx'
```

As part of zerofilling no vital data is removed.

## 4.3.4.4 Aria Storage Formats

### Contents

1. [Fixed-length](#)
2. [Dynamic](#)
3. [Page](#)
4. [Transactional](#)

The [Aria](#) storage engine supports three different table storage formats.

These are FIXED, DYNAMIC and PAGE, and they can be set with the ROW FORMAT option in the [CREATE TABLE](#) statement. PAGE is the default format, while FIXED and DYNAMIC are essentially the same as the [MyISAM formats](#).

The [SHOW TABLE STATUS](#) statement can be used to see the storage format used by a table.

### Fixed-length

Fixed-length (or static) tables contain records of a fixed-length. Each column is the same length for all records, regardless of the actual contents. It is the default format if a table has no BLOB, TEXT, VARCHAR or VARBINARY fields, and no ROW FORMAT is provided. You can also specify a fixed table with ROW\_FORMAT=FIXED in the table definition.

Tables containing BLOB or TEXT fields cannot be FIXED, as by design these are both dynamic fields.

Fixed-length tables have a number of characteristics

- fast, since MariaDB will always know where a record begins
- easy to cache
- take up more space than dynamic tables, as the maximum amount of storage space will be allocated to each record.
- reconstructing after a crash is uncomplicated due to the fixed positions
- no fragmentation or need to re-organize, unless records have been deleted and you want to free the space up.

### Dynamic

Dynamic tables contain records of a variable length. It is the default format if a table has any BLOB, TEXT, VARCHAR or VARBINARY fields, and no ROW FORMAT is provided. You can also specify a DYNAMIC table with ROW\_FORMAT=DYNAMIC in the table definition.

Dynamic tables have a number of characteristics

- Each row contains a header indicating the length of the row.
- Rows tend to become fragmented easily. UPDATING a record to be longer will likely ensure it is stored in different places on the disk.
- All string columns with a length of four or more are dynamic.
- They require much less space than fixed-length tables.
- Restoring after a crash is more complicated than with FIXED tables.

### Page

Page format is the default format for Aria tables, and is the only format that can be used if TRANSACTIONAL=1.

Page tables have a number of characteristics:

- It's cached by the page cache, which gives better random performance as it uses fewer system calls.
- Does not fragment as easily as the DYNAMIC format during UPDATES. The maximum number of fragments are very low.
- Updates more quickly than dynamic tables.

- Has a slight storage overhead, mainly notable on very small rows
- Slower to perform a full table scan
- Slower if there are multiple duplicated keys, as Aria will first write a row, then keys, and only then check for duplicates

## Transactional

See [Aria Storage Engine](#) for the impact of the TRANSACTIONAL option on the row format.

See [Server System Variables](#) for a complete list of system variables and instructions on setting system variables.

Also see the [Full list of MariaDB options, system and status variables](#).

### aria\_block\_size

- **Description:** Block size to be used for Aria index pages. Changing this requires dumping, deleting old tables and deleting all log files, and then restoring your Aria tables. If key lookups take too long (and one has to search roughly 8192/2 by default to find each key), can be made smaller, e.g.

2048  
or  
4096

- **Commandline:**

--aria-block-size=#

- **Scope:** Global
- **Dynamic:** No
- **Data Type:**

numeric

- **Default Value:**

8192

### aria\_checkpoint\_interval

- **Description:** Interval in seconds between automatic checkpoints. 0 means 'no automatic checkpoints' which makes sense only for testing.
- **Commandline:**

--aria-checkpoint-interval=#

- **Scope:** Global
- **Dynamic:** Yes
- **Data Type:**

numeric

- **Default Value:**

- **Range:**

```
0
to
4294967295
```

---

### `aria_checkpoint_log_activity`

- **Description:** Number of bytes that the transaction log has to grow between checkpoints before a new checkpoint is written to the log.
- **Commandline:**

```
aria-checkpoint-log-activity=#
```

- **Scope:** Global

- **Dynamic:** Yes

- **Data Type:**

```
numeric
```

- **Default Value:**

```
1048576
```

- **Range**

```
0
to
4294967295
```

---

### `aria_encrypt_tables`

- **Description:** Enables automatic encryption of all user-created Aria tables that have the

`ROW_FORMAT`

table option set to

`PAGE`

. See [Data at Rest Encryption](#) and [Enabling Encryption for User-created Tables](#) .

- **Commandline:**

```
aria-encrypt-tables={0|1}
```

- **Scope:** Global

- **Dynamic:** Yes

- **Data Type:**

```
boolean
```

- **Default Value:**

```
OFF
```

- **Introduced:** [MariaDB 10.1.3](#)

---

### `aria_force_start_after_recovery_failures`

- **Description:** Number of consecutive log recovery failures after which logs will be automatically deleted to cure the problem; 0 (the default) disables the feature.

- **Commandline:**

```
--aria-force-start-after-recovery-failures=#
```

- **Scope:** Global

- **Dynamic:** No

- **Data Type:**

numeric

- **Default Value:**

0

---

## aria\_group\_commit

- **Description:** Specifies Aria [group commit mode](#).

- **Commandline:**

--aria\_group\_commit="value"

- **Alias:**

maria\_group\_commit

- **Scope:** Global

- **Dynamic:** No

- **Data Type:**

string

- **Valid values:**

◦

none

- *Group commit is disabled.*

◦

hard

- *Wait the number of microseconds specified by aria\_group\_commit\_interval before actually doing the commit. If the interval is 0 then just check if any other threads have requested a commit during the time this commit was preparing (just before sync() file) and send their data to disk also before sync().*

◦

soft

- *The service thread will wait the specified time and then sync() to the log. If the interval is 0 then it won't wait for any commits (this is dangerous and should generally not be used in production)*

- **Default Value:**

none

---

## aria\_group\_commit\_interval

- **Description:** Interval between [Aria group commits](#) in microseconds (1/1000000 second) for other threads to come and do a commit in "hard" mode and sync()/commit at all in "soft" mode. Option only has effect if [aria\\_group\\_commit](#) is used.

- **Commandline:**

--aria\_group\_commit\_interval=#

- **Alias:**

maria\_group\_commit\_interval

- **Scope:** Global

- **Dynamic:** No

- **Type:** numeric

- **Valid Values:**

- **Default Value:**

0

(no waiting)

- **Range:**

0-4294967295

---

## aria\_log\_file\_size

- **Description:** Limit for Aria transaction log size

- **Commandline:**

```
--aria-log-file-size=#
```

- **Scope:** Global
  - **Dynamic:** Yes
  - **Data Type:**  
    numeric
  - **Default Value:**  
    1073741824
- 

### aria\_log\_purge\_type

- **Description:** Specifies how the Aria transactional log will be purged. Set to  
    at\_flush  
    to keep a copy of the transaction logs (good as an extra backup). The logs will stay until the next **FLUSH LOGS** ;

- **Commandline:**  
    --aria-log-purge-type=name

- **Scope:** Global
- **Dynamic:** Yes
- **Data Type:**  
    enumeration

- **Default Value:**  
    immediate

- **Valid Values:**  
    immediate  
    ,  
    external  
    ,  
    at\_flush
- 

### aria\_max\_sort\_file\_size

- **Description:** Don't use the fast sort index method to created index if the temporary file would get bigger than this.
- **Commandline:**  
    --aria-max-sort-file-size=#

- **Scope:** Global
- **Dynamic:** Yes
- **Data Type:**  
    numeric

- **Default Value:**  
    9223372036853727232

- **Range:**  
    0  
    to  
    9223372036854775807
- 

### aria\_page\_checksum

- **Description:** Determines whether index and data should use page checksums for extra safety. Can be overridden per table with **PAGE\_CHECKSUM** clause in **CREATE TABLE** .

- **Commandline:**  
    --aria-page-checksum=#

- **Scope:** Global
  - **Dynamic:** Yes
  - **Data Type:**  
boolean
- **Default Value:**  
ON
- 

### aria\_pagecache\_age\_threshold

- **Description:** This characterizes the number of hits a hot block has to be untouched until it is considered aged enough to be downgraded to a warm block. This specifies the percentage ratio of that number of hits to the total number of blocks in the page cache.
  - **Commandline:**  
--aria-pagecache-age-threshold=#
- **Scope:** Global
  - **Dynamic:** Yes
  - **Data Type:**  
numeric
- **Default Value:**  
300
- **Range:**  
100  
to  
9999900
- 

### aria\_pagecache\_buffer\_size

- **Description:** The size of the buffer used for index and data blocks for Aria tables. This can include explicit Aria tables, system tables, and temporary tables. Increase this to get better handling and measure by looking at [aria-status-variables/#aria\\_pagecache\\_reads](#) (should be small) vs [aria-status-variables/#aria\\_pagecache\\_read\\_requests](#) .
  - **Commandline:**  
--aria-pagecache-buffer-size=#
- **Scope:** Global
  - **Dynamic:** No
  - **Data Type:**  
numeric
- **Default Value:**  
134217720  
(128MB)
- **Range:**  
131072  
(128KB) upwards
- 

### aria\_pagecache\_division\_limit

- **Description:** The minimum percentage of warm blocks in the key cache.
  - **Commandline:**  
--aria-pagecache-division-limit=#
- **Scope:** Global
  - **Dynamic:** Yes
  - **Data Type:**  
numeric
- **Default Value:**

100

- **Range:**

1  
to  
100

---

## aria\_pagecache\_file\_hash\_size

- **Description:** Number of hash buckets for open and changed files. If you have many Aria files open you should increase this for faster flushing of changes. A good value is probably 1/10th of the number of possible open Aria files.

- **Commandline:**

--aria-pagecache-file-hash-size=#

- **Scope:** Global

- **Dynamic:** No

- **Data Type:**

numeric

- **Default Value:**

512

- **Range:**

128  
to  
16384

- **Introduced:** MariaDB 10.0.13
- 

## aria\_recover

- **Description:**

aria\_recover  
has been renamed to  
aria\_recover\_options  
in MariaDB 10.2.0 . See [aria\\_recover\\_options](#) for the description.

---

## aria\_recover\_options

- **Description:** Specifies how corrupted tables should be automatically repaired. More than one option can be specified, for example

FORCE, BACKUP

.

NORMAL  
: Normal automatic repair, the default until MariaDB 10.2.3

o

OFF  
: Autorecovery is disabled, the equivalent of not using the option

o

QUICK  
: Does not check rows in the table if there are no delete blocks.

o

FORCE  
: Runs the recovery even if it determines that more than one row from the data file will be lost.

o

BACKUP  
: Keeps a backup of the data files.

- **Commandline:**

--aria-recover-options[=#]

- **Scope:** Global

- **Dynamic:** Yes

- **Data Type:**  
enumeration

- **Default Value:**

- BACKUP, QUICK  
( $\geq$  MariaDB 10.2.4 )
- NORMAL  
( $\leq$  MariaDB 10.2.3 )

- **Valid Values:**

- NORMAL
- ,
- BACKUP
- ,
- FORCE
- ,
- QUICK
- ,
- OFF

- **Introduced:** MariaDB 10.2.0
- 

### aria\_repair\_threads

- **Description:** Number of threads to use when repairing Aria tables. The value of 1 disables parallel repair. Increasing from the default will usually result in faster repair, but will use more CPU and memory.

- **Commandline:**

- aria-repair-threads=#

- **Scope:** Global, Session

- **Dynamic:** Yes

- **Data Type:**

- numeric

- **Default Value:**

- 1

---

### aria\_sort\_buffer\_size

- **Description:** The buffer that is allocated when sorting the index when doing a [REPAIR](#) or when creating indexes with [CREATE INDEX](#) or [ALTER TABLE](#).

- **Commandline:**

- aria-sort-buffer-size=#

- **Scope:** Global, Session

- **Dynamic:** Yes

- **Data Type:**

- numeric

- **Default Value:**

- 268434432

- (from MariaDB 10.0.3 ),

- 134217728

- (before MariaDB 10.0.3 )

---

### aria\_stats\_method

- **Description:** Determines how NULLs are treated for Aria index statistics purposes. If set to

- nulls\_equal

- , all NULL index values are treated as a single group. This is usually fine, but if you have large numbers of NULLs the average group size

is slanted higher, and the optimizer may miss using the index for ref accesses when it would be useful. If set to

`nulls_unequal`

, the default, the opposite approach is taken, with each NULL forming its own group of one. Conversely, the average group size is slanted lower, and the optimizer may use the index for ref accesses when not suitable. Setting to

`nulls_ignored`

ignores NULLs altogether from index group calculations. Statistics need to be recalculated after this method is changed. See also [Index Statistics](#) , [myisam\\_stats\\_method](#) and [innodb\\_stats\\_method](#) .

- **Commandline:**

```
--aria-stats-method=#
```

- **Scope:** Global, Session

- **Dynamic:** Yes

- **Data Type:**

`numeric`

- **Default Value:**

`nulls_unequal`

- **Valid Values:**

`nulls_equal`

,

`nulls_unequal`

,

`nulls_ignored`

## `aria_sync_log_dir`

- **Description:** Controls syncing directory after log file growth and new file creation.

- **Commandline:**

```
--aria-sync-log-dir=#
```

- **Scope:** Global

- **Dynamic:** Yes

- **Data Type:**

`enumeration`

- **Default Value:**

`NEWFILE`

- **Valid Values:**

`NEWFILE`

,

`NEVER`

,

`ALWAYS`

## `aria_used_for_temp_tables`

- **Description:** Readonly variable indicating whether the [Aria](#) storage engine is used for temporary tables. If set to

`ON`

, the default, the Aria storage engine is used. If set to

`OFF`

, MariaDB reverts to using [MyISAM](#) for on-disk temporary tables. The [MEMORY](#) storage engine is used for temporary tables regardless of this variable's setting where appropriate. The default can be changed by not using the

`--with-aria-tmp-tables`

option when building MariaDB.

- **Commandline:** No

- **Scope:** Global

- **Dynamic:** No

- **Data Type:**

`boolean`

- **Default Value:**

`ON`

---

## deadlock\_search\_depth\_long

- **Description:** Long search depth for the [two-step deadlock detection](#). Only used by the [Aria](#) storage engine.
- **Commandline:**

```
--deadlock-search-depth-long=#
```

- **Scope:** Global, Session

- **Dynamic:** Yes

- **Data Type:**

```
    numeric
```

- **Default Value:**

```
    15
```

- **Range:**

```
    0
```

```
    to
```

```
    33
```

---

## deadlock\_search\_depth\_short

- **Description:** Short search depth for the [two-step deadlock detection](#). Only used by the [Aria](#) storage engine.
- **Commandline:**

```
--deadlock-search-depth-short=#
```

- **Scope:** Global, Session

- **Dynamic:** Yes

- **Data Type:**

```
    numeric
```

- **Default Value:**

```
    4
```

- **Range:**

```
    0
```

```
    to
```

```
    32
```

---

## deadlock\_timeout\_long

- **Description:** Long timeout in microseconds for the [two-step deadlock detection](#). Only used by the [Aria](#) storage engine.
- **Commandline:**

```
--deadlock-timeout-long=#
```

- **Scope:** Global, Session

- **Dynamic:** Yes

- **Data Type:**

```
    numeric
```

- **Default Value:**

```
    50000000
```

- **Range:**

```
    0
```

```
    to
```

```
    4294967295
```

```
deadlock_timeout_short
```

- **Description:** Short timeout in microseconds for the [two-step deadlock detection](#). Only used by the [Aria storage engine](#).

- **Commandline:**

```
--deadlock-timeout-short=#
```

- **Scope:** Global, Session

- **Dynamic:** Yes

- **Data Type:**

```
numeric
```

- **Default Value:**

```
10000
```

- **Range:**

```
0
```

```
to
```

```
4294967295
```

## 4.3.4.7 Aria Group Commit

Since [MariaDB 5.2](#), the [Aria storage engine](#) has included a feature to group commits to speed up concurrent threads doing many inserts into the same or different Aria tables.

By default, group commit for Aria is turned off. It is controlled by the [aria\\_group\\_commit](#) and [aria\\_group\\_commit\\_interval](#) system variables.

Information on setting server variables can be found on the [Server System Variables](#) page.

## Terminology

- A

```
commit  
is  
flush of logs  
followed by a sync.
```

- 

```
sent to disk  
means written to disk but not sync()ed,
```

- 

```
flushed  
mean sent to disk and synced().
```

- 

```
LSN  
means log serial number. It's refers to the position in the transaction log.
```

## Non Group commit logic (aria\_group\_commit="none")

The thread which first started the

```
commit
```

is performing the actual flush of logs. Other threads set the new goal (LSN) of the next pass (if it is maximum) and wait for the pass end or just wait for the pass end.

The effect of this is that a flush (write of logs + sync) will save all data for all threads/transactions that have been waiting since the last flush.

## If hard group commit is enabled (aria\_group\_commit="hard")

### If hard commit and aria\_group\_commit\_interval=0

The first thread sends all changed buffers to disk. This is repeated as long as there are new LSNs added. The process can not loop forever because we have a limited number of threads and they will wait for the data to be synced.

Pseudo code:

```

do
    send changed buffers to disk
    while new_goal
    sync

```

## If hard commit and aria\_group\_commit\_interval > 0

If less than rate microseconds has passed since the last sync, then after buffers have been sent to disk, wait until rate microseconds has passed since last sync, do sync and return. This ensures that if we call sync infrequently we don't do any waits.

## If soft group commit is enabled (aria\_group\_commit="soft")

Note that soft group commit should only be used if you can afford to lose a few rows if your machine shuts down hard (as in the case of a power failure).

Works like in

```
non group commit'
```

but the thread doesn't do any real sync(). If aria\_group\_commit\_interval is not zero, the sync() will be performed by a service thread with the given rate when needed (new LSN appears). If aria\_group\_commit\_interval is zero, there will be no sync() calls.

## Code

The code for this can be found in storage/maria/ma\_loghandler.c::translog\_flush()

### 4.3.4.8 Benchmarking Aria

We have not yet had time to benchmark [Aria](#) properly. Here follows some things that have been discussed on the [maria-discuss](#) email list.

## Aria used for internal temporary tables

By default Aria (instead of MyISAM) is used for the internal temporary tables when MEMORY tables overflows to disk or MEMORY tables can't be used (for example when you are using temporary results with BLOB's). In most cases Aria should give you better performance than using MyISAM, but this is not always the case.

```

CREATE TABLE `t1` (`id` int(11) DEFAULT NULL, `tea` text)
ENGINE=MyISAM DEFAULT CHARSET=latin1;
insert t1 select rand()*2e8, repeat(rand(), rand()*64) from t1;

```

Repeat the last row until you get 2097152 rows.

The queries tested

```

Q1: SELECT id, tea from t1 group by left(id,1) order by null;
Q2: SELECT id, count(*), tea from t1 group by left(id,1) order by null;
Q3: SELECT id, tea from t1 group by left(id,2) order by null;
Q4: SELECT id, count(*), tea from t1 group by left(id,2) order by null;
Q5: SELECT id, tea from t1 group by id % 100 order by null;
Q6: SELECT id, count(*), tea from t1 group by id % 100 order by null;

```

Results (times in seconds, lower is better):

| Test | Aria 8K page size | Aria 2K page size | MyISAM |
|------|-------------------|-------------------|--------|
| Q1   | 3.08              | 2.41              | 2.17   |
| Q2   | 6.24              | 5.21              | 12.89  |
| Q3   | 4.87              | 4.05              | 4.04   |
| Q4   | 8.20              | 7.04              | 15.14  |
| Q5   | 7.10              | 6.37              | 6.28   |
| Q6   | 10.38             | 9.09              | 17.00  |

The good news is that for common group by queries that is using summary functions there is a close to 50 % speedup of using Aria for internal temporary tables.

Note that queries Q1,Q3 and Q5 are not typical queries as there is no sum functions involved. In this case rows are just written to the tmp tables and there is no updates. As soon as there are summary functions and updates the new row format in Aria gives a close to 50 % speedup.

The above table also shows how the page size (determined by the [aria\\_block\\_size](#) system variable) affects the performance. The reason for the difference is that there is more data to move back/from the page cache for inserting of keys. (When reading data we are normally not copying pages). The bigger page size however allows longer keys and fewer index levels so for bigger data sets the different should be smaller. It's possible to in the future

optimize Aria to not copy pages from the page cache also for index writes and then this difference should disappear.

The default page size for Aria is 8K.

If you want to run MariaDB with MyISAM for temporary tables, don't use the configure option '--with-aria-tmp-tables' when building MariaDB.

## 4.3.4.9 Aria Two-step Deadlock Detection

### Description

The [Aria storage engine](#) can automatically detect and deal with deadlocks (see the [Wikipedia deadlocks article](#) ).

This feature is controlled by four configuration variables, two that control the search depth and two that control the timeout.

- `deadlock_search_depth_long`
- `deadlock_search_depth_short`
- `deadlock_timeout_long`
- `deadlock_timeout_short`

### How it Works

If Aria is ever unable to obtain a lock, we might have a deadlock. There are two primary ways for detecting if a deadlock has actually occurred. First is to search a wait-for graph (see the [wait-for graph on Wikipedia](#)) and the second is to just wait and let the deadlock exhibit itself. Aria Two-step Deadlock Detection does a combination of both.

First, if the lock request cannot be granted immediately, we do a short search of the wait-for graph with a small search depth as configured by the `deadlock_search_depth_short`

variable. We have a depth limit because the graph can (theoretically) be arbitrarily big and we don't want to recursively search the graph arbitrarily deep. This initial, short search is very fast and most deadlocks will be detected right away. If no deadlock cycles are found with the short search the system waits for the amount of time configured in

`deadlock_timeout_short`

to see if the lock conflicts will be removed and the lock can be granted. Assuming this did not happen and the lock request still waits, the system then moves on to step two, which is a repeat of the process but this time searching deeper using the

`deadlock_search_depth_long`

. If no deadlock has been detected, it waits

`deadlock_timeout_long`

and times out.

When a deadlock is detected the system uses a weighting algorithm to determine which thread in the deadlock should be killed and then kills it.

## 4.3.4.10 Aria Encryption Overview

### Contents

1. [Basic Configuration](#)
2. [Determining Whether a Table is Encrypted](#)
3. [Encryption and the Aria Log](#)

MariaDB can encrypt data in tables that use the [Aria storage engine](#). This includes both user-created tables and internal on-disk temporary tables that use the Aria storage engine. This ensures that your Aria data is only accessible through MariaDB.

For encryption with the InnoDB and XtraDB storage engines, see [Encrypting Data for InnoDB/XtraDB](#).

### Basic Configuration

In order to enable encryption for tables using the [Aria storage engine](#), there are a couple server system variables that you need to set and configure. Most users will want to set

`aria_encrypt_tables`

and

`encrypt_tmp_disk_tables`

Users of data-at-rest encryption will also need to have a [key management and encryption plugin](#) configured. Some examples are [File Key Management Plugin](#) and [AWS Key Management Plugin](#).

```
[mariadb]
...
# File Key Management
plugin_load_add = file_key_management
file_key_management_filename = /etc/mysql/encryption/keyfile.enc
file_key_management_filekey = FILE:/etc/mysql/encryption/keyfile.key
file_key_management_encryption_algorithm = AES_CTR

# Aria Encryption
aria_encrypt_tables=ON
encrypt_tmp_disk_tables=ON
```

## Determining Whether a Table is Encrypted

The InnoDB storage engine has the [information\\_schema.INNODB\\_TABLESPACES\\_ENCRYPTION table](#) that can be used to get information about which tables are encrypted. Aria does not currently have anything like that (see [MDEV-17324](#) about that).

To determine whether an Aria table is encrypted, you currently have to search the data file for some plain text that you know is in the data.

For example, let's say that we have the following table:

```
SELECT * FROM db1.aria_tab LIMIT 1;
+----+----+
| id | str |
+----+----+
| 1  | str1 |
+----+----+
1 row in set (0.00 sec)
```

Then, we could search the data file that belongs to

```
db1.aria_tab
for
str1
using a command-line tool, such as strings :
```

```
$ sudo strings /var/lib/mysql/db1/aria_tab.MAD | grep "str1"
str1
```

If you can find the plain text of the string, then you know that the table is not encrypted.

## Encryption and the Aria Log

Only Aria tables are currently encrypted. The [Aria log](#) is not yet encrypted. See [MDEV-8587](#) about that.

### 4.3.4.11 The Aria Name

#### Contents

1. [Backstory](#)
2. [Renaming Maria \(the engine\)](#)
3. [See Also](#)

The [Aria](#) storage engine used to be called Maria. This page gives the history and background of how and why this name was changed to Aria.

## Backstory

When starting what became the MariaDB project, Monty and the initial developers only planned to work on a next generation MyISAM storage engine replacement. This storage engine would be crash safe and eventually support transactions. Monty named the storage engine, and the project, after his daughter, Maria.

Work began in earnest on the Maria storage engine but the plans quickly expanded and morphed and soon the developers were not just working on a storage engine, but on a complete branch of the MySQL database. Since the project was already called Maria, it made sense to call the whole database server MariaDB.

## Renaming Maria (the engine)

So now there was the database, MariaDB, and the storage engine, Maria. To end the confusion this caused, the decision was made to rename the storage engine.

Monty's first suggestion was to name it *Lucy*, after his dog, but few who heard it liked that idea. So the decision was made that the next best thing was for the community to suggest and vote on names.

This was done by running a contest in 2009 through the end of May 2010. After that the best names were voted on by the community and Monty picked and [announced the winner](#) (Aria) at OSCON 2010 in Portland.

The winning entry was submitted by Chris Tooley. He received a Linux-powered [System 76](#) Meerkat NetTop as his prize for suggesting the winning name from Monty Program.

## See Also

- [Why is the Software Called MariaDB?](#)

### 4.3.5 Archive

The `ARCHIVE` storage engine is a storage engine that uses gzip to compress rows. It is mainly used for storing large amounts of data, without indexes, with only a very small footprint.

A table using the `ARCHIVE` storage engine is stored in two files on disk. There's a table definition file with an extension of `.frm`, and a data file with the extension `.ARZ`. At times during optimization, a `.ARN` file will appear.

New rows are inserted into a compression buffer and are flushed to disk when needed. `SELECT`s cause a flush. Sometimes, rows created by multi-row inserts are not visible until the statement is complete.

`ARCHIVE` allows a maximum of one key. The key must be on an `AUTO_INCREMENT` column, and can be a `PRIMARY KEY` or a non-unique key. However, it has a limitation: it is not possible to insert a value which is lower than the next `AUTO_INCREMENT` value.

#### Contents

1. [Installing the Plugin](#)
2. [Uninstalling the Plugin](#)
3. [Characteristics](#)

## Installing the Plugin

Although the plugin's shared library is distributed with MariaDB by default, the plugin is not actually installed by MariaDB by default. There are two methods that can be used to install the plugin with MariaDB.

The first method can be used to install the plugin without restarting the server. You can install the plugin dynamically by executing `INSTALL SONAME` or `INSTALL PLUGIN`. For example:

```
INSTALL SONAME 'ha_archive';
```

The second method can be used to tell the server to load the plugin when it starts up. The plugin can be installed this way by providing the `--plugin-load` or the `--plugin-load-add` options. This can be specified as a command-line argument to `mysqld` or it can be specified in a relevant server option group in an option file. For example:

```
[mariadb]
...
plugin_load_add = ha_archive
```

## Uninstalling the Plugin

You can uninstall the plugin dynamically by executing `UNINSTALL SONAME` or `UNINSTALL PLUGIN`. For example:

```
UNINSTALL SONAME 'ha_archive';
```

If you installed the plugin by providing the `--plugin-load` or the `--plugin-load-add` options in a relevant server option group in an option file, then those options should be removed to prevent the plugin from being loaded the next time the server is restarted.

## Characteristics

- Supports `INSERT` and `SELECT`, but not `DELETE`, `UPDATE` or `REPLACE`.
- Data is compressed with zlib as it is inserted, making it very small.
- Data is slow the select, as it needs to be uncompressed, and, besides the `query cache`, there is no cache.
- Supports `AUTO_INCREMENT` (since MariaDB/MySQL 5.1.6), which can be a unique or a non-unique index.
- Since MariaDB/MySQL 5.1.6, selects scan past BLOB columns unless they are specifically requested, making these queries much more efficient.
- Does not support `spatial` data types.
- Does not support `transactions`.
- Does not support foreign keys.
- Does not support `virtual columns`.
- No storage limit.
- Supports row locking.

- Supports [table discovery](#), and the server can access ARCHIVE tables even if the corresponding .frm file is missing.
- [OPTIMIZE TABLE](#) and [REPAIR TABLE](#) can be used to compress the table in its entirety, resulting in slightly better compression.
- With MariaDB, it is possible to upgrade from the MySQL 5.0 format without having to dump the tables.
- [INSERT DELAYED](#) is supported.
- Running many SELECTs during the insertions can deteriorate the compression, unless only multi-rows INSERTs and [INSERT DELAYED](#) are used.

No items found.

There are [3 related questions](#).

## 4.3.6 BLACKHOLE

The

BLACKHOLE

storage engine accepts data but does not store it and always returns an empty result.

A table using the

BLACKHOLE

storage engine consists of a single .frm table format file, but no associated data or index files.

This storage engine can be useful, for example, if you want to run complex filtering rules on a slave without incurring any overhead on a master. The master can run a

BLACKHOLE

storage engine, with the data replicated to the slave for processing.

### Contents

- [1. Installing the Plugin](#)
- [2. Uninstalling the Plugin](#)

  - [1. Using with DML](#)
  - [2. Using with Replication](#)
  - [3. Using with Triggers](#)
  - [4. Using with Foreign Keys](#)
  - [5. Using with Virtual Columns](#)
  - [6. Using with AUTO\\_INCREMENT](#)
- [4. Limits](#)
- [5. Examples](#)

## Installing the Plugin

Although the plugin's shared library is distributed with MariaDB by default, the plugin is not actually installed by MariaDB by default. There are two methods that can be used to install the plugin with MariaDB.

The first method can be used to install the plugin without restarting the server. You can install the plugin dynamically by executing [INSTALL SONAME](#) or [INSTALL PLUGIN](#). For example:

```
INSTALL SONAME 'ha_blackhole';
```

The second method can be used to tell the server to load the plugin when it starts up. The plugin can be installed this way by providing the [--plugin-load](#) or the [--plugin-load-add](#) options. This can be specified as a command-line argument to [mysqld](#) or it can be specified in a relevant server [option group](#) in an [option file](#). For example:

```
[mariadb]
...
plugin_load_add = ha_blackhole
```

## Uninstalling the Plugin

You can uninstall the plugin dynamically by executing [UNINSTALL SONAME](#) or [UNINSTALL PLUGIN](#). For example:

```
UNINSTALL SONAME 'ha_blackhole';
```

If you installed the plugin by providing the [--plugin-load](#) or the [--plugin-load-add](#) options in a relevant server [option group](#) in an [option file](#), then those options should be removed to prevent the plugin from being loaded the next time the server is restarted.

## Using the BLACKHOLE Storage Engine

### Using with DML

[INSERT](#), [UPDATE](#), and [DELETE](#) statements all work with the BLACKHOLE storage engine. However, no data changes are actually applied.

## Using with Replication

If the binary log is enabled, all SQL statements will be logged as usual, and replicated to any slave servers. However, since rows are not stored, it is important to use statement-based rather than the row or mixed format, as [UPDATE](#) and [DELETE](#) statements are neither logged nor replicated. See [Binary Log Formats](#).

## Using with Triggers

Some [triggers](#) work with the BLACKHOLE storage engine.

BEFORE triggers for [INSERT](#) statements are still activated.

Triggers for [UPDATE](#) and [DELETE](#) statements are **not** activated.

Triggers with the FOR EACH ROW clause do not apply, since the tables have no rows.

## Using with Foreign Keys

Foreign keys are not supported. If you convert an [InnoDB](#) table to BLACKHOLE, then the foreign keys will disappear. If you convert the same table back to InnoDB, then you will have to recreate them.

## Using with Virtual Columns

If you convert an [InnoDB](#) table which contains [virtual columns](#) to BLACKHOLE, then it produces an error.

## Using with AUTO\_INCREMENT

Because a BLACKHOLE table does not store data, it will not maintain the [AUTO\\_INCREMENT](#) value. If you are replicating to a table that can handle [AUTO\\_INCREMENT](#) columns, and are not explicitly setting the primary key auto-increment value in the [INSERT](#) query, or using the [SET INSERT\\_ID](#) statement, inserts will fail on the slave due to duplicate keys.

## Limits

The maximum key size is:

- 3500 bytes (>= [MariaDB 10.1.48](#), [MariaDB 10.2.35](#), [MariaDB 10.3.26](#), [MariaDB 10.4.16](#) and [MariaDB 10.5.7](#))
- 1000 bytes (<= [MariaDB 10.1.47](#), [MariaDB 10.2.34](#), [MariaDB 10.3.25](#), [MariaDB 10.4.15](#) and [MariaDB 10.5.6](#)).

## Examples

```
CREATE TABLE table_name (
    id int unsigned primary key not null,
    v varchar(30)
) ENGINE=BLACKHOLE;

INSERT INTO table_name VALUES (1, 'bob'),(2, 'jane');

SELECT * FROM table_name;
Empty set (0.001 sec)
```

## 4.3.7 CONNECT

Note: You can download a [PDF version of the CONNECT documentation](#) (1.7.0003).

| Connect Version   | Introduced                                                                                                                            | Maturity |

The CONNECT storage engine enables MariaDB to access external local or remote data (MED). This is done by defining tables based on different data types, in particular files in various formats, data extracted from other DBMS or products (such as Excel or MongoDB) via ODBC or JDBC, or data retrieved from the environment (for example DIR, WMI, and MAC tables)

This storage engine supports table partitioning, MariaDB virtual columns and permits defining *special* columns such as ROWID, FILEID, and SERVID.

No precise definition of maturity exists. Because CONNECT handles many table types, each type has a different maturity depending on whether it is old and well-tested, less well-tested or newly implemented. This will be indicated for all data types.

## 4.3.7.1 Introduction to the CONNECT Engine

CONNECT is not just a new "YASE" (Yet another Storage Engine) that provides another way to store data with additional features. It brings a new dimension to MariaDB, already one of the best products to deal with traditional database transactional applications, further into the world of business intelligence and data analysis, including NoSQL facilities. Indeed, BI is the set of techniques and tools for the transformation of raw data into meaningful

and useful information. And where is this data?

"It's amazing in an age where relational databases reign supreme when it comes to managing data that so much information still exists outside RDBMS engines in the form of flat files and other such constructs. In most enterprises, data is passed back and forth between disparate systems in a fashion and speed that would rival the busiest expressways in the world, with much of this data existing in common, delimited files. Target systems intercept these source files and then typically proceed to load them via ETL (extract, transform, load) processes into databases that then utilize the information for business intelligence, transactional functions, or other standard operations. ETL tasks and data movement jobs can consume quite a bit of time and resources, especially if large volumes of data are present that require loading into a database. This being the case, many DBAs welcome alternative means of accessing and managing data that exists in file format."

This has been written by Robin Schumacher. [1]

What he describes is known as MED (Management of External Data) enabling the handling of data not stored in a DBMS database as if it were stored in tables. An ISO standard exists that describes one way to implement and use MED in SQL by defining foreign tables for which an external FDW (Foreign Data Wrapper) has been developed in C.

However, since this was written, a new source of data was developed as the "cloud". Data are existing worldwide and, in particular, can be obtained in JSON or XML format in answer to REST queries. From [Connect 1.06.0010](#), it is possible to create JSON, XML or CSV tables based on data retrieved from such REST queries.

MED as described above is a rather complex way to achieve this goal and MariaDB does not support the ISO SQL/MED standard. But, to cover the need, possibly in transactional but mostly in decision support applications, the CONNECT storage engine supports MED in a much simpler way.

The main features of CONNECT are:

1. No need for additional SQL language extensions.
2. Embedded wrappers for many external data types (files, data sources, virtual).
3. NoSQL query facilities for [JSON](#), [XML](#), HTML files and using JSON UDFs.
4. NoSQL data obtained from REST queries (requires `cpprestsdk`).
5. NoSQL new data type [MONGO](#) accessing MongoDB collections as relational tables.
6. Read/Write access to external files of most commonly used formats.
7. Direct access to most external data sources via ODBC, JDBC and MySQL or MongoDB API.
8. Only used columns are retrieved from external scan.
9. Push-down WHERE clauses when appropriate.
10. Support of special and virtual columns.
11. Parallel execution of multi-table tables (currently unavailable).
12. Supports partitioning by sub-files or by sub-tables (enabling table sharding).
13. Support of MRR for SELECT, UPDATE and DELETE.
14. Provides remote, block, dynamic and virtual indexing.
15. Can execute complex queries on remote servers.
16. Provides an API that allows writing additional FDW in C++.

With CONNECT, MariaDB has one of the most advanced implementations of MED and NoSQL, without the need for complex additions to the SQL syntax (foreign tables are "normal" tables using the CONNECT engine).

Giving MariaDB easy and natural access to external data enables the use of all of its powerful functions and SQL-handling abilities for developing business intelligence applications.

With version 1.07 of CONNECT, retrieving data from REST queries is available in all binary distributed version of MariaDB, and, from 1.07.002, CONNECT allows workspaces greater than 4GB.

---

1. ↑ Robin Schumacher is Vice President Products at DataStax and former Director of Product Management at MySQL. He has over 13 years of database experience in DB2, MySQL, Oracle, SQL Server and other database engines.

## 4.3.7.2 Installing the CONNECT Storage Engine

The

CONNECT

storage engine enables MariaDB to access external local or remote data (MED). This is done by defining tables based on different data types, in particular files in various formats, data extracted from other DBMS or products (such as Excel or MongoDB) via ODBC or JDBC, or data retrieved from the environment (for example DIR, WMI, and MAC tables)

This storage engine supports table partitioning, MariaDB virtual columns and permits defining special columns such as ROWID, FILEID, and SERVID.

The storage engine must be installed before it can be used.

## Contents

- 1. [Installing the Plugin's Package](#)
  - 1. [Installing on Linux](#)
    - 1. [Installing with a Package Manager](#)
      - 1. [Installing with yum/dnf](#)
      - 2. [Installing with apt-get](#)
      - 3. [Installing with zypper](#)
  - 2. [Installing the Plugin](#)
  - 3. [Uninstalling the Plugin](#)
  - 4. [Installing Dependencies](#)
    - 1. [Installing unixODBC](#)
  - 5. [See Also](#)

## Installing the Plugin's Package

The

CONNECT  
storage engine's shared library is included in MariaDB packages as the  
`ha_connect.so`  
or  
`ha_connect.so`  
shared library on systems where it can be built.

## Installing on Linux

The

CONNECT  
storage engine is included in [binary tarballs](#) on Linux.

### Installing with a Package Manager

The

CONNECT  
storage engine can also be installed via a package manager on Linux. In order to do so, your system needs to be configured to install from one of the MariaDB repositories.

You can configure your package manager to install it from MariaDB Corporation's MariaDB Package Repository by using the [MariaDB Package Repository setup script](#).

You can also configure your package manager to install it from MariaDB Foundation's MariaDB Repository by using the [MariaDB Repository Configuration Tool](#).

#### Installing with yum/dnf

On RHEL, CentOS, Fedora, and other similar Linux distributions, it is highly recommended to install the relevant [RPM package](#) from MariaDB's repository using

`yum`

or

`dnf`

. Starting with RHEL 8 and Fedora 22,

`yum`

has been replaced by

`dnf`

, which is the next major version of

`yum`

. However,

`yum`

commands still work on many systems that use

`dnf`

. For example:

```
sudo yum install MariaDB-connect-engine
```

#### Installing with apt-get

On Debian, Ubuntu, and other similar Linux distributions, it is highly recommended to install the relevant [DEB package](#) from MariaDB's repository using

```
apt-get
```

. For example:

```
sudo apt-get install mariadb-plugin-connect
```

Installing with zypper

On SLES, OpenSUSE, and other similar Linux distributions, it is highly recommended to install the relevant [RPM package](#) from MariaDB's repository using

```
zypper
```

. For example:

```
sudo zypper install MariaDB-connect-engine
```

## Installing the Plugin

Once the shared library is in place, the plugin is not actually installed by MariaDB by default. There are two methods that can be used to install the plugin with MariaDB.

The first method can be used to install the plugin without restarting the server. You can install the plugin dynamically by executing

```
INSTALL SONAME
```

or

```
INSTALL PLUGIN
```

. For example:

```
INSTALL SONAME 'ha_connect';
```

The second method can be used to tell the server to load the plugin when it starts up. The plugin can be installed this way by providing the

```
--plugin-load
```

or the

```
--plugin-load-add
```

options. This can be specified as a command-line argument to

```
mysqld
```

or it can be specified in a relevant server [option group](#) in an [option file](#). For example:

```
[mariadb]
...
plugin_load_add = ha_connect
```

## Uninstalling the Plugin

You can uninstall the plugin dynamically by executing

```
UNINSTALL SONAME
```

or

```
UNINSTALL PLUGIN
```

. For example:

```
UNINSTALL SONAME 'ha_connect';
```

If you installed the plugin by providing the

```
--plugin-load
```

or the

```
--plugin-load-add
```

options in a relevant server [option group](#) in an [option file](#), then those options should be removed to prevent the plugin from being loaded the next time the server is restarted.

## Installing Dependencies

The

CONNECT

storage engine has some external dependencies.

## Installing unixODBC

The

CONNECT

storage engine requires an ODBC library. On Unix-like systems, that usually means installing [unixODBC](#). On some systems, this is installed as the

unixODBC

package. For example:

```
sudo yum install unixODBC
```

On other systems, this is installed as the

libodbc1

package. For example:

```
sudo apt-get install libodbc1
```

If you do not have the ODBC library installed, then you may get an error about a missing library when you attempt to install the plugin. For example:

```
INSTALL SONAME 'ha_connect';
ERROR 1126 (HY000): Can't open shared library '/home/ian/MariaDB_Downloads/10.1.17/lib/plugin/ha_connect.so'
(errno: 2, libodbc.so.1: cannot open shared object file: No such file or directory)
```

### 4.3.7.3 Creating and Dropping CONNECT Tables

#### Contents

1. [Table Options](#)
2. [Column Options](#)
3. [Index Options](#)

Create Table statements for “CONNECT” tables are standard MariaDB create statements specifying

engine=CONNECT

. There are a few additional table and column options specific to CONNECT.

## Table Options

| Table Option   | Type    | Description                                                                                                                                                                                                                                                            |
|----------------|---------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| AVG_ROW_LENGTH | Integer | Can be specified to help CONNECT estimate the size of a variable record table length.                                                                                                                                                                                  |
| BLOCK_SIZE     | Integer | The number of rows each block of a <a href="#">FIX</a> , <a href="#">BIN</a> , <a href="#">DBF</a> , or <a href="#">VEC</a> table contains. For an <a href="#">ODBC</a> table this is the RowSet size option. For a <a href="#">JDBC</a> table this is the fetch size. |

|              |         |                                                                                                                                                                                                                              |
|--------------|---------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| CATFUNC      | String  | The catalog function used by a <a href="#">catalog table</a> .                                                                                                                                                               |
| COLIST       | String  | The column list of <a href="#">OCCUR</a> tables or \$project of <a href="#">MONGO</a> tables.                                                                                                                                |
| COMPRESS     | Number  | <p>1<br/>or<br/>2</p> <p>if the data file is g-zip compressed. Defaults to 0. Before CONNECT 1.05.0001, this was boolean, and true if the data file is compressed.</p>                                                       |
| CONNECTION   | String  | Specifies the connection of an <a href="#">ODBC</a> , <a href="#">JDBC</a> or <a href="#">MYSQL</a> table.                                                                                                                   |
| DATA_CHARSET | String  | The character set used in the external file or data source.                                                                                                                                                                  |
| DBNAME       | String  | The target database for <a href="#">ODBC</a> , <a href="#">JDBC</a> , <a href="#">MYSQL</a> , <a href="#">catalog</a> , and <a href="#">PROXY</a> based tables. The database concept is sometimes known as a <i>schema</i> . |
| ENGINE       | String  | Must be specified as<br>CONNECT<br>.                                                                                                                                                                                         |
| ENDING       | Integer | End of line length. Defaults to<br>1<br>for Unix/Linux and<br>2<br>for Windows.                                                                                                                                              |
| FILE_NAME    | String  | The file (path) name for all table types based on files. Can be absolute or relative to the current data directory. If not specified, this is an <a href="#">Inward table</a> and a default value is used.                   |
| FILTER       | String  | To filter an external table. Currently MONGO tables only.                                                                                                                                                                    |
| HEADER       | Integer | Applies to <a href="#">CSV</a> , <a href="#">VEC</a> , and <a href="#">HTML</a> files. Its meaning depends on the table type.                                                                                                |
| HTTP         | String  | The HTTP of the client of REST queries. From <a href="#">Connect 1.06.0010</a> .                                                                                                                                             |
| HUGE         | Boolean | To specify that a table file can be larger than 2GB. For a <a href="#">MYSQL</a> table, prevents the result set from being stored in memory.                                                                                 |
| LRECL        | Integer | The file record size (often calculated by default).                                                                                                                                                                          |

|             |         |                                                                                                                                                                                                                                                                                                                              |
|-------------|---------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| MAPPED      | Boolean | Specifies whether <i>file mapping</i> is used to handle the table file.                                                                                                                                                                                                                                                      |
| MODULE      | String  | The (path) name of the DLL or shared lib implementing the access of a non-standard ( <a href="#">OEM</a> ) table type.                                                                                                                                                                                                       |
| MULTIPLE    | Integer | Used to specify multiple file tables.                                                                                                                                                                                                                                                                                        |
| OPTION_LIST | String  | Used to specify all other options not yet directly defined.                                                                                                                                                                                                                                                                  |
| QCHAR       | String  | Specifies the character used for quoting some fields of a <a href="#">CSV</a> table or the identifiers of an <a href="#">ODBC / JDBC</a> tables.                                                                                                                                                                             |
| QUOTED      | Integer | The level of quoting used in <a href="#">CSV</a> table files.                                                                                                                                                                                                                                                                |
| READONLY    | Boolean | True if the data file must not be modified or erased.                                                                                                                                                                                                                                                                        |
| SEP_CHAR    | String  | Specifies the field separator character of a <a href="#">CSV</a> or <a href="#">XCOL</a> table. Also, used to specify the Jpath separator for <a href="#">JSON tables</a> .                                                                                                                                                  |
| SEPINDEX    | Boolean | When true, indexes are saved in separate files.                                                                                                                                                                                                                                                                              |
| SPLIT       | Boolean | True for a <a href="#">VEC</a> table when all columns are in separate files.                                                                                                                                                                                                                                                 |
| SRCDEF      | String  | The source definition of a table retrieved via <a href="#">ODBC</a> , <a href="#">JDBC</a> or the MySQL API or used by a <a href="#">PIVOT</a> table.                                                                                                                                                                        |
| SUBTYPE     | String  | The subtype of an <a href="#">OEM</a> table type.                                                                                                                                                                                                                                                                            |
| TABLE_LIST  | String  | The comma separated list of TBL table sub-tables.                                                                                                                                                                                                                                                                            |
| TABLE_TYPE  | String  | The external table <code>type : DOS , FIX , BIN , CSV , FMT , XML , JSON ,INI , DBF , VEC , ODBC , JDBC , MYSQL , TBL , PROXY , XCOL , OCCUR , PIVOT , ZIP , VIR , DIR , WMI , MAC , and OEM</code> . Defaults to <a href="#">DOS</a> , <a href="#">MYSQL</a> , or <a href="#">PROXY</a> depending on what options are used. |
| TABNAME     | String  | The target table or node for <a href="#">ODBC</a> , <a href="#">JDBC</a> , <a href="#">MYSQL</a> , <a href="#">PROXY</a> , or <a href="#">catalog tables</a> ; or the top node name for <a href="#">XML</a> tables.                                                                                                          |

|            |         |                                                                                                                                |
|------------|---------|--------------------------------------------------------------------------------------------------------------------------------|
| URI        | String  | The URI of a REST request.. From <a href="#">Connect 1.06.0010</a> .                                                           |
| XFILE_NAME | String  | The file (path) base name for table index files. Can be absolute or relative to the data directory. Defaults to the file name. |
| ZIPPED     | Boolean | True if the table file(s) is/are zipped in one or several zip files.                                                           |

All integers in the above table are unsigned big integers.

Because CONNECT handles many table types; many table type specific options are not in the above list and must be entered using the `OPTION_LIST` option. The syntax to use is:

```
... option_list='opname1=opvalue1,opname2=opvalue2...'
```

Be aware that until Connect 1.5.5, no blanks should be inserted before or after the '

```
=  
' and '  
,  
' characters. The option name is all that is between the start of the string or the last '  
,  
' character and the next '  
=  
' character, and the option value is all that is between this '  
=  
' character and the next '  
,  
' or end of string. For instance:
```

```
option_list='name=TABLE,coltype=HTML,attribute=border=1;cellpadding=5,headattr=bgcolor=yellow';
```

This defines four options,

```
name  
'  
coltype  
'  
attribute  
, and '  
headattr  
'; with values '  
TABLE  
'  
HTML  
'  
border=1;cellpadding=5  
, and '  
bgcolor=yellow  
' respectively. The only restriction is that values cannot contain commas, but they can contain equal signs.
```

## Column Options

| Column Option | Type   | Description                                             |
|---------------|--------|---------------------------------------------------------|
| DATE_FORMAT   | String | The format indicating how a date is stored in the file. |
| DISTRIB       | Enum   | "scattered", "clustered", "sorted" (ascending).         |

|                           |         |                                                            |
|---------------------------|---------|------------------------------------------------------------|
| <code>FIELD_FORMAT</code> | String  | The column format for some table types.                    |
| <code>FIELD_LENGTH</code> | Integer | Set the internal field length for DATE columns.            |
| <code>FLAG</code>         | Integer | An integer value whose meaning depends on the table type.  |
| <code>JPATH</code>        | String  | The Json path of JSON table columns.                       |
| <code>MAX_DIST</code>     | Integer | Maximum number of distinct values in this column.          |
| <code>SPECIAL</code>      | String  | The name of the SPECIAL column that set this column value. |
| <code>XPATH</code>        | String  | The XML path of XML table columns.                         |

- The

`MAX_DIST`  
and  
`DISTRIB`

column options are used for block indexing.

- All integers in the above table are unsigned big integers.
- `JPATH` and `XPATH` were added to make `CREATE TABLE` statements more readable, but they do the same thing as `FIELD_FORMAT` and any of them can be used with the same result.

## Index Options

| Index Option        | Type    | Description                 |
|---------------------|---------|-----------------------------|
| <code>DYNAM</code>  | Boolean | Set the index as “dynamic”. |
| <code>MAPPED</code> | Boolean | Use index file mapping.     |

**Note 1:** Creating a CONNECT table based on file does not erase or create the file if the file name is specified in the `CREATE TABLE` statement (“`outward`” table). If the file does not exist, it will be populated by subsequent `INSERT` or `LOAD` commands or by the “AS select statement” of the `CREATE TABLE` command. Unlike the CSV engine, CONNECT easily permits the creation of tables based on already existing files, for instance files made by other applications. However, if the file name is not specified, a file with a name defaulting to

`tablename.tablename`  
will be created in the data directory (“`inward`” table).

**Note 2:** Dropping a CONNECT table is done with a standard `DROP` statement. For `outward tables`, this drops only the CONNECT table definition but does not erase the corresponding data file and index files. Use

`DELETE`  
or  
`TRUNCATE`

to do so. This is contrary to data and index files of `inward tables` are erased on `DROP` like for other MariaDB engines.

## 4.3.7.4 CONNECT Data Types

## Contents

1. [TYPE\\_STRING](#)
2. [TYPE\\_INT](#)
3. [TYPE\\_SHORT](#)
4. [TYPE\\_TINY](#)

  3. [Handling dates that are out of the range of supported CONNECT dates](#)
9. [NULL handling](#)
10. [Unsigned numeric types](#)
11. [Data type conversion](#)

Many data types make no or little sense when applied to plain files. This why [CONNECT](#) supports only a restricted set of data types. However, ODBC, JDBC or MYSQL source tables may contain data types not supported by CONNECT. In this case, CONNECT makes an automatic conversion to a similar supported type when it is possible.

The data types currently supported by CONNECT are:

| Type name   | Description            | Used for                                                                                                                  |
|-------------|------------------------|---------------------------------------------------------------------------------------------------------------------------|
| TYPE_STRING | Zero ended string      | <a href="#">char</a> , <a href="#">varchar</a> , <a href="#">text</a>                                                     |
| TYPE_INT    | 4 bytes integer        | <a href="#">int</a> , <a href="#">mediumint</a> , <a href="#">integer</a>                                                 |
| TYPE_SHORT  | 2 bytes integer        | <a href="#">smallint</a>                                                                                                  |
| TYPE_TINY   | 1 byte integer         | <a href="#">tinyint</a>                                                                                                   |
| TYPE_BIGINT | 8 bytes integer        | <a href="#">bigint</a> , <a href="#">longlong</a>                                                                         |
| TYPE_DOUBLE | 8 bytes floating point | <a href="#">double</a> , <a href="#">float</a> , <a href="#">real</a>                                                     |
| TYPE_DECIM  | Numeric value          | <a href="#">decimal</a> , <a href="#">numeric</a> , <a href="#">number</a>                                                |
| TYPE_DATE   | 4 bytes integer        | <a href="#">date</a> , <a href="#">datetime</a> , <a href="#">time</a> , <a href="#">timestamp</a> , <a href="#">year</a> |

## TYPE\_STRING

This type corresponds to what is generally known as [CHAR](#) or [VARCHAR](#) by database users, or as strings by programmers. Columns containing characters have a maximum length but the character string is of fixed or variable length depending on the file format.

The [DATA\\_CHARSET](#) option must be used to specify the character set used in the data source or file. Note that, unlike usually with MariaDB, when a multi-byte character set is used, the column size represents the number of bytes the column value can contain, not the number of characters.

## TYPE\_INT

The ] [INTEGER](#) type contains signed integer numeric 4-byte values (the *int* of the C language) ranging from

-2,147,483,648  
to  
2,147,483,647  
for signed type and  
0  
to

4,294,967,295  
for unsigned type.

## TYPE\_SHORT

The SHORT data type contains signed [integer numeric 2-byte](#) values (the *short integer* of the C language) ranging from

-32,768  
to  
32,767  
for signed type and  
0  
to  
65,535  
for unsigned type.

## TYPE\_TINY

The TINY data type contains [integer numeric 1-byte](#) values (the *char* of the C language) ranging from

-128  
to  
127  
for signed type and  
0  
to  
255  
for unsigned type. For some table types, TYPE\_TINY is used to represent Boolean values (0 is false, anything else is true).

## TYPE\_BIGINT

The [BIGINT](#) data type contains signed integer 8-byte values (the *long long* of the C language) ranging from

-9,223,372,036,854,775,808  
to  
9,223,372,036,854,775,807  
for signed type and from  
0  
to  
18,446,744,073,709,551,615  
for unsigned type.

Inside tables, the coding of all integer values depends on the table type. In tables represented by text files, the number is written in characters, while in tables represented by binary files (

BIN  
or  
VEC

) the number is directly stored in the binary representation corresponding to the platform.

The *length* (or *precision*) specification corresponds to the length of the table field in which the value is stored for text files only. It is used to set the output field length for all table types.

## TYPE\_DOUBLE

The DOUBLE data type corresponds to the C language [double](#) type, a floating-point double precision value coded with 8 bytes. Like for integers, the internal coding in tables depends on the table type, characters for text files, and platform binary representation for binary files.

The *length* specification corresponds to the length of the table field in which the value is stored for text files only. The *scale* (was *precision*) is the number of decimal digits written into text files. For binary table types (BIN and VEC) this does not apply. The *length* and *scale* specifications are used to set the output field length and number of decimals for all types of tables.

## TYPE\_DECIM

The DECIMAL data type corresponds to what MariaDB or ODBC data sources call NUMBER, NUMERIC, or [DECIMAL](#) : a numeric value with a maximum number of digits (the *precision*) some of them eventually being decimal digits (the *scale*). The internal coding in CONNECT is a character representation of the number. For instance:

```
colname decimal(14,6)
```

This defines a column *colname* as a number having a *precision* of 14 and a *scale* of 6. Supposing it is populated by:

```
insert into xxx values (-2658.74);
```

The internal representation of it will be the character string

```
-2658.740000
```

. The way it is stored in a file table depends on the table type. The *length* field specification corresponds to the length of the table field in which the value is stored and is calculated by CONNECT from the *precision* and the *scale* values. This length is *precision* plus 1 if *scale* is not 0 (for the decimal point) plus 1 if this column is not unsigned (for the eventual minus sign). In fix formatted tables the number is right justified in the field of width *length*, for variable formatted tables, such as CSV, the field is the representing character string.

Because this type is mainly used by CONNECT to handle numeric or decimal fields of ODBC, JDBC and MySQL table types, CONNECT does not provide decimal calculations or comparison by itself. This is why decimal columns of CONNECT tables cannot be indexed.

## DATE Data type

Internally, date/time values are stored by CONNECT as a signed 4-byte integer. The value 0 corresponds to 01 January 1970 12:00:00 am coordinated universal time ([UTC](#)). All other date/time values are represented by the number of seconds elapsed since or before midnight (00:00:00), 1 January 1970, to that date/time value. Date/time values before midnight 1 January 1970 are represented by a negative number of seconds.

CONNECT handles dates from **13 December 1901, 20:45:52 to 18 January 2038, 19:14:07**.

Although date and time information can be represented in both CHAR and INTEGER data types, the DATE data type has special associated properties. For each DATE value, CONNECT can store all or only some of the following information: century, year, month, day, hour, minute, and second.

## Date Format in Text Tables

Internally, date/time values are handled as a signed 4-byte integer. But in text tables (type DOS, FIX, CSV, FMT, and DBF) dates are most of the time stored as a formatted character string (although they also can be stored as a numeric string representing their internal value). Because there are infinite ways to format a date, the format to use for decoding dates, as well as the field length in the file, must be associated to date columns (except when they are stored as the internal numeric value).

Note that this associated format is used only to describe the way the temporal value is stored internally. This format is used both for output to decode the date in a SELECT statement as well as for input to encode the date in INSERT or UPDATE statements. However, what is kept in this value depends on the data type used in the column definition (all the MariaDB temporal values can be specified). When creating a table, the format is associated to a date column using the DATE\_FORMAT option in the column definition, for instance:

```
create table birthday (
  Name varchar(17),
  Bday date field_length=10 date_format='MM/DD/YYYY',
  Btime time field_length=8 date_format='hh:mm tt')
engine=CONNECT table_type=CSV;

insert into birthday values ('Charlie','2012-11-12','15:30:00');

select * from birthday;
```

The SELECT query returns:

| Name    | Bday       | Btime    |
|---------|------------|----------|
| Charlie | 2012-11-12 | 15:30:00 |

The values of the INSERT statement must be specified using the standard MariaDB syntax and these values are displayed as MariaDB temporal values. Sure enough, the column formats apply only to the way these values are represented inside the CSV files. Here, the inserted record will be:

```
Charlie,11/12/2012,03:30 PM
```

**Note:** The field\_length option exists because the MariaDB syntax does not allow specifying the field length between parentheses for temporal column types. If not specified, the field length is calculated from the date format (sometimes as a max value) or made equal to the default length value if there is no date format. In the above example it could have been removed as the calculated values are the ones specified. However, if the table type would have been DOS or FIX, these values could be adjusted to fit the actual field length within the file.

A CONNECT format string consists of a series of elements that represent a particular piece of information and define its format. The elements will be recognized in the order they appear in the format string. Date and time format elements will be replaced by the actual date and time as they appear in the source string. They are defined by the following groups of characters:

| Element | Description                                                                     |
|---------|---------------------------------------------------------------------------------|
| YY      | The last two digits of the year (that is, 1996 would be coded as "96").         |
| YYYY    | The full year (that is, 1996 could be entered as "96" but displayed as "1996"). |
| MM      | The one or two-digit month number.                                              |
| MMM     | The three-character month abbreviation.                                         |

|      |                                                                     |
|------|---------------------------------------------------------------------|
| MMMM | The full month name.                                                |
| DD   | The one or two-digit month day.                                     |
| DDD  | The three-character weekday abbreviation.                           |
| DDDD | The full weekday name.                                              |
| hh   | The one or two-digit hour in 12-hour or 24-hour format.             |
| mm   | The one or two-digit minute.                                        |
| ss   | The one or two-digit second.                                        |
| t    | The one-letter AM/PM abbreviation (that is, AM is entered as "A").  |
| tt   | The two-letter AM/PM abbreviation (that is, AM is entered as "AM"). |

## Usage Notes

- To match the source string, you can add body text to the format string, enclosing it in single quotes or double quotes if it would be ambiguous. Punctuation marks do not need to be quoted.
- The hour information is regarded as 12-hour format if a “t” or “tt” element follows the “hh” element in the format or as 24-hour format otherwise.
- The “MM”, “DD”, “hh”, “mm”, “ss” elements can be specified with one or two letters (e.g. “MM” or “M”) making no difference on input, but placing a leading zero to one-digit values on output [1] for two-letter elements.
- If the format contains elements DDD or DDDD, the day of week name is skipped on input and ignored to calculate the internal date value. On output, the correct day of week name is generated and displayed.
- Temporal values are always stored as numeric in [BIN](#) and [VEC](#) tables.

## Handling dates that are out of the range of supported CONNECT dates

If you want to make a table containing, for instance, historical dates not being convertible into CONNECT dates, make your column CHAR or VARCHAR and store the dates in the MariaDB format. All date functions applied to these strings will convert them to MariaDB dates and will work as if they were real dates. Of course they must be inserted and will be displayed using the MariaDB format.

## NULL handling

CONNECT handles [null values](#) for data sources able to produce nulls. Currently this concerns mainly the [ODBC](#), [JDBC](#), [MONGO](#), [MYSQL](#), [XML](#), [JSON](#) and [INI](#) table types. For INI, [JSON](#), MONGO or XML types, null values are returned when the key is missing in the section (INI) or when the corresponding node does not exist in a row (XML, JSON, MONGO).

For other file tables, the issue is to define what a null value is. In a numeric column, 0 can sometimes be a valid value but, in some other cases, it can make no sense. The same for character columns; is a blank field a valid value or not?

A special case is DATE columns with a DATE\_FORMAT specified. Any value not matching the format can be regarded as NULL.

CONNECT leaves the decision to you. When declaring a column in the [CREATE TABLE](#) statement, if it is declared NOT NULL, blank or zero values will be considered as valid values. Otherwise they will be considered as NULL values. In all cases, nulls are replaced on insert or update by pseudo null values, a zero-length character string for text types or a zero value for numeric types. Once converted to pseudo null values, they will be recognized as NULL only for columns declared as nullable.

For instance:

```
create table t1 (a int, b char(10)) engine=connect;
insert into t1 values (0,'zero'),(1,'one'),(2,'two'),(null,'???');
select * from t1 where a is null;
```

The select query replies:

| a    | b    |
|------|------|
| NULL | zero |
| NULL | ???  |

Sure enough, the value 0 entered on the first row is regarded as NULL for a nullable column. However, if we execute the query:

```
select * from t1 where a = 0;
```

This will return no line because a NULL is not equal to 0 in an SQL where clause.

Now let us see what happens with not null columns:

```
create table t1 (a int not null, b char(10) not null) engine=connect;
insert into t1 values (0,'zero'),(1,'one'),(2,'two'),(null,'???');
```

The insert statement will produce a warning saying:

| Level   | Code | Message                   |
|---------|------|---------------------------|
| Warning | 1048 | Column 'a' cannot be null |

It is replaced by a pseudo null

0

on the fourth row. Let us see the result:

```
select * from t1 where a is null;
select * from t1 where a = 0;
```

The first query returns no rows, 0 are valid values and not NULL. The second query replies:

| a | b    |
|---|------|
| 0 | zero |
| 0 | ???  |

It shows that the NULL inserted value was replaced by a valid 0 value.

## Unsigned numeric types

They are supported by CONNECT since version 1.01.0010 for fixed numeric types (TINY, SHORT, INTEGER, and BITINT).

## Data type conversion

CONNECT is able to convert data from one type to another in most cases. These conversions are done without warning even when this leads to truncation or loss of precision. This is true, in particular, for tables of type ODBC, JDBC, MYSQL and PROXY (via MySQL) because the source table may contain some data types not supported by CONNECT. They are converted when possible to CONNECT types.

When converted, MariaDB types are converted as:

| MariaDB Types            | CONNECT Type              | Remark                                                                              |
|--------------------------|---------------------------|-------------------------------------------------------------------------------------|
| integer , medium integer | TYPE_INT                  | 4 byte integer                                                                      |
| small integer            | TYPE_SHORT                | 2 byte integer                                                                      |
| tiny integer             | TYPE_TINY                 | 1 byte integer                                                                      |
| char , varchar           | TYPE_STRING               | Same length                                                                         |
| double , float , real    | TYPE_DOUBLE               | 8 byte floating point                                                               |
| decimal , numeric        | TYPE_DECIM                | Length depends on precision and scale                                               |
| all date related types   | TYPE_DATE                 | Date format can be set accordingly                                                  |
| bigint , longlong        | TYPE_BIGINT               | 8 byte integer                                                                      |
| enum , set               | TYPE_STRING               | Numeric value not accessible                                                        |
| All text types           | TYPE_STRING<br>TYPE_ERROR | Depending on the value of the <code>connect_type_conv</code> system variable value. |
| Other types              | TYPE_ERROR                | Not supported, no conversion provided.                                              |

For `ENUM`, the length of the column is the length of the longest value of the enumeration. For `SET` the length is enough to contain all the set values concatenated with comma separator.

In the case of `TEXT` columns, the handling depends on the values given to the `connect_type_conv` and `connect_conv_size` system variables.

Note: `BLOB` is currently not converted by default until a `TYPE_BIN` type is added to CONNECT. However, the `FORCE` option (from Connect 1.06.006) can be specified for blob columns containing text and the `SKIP` option also applies to ODBC BLOB columns.

ODBC SQL types are converted as:

| SQL Types             | Connect Type | Remark                                                                                                                                                   |
|-----------------------|--------------|----------------------------------------------------------------------------------------------------------------------------------------------------------|
| SQL_CHAR, SQL_VARCHAR | TYPE_STRING  |                                                                                                                                                          |
| SQL_LONGVARCHAR       | TYPE_STRING  | len = min(abs(len), connect_conv_size)<br>If the column is generated by discovery (columns not specified) its length is <code>connect_conv_size</code> . |

|                                              |             |                                                                                                                                                          |
|----------------------------------------------|-------------|----------------------------------------------------------------------------------------------------------------------------------------------------------|

| TIMESTAMP                     | TYPE_DATE                 | len = 19 + ((scale) ? (scale +1) : 0)                                                                                                                      |
| BIGINT                        | TYPE_BIGINT               |                                                                                                                                                            |
| UUID (specific to PostgreSQL) | TYPE_STRING<br>TYPE_ERROR | len=36<br>If <a href="#">connect_type_conv=NO</a>                                                                                                          |
| Other types                   | TYPE_ERROR                | <i>Not supported.</i>                                                                                                                                      |

Note: The [connect\\_type\\_conv](#) SKIP option also applies to ODBC and JDBC tables.

1. ↑ Here input and output are used to specify respectively decoding the date to get its numeric value from the data file and encoding a date to write it in the table file. Input is performed within [SELECT](#) queries; output is performed in [UPDATE](#) or [INSERT](#) queries.

## 4.3.7.5 Current Status of the CONNECT Handler

The current CONNECT handler is a GA (stable) release. It was written starting both from an aborted project written for MySQL in 2004 and from the “DBCONNECT” program. It was tested on all the examples described in this document, and is distributed with a set of 53 test cases. Here is a not limited list of future developments:

1. Adding more table types.
2. Make more tests files (53 are already made)
3. Adding more data types, in particular unsigned ones (done for unsigned).
4. Supporting indexing on nullable and decimal columns.
5. Adding more optimize tools (block indexing, dynamic indexing, etc.) (done)
6. Supporting MRR (done)
7. Supporting partitioning (done)
8. Getting NOSQL data from the Net as answers from REST queries (done)

No programs are bug free, especially new ones. Please [report all bugs](#) or documentation errors using the means provided by MariaDB.

## 4.3.7.6 CONNECT Table Types

The main feature of [CONNECT](#) is to give MariaDB the ability to handle tables from many sources, native files, other DBMS's tables, or special “virtual” tables. Moreover, for all tables physically represented by data files, CONNECT recognizes many different file formats, described below but not limited in the future to this list, because more can be easily added to it on demand ([OEM tables](#) ).

Note: You can download a [PDF version of the CONNECT documentation \(1.7.0003\)](#).

### CONNECT Table Types Overview

*CONNECT can handle many table formats.*

### Inward and Outward Tables

*The two broad categories of CONNECT tables.*

### CONNECT Table Types - Data Files

*CONNECT plain DOS or UNIX data files.*

### CONNECT Zipped File Tables

*When the table file or files are compressed in one or several zip files.*

### CONNECT DOS and FIX Table Types

*CONNECT tables based on text files*

### CONNECT DBF Table Type

*CONNECT dBASE III or IV tables.*

### CONNECT BIN Table Type

*CONNECT binary files in which each row is a logical record of fixed length*

### CONNECT VEC Table Type

*CONNECT binary files organized in vectors*

### CONNECT CSV and FMT Table Types

*Variable length CONNECT data files.*

### CONNECT - NoSQL Table Types

*Based on files that do not match the relational format but often represent hierarchical data.*

### CONNECT - Files Retrieved Using Rest Queries

*JSON, XML and CSV data files can be retrieved as results from REST queries.*

### CONNECT JSON Table Type

*JSON (JavaScript Object Notation) is a widely-used lightweight data-interchange format.*

### CONNECT XML Table Type

*CONNECT XML files*

## CONNECTINI Table Type

*CONNECTINI Windows configuration or initialization files.*

## CONNECT - External Table Types

**1** *Access tables belonging to the current or another server.*

## CONNECT ODBC Table Type: Accessing Tables From Another DBMS

**3** *CONNECT Table Types - ODBC Table Type: Accessing Tables from other DBMS*

## CONNECT JDBC Table Type: Accessing Tables from Another DBMS

*Using JDBC to access other tables.*

## CONNECT MONGO Table Type: Accessing Collections from MongoDB

**1** *Used to directly access MongoDB collections as tables.*

## CONNECT MYSQL Table Type: Accessing MySQL/MariaDB Tables

**5** *Accessing a MySQL or MariaDB table or view*

## CONNECT PROXY Table Type

*Tables that access and read the data of another table or view*

## CONNECT XCOL Table Type

*Based on another table/view, used when object tables have a column that contains a list of values*

## CONNECT OCCUR Table Type

*Extension to the PROXY type when referring to a table/view having several c...*

## CONNECT PIVOT Table Type

**2** *Transform the result of another table into another table along "pivot" and "fact" columns.*

## CONNECT TBL Table Type: Table List

**2** *Define a table as a list of tables of any engine and type.*

## CONNECT - Using the TBL and MYSQL Table Types Together

*Used together, the TBL and MYSQL types lift all the limitations of the FEDERATED and MERGE engines*

## CONNECT Table Types - Special "Virtual" Tables

*VIR, WMI and MAC special table types*

## CONNECT Table Types - VIR

*VIR virtual type for CONNECT*

## CONNECT Table Types - OEM: Implemented in an External LIB

*CONNECT OEM table types are implemented in an external library.*

## CONNECT Table Types - Catalog Tables

*Catalog tables return information about another table or data source*

## 4.3.7.6.1 CONNECT Table Types Overview

CONNECT can handle very many table formats; it is indeed one of its main features. The Type option specifies the type and format of the table. The Type options available values and their descriptions are listed in the following table:

| Type    | Description                                                                                                                                                                                                                                                                                                                          |
|---------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| BIN     | Binary file with numeric values in platform representation, also with columns at fixed offset within records and fixed record length.                                                                                                                                                                                                |
| BSON    | (Temporary) JSON table handled by the new JSON handling.                                                                                                                                                                                                                                                                             |
| CSV *\$ | "Comma Separated Values" file in which each variable length record contains column values separated by a specific character (defaulting to the comma)                                                                                                                                                                                |
| DBF *   | File having the dBASE format.                                                                                                                                                                                                                                                                                                        |
| DOS     | The table is contained in one or several files. The file format can be refined by some other options of the command or more often using a specific type as many of those described below. Otherwise, it is a flat text file where columns are placed at a fixed offset within each record, the last column being of variable length. |

|                 |                                                                                                                                                                                                                                 |
|-----------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>DIR</b>      | Virtual table that returns a file list like the Unix<br>ls<br>or DOS<br>dir<br>command.                                                                                                                                         |
| <b>FIX</b>      | Text file arranged like DOS but with fixed length records.                                                                                                                                                                      |
| <b>FMT</b>      | File in which each record contains the column values in a non-standard format (the same for each record) This format is specified in the column definition.                                                                     |
| <b>INI</b>      | File having the format of the initialization or configuration files used by many applications.                                                                                                                                  |
| <b>JDBC *</b>   | Table accessed via a JDBC driver.                                                                                                                                                                                               |
| <b>JSON *\$</b> | File having the JSON format.                                                                                                                                                                                                    |
| <b>MAC</b>      | Virtual table returning information about the machine and network cards (Windows only).                                                                                                                                         |
| <b>MONGO *</b>  | Table accessed via the MongoDB C Driver API.                                                                                                                                                                                    |
| <b>MYSQL *</b>  | Table accessed using the MySQL API like the FEDERATED engine.                                                                                                                                                                   |
| <b>OCCUR *</b>  | A table based on another table existing on the current server, several columns of the object table containing values that can be grouped in only one column.                                                                    |
| <b>ODBC *</b>   | Table extracted from an application accessible via ODBC or unixODBC. For example from another DBMS or from an Excel spreadsheet.                                                                                                |
| <b>OEM *</b>    | Table of any other formats not directly handled by CONNECT but whose access is implemented by an external FDW (foreign data wrapper) written in C++ (as a DLL or Shared Library).                                               |
| <b>PIVOT *</b>  | Used to "pivot" the display of an existing table or view.                                                                                                                                                                       |
| <b>PROXY *</b>  | A table based on another table existing on the current server.                                                                                                                                                                  |
| <b>TBL *</b>    | Accessing a collection of tables as one table (like the MERGE engine does for MyISAM tables)                                                                                                                                    |
| <b>VEC</b>      | Binary file organized in vectors, in which column values are grouped consecutively, either split in separate files or in a unique file.                                                                                         |
| <b>VIR*</b>     | Virtual table containing only special and virtual columns.                                                                                                                                                                      |
| <b>WMI *</b>    | Windows Management Instrumentation table displaying information coming from a WMI provider. This type enables to get in tabular format all sorts of information about the machine hardware and operating system (Windows only). |
| <b>XCOL *</b>   | A table based on another table existing on the current server with one of its columns containing comma separated values.                                                                                                        |
| <b>XML *\$</b>  | File having the XML or HTML format.                                                                                                                                                                                             |
| <b>ZIP</b>      | Table giving information about the contents of a zip file.                                                                                                                                                                      |

## Catalog Tables

For all table types marked with a '\*' in the table above, CONNECT is able to analyze the data source to retrieve the column definition. This can be used to define a "catalog" table that displays the column description of the source, or to create a table without specifying the column definition that will be automatically constructed by CONNECT when creating the table.

When marked with a '\$' the file can be the result returned by a REST query.

### 4.3.7.6.2 Inward and Outward Tables

#### Contents

- 1. [Outward Tables](#)
  - 1. [Altering Outward Tables](#)
- 2. [Inward Tables](#)
  - 1. [Altering Inward Tables](#)

There are two broad categories of file-based CONNECT tables. Inward and Outward. They are described below.

## Outward Tables

Tables are "outward" when their file name is specified in the CREATE TABLE statement using the `file_name` option.

Firstly, remember that CONNECT implements MED (Management of External Data). This means that the "true" CONNECT tables – "outward tables" – are based on data that belongs to files that can be produced by other applications or data imported from another DBMS.

Therefore, their data is "precious" and should not be modified except by specific commands such as `INSERT`, `UPDATE`, or `DELETE`. For other

commands such as [CREATE](#), [DROP](#), or [ALTER](#) their data is never modified or erased.

Outward tables can be created on existing files or external tables. When they are dropped, only the local description is dropped, the file or external table is not dropped or erased. Also, [DROP TABLE](#) does not erase the indexes.

[ALTER TABLE](#) produces the following warning, as a reminder:

```
Warning (Code 1105): This is an outward table, table data were not modified.
```

If the specified file does not exist, it is created when data is inserted into the table. If a [SELECT](#) is issued before the file is created, the following error is produced:

```
Warning (Code 1105): Open(rb) error 2 on <file_path>: No such file or directory
```

## Altering Outward Tables

When an [ALTER TABLE](#) is issued, it just modifies the table definition accordingly without changing the data. [ALTER](#) can be used safely to, for instance, modify options such as [MAPPED](#), [HUGE](#) or [READONLY](#) but with extreme care when modifying column definitions or order options because some column options such as [FLAG](#) should also be modified or may become wrong.

Changing the table type with [ALTER](#) often makes no sense. But many suspicious alterations can be acceptable if they are just meant to correct an existing wrong definition.

Translating a CONNECT table to another engine is fine but the opposite is forbidden when the target CONNECT table is not table based or when its data file exists (because when the target table data cannot be changed and if the source table is dropped, the table data would be lost). However, it can be done to create a new file-based tables when its file does not exist or is void.

Creating or dropping indexes is accepted because it does not modify the table data. However, it is often unsafe to do it with an [ALTER TABLE](#) statement that does other modifications.

Of course, all changes are acceptable for empty tables.

**Note:** Using outward tables requires the [FILE](#) privilege.

## Inward Tables

A special type of file-based CONNECT tables are "inward" tables. They are file-based tables whose file name is not specified in the [CREATE TABLE](#) statement (no `file_name` option).

Their file will be located in the current database directory and their name will default to `tablename.type` where `tablename` is the table name and `type` is the table type folded to lower case. When they are created without using a

```
CREATE TABLE ... SELECT ...
statement, an empty file is made at create time and they can be populated by further inserts.
```

They behave like tables of other storage engines and, unlike outward CONNECT tables, they are erased when the table is dropped. Of course they should not be read-only to be usable. Even though their utility is limited, they can be used for testing purposes or when the user does not have the [FILE](#) privilege.

## Altering Inward Tables

One thing to know, because CONNECT builds indexes in a specific way, is that all index modifications are done using an "in-place" algorithm – meaning not using a temporary table. This is why, when indexing is specified in an [ALTER TABLE](#) statement containing other changes that cannot be done "in-place", the statement cannot be executed and raises an error.

Converting an inward table to an outward table, using an [ALTER TABLE](#) statement specifying a new file name and/or a new table type, is restricted the same way it is when converting a table from another engine to an outward table. However there are no restrictions to convert another engine table to a CONNECT inward table.

## 4.3.7.6.3 CONNECT Table Types - Data Files

### Contents

1. [Multiple File Tables](#)
2. [Record Format](#)
3. [File Mapping](#)
4. [Big File Tables](#)
5. [Compressed File Tables](#)
6. [Relational Formatted Tables](#)
7. [NoSQL Table Types](#)

Most of the tables processed by CONNECT are just plain DOS or UNIX data files, logically regarded as tables thanks to the description given when creating the table. This description comes from the

[CREATE TABLE](#)

statement. Depending on the application, these tables can already exist as data files, used as is by CONNECT, or can have been physically

made by CONNECT as the result of a

```
CREATE TABLE ... SELECT ...
and/or INSERT statement(s).
```

The file *path/name* is given by the

```
FILE_NAME
option. If it is a relative path/name, it will be relative to the database directory, the one containing the table
.FR
file.
```

Unless specified, the maturity of file table types is stable.

## Multiple File Tables

A **multiple** file table is one that is physically contained in several files of the same type instead of just one. These files are processed sequentially during the process of a query and the result is the same as if all the table files were merged into one. This is great to process files coming from different sources (such as cash register log files) or made at different time periods (such as bank monthly reports) regarded as one table. Note that the operations on such files are restricted to sequential Select and Update; and that VEC multiple tables are not supported by CONNECT. The file list depends on the setting of the **multiple** option of the

```
CREATE TABLE
statement for that table.
```

Multiple tables are specified by the option MULTIPLE= *n* , which can take four values:

|   |                                                                                                                                                                    |
|---|--------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0 | Not a multiple table (the default). This can be used in an <a href="#">ALTER TABLE</a> statement.                                                                  |
| 1 | The table is made from files located in the same directory. The FILE_NAME option is a pattern such as<br>'cash*.log'<br>that all the table file path/names verify. |
| 2 | The FILE_NAME gives the name of a file that contains the path/names of all the table files. This file can be made using a DIR table.                               |
| 3 | Like multiple=1 but also including eligible files from the directory sub-folders.                                                                                  |

The

```
FILEID
special column, described here , allows query pruning by filtering the file list or doing some grouping on the files that make a multiple table.
```

**Note:** Multiple was not initially implemented for XML tables. This restriction was removed in version 1.02.

## Record Format

This characteristic applies to table files handled by the operating system input/output functions. It is **fixed** for table types **FIX** , **BIN** , **DBF** and **VEC** , and it is variable for **DOS** , **VCT**, **FMT** and some **JSON** tables.

For fixed tables, most I/O operations are done by block of BLOCK\_SIZE rows. This diminishes the number of I/O's and enables block indexing.

Starting with CONNECT version 1.6.6, the BLOCK\_SIZE option can also be specified for variable tables. Then, a file similar to the block indexing file is created by CONNECT that gives the size in bytes of each block of BLOCK\_SIZE rows. This enables the use of block I/Os and block indexing to variable tables. It also enables CONNECT to return the exact row number for info commands

## File Mapping

For file-based tables of reasonable size, processing time can be greatly enhanced under Windows(TM) and some flavors of UNIX or Linux by using the technique of "file mapping", in which a file is processed as if it were entirely in memory. Mapping is specified when creating the table by the use of the

```
MAPPED=YES
option. This does not apply to tables not handled by system I/O functions (
```

```
XML
```

and

```
INI
```

).

## Big File Tables

Because all files are handled by the standard input/output functions of the operating system, their size is limited to 2GB, the maximum size handled by standard functions. For some table types, CONNECT can deal with files that are larger than 2GB, or prone to become larger than this limit. These are the **FIX** , **BIN** and **VEC** types. To tell connect to use input/output functions dealing with big files, specify the option

```
huge=1
or
```

huge=YES

for that table. Note however that CONNECT cannot randomly access tables having more than 2G records.

## Compressed File Tables

CONNECT can make and process some tables whose data file is compressed. The only supported compression format is the zlib format. Zip and zlib formats are supported differently. The table types that can be compressed are [DOS](#), [FIX](#), [BIN](#), [CSV](#) and [FMT](#). This can save some disk space at the cost of a somewhat longer processing time.

Some restrictions apply to compressed tables:

- Compressed tables are not indexable.
- Update and partial delete are not supported.

Use the numeric compress option to specify a compressed table:

1. Not compressed
2. Compressed in zlib format.
3. Made of compressed blocks of block\_size records (enabling block indexing)

## Relational Formatted Tables

These are based on files whose records represent one table row. Only the column representation within each record can differ. The following relational formatted tables are supported:

- [DOS and FIX Table Types](#)
- [DBF Table Type](#)
- [BIN Table Type](#)
- [VEC Table Type](#)
- [CSV and FMT Table Types](#)

## NoSQL Table Types

These are based on files that do not match the relational format but often represent hierarchical data. CONNECT can handle JSON, INI-CFG, XML and some HTML files..

The way it is done is different from what PostgreSQL does. In addition to including in a table some column values of a specific data format (JSON, XML) to be handled by specific functions, CONNECT can directly use JSON, XML or INI files that can be produced by other applications and this is the table definition that describes where and how the contained information must be retrieved.

This is also different from what MariaDB does with [dynamic columns](#), which is close to what MySQL and PostgreSQL do with the JSON column type.

The following NoSQL types are supported:

- [XML Table Type](#)
- [JSON Table Type](#)
- [INI Table Type](#)

## 4.3.7.6.4 CONNECT Zipped File Tables

MariaDB starting with [10.2.4](#)

Connect can work on table files that are compressed in one or several zip files.

The specific options used when creating tables based on zip files are:

| Table Option | Type    | Description                                                                                                                                                                                                                                               |
|--------------|---------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| ZIPPED       | Boolean | Required to be set as true.                                                                                                                                                                                                                               |
| ENTRY*       | String  | The optional name or pattern of the zip entry or entries to be used with the table. If not specified, all entries or only the first one will be used depending on the mulentries option setting.                                                          |
| MULENTRIES*  | Boolean | True if several entries are part of the table. If not specified, it defaults to false if the entry option is not specified. If the entry option is specified, it defaults to true if the entry name contains wildcard characters or false if it does not. |
| APPEND*      | Boolean | Used when creating new zipped tables (see below)                                                                                                                                                                                                          |
| LOAD*        | String  | Used when creating new zipped tables (see below)                                                                                                                                                                                                          |

Options marked with a '\*' must be specified in the option list.

Examples of use:

Example 1: Single CSV File Included in a Single ZIP File

Let's suppose you have a CSV file from which you would create a table by:

```
create table emp
... optional column definition
engine=connect table_type=CSV file_name='E:/Data/employee.csv'
sep_char=';' header=1;
```

If the CSV file is included in a ZIP file, the CREATE TABLE becomes:

```
create table empzip
... optional column definition
engine=connect table_type=CSV file_name='E:/Data/employee.zip'
sep_char=';' header=1 zipped=1 option_list='Entry=emp.csv';
```

The `file_name` option is the name of the zip file. The `entry` option is the name of the entry inside the zip file. If there is only one entry file inside the zip file, this option can be omitted.

## Example 2: Several CSV Files Included in a Single ZIP File

If the table is made from several files such as `emp01.csv`, `emp02.csv`, etc., the standard create table would be:

```
create table empmul (
... required column definition
) engine=connect table_type=CSV file_name='E:/Data/emp*.csv'
sep_char=';' header=1 multiple=1;
```

But if these files are all zipped inside a unique zip file, it becomes:

```
create table empzmul
... required column definition
engine=connect table_type=CSV file_name='E:/Data/emp.zip'
sep_char=';' header=1 zipped=1 option_list='Entry=emp*.csv';
```

Here the `entry` option is the pattern that the files inside the zip file must match. If all entry files are ok, the `entry` option can be omitted but the Boolean option `mulentries` must be specified as true.

## Example 3: Single CSV File included in Multiple ZIP Files (Without considering subfolders)

If the table is created on several zip files, it is specified as for all other multiple tables:

```
create table zempmul (
... required column definition
) engine=connect table_type=CSV file_name='E:/Data/emp*.zip'
sep_char=';' header=1 multiple=1 zipped=yes
option_list='Entry=employee.csv';
```

Here again the `entry` option is used to restrict the entry file(s) to be used inside the zip files and can be omitted if all are ok.

The column descriptions can be retrieved by the discovery process for table types allowing it. It cannot be done for multiple tables or multiple entries.

A catalog table can be created by adding `catfunc=columns`. This can be used to show the column definitions of multiple tables. `Multiple` must be set to false and the column definitions will be the ones of the first table or entry.

This first implementation has some restrictions:

1. Zipped tables are read-only. `UPDATE` and `DELETE` are not supported. However, `INSERT` is supported in a specific way when making tables.
2. The inside files are decompressed into memory. Memory problems may arise with huge files.
3. Only file types that can be handled from memory are eligible for this. This includes `DOS`, `FIX`, `BIN`, `CSV`, `FMT`, `DBF`, `JSON`, and `XML` table types, as well as types based on these such as `XCOL`, `OCCUR` and `PIVOT`.

Optimization by indexing or block indexing is possible for table types supporting it. However, it applies to the uncompressed table. This means that the whole table is always uncompressed.

Partitioning is also supported. See how to do it in the section about partitioning.

## Creating New Zipped Tables

Tables can be created to access already existing zip files. However, is it also possible to make the zip file from an existing file or table. Two ways are available to make the zip file:

### Insert Method

`insert` can be used to make the table file for table types based on records (this excludes DBF, XML and JSON when `pretty` is not 0). However, the current

implementation of the used package (minizip) does not support adding to an already existing zip entry. This means that when executing an insert statement the inserted records are not added but replace the existing ones. CONNECT protects existing data by not allowing such inserts, Therefore, only three ways are available to do so:

1. Using only one insert statement to make the whole table. This is possible only for small tables and is principally useful when making tests.
2. Making the table from the data of another table. This can be done by executing an "insert into table select \* from another\_table" or by specifying "as select \* from another\_table" in the create table statement.
3. Making the table from a file whose format enables to use the "load data infile" statement.

To add a new entry in an existing zip file, specify "append=YES" in the option list. When inserting several entries, use ALTER to specify the required options, for instance:

```
create table znumul (
Chiffre int(3) not null,
Lettre char(16) not null
engine=CONNECT table_type=CSV
file_name='C:/Data/FMT/mnum.zip' header=1 lrecl=20 zipped=1
option_list='Entry=Num1';
insert into znumul select * from num1;
alter table znumul option_list='Entry=Num2,Append=YES';
insert into znumul select * from num2;
alter table znumul option_list='Entry=Num3,Append=YES';
insert into znumul select * from num3;
alter table znumul option_list='Entry=Num*,Append=YES';
select * from znumul;
```

The last ALTER is needed to display all the entries.

## File Zipping Method

This method enables to make the zip file from another file when creating the table. It applies to all table types including DBF, XML and JSON. It is specified in the create table statement with the load option. For example:

```
create table XSERVZIP (
NUMERO varchar(4) not null,
LIEU varchar(15) not null,
CHEF varchar(5) not null,
FONCTION varchar(12) not null,
NOM varchar(21) not null
engine=CONNECT table_type=XML file_name='E:/Xml/perso.zip' zipped=1
option_list='entry=services,load=E:/Xml/serv2.xml';
```

When executing this statement, the *serv2.xml* file will be zipped as */perso.zip*. The entry name can be specified or defaults to the source file name.

If the column descriptions are specified, the table can be used later to read from the zipped table, but they are not used when creating the zip file. Thus, a fake column (there must be one) can be specified and another table created to read the zip file. This one can take advantage of the discovery process to avoid providing the columns description for table types allowing it. For instance:

```
create table mkzq (whatever int)
engine=connect table_type=DBF zipped=1
file_name='C:/Data/EAUX/dbf/CQUART.ZIP'
option_list='Load=C:/Data/EAUX/dbf/CQUART.DBF';

create table zquart
engine=connect table_type=DBF zipped=1
file_name='C:/Data/EAUX/dbf/CQUART.ZIP';
```

It is also possible to create a multi-entries table from several files:

```
CREATE TABLE znewcities (
_id char(5) NOT NULL,
city char(16) NOT NULL,
lat double(18,6) NOT NULL `FIELD_FORMAT`='loc:[0]',
lng double(18,6) NOT NULL `FIELD_FORMAT`='loc:[1]',
pop int(6) NOT NULL,
state char(2) NOT NULL
) ENGINE=CONNECT TABLE_TYPE=JSON FILE_NAME='E:/Json/newcities.zip' ZIPPED=1 LRECL=1000 OPTION_LIST='Load=E:/Json/city_*.json,mul',
```

Here the files to load are specified with wildcard characters and the *mulentries* options must be specified. However, the *entry* option must not be specified, entry names will be made from the file names. Provide a fake column description if the files have different column layout, but specific tables will have to be created to read each of them.

## ZIP Table Type

A ZIP table type is also available. It is not meant to read the inside files but to display information about the zip file contents. For instance:

```
create table xzipinfo2 (
entry varchar(256)not null,
cmpsize bigint not null flag=1,
uncsize bigint not null flag=2,
method int not null flag=3,
date datetime not null flag=4)
engine=connect table_type=ZIP file_name='E:/Data/Json/cities.zip';
```

This will display the name, compressed size, uncompressed size, and compress method of all entries inside the zip file. Column names are irrelevant; these are flag values that mean what information to retrieve.

It is possible to retrieve this information from several zip files by specifying the multiple option:

```
create table TestZip1 (
entry varchar(260)not null,
cmpsize bigint not null flag=1,
uncsize bigint not null flag=2,
method int not null flag=3,
date datetime not null flag=4,
zipname varchar(256) special='FILEID')
engine=connect table_type=ZIP multiple=1
file_name='C:/Data/Ziptest/CCAM06300_DBF_PART*.zip';
```

Here we added the special column zipname to get the name of the zip file for each entry.

## 4.3.7.6.5 CONNECT DOS and FIX Table Types

### Contents

1. [Overview](#)
2. [Specifying the Field Format](#)
3. [Example](#)

### Overview

Tables of type DOS and FIX are based on text files (see [CONNECT Table Types - Data Files](#) ). Within a record, column fields are positioned at a fixed offset from the beginning of the record. Except sometimes for the last field, column fields are also of fixed length. If the last field has varying length, the type of the table is DOS. For instance, having the file *dept.dat* formatted like:

|                   |                   |                        |
|-------------------|-------------------|------------------------|
| 0318 KINGSTON     | 70012 SALES       | Bank/Insurance         |
| 0021 ARMONK       | 87777 CHQ         | Corporate headquarter  |
| 0319 HARRISON     | 40567 SALES       | Federal Administration |
| 2452 POUGHKEEPSIE | 31416 DEVELOPMENT | Research & development |

You can define a table based on it with:

```
create table department (
number char(4) not null,
location char(15) not null flag=5,
director char(5) not null flag=20,
function char(12) not null flag=26,
name char(22) not null flag=38)
engine=CONNECT table_type=DOS file_name='dept.dat';
```

Here the flag column option represents the offset of this column inside the records. If the offset of a column is not specified, it defaults to the end of the previous column and defaults to 0 for the first one. The

*lrecl*

parameter that represents the maximum size of a record is calculated by default as the end of the rightmost column and can be unspecified except when some trailing information exists after the rightmost column.

**Note:** A special case is files having an encoding such as UTF-8 (for instance specifying

*charset=UTF8*

) in which some characters may be represented with several bytes. Unlike the type size that MariaDB interprets as a number of characters, the

*lrecl*

*value* is the record size in bytes and the flag value represents the offset of the field in the record in bytes. If the flag and/or the

*lrecl*

*value* are not specified, they will be calculated by the number of characters in the fields multiplied by a value that is the maximum size in bytes of a character for the corresponding charset. For UTF-8 this value is 3 which is often far too much as there are very few characters requiring 3 bytes to be represented. When creating a new file, you are on the safe side by only doubling the maximum number of characters of a field to

calculate the offset of the next field. Of course, for already existing files, the offset must be specified according to what it is in it.

Although the field representation is always text in the table file, you can freely choose the corresponding column type, characters, date, integer or floating point according to its contents.

Sometimes, as in the *number* column of the above *department* table, you have the choice of the type, numeric or characters. This will modify how the column is internally handled — in characters

```
0021  
is different from  
21  
but not in numeric — as well as how it is displayed.
```

If the last field has fixed length, the table should be referred as having the type

```
FIX  
. For instance, to create a table on the file boys.txt :
```

|        |          |            |            |
|--------|----------|------------|------------|
| John   | Boston   | 25/01/1986 | 02/06/2010 |
| Henry  | Boston   | 07/06/1987 | 01/04/2008 |
| George | San Jose | 10/08/1981 | 02/06/2010 |
| Sam    | Chicago  | 22/11/1979 | 10/10/2007 |
| James  | Dallas   | 13/05/1992 | 14/12/2009 |
| Bill   | Boston   | 11/09/1986 | 10/02/2008 |

You can for instance use the command:

```
create table boys (  
    name char(12) not null,  
    city char(12) not null,  
    birth date not null date_format='DD/MM/YYYY',  
    hired date not null date_format='DD/MM/YYYY' flag=36  
engine=CONNECT table_type=FIX file_name='boys.txt' lrecl=48;
```

Here some *flag* options were not specified because the fields have no intermediate space between them except for the last column. The offsets are calculated by default adding the field length to the *offset* of the preceding field. However, for formatted date columns, the offset in the file depends on the format and cannot be calculated by default. For fixed files, the *lrec* option is the physical length of the record including the line ending character(s). It is calculated by adding to the end of the last field 2 bytes under Windows (CRLF) or 1 byte under UNIX. If the file is imported from another operating system, the

```
ENDING  
option will have to be specified with the proper value.
```

For this table, the last offset and the record length must be specified anyway because the date columns have field length coming from their format that is not known by CONNECT. Do not forget to add the line ending length to the total length of the fields.

This table is displayed as:

| name   | city     | birth      | hired      |
|--------|----------|------------|------------|
| John   | Boston   | 1986-01-25 | 2010-06-02 |
| Henry  | Boston   | 1987-06-07 | 2008-04-01 |
| George | San Jose | 1981-08-10 | 2010-06-02 |
| Sam    | Chicago  | 1979-11-22 | 2007-10-10 |
| James  | Dallas   | 1992-05-13 | 2009-12-14 |
| Bill   | Boston   | 1986-09-11 | 2008-02-10 |

Whenever possible, the fixed format should be preferred to the varying one because it is much faster to deal with fixed tables than with variable tables. Sure enough, instead of being read or written record by record, FIX tables are processed by blocks of

```
BLOCK_SIZE  
records, resulting in far less input/output operations to execute. The block size defaults to 100 if not specified in the Create Table statement.
```

**Note 1:** It is not mandatory to declare in the table all the fields existing in the source file. However, if some fields are ignored, the *flag* option of the following field and/or the *lrec* option will have to be specified.

**Note 2:** Some files have an EOF marker (CTRL+Z 1A) that can prevent the table to be recognized as fixed because the file length is not a multiple of the fixed record size. To indicate this, use in the option list the create option EOF. For instance, if after creating the FIX table *xtab* on the file *foo.dat* that you know have fixed record size, you get, when you try to use it, a message such as:

```
File foo.dat is not fixed length, len=302587 lrecl=141
```

After checking that the LRECL default or specified specification is correct, you can indicate to ignore that extra EOF character by:

```
alter table xtab option_list='eof=1';
```

Of course, you can specify this option directly in the Create statement. All this applies to some other table types, in particular to BIN tables.

**Note 3:** The width of the fields is the length specified in the column declaration. For instance for a column declared as:

```
number int(3) not null,
```

The field width in the file is 3 characters. This is the value used to calculate the offset of the next field if it is not specified. If this length is not specified, it defaults to the MySQL default type length.

## Specifying the Field Format

Some files have specific format for their numeric fields. For instance, the decimal point is absent and/or the field should be filled with leading zeros. To deal with such files, as well in reading as in writing, the format can be specified in the

```
CREATE TABLE
```

column definition. The syntax of the field format specification is:

```
Field_format='[Z][N][d]'
```

The optional parts of the format are:

- Z** The field has leading zeros
- N** No decimal point exist in the file
- d** The number of decimals, defaults to the column precision

## Example

Let us see how it works in the following example. We define a table based on the file xfmt.txt having eight fields of 12 characters:

```
create table xfmt (
    col1 double(12,3) not null,
    col2 double(12,3) not null field_format='4',
    col3 double(12,2) not null field_format='N3',
    col4 double(12,3) not null field_format='Z',
    col5 double(12,3) not null field_format='Z3',
    col6 double(12,5) not null field_format='ZN5',
    col7 int(12) not null field_format='N3',
    col8 smallint(12) not null field_format='N3')
engine=CONNECT table_type=FIX file_name='xfmt.txt';

insert into xfmt values(4567.056,4567.056,4567.056,4567.056,-23456.8,
    3.14159,4567,4567);
select * from xfmt;
```

The first row is displayed as:

| COL1     | COL2     | COL3    | COL4     | COL5       | COL6    | COL7 | COL8 |
|----------|----------|---------|----------|------------|---------|------|------|
| 4567.056 | 4567.056 | 4567.06 | 4567.056 | -23456.800 | 3.14159 | 4567 | 4567 |

The number of decimals displayed for all float columns is the column precision, the second argument of the column type option. Of course, integer columns have no decimals, although their formats specify some.

More interesting is the file layout. To see it let us define another table based on the same file but whose columns are all characters:

```
create table cfmt (
    col1 char(12) not null,
    col2 char(12) not null,
    col3 char(12) not null,
    col4 char(12) not null,
    col5 char(12) not null,
    col6 char(12) not null,
    col7 char(12) not null,
    col8 char(12) not null)
engine=CONNECT table_type=FIX file_name='xfmt.txt';
select * from cfmt;
```

The (transposed) display of the select command shows the file text layout for each field. Below a third column was added in this document to comment this result.

| Column | Row 1 | Comment (all numeric fields are written right justified) |
|--------|-------|----------------------------------------------------------|
|        |       |                                                          |

|             |              |                                                                                                                                 |
|-------------|--------------|---------------------------------------------------------------------------------------------------------------------------------|
| <b>COL1</b> | 4567.056     | No format, the value was entered as is.                                                                                         |
| <b>COL2</b> | 4567.0560    | The format '4' forces to write 4 decimals.                                                                                      |
| <b>COL3</b> | 4567060      | N3 → No decimal point. The last 3 digits are decimals. However, the second decimal was rounded because of the column precision. |
| <b>COL4</b> | 00004567.056 | Z → Leading zeros, 3 decimals (the column precision)                                                                            |
| <b>COL5</b> | -0023456.800 | Z3 → (Minus sign) leading zeros, 3 decimals.                                                                                    |
| <b>COL6</b> | 000000314159 | ZN5 → Leading zeros, no decimal point, 5 decimals.                                                                              |
| <b>COL7</b> | 4567000      | N3 → No decimal point. The last 3 digits are decimals.                                                                          |
| <b>COL8</b> | 4567000      | Same. Any decimals would be ignored.                                                                                            |

**Note:** For columns internally using double precision floating-point numbers, MariaDB limits the decimal precision of any calculation to the column precision. The declared column precision should be at least the number of decimals of the format to avoid a loss of decimals as it happened for

col3

of the above example.

## 4.3.7.6.6 CONNECT DBF Table Type

### Contents

- 1. [Overview](#)
- 2. [Conversion of dBASE Data Types](#)
- 3. [Reading soft deleted lines of a DBF table](#)

## Overview

A table of type

DBF

is physically a dBASE III or IV formatted file (used by many products like dBASE, Xbase, FoxPro etc.). This format is similar to the [FIX](#) type format with in addition a prefix giving the characteristics of the file, describing in particular all the fields (columns) of the table.

Because

DBF

files have a header that contains Meta data about the file, in particular the column description, it is possible to create a table based on an existing

DBF

file without giving the column description, for instance:

```
create table cust engine=CONNECT table_type=DBF file_name='cust.dbf';
```

To see what CONNECT has done, you can use the

DESCRIBE

or

SHOW CREATE TABLE

commands, and eventually modify some options with the

ALTER TABLE

command.

The case of deleted lines is handled in a specific way for DBF tables. Deleted lines are not removed from the file but are "soft deleted" meaning they are marked as deleted. In particular, the number of lines contained in the file header does not take care of soft deleted lines. This is why if you execute these

two commands applied to a DBF table named *tabdbf*:

```
select count(*) from tabdbf;
select count(*) from tabdbf where 1;
```

They can give a different result, the (fast) first one giving the number of physical lines in the file and the second one giving the number of line that are not (soft) deleted.

The commands UPDATE, INSERT, and DELETE can be used with DBF tables. The DELETE command marks the deleted lines as suppressed but keeps them in the file. The INSERT command, if it is used to populate a newly created table, constructs the file header before inserting new lines.

**Note:** For DBF tables, column name length is limited to 11 characters and field length to 256 bytes.

## Conversion of dBASE Data Types

CONNECT handles only types that are stored as characters.

| Symbol | DBF Type        | CONNECT Type                        | Description                                                                                         |
|--------|-----------------|-------------------------------------|-----------------------------------------------------------------------------------------------------|
| B      | Binary (string) | TYPE_STRING                         | 10 digits representing a .DBT block number.                                                         |
| C      | Character       | TYPE_STRING                         | All OEM code page characters - padded with blanks to the width of the field.                        |
| D      | Date            | TYPE_DATE                           | 8 bytes - date stored as a string in the format YYYYMMDD.                                           |
| N      | Numeric         | TYPE_INT TYPE_BIGINT<br>TYPE_DOUBLE | Number stored as a string, right justified, and padded with blanks to the width of the field.       |
| L      | Logical         | TYPE_STRING                         | 1 byte - initialized to 0x20 otherwise T or F.                                                      |
| M      | Memo (string)   | TYPE_STRING                         | 10 digits representing a .DBT block number.                                                         |
| @      | Timestamp       | Not supported                       | 8 bytes - two longs, first for date, second for time. It is the number of days since 01/01/4713 BC. |
| I      | Long            | Not supported                       | 4 bytes. Leftmost bit used to indicate sign, 0 negative.                                            |
| +      | Autoincrement   | Not supported                       | Same as a Long                                                                                      |
| F      | Float           | TYPE_DOUBLE                         | Number stored as a string, right justified, and padded with blanks to the width of the field.       |
| O      | Double          | Not supported                       | 8 bytes - no conversions, stored as a double.                                                       |
| G      | OLE             | TYPE_STRING                         | 10 digits representing a .DBT block number.                                                         |

For the N numeric type, CONNECT converts it to TYPE\_DOUBLE if the decimals value is not 0, to TYPE\_BIGINT if the length value is greater than 10, else to TYPE\_INT.

For M, B, and G types, CONNECT just returns the DBT number.

## Reading soft deleted lines of a DBF table

It is possible to read these lines by changing the read mode of the table. This is specified by an option

READMODE

that can take the values:

- 0 Standard mode. This is the default option.
- 1 Read all lines including soft deleted ones.
- 2 Read only the soft deleted lines.

For example, to read all lines of the *tabdbf* table, you can do:

```
alter table tabdbf option_list='Readmode=1';
```

To come back to normal mode, specify READMODE=0.

## 4.3.7.6.7 CONNECT BIN Table Type

### Contents

- 1. Overview
- 2. Type Conversion in BIN Tables
- 3. Example
- 4. Numeric fields alignment

# Overview

A table of type BIN is physically a binary file in which each row is a logical record of fixed length [1]. Within a record, column fields are of a fixed offset and length as with [FIX tables](#). Specific to BIN tables is that numerical values are internally encoded using native platform representation, so no conversion is needed to handle numerical values in expressions.

It is not required that the lines of a BIN file be separated by characters such as CR and/or LF but this is possible. In such an event, the */rec/* option must be specified accordingly.

**Note:** Unlike for the [DOS and FIX types](#), the width of the fields is the length of their internal representation in the file. For instance for a column declared as:

```
number int(5) not null,
```

The field width in the file is 4 characters, the size of a binary integer. This is the value used to calculate the offset of the next field if it is not specified. Therefore, if the next field is placed 5 characters after this one, this declaration is not enough, and the flag option will have to be used on the next field.

## Type Conversion in BIN Tables

Here are the correspondences between the column type and field format provided by default:

| Column type          | File default format             |
|----------------------|---------------------------------|
| Char( <i>n</i> )     | Text of <i>n</i> characters.    |
| Date                 | Integer (4 bytes)               |
| Int( <i>n</i> )      | Integer (4 bytes)               |
| Smallint( <i>n</i> ) | Short integer (2 bytes)         |
| TinyInt( <i>n</i> )  | Char (1 Byte)                   |
| Bigint( <i>n</i> )   | Large integer (8 bytes)         |
| Double( <i>n,d</i> ) | Double floating point (8 bytes) |

However, the column type need not necessarily match the field format within the table file. In particular, this occurs for field formats that correspond to numeric types that are not handled by CONNECT [2]. Indeed, BIN table files may internally contain float numbers or binary numbers of any byte length in big-endian or little-endian representation [3]. Also, as in [DOS or FIX types](#) tables, you may want to handle some character fields as numeric or vice versa.

This is why it is possible to specify the field format when it does not correspond to the column type default using the *field\_format* column option in the [CREATE TABLE](#) statement. Here are the available field formats for BIN tables:

| Field_format                          | Internal representation                                                                  |
|---------------------------------------|------------------------------------------------------------------------------------------|
| [ <i>n</i> ]{L or B or H}{ <i>n</i> } | <i>n</i> bytes binary number in little endian, big endian or host endian representation. |
| C                                     | Characters string ( <i>n</i> bytes)                                                      |
| I                                     | integer (4 bytes)                                                                        |
| D                                     | Double float (8 bytes)                                                                   |
| S                                     | Short integer (2 bytes)                                                                  |
| T                                     | Tiny integer (1 byte)                                                                    |
| G                                     | Big integer (8 bytes)                                                                    |
| F or R                                | Real or float (Floating point number on 4 bytes)                                         |
| X                                     | Use the default format field for the column type                                         |

All field formats (except the first one) are a one-character specification [4]. 'X' is equivalent to not specifying the field format. For the 'C' character specification, *n* is the column width as specified with the column type. For one-column formats, the number of bytes of the numeric fields corresponds to what it is on most platforms. However, it could vary for some. The G, I, S and T formats are deprecated because they correspond to supported data types and may not be supported in future versions.

## Example

Here is an example of a BIN table. The file record layout is supposed to be:

```
NNNNCCCCCCCCIIIISSFFFFSS
```

Here N represents numeric characters, C any characters, I integer bytes, S short integer bytes, and F float number bytes. The

<sup>1111</sup>

field contains a date in numeric format.

The table could be created by:

```
create table testbal (
fig int(4) not null field_format='C',
name char(10) not null,
birth date not null field_format='L',
id char(5) not null field_format='L2',
salary double(9,2) not null default 0.00 field_format='F',
dept int(4) not null field_format='L2')
engine=CONNECT table_type=BIN block_size=5 file_name='Testbal.dat';
```

Specifying the little-endian representation for binary values is not useful on most machines, but makes the create table statement portable on a machine using big endian, as well as the table file.

The field offsets and the file record length are calculated according the column internal format and eventually modified by the field format. It is not necessary to specify them for a packed binary file without line endings. If a line ending is desired, specify the ending option or specify the

```
lrec1
option adding the ending width. The table can be filled by:
```

```
insert into testbal values
(5500,'ARCHIBALD','1980-01-25','3789',4380.50,318),
(123,'OLIVER','1953-08-10',23456,3400.68,2158),
(3123,'FOO','2002-07-23','888',default,318);
```

Note that the types of the inserted values must match the column type, not the field format type.

The query:

```
select * from testbal;
```

returns:

| fig  | name      | birth      | id    | salary  | dept |
|------|-----------|------------|-------|---------|------|
| 5500 | ARCHIBALD | 1980-01-25 | 3789  | 4380.50 | 318  |
| 123  | OLIVER    | 1953-08-10 | 23456 | 3400.68 | 2158 |
| 3123 | FOO       | 2002-07-23 | 888   | 0.00    | 318  |

## Numeric fields alignment

In binary files, numeric fields and record length can be aligned on 4-or-8-byte boundaries to optimize performance on certain processors. This can be modified in the OPTION\_LIST with an "align" option ("packed" meaning

```
align=1
is the default).
```

1. ↑ Sometimes it can be a physical record if LF or CRLF have been written in the file.
2. ↑ Most of these are obsolete because CONNECT supports all column types except float
3. ↑ The default endian representation used in the table file can be specified by setting the ENDIAN option as 'L' or 'B' in the option list.
4. ↑ It can be specified with more than one character, but only the first one is significant.

## 4.3.7.6.8 CONNECT VEC Table Type

### Contents

1. [Integral vector formats](#)
2. [Differences between vector formats](#)
3. [Header option](#)

**Warning:** Avoid using this table type in production applications. This file format is specific to CONNECT and may not be supported in future versions.

Tables of type

VEC

are binary files that in some cases can provide good performance on read-intensive query workloads. CONNECT organizes their data on disk as columns of values from the same attribute, as opposed to storing it as rows of tabular records. This organization means that when a query needs to access only a few columns of a particular table, only those columns need to be read from disk. Conversely, in a row-oriented table, all values in a table are typically read from disk, wasting I/O bandwidth.

CONNECT provides two integral VEC formats, in which each column's data is adjacent.

## Integral vector formats

In these true vertical formats, the VEC files are made of all the data of the first column, followed by all the data of the second column etc. All this can be in one physical file or each column data can be in a separate file. In the first case, the option `max_rows=m`, where m is the estimate of the maximum size (number of rows) of the table, must be specified to be able to insert some new records. This leaves an empty space after each column area in which new data can be inserted. In the second case, the "Split" option can be specified [2] at table creation and each column will be stored in a file named sequentially from the table file name followed by the rank of the column. Inserting new lines can freely augment such a table.

## Differences between vector formats

These formats correspond to different needs. The integral vector format provides the best performance gain. It will be chosen when the speed of decisional queries must be optimized.

In the case of a unique file, inserting new data will be limited but there will be only one open and close to do. However, the size of the table cannot be calculated from the file size because of the eventual unused space in the file. It must be kept in a header containing the maximum number of rows and the current number of valid rows in the table. To achieve this, specify the option `Header= n` when creating the table. If

`n=1`  
the header will be placed at the beginning of the file, if  
`n=2`  
it will be a separate file with the type '.blk', and if  
`n=3`

the header will be place at the end of the file. This last value is provided because batch inserting is sometimes slower when the header is at the beginning of the file. If not specified, the header option will default to 2 for this table type.

On the other hand, the "Split" format with separate files have none of these issues, and is a much safer solution when the table must frequently inserted or shared among several users.

For instance:

```
create table vtab (
  a int not null,
  b char(10) not null
  engine=CONNECT table_type=VEC file_name='vt.vec';
```

This table, split by default, will have the column values in files vt1.vec and vt2.vec.

For vector tables, the option `block_size=n` is used for block reading and writing; however, to have a file made of blocks of equal size, the internal value of the `max_rows=m` option is eventually increased to become a multiple of n.

Like for BIN tables, numeric values are stored using platform internal layout, the correspondence between column types and internal format being the same than the default ones given above for BIN. However, field formats are not available for VEC tables.

## Header option

This applies to VEC tables that are not split. Because the file size depends on the MAX\_ROWS value, CONNECT cannot know how many valid records exist in the file. Depending on the value of the HEADER option, this information is stored in a header that can be placed at the beginning of the file, at the end of the file or in a separate file called fn.blk. The valid values for the HEADER option are:

- 0 Defaults to 2 for standard tables and to 3 for inward tables.
- 1 The header is at the beginning of the file.
- 2 The header is in a separate file.
- 3 The header is at the end of the file.

The value 2 can be used when dealing with files created by another application with no header. The value 3 makes sometimes inserting in the file faster than when the header is at the beginning of the file.

Note: VEC being a file format specific to CONNECT, no big endian / little endian conversion is provided. These files are not portable between machines using a different byte order setting.

## 4.3.7.6.9 CONNECT CSV and FMT Table Types

## Contents

- 1. CSV Type
  - 1. Restrictions on CSV Tables
- 2. FMT Type
- 3. Column Format Specification of FMT tables
- 4. Optional Fields
- 5. Bad Record Error Processing
- 6. Fields Containing a Formatted Date

## CSV Type

Many source data files are formatted with variable length fields and records. The simplest format, known as

CSV

(Comma Separated Variables), has column fields separated by a separator character. By default, the separator is a comma but can be specified by the

SEP\_CHAR

option as any character, for instance a semi-colon.

If the CSV file first record is the list of column names, specifying the

HEADER=1

option will skip the first record on reading. On writing, if the file is empty, the column names record is automatically written.

For instance, given the following *people.csv* file:

```
Name;birth;children
"Archibald";17/05/01;3
"Nabucho";12/08/03;2
```

You can create the corresponding table by:

```
create table people (
    name char(12) not null,
    birth date not null date_format='DD/MM/YY',
    children smallint(2) not null
engine=CONNECT table_type=CSV file_name='people.csv'
header=1 sep_char=';' quoted=1;
```

For CSV tables, the *flag* column option is the rank of the column into the file starting from 1 for the leftmost column. This is to enable having column displayed in a different order than in the file and/or to define the table specifying only some columns of the CSV file. For instance:

```
create table people (
    name char(12) not null,
    children smallint(2) not null flag=3,
    birth date not null flag=2 date_format='DD/MM/YY')
engine=CONNECT table_type=CSV file_name='people.csv'
header=1 sep_char=';' quoted=1;
```

In this case the command:

```
select * from people;
```

will display the table as:

| name      | children | birth      |
|-----------|----------|------------|
| Archibald | 3        | 2001-05-17 |
| Nabucho   | 2        | 2003-08-12 |

Many applications produce CSV files having some fields quoted, in particular because the field text contains the separator character. For such files, specify the 'QUOTED= *n*' option to indicate the level of quoting and/or the '

QCHAR=c

' to specify what is this eventual quoting character, which is

"

by default. Quoting with single quotes must be specified as

QCHAR='''

. On writing, fields will be quoted depending on the value of the quoting level, which is

-1

by default meaning no quoting:

0 The fields between quotes are read and the quotes discarded. On writing, fields will be quoted only if they contain the separator character or begin with the quoting character. If they contain the quoting character, it will be doubled.

1 Only text fields will be written between quotes, except null fields. This includes also the column names of an eventual header.

2 All fields will be written between quotes, except null fields.

3 All fields will be written between quotes, including null fields.

Files written this way are successfully read by most applications including spreadsheets.

**Note 1:** If only the QCHAR option is specified, the QUOTED option will default to 1.

**Note 2:** For CSV tables whose separator is the tab character, specify

```
sep_char='\t'
```

**Note 3:** When creating a table on an existing CSV file, you can let CONNECT analyze the file and make the column description. However, this is not an elaborate analysis of the file and, for instance,

DATE

fields will not be recognized as such but will be regarded as string fields.

## Restrictions on CSV Tables

- If

```
secure_file_priv
```

is set to the path of some directory, then CSV tables can only be created with files in that directory.

## FMT Type

FMT tables handle files of various formats that are an extension of the concept of CSV files. CONNECT supports these files providing all lines have the same format and that all fields present in all records are recognizable (optional fields must have recognizable delimiters). These files are made by specific application and CONNECT handles them in read only mode.

FMT tables must be created as CSV tables, specifying their type as FMT. In addition, each column description must be added to its format specification.

## Column Format Specification of FMT tables

The input format for each column is specified as a FIELD\_FORMAT option. A simple example is:

```
IP Char(15) not null field_format=' %n%s%n',
```

In the above example, the format for this (1st) field is

' %n%s%n'

. Note that the blank character at the beginning of this format is significant. No trailing blank should be specified in the column formats.

The syntax and meaning of the column input format is the one of the C **scanf** function.

However, CONNECT uses the input format in a specific way. Instead of using it to directly store the input value in the column buffer; it uses it to delimit the sub string of the input record that contains the corresponding column value. Retrieving this value is done later by the column functions as for standard CSV files.

This is why all column formats are made of five components:

1. An eventual description of what is met and ignored before the column value.
2. A marker of the beginning of the column value written as

%n

(or

%m

for optional fields).

5. An eventual description of what is met after the column value (not valid is

%m

was used).

For example, taking the file *funny.txt*:

```
12345, 'BERTRAND', #200;5009.13
56, 'POIROT-DELMOTTE', #4256 ;18009
345 , 'TRUCMUCHE' , #67; 19000.25
```

You can make a table *fmtsamp*e with 4 columns ID, NAME, DEPNO and SALARY, using the Create Table statement and column formats:

```
create table FMTSAMPLE (
  ID Integer(5) not null field_format=' %n%d%n',
  NAME Char(16) not null field_format=' ''%n[%^']%n''',
  DEPNO Integer(4) not null field_format=' ', #%n%d%n',
  SALARY Double(12,2) not null field_format=' ; %n%f%n')
Engine=CONNECT table_type=FMT file_name='funny.txt';
```

**Field 1** is an integer (

%d  
with eventual leading blanks.

**Field 2** is separated from field 1 by optional blanks, a comma, and other optional blanks and is between single quotes. The leading quote is included in component 1 of the column format, followed by the

%n  
marker. The column value is specified as  
%[^']  
meaning to keep any characters read until a quote is met. The ending marker (

%n  
) is followed by the 5th component of the column format, the single quote that follows the column value.

**Field 3**, also separated by a comma, is a number preceded by a pound sign.

**Field 4**, separated by a semicolon eventually surrounded by blanks, is a number with an optional decimal point (

%f  
).

This table will be displayed as:

| ID    | NAME            | DEPNO | SALARY   |
|-------|-----------------|-------|----------|
| 12345 | BERTRAND        | 200   | 5009.13  |
| 56    | POIROT-DELMOTTE | 4256  | 18009.00 |
| 345   | TRUCMUCHE       | 67    | 19000.25 |

## Optional Fields

To be recognized, a field normally must be at least one character long. For instance, a numeric field must have at least one digit, or a character field cannot be void. However many existing files do not follow this format.

Let us suppose for instance that the preceding example file could be:

```
12345, 'BERTRAND', #200;5009.13
56, 'POIROT-DELMOTTE', # ;18009
345 , ' ', #67; 19000.25
```

This will display an error message such as "*Bad format line x field y of FMTSAMPLE*". To avoid this and accept these records, the corresponding fields must be specified as "optional". In the above example, fields 2 and 3 can have null values (in lines 3 and 2 respectively). To specify them as optional, their format must be terminated by

%m  
(instead of the second  
%n

```
create table FMTSAMPLE (
  ID Integer(5) not null field_format=' %n%d%n',
  NAME Char(16) not null field_format=' ''%n[%^']%m',
  DEPNO Integer(4) field_format=' ', #%n%d%m',
  SALARY Double(12,2) field_format=' ; %n%f%n')
Engine=CONNECT table_type=FMT file_name='funny.txt';
```

Note that, because the statement must be terminated by

%m  
with no additional characters, skipping the ending quote of field 2 was moved from the end of the second column format to the beginning of the third column format.

The table result is:

| ID    | NAME     | DEPNO | SALARY   |
|-------|----------|-------|----------|
| 12345 | BERTRAND | 200   | 5,009.13 |

|     |                 |      |           |
|-----|-----------------|------|-----------|
| 56  | POIROT-DELMOTTE | NULL | 18,009.00 |
| 345 | NULL            | 67   | 19,000.25 |

Missing fields are replaced by null values if the column is nullable, blanks for character strings and 0 for numeric fields if it is not.

**Note 1:** Because the formats are specified between quotes, quotes belonging to the formats must be doubled or escaped to avoid a CREATE TABLE statement syntax error.

**Note 2:** Characters separating columns can be included as well in component 5 of the preceding column format or in component 1 of the succeeding column format but for blanks, which should be always included in component 1 of the succeeding column format because line trailing blanks can be sometimes lost. This is also mandatory for optional fields.

**Note 3:** Because the format is mainly used to find the sub-string corresponding to a column value, the field specification does not necessarily match the column type. For instance supposing a table contains two integer columns, NBONE and NBTWO, the two lines describing these columns could be:

```
NBONE integer(5) not null field_format=' %n%d%n',
NBTWO integer(5) field_format=' %n%s%n',
```

The first one specifies a required integer field (

%d

), the second line describes a field that can be an integer, but can be replaced by a "-" (or any other) character. Specifying the format specification for this column as a character field (

%s

) enables to recognize it with no error in all cases. Later on, this field will be converted to integer by the column read function, and a null 0 value will be generated for field specified in their format as non-numeric.

## Bad Record Error Processing

When no match is found for a column field the process aborts with a message such as:

```
Bad format line 3 field 4 of funny.txt
```

This can mean as well that one line of the input line is ill formed or that the column format for this field has been wrongly specified. When you know that your file contains records that are ill formatted and should be eliminated from normal processing, set the "maxerr" option of the CREATE TABLE statement, for instance:

```
Option_list='maxerr=100'
```

This will indicate that no error message be raised for the 100 first wrong lines. You can set Maxerr to a number greater than the number of wrong lines in your files to ignore them and get no errors.

Additionally, the "accept" option permit to keep those ill formatted lines with the bad field, and all succeeding fields of the record, nullified. If "accept" is specified without "maxerr", all ill formatted lines will be accepted.

**Note:** This error processing also applies to CSV tables.

## Fields Containing a Formatted Date

A special case is one of columns containing a formatted date. In this case, two formats must be specified:

1. The field recognition format used to delimit the date in the input record.
2. The date format used to interpret the date.
3. The field length option if the date representation is different than the standard type size.

For example, let us suppose we have a web log source file containing records such as:

```
165.91.215.31 - - [17/Jul/2001:00:01:13 -0400] - "GET /usnews/home.htm HTTP/1.1" 302
```

The create table statement shall be like this:

```
create table WEBSAMP (
  IP char(15) not null field_format=' %n%s%n',
  DATE datetime not null field_format=' -- [%n%s% -0400]' 
  date_format='DD/MMM/YYYY:hh:mm:ss' field_length=20,
  FILE char(128) not null field_format=' - "GET %n%s%n',
  HTTP double(4,2) not null field_format=' HTTP/%n%f%n',
  NBONE int(5) not null field_format=' %n%d%n')
Engine=CONNECT table_type=FMT lrecl=400
file_name='e:\\data\\token\\Websamp.dat';
```

**Note 1:** Here,

```
field_length=20  
was necessary because the default size for datetime columns is only 19. The  
lrec1=400  
was also specified because the actual file contains more information in each records making the record size calculated by default too small.
```

**Note 2:** The file name could have been specified as

```
'e:/data/token/Websamp.dat'
```

**Note 3:** FMT tables are currently read only.

## 4.3.7.6.10 CONNECT - NoSQL Table Types

They are based on files that do not match the relational format but often represent hierarchical data. CONNECT can handle **JSON**, **INI-CFG**, **XML**, and some **HTML** files.

The way it is done is different from what MySQL or PostgreSQL does. In addition to including in a table some column values of a specific data format (JSON, XML) to be handled by specific functions, CONNECT can directly use JSON, XML or INI files that are produced by other applications, and this is the table definition that describes where and how the contained information must be retrieved.

This is also different from what MariaDB does with dynamic columns, which is close to what MySQL and PostgreSQL do with the **JSON** column type.

Note: The **LEVEL** option used with these tables should, from Connect 1.07.0002, be specified as **DEPTH**. Also, what was specified with the **FIELD\_FORMAT** column option should now also be specified using **JPATH** or **XPATH**.

## 4.3.7.6.11 CONNECT - Files Retrieved Using Rest Queries

Starting with **CONNECT version 1.07.0001**, JSON, XML and possibly CSV data files can be retrieved as results from REST queries when creating or querying such tables. This is done internally by CONNECT using the CURL program generally available on all systems (if not just install it).

This can also be done using the Microsoft Casablanca (cpprestsdk) package. To enable it, first, install the package as explained in <https://github.com/microsoft/cpprestsdk>. Then make the GetRest library (dll or so) as explained in [Making the GetRest Library](#).

Note: If both are available, cpprestsdk is used preferably because it is faster. This can be changed by specifying 'curl=1' in the option list.

Note: If you want to use this feature with an older distributed version of MariaDB not featuring REST, it is possible to add it as an OEM module as explained in [Adding the REST Feature as a Library Called by an OEM Table](#).

### Creating Tables using REST

To do so, specify the HTTP of the web client and eventually the URI of the request in the **CREATE TABLE** statement. For example, for a query returning JSON data:

```
CREATE TABLE webusers (  
    id bigint(2) NOT NULL,  
    name char(24) NOT NULL,  
    username char(16) NOT NULL,  
    email char(25) NOT NULL,  
    address varchar(256) DEFAULT NULL,  
    phone char(21) NOT NULL,  
    website char(13) NOT NULL,  
    company varchar(256) DEFAULT NULL  
) ENGINE=CONNECT DEFAULT CHARSET=utf8  
TABLE_TYPE=JSON FILE_NAME='users.json' HTTP='http://jsonplaceholder.typicode.com' URI='/users';
```

As with standard JSON tables, discovery is possible, meaning that you can leave CONNECT to define the columns by analyzing the JSON file. Here you could just do:

```
CREATE TABLE webusers  
ENGINE=CONNECT DEFAULT CHARSET=utf8  
TABLE_TYPE=JSON FILE_NAME='users.json'  
HTTP='http://jsonplaceholder.typicode.com' URI='/users';
```

For example, executing:

```
SELECT name, address FROM webusers2 LIMIT 1;
```

returns:

| name          | address                                                      |
|---------------|--------------------------------------------------------------|
| Leanne Graham | Kulas Light Apt. 556 Gwenborough 92998-3874 -37.3159 81.1496 |

Here we see that for some complex elements such as **address**, which is a Json object containing values and objects, CONNECT by default has just listed their texts separated by blanks. But it is possible to ask it to analyze in more depth the json result by adding the **DEPTH** option. For instance:

```

CREATE OR REPLACE TABLE webusers
ENGINE=CONNECT DEFAULT CHARSET=utf8
TABLE_TYPE=JSON FILE_NAME='users.json'
HTTP='http://jsonplaceholder.typicode.com' URI='/users'
OPTION_LIST='Depth=2';

```

Then the table will be created as:

```

CREATE TABLE `webusers3` (
`id` bigint(2) NOT NULL,
`name` char(24) NOT NULL,
`username` char(16) NOT NULL,
`email` char(25) NOT NULL,
`address_street` char(17) NOT NULL `JPATH`='$.address.street',
`address_suite` char(9) NOT NULL `JPATH`='$.address.suite',
`address_city` char(14) NOT NULL `JPATH`='$.address.city',
`address_zipcode` char(10) NOT NULL `JPATH`='$.address.zipcode',
`address_geo_lat` char(8) NOT NULL `JPATH`='$.address.geo.lat',
`address_geo_lng` char(9) NOT NULL `JPATH`='$.address.geo.lng',
`phone` char(21) NOT NULL,
`website` char(13) NOT NULL,
`company_name` char(18) NOT NULL `JPATH`='$.company.name',
`company_catchPhrase` char(40) NOT NULL `JPATH`='$.company.catchPhrase',
`company_bs` varchar(36) NOT NULL `JPATH`='$.company.bs'
) ENGINE=CONNECT DEFAULT CHARSET=utf8 `TABLE_TYPE`='JSON' `FILE_NAME`='users.json' `OPTION_LIST`='Depth=2' `HTTP`='http://jsonpl

```

Allowing one to get all the values of the Json result, for example:

```
SELECT name, address_city city, company_name company FROM webusers3;
```

That results in:

| name                           | city               | company           |
|--------------------------------|--------------------|-------------------|
| Leanne Graham                  | Gwenborough        | Romaguera-Crona   |
| Ervin Howell                   | Wisokyburgh        | Deckow-Crist      |
| Clementine Bauch McKenziehaven | Romaguera-Jacobson |                   |
| Patricia Lebsack               | South Elvis        | Robel-Corkery     |
| Chelsey Dietrich               | Roscoeview         | Keebler LLC       |
| Mrs. Dennis Schulist           | South Christy      | Considine-Lockman |
| Kurtis Weissnat                | Howemouth          | Johns Group       |
| Nicholas Runolfsdottir V       | Aliyaview          | Abernathy Group   |
| Glenna Reichert                | Bartholomebury     | Yost and Sons     |
| Clementina DuBuque             | Lebsackbury        | Hoeger LLC        |

Of course, the complete create table (obtained by SHOW CREATE TABLE) can later be edited to make your table return exactly what you want to get. See the [JSON table type](#) for details about what and how to specify these.

Note that such tables are read only. In addition, the data will be retrieved from the web each time you query the table with a `SELECT` statement. This is fine if the result varies each time, such as when you query a weather forecasting site. But if you want to use the retrieved file many times without reloading it, just create another table on the same file without specifying the HTTP option.

Note: For JSON tables, specifying the file name is optional and defaults to tablename.type. However, you should specify it if you want to use the file later for other tables.
