# Chapter Contents

## 1 SQL Statements and Structure

### 1.1 SQL Statements

## 2 MariaDB Administration

### 2.1 Getting, Installing and Upgrading MariaDB

## 3 High Availability & Performance Tuning

## 4 Columns, Storage Engines, and Plugins

### 4.1 Data Types

### 4.4 Plugins

## 5 MariaDB Community Bug Reporting

# Table of Contents

## 1 SQL Statements and Structure

### 1.1 SQL Statements

#### 1.1.1 Account Management SQL Commands

1.1.1.1 CREATE USER

1.1.1.2 ALTER USER

1.1.1.3 DROP USER

1.1.1.4 GRANT

1.1.1.5 RENAME USER

1.1.1.6 REVOKE

1.1.1.7 SET PASSWORD

1.1.1.8 CREATE ROLE

1.1.1.9 DROP ROLE

1.1.1.10 SET ROLE

1.1.1.11 SET DEFAULT ROLE

1.1.1.12 SHOW GRANTS

1.1.1.13 SHOW CREATE USER

#### 1.1.2 Administrative SQL Statements

##### 1.1.2.1 Table Statements

1.1.2.1.1 ALTER

1.1.2.1.1.1 ALTER TABLE

1.1.2.1.1.2 ALTER DATABASE

1.1.2.1.1.3 ALTER EVENT

1.1.2.1.1.4 ALTER FUNCTION

1.1.2.1.1.5 ALTER LOGFILE GROUP

1.1.2.1.1.6 ALTER PROCEDURE

1.1.2.1.1.7 ALTER SEQUENCE

1.1.2.1.1.8 ALTER SERVER

1.1.2.1.1.9 ALTER TABLESPACE

1.1.2.1.1.10 ALTER USER

1.1.2.1.2 ALTER VIEW

1.1.2.1.3 ANALYZE TABLE

1.1.2.1.4 CHECK TABLE

1.1.2.1.5 CHECK VIEW

1.1.2.1.6 CHECKSUM TABLE

1.1.2.1.7 CREATE TABLE

1.1.2.1.8 DELETE

1.1.2.1.9 DROP TABLE

1.1.2.1.10 Installing System Tables (`mysql_install_db`)

1.1.2.1.11 mysqlcheck

1.1.2.1.12 OPTIMIZE TABLE

1.1.2.1.13 RENAME TABLE

1.1.2.1.14 REPAIR TABLE

1.1.2.1.15 REPAIR VIEW

1.1.2.1.16 REPLACE

1.1.2.1.17 SHOW COLUMNS

1.1.2.1.18 SHOW CREATE TABLE

1.1.2.1.19 SHOW INDEX

1.1.2.1.20 TRUNCATE TABLE

1.1.2.1.21 UPDATE

1.1.2.1.22 IGNORE

1.1.2.1.23 System-Versioned Tables

## 1.1.2.2 ANALYZE and EXPLAIN Statements

1.1.2.2.1 ANALYZE FORMAT=JSON

1.1.2.2.2 ANALYZE FORMAT=JSON Examples

1.1.2.2.3 ANALYZE Statement

1.1.2.2.4 EXPLAIN

1.1.2.2.5 EXPLAIN ANALYZE

1.1.2.2.6 EXPLAIN FORMAT=JSON

1.1.2.2.7 SHOW EXPLAIN

1.1.2.2.8 Using Buffer UPDATE Algorithm

## 1.1.2.3 BACKUP Commands

1.1.2.3.1 BACKUP STAGE

1.1.2.3.2 BACKUP LOCK

1.1.2.3.3 Mariabackup and BACKUP STAGE Commands

1.1.2.3.4 Storage Snapshots and BACKUP STAGE Commands

## 1.1.2.4 FLUSH Commands

1.1.2.4.1 FLUSH

1.1.2.4.2 FLUSH QUERY CACHE

1.1.2.4.3 FLUSH TABLES FOR EXPORT

## 1.1.2.5 Replication Commands

1.1.2.5.1 CHANGE MASTER TO

1.1.2.5.2 START SLAVE

1.1.2.5.3 STOP SLAVE

1.1.2.5.4 RESET SLAVE

1.1.2.5.5 SET GLOBAL SQL\_SLAVE\_SKIP\_COUNTER

1.1.2.5.6 SHOW RELAYLOG EVENTS

1.1.2.5.7 SHOW SLAVE STATUS

1.1.2.5.8 SHOW MASTER STATUS

1.1.2.5.9 SHOW SLAVE HOSTS

1.1.2.5.10 RESET MASTER

1.1.2.6 Plugin SQL Statements

1.1.2.6.1 SHOW PLUGINS

1.1.2.6.2 SHOW PLUGINS SONAME

1.1.2.6.3 INSTALL PLUGIN

1.1.2.6.4 UNINSTALL PLUGIN

1.1.2.6.5 INSTALL SONAME

1.1.2.6.6 UNINSTALL SONAME

1.1.2.6.7 mysql\_plugin

1.1.2.7 SET Commands

1.1.2.7.1 SET

1.1.2.7.2 SET CHARACTER SET

1.1.2.7.3 SET GLOBAL SQL\_SLAVE\_SKIP\_COUNTER

1.1.2.7.4 SET NAMES

1.1.2.7.5 SET PASSWORD

1.1.2.7.6 SET ROLE

1.1.2.7.7 SET SQL\_LOG\_BIN

1.1.2.7.8 SET STATEMENT

1.1.2.7.9 SET TRANSACTION

1.1.2.7.10 SET Variable

1.1.2.8 SHOW

1.1.2.8.1 About SHOW

### 1.1.2.9.3 The mysql Database Tables

- 1.1.2.9.3.1 mysql.column\_stats Table
- 1.1.2.9.3.2 mysql.columns\_priv Table
- 1.1.2.9.3.3 mysql.db Table
- 1.1.2.9.3.4 mysql.event Table
- 1.1.2.9.3.5 mysql.func Table
- 1.1.2.9.3.6 mysql.general\_log Table
- 1.1.2.9.3.7 mysql.global\_priv Table
- 1.1.2.9.3.8 mysql.gtid\_slave\_pos Table
- 1.1.2.9.3.9 mysql.help\_category Table
- 1.1.2.9.3.10 mysql.help\_keyword Table
- 1.1.2.9.3.11 mysql.help\_relation Table
- 1.1.2.9.3.12 mysql.help\_topic Table
- 1.1.2.9.3.13 mysql.index\_stats Table
- 1.1.2.9.3.14 mysql.innodb\_index\_stats
- 1.1.2.9.3.15 mysql.innodb\_table\_stats
- 1.1.2.9.3.16 mysql.password\_reuse\_check\_history Table
- 1.1.2.9.3.17 mysql.plugin Table
- 1.1.2.9.3.18 mysql.proc Table
- 1.1.2.9.3.19 mysql.procs\_priv Table
- 1.1.2.9.3.20 mysql.roles\_mapping Table
- 1.1.2.9.3.21 mysql.servers Table
- 1.1.2.9.3.22 mysql.slow\_log Table
- 1.1.2.9.3.23 mysql.tables\_priv Table
- 1.1.2.9.3.24 mysql.table\_stats Table
- 1.1.2.9.3.25 mysql.time\_zone Table
- 1.1.2.9.3.26 mysql.time\_zone\_leap\_second Table
- 1.1.2.9.3.27 mysql.time\_zone\_name Table
- 1.1.2.9.3.28 mysql.time\_zone\_transition Table
- 1.1.2.9.3.29 mysql.time\_zone\_transition\_type Table
- 1.1.2.9.3.30 mysql.transaction\_registry Table
- 1.1.2.9.3.31 mysql.user Table
- 1.1.2.9.3.32 Spider mysql Database Tables
  - 1.1.2.9.3.32.1 mysql.spider\_link\_failed\_log Table
  - 1.1.2.9.3.32.2 mysql.spider\_link\_mon\_servers Table
  - 1.1.2.9.3.32.3 mysql.spider\_tables Table
  - 1.1.2.9.3.32.4 mysql.spider\_table\_crd Table
  - 1.1.2.9.3.32.5 mysql.spider\_table\_position\_for\_recovery Table
  - 1.1.2.9.3.32.6 mysql.spider\_table\_sts Table
  - 1.1.2.9.3.32.7 mysql.spider\_xa Table
  - 1.1.2.9.3.32.8 mysql.spider\_xa\_failed\_log Table
  - 1.1.2.9.3.32.9 mysql.spider\_xa\_member Table

### 1.1.2.9.4 Sys Schema

- 1.1.2.9.4.1 Sys Schema sys\_config Table

### 1.1.2.9.5 mariadb\_schema

### 1.1.2.9.6 Writing Logs Into Tables

- 1.1.2.10 BINLOG
  - 1.1.2.11 PURGE BINARY LOGS
  - 1.1.2.12 CACHE INDEX
  - 1.1.2.13 DESCRIBE
  - 1.1.2.14 EXECUTE Statement
  - 1.1.2.15 HELP Command
  - 1.1.2.16 KILL [CONNECTION | QUERY]
  - 1.1.2.17 LOAD INDEX
  - 1.1.2.18 RESET
  - 1.1.2.19 SHUTDOWN
  - 1.1.2.20 USE

## 2 MariaDB Administration

- 2.1 Getting, Installing and Upgrading MariaDB
  - 2.1.1 Where to Download MariaDB
  - 2.1.2 MariaDB Binary Packages

## 2.1.2.1 Installing MariaDB RPM Files

- 2.1.2.1.1 About the MariaDB RPM Files
- 2.1.2.1.2 Installing MariaDB with yum/dnf
- 2.1.2.1.3 Installing MariaDB with zypper
- 2.1.2.1.4 Installing MariaDB With the rpm Tool
- 2.1.2.1.5 Checking MariaDB RPM Package Signatures
- 2.1.2.1.6 Troubleshooting MariaDB Installs on Red Hat/CentOS
- 2.1.2.1.7 MariaDB for DirectAdmin Using RPMs
- 2.1.2.1.8 MariaDB Installation (Version 10.1.21) via RPMs on CentOS 7
- 2.1.2.1.9 Why Source RPMs (SRPMs) Aren't Packaged For Some Platforms
- 2.1.2.1.10 Building MariaDB from a Source RPM

## 2.1.2.2 Installing MariaDB .deb Files

- 2.1.2.3 Installing MariaDB MSI Packages on Windows
- 2.1.2.4 Installing MariaDB Server PKG packages on macOS
- 2.1.2.5 Installing MariaDB Binary Tarballs
- 2.1.2.6 Installing MariaDB Server on macOS Using Homebrew
- 2.1.2.7 Installing MariaDB Windows ZIP Packages

## 2.1.2.8

- 2.1.2.8.1 Get, Build and Test Latest MariaDB the Lazy Way
- 2.1.2.8.2 MariaDB Source Code
- 2.1.2.8.3 Build Environment Setup for Linux
- 2.1.2.8.4 Generic Build Instructions
- 2.1.2.8.5 Compiling MariaDB with Extra Modules/Options
  - 2.1.2.8.5.1 Compiling MariaDB with TCMalloc
  - 2.1.2.8.5.2 Compiling MariaDB with Vanilla XtraDB
  - 2.1.2.8.5.3 Specifying Which Plugins to Build
- 2.1.2.8.6 Creating the MariaDB Source Tarball
- 2.1.2.8.7 Creating the MariaDB Binary Tarball
- 2.1.2.8.8 Build Environment Setup for Mac
- 2.1.2.8.9 Building MariaDB From a Source RPM
- 2.1.2.8.10 Building MariaDB on CentOS
- 2.1.2.8.11 Building MariaDB on Fedora
- 2.1.2.8.12 Building MariaDB on Debian
- 2.1.2.8.13 Building MariaDB on FreeBSD
- 2.1.2.8.14 Building MariaDB on Gentoo
- 2.1.2.8.15 Building MariaDB on Solaris and OpenSolaris
- 2.1.2.8.16 Building MariaDB on Ubuntu
- 2.1.2.8.17 Building MariaDB on Windows
- 2.1.2.8.18 Installing MariaDB Server on macOS Using Homebrew
- 2.1.2.8.19 Creating a Debian Repository
- 2.1.2.8.20 Building MariaDB From Source Using musl-based GNU/Linux
- 2.1.2.8.21 Compiling MariaDB for Debugging
- 2.1.2.8.22 Cross-compiling MariaDB

- 2.1.2.8.23 MariaDB Source Configuration Options
- 2.1.2.8.24 Building RPM Packages From Source
- 2.1.2.8.25 Compile and Using MariaDB with AddressSanitizer (ASAN)
- 2.1.2.9 Distributions Which Include MariaDB
- 2.1.2.10 Running Multiple MariaDB Server Processes
- 2.1.2.11 Installing MariaDB Alongside MySQL
- 2.1.2.12 GPG
- 2.1.2.13 MariaDB Deprecation Policy
- 2.1.2.14 Automated MariaDB Deployment and Administration
  - 2.1.2.14.1 Why to Automate MariaDB Deployments and Management
  - 2.1.2.14.2 A Comparison Between Automation Systems
  - 2.1.2.14.3 Ansible and MariaDB
    - 2.1.2.14.3.1 Ansible Overview for MariaDB Users
    - 2.1.2.14.3.2 Deploying to Remote Servers with Ansible
    - 2.1.2.14.3.3 Deploying Docker Containers with Ansible
    - 2.1.2.14.3.4 Installing MariaDB .deb Files with Ansible
    - 2.1.2.14.3.5 Running mariadb-tzinfo-to-sql with Ansible
    - 2.1.2.14.3.6 Managing Secrets in Ansible
  - 2.1.2.14.4 Puppet and MariaDB

## 2.1.4 Downgrading between Major Versions of MariaDB

## 2.1.5 Compiling MariaDB From Source

## 2.1.6

- 2.1.6.1 Starting and Stopping MariaDB
- 2.1.6.2 Configuring MariaDB with Option Files
- 2.1.6.3 mysqld Configuration Files and Groups
- 2.1.6.4 mysqld Options
- 2.1.6.5 What to Do if MariaDB Doesn't Start
- 2.1.6.6 Running MariaDB from the Build Directory
- 2.1.6.7 mysql.server
- 2.1.6.8 mysqld\_safe
- 2.1.6.9 mysqladmin
- 2.1.6.10 Switching Between Different Installed MariaDB Versions
- 2.1.6.11 Specifying Permissions for Schema (Data) Directories and Tables
- 2.1.6.12 mysqld\_multi
- 2.1.6.13 launchd
- 2.1.6.14 systemd
- 2.1.6.15 sysVinit

2.1.6.16 mariadb-admin

2.1.6.17 mariadb

2.1.6.18 mariadb-multi

2.1.6.19 mariadb-safe

## 2.1.7 MariaDB Performance & Advanced Configurations

2.1.7.1 Fusion-io

    2.1.7.1.1 Fusion-io Introduction

    2.1.7.1.2 Atomic Write Support

    2.1.7.1.3 InnoDB Page Flushing

2.1.7.3 Configuring Linux for MariaDB

2.1.7.4 Configuring MariaDB for Optimal Performance

2.1.7.5 Configuring Swappiness

## 2.1.8 Troubleshooting Installation Issues

2.1.8.1 Troubleshooting Connection Issues

2.1.8.2 Installation issues on Windows

2.1.8.3 Troubleshooting MariaDB Installs on Red Hat/CentOS

2.1.8.4 Installation issues on Debian and Ubuntu

    2.1.8.4.1 Differences in MariaDB in Debian (and Ubuntu)

    2.1.8.4.2 Moving from MySQL to MariaDB in Debian 9

    2.1.8.4.3 Creating a Debian Repository

    2.1.8.4.4 apt-upgrade Fails, But the Database is Running

2.1.8.5 What to Do if MariaDB Doesn't Start

2.1.8.6 Installing on an Old Linux Version

2.1.8.7 Error: symbol mysql\_get\_server\_name, version libmysqlclient\_16 not defined

## 2.1.9 Installing System Tables (mysql\_install\_db)

2.1.10 mysql\_install\_db.exe

2.1.11 Configuring MariaDB with Option Files

2.1.12 MariaDB Environment Variables

2.1.13 MariaDB on Amazon AWS

2.1.14 Migrating to MariaDB

    2.1.14.1 Migrating to MariaDB from MySQL

        2.1.14.1.1 MySQL vs MariaDB: Performance

        2.1.14.1.2 MariaDB versus MySQL: Compatibility

        2.1.14.1.3 Upgrading from MySQL to MariaDB

        2.1.14.1.4

# 3 High Availability & Performance Tuning

# 4 Columns, Storage Engines, and Plugins

## 4.1 Data Types

    4.1.1 Numeric Data Types

#### 4.1.1.1 Numeric Data Type Overview

4.1.1.2 TINYINT

4.1.1.3 BOOLEAN

4.1.1.4 SMALLINT

4.1.1.5 MEDIUMINT

4.1.1.6 INT

4.1.1.7 INTEGER

4.1.1.8 BIGINT

4.1.1.9 DECIMAL

4.1.1.10 DEC, NUMERIC, FIXED

4.1.1.11 NUMBER

4.1.1.12 FLOAT

4.1.1.13 DOUBLE

4.1.1.14 DOUBLE PRECISION

4.1.1.15 BIT

4.1.1.16 Floating-point Accuracy

4.1.1.17 INT1

4.1.1.18 INT2

4.1.1.19 INT3

4.1.1.20 INT4

4.1.1.21 INT8

#### 4.1.2 String Data Types

4.1.2.1 String Literals

4.1.2.2 BINARY

4.1.2.3 BLOB

4.1.2.4 BLOB and TEXT Data Types

4.1.2.5 CHAR

4.1.2.6 CHAR BYTE

4.1.2.7 ENUM

4.1.2.9 JSON Data Type

4.1.2.10 MEDIUMBLOB

4.1.2.11 MEDIUMTEXT

4.1.2.12 LONGBLOB

4.1.2.13 LONG and LONG VARCHAR

4.1.2.14 LONGTEXT

4.1.2.15 ROW

4.1.2.16 TEXT

4.1.2.17 TINYBLOB

4.1.2.18 TINYTEXT

4.1.2.19 VARBINARY

- 4.1.2.20 VARCHAR
  - 4.1.2.21 SET Data Type
  - 4.1.2.22 UUID Data Type
  - 4.1.2.23 Data Type Storage Requirements
  - 4.1.2.24 Supported Character Sets and Collations
  - 4.1.2.25 Character Sets and Collations
- 4.1.3 Data and Time Data Types
    - 4.1.3.1 DATE
    - 4.1.3.2 TIME
    - 4.1.3.3 DATETIME
    - 4.1.3.4 TIMESTAMP
    - 4.1.3.5 YEAR Data Type
  - 4.1.4 Geometry Types
  - 4.1.5 AUTO\_INCREMENT
  - 4.1.6 Data Type Storage Requirements
  - 4.1.7 AUTO\_INCREMENT FAQ
  - 4.1.8 NULL Values
- 4.2.1 Character Set and Collation Overview
  - 4.2.2 Supported Character Sets and Collations
  - 4.2.3 Setting Character Sets and Collations

## 5 MariaDB Community Bug Reporting

# 1 SQL Statements and Structure

## 1.1 SQL Statements

### 1.1.1 Account Management SQL Commands

#### 1.1.1.1 CREATE USER

##### Syntax

```
CREATE [OR REPLACE] USER [IF NOT EXISTS]
  user_specification [,user_specification ...]
  [REQUIRE {NONE | tls_option [[AND] tls_option ...]} ]
  [WITH resource_option [resource_option ...] ]
  [Lock_option] [password_option]

user_specification:
  username [authentication_option]

authentication_option:
  IDENTIFIED BY 'password'
  | IDENTIFIED BY PASSWORD 'password_hash'
  | IDENTIFIED {VIA|WITH} authentication_rule [OR authentication_rule ...]

authentication_rule:
  authentication_plugin
  | authentication_plugin {USING|AS} 'authentication_string'
  | authentication_plugin {USING|AS} PASSWORD('password')

tls_option:
  SSL
  | X509
  | CIPHER 'cipher'
  | ISSUER 'issuer'
  | SUBJECT 'subject'

resource_option:
  MAX_QUERIES_PER_HOUR count
  | MAX_UPDATES_PER_HOUR count
  | MAX_CONNECTIONS_PER_HOUR count
  | MAX_USER_CONNECTIONS count
  | MAX_STATEMENT_TIME time

password_option:
  PASSWORD EXPIRE
  | PASSWORD EXPIRE DEFAULT
  | PASSWORD EXPIRE NEVER
  | PASSWORD EXPIRE INTERVAL N DAY

lock_option:
  ACCOUNT LOCK
  | ACCOUNT UNLOCK
}
```

11. [See Also](#)

## Description

The

```
CREATE USER
```

statement creates new MariaDB accounts. To use it, you must have the global [CREATE USER](#) privilege or the [INSERT](#) privilege for the [mysql](#) database. For each account,

```
CREATE USER
```

creates a new row in [mysql.user](#) (until MariaDB 10.3 this is a table, from MariaDB 10.4 it's a view) or [mysql.global\\_priv\\_table](#) (from MariaDB 10.4 ) that has no privileges.

If any of the specified accounts, or any permissions for the specified accounts, already exist, then the server returns

```
ERROR 1396 (HY000)
```

. If an error occurs,

```
CREATE USER
```

will still create the accounts that do not result in an error. Only one error is produced for all users which have not been created:

```
ERROR 1396 (HY000):
```

```
Operation CREATE USER failed for 'u1'@'%','u2'@'%'
```

```
CREATE USER
```

, [DROP USER](#) , [CREATE ROLE](#) , and [DROP ROLE](#) all produce the same error code when they fail.

See [Account Names](#) below for details on how account names are specified.

## OR REPLACE

If the optional

```
OR REPLACE
```

clause is used, it is basically a shortcut for:

```
DROP USER IF EXISTS name;  
CREATE USER name ...;
```

For example:

```
CREATE USER foo2@test IDENTIFIED BY 'password';  
ERROR 1396 (HY000): Operation CREATE USER failed for 'foo2'@'test'
```

```
CREATE OR REPLACE USER foo2@test IDENTIFIED BY 'password';  
Query OK, 0 rows affected (0.00 sec)
```

## IF NOT EXISTS

When the

```
IF NOT EXISTS
```

clause is used, MariaDB will return a warning instead of an error if the specified user already exists.

For example:

```
CREATE USER foo2@test IDENTIFIED BY 'password';
ERROR 1396 (HY000): Operation CREATE USER failed for 'foo2'@'test'

CREATE USER IF NOT EXISTS foo2@test IDENTIFIED BY 'password';
Query OK, 0 rows affected, 1 warning (0.00 sec)

SHOW WARNINGS;
+-----+-----+
| Level | Code | Message
+-----+-----+
| Note  | 1973 | Can't create user 'foo2'@'test'; it already exists |
+-----+-----+
```

## Authentication Options

### IDENTIFIED BY 'password'

The optional

IDENTIFIED BY

clause can be used to provide an account with a password. The password should be specified in plain text. It will be hashed by the [PASSWORD](#) function prior to being stored in the [mysql.user](#) / [mysql.global\\_priv\\_table](#) table.

For example, if our password is

mariadb

, then we can create the user with:

```
CREATE USER foo2@test IDENTIFIED BY 'mariadb';
```

If you do not specify a password with the

IDENTIFIED BY

clause, the user will be able to connect without a password. A blank password is not a wildcard to match any password. The user must connect without providing a password if no password is set.

The only [authentication plugins](#) that this clause supports are [mysql\\_native\\_password](#) and [mysql\\_old\\_password](#).

### IDENTIFIED BY PASSWORD 'password\_hash'

The optional

IDENTIFIED BY PASSWORD

clause can be used to provide an account with a password that has already been hashed. The password should be specified as a hash that was provided by the [PASSWORD](#) function. It will be stored in the [mysql.user](#) / [mysql.global\\_priv\\_table](#) table as-is.

For example, if our password is

mariadb

, then we can find the hash with:

```
SELECT PASSWORD('mariadb');
+-----+
| PASSWORD('mariadb')           |
+-----+
| *54958E764CE10E50764C2EECB71D01F08549980 |
+-----+
1 row in set (0.00 sec)
```

And then we can create a user with the hash:

```
CREATE USER foo2@test IDENTIFIED BY PASSWORD '*54958E764CE10E50764C2EECB71D01F08549980';
```

If you do not specify a password with the

IDENTIFIED BY

clause, the user will be able to connect without a password. A blank password is not a wildcard to match any password. The user must connect without providing a password if no password is set.

The only [authentication plugins](#) that this clause supports are [mysql\\_native\\_password](#) and [mysql\\_old\\_password](#).

### IDENTIFIED {VIA|WITH} authentication\_plugin

The optional

IDENTIFIED VIA authentication\_plugin

allows you to specify that the account should be authenticated by a specific [authentication plugin](#). The plugin name must be an active authentication plugin as per [SHOW PLUGINS](#). If it doesn't show up in that output, then you will need to install it with [INSTALL PLUGIN](#) or [INSTALL SONAME](#).

For example, this could be used with the [PAM authentication plugin](#):

```
CREATE USER foo2@test IDENTIFIED VIA pam;
```

Some authentication plugins allow additional arguments to be specified after a

USING

or

AS

keyword. For example, the [PAM authentication plugin](#) accepts a [service name](#):

```
CREATE USER foo2@test IDENTIFIED VIA pam USING 'mariadb';
```

The exact meaning of the additional argument would depend on the specific authentication plugin.

MariaDB starting with [10.4.0](#)

The

USING

or

AS

keyword can also be used to provide a plain-text password to a plugin if it's provided as an argument to the [PASSWORD\(\)](#) function. This is only valid for [authentication plugins](#) that have implemented a hook for the [PASSWORD\(\)](#) function. For example, the [ed25519](#) authentication plugin supports this:

```
CREATE USER safe@'%' IDENTIFIED VIA ed25519 USING PASSWORD('secret');
```

MariaDB starting with [10.4.3](#)

One can specify many authentication plugins, they all work as alternatives ways of authenticating a user:

```
CREATE USER safe@'%' IDENTIFIED VIA ed25519 USING PASSWORD('secret') OR unix_socket;
```

By default, when you create a user without specifying an authentication plugin, MariaDB uses the [mysql\\_native\\_password](#) plugin.

## TLS Options

By default, MariaDB transmits data between the server and clients without encrypting it. This is generally acceptable when the server and client run on the same host or in networks where security is guaranteed through other means. However, in cases where the server and client exist on separate networks or they are in a high-risk network, the lack of encryption does introduce security concerns as a malicious actor could potentially eavesdrop on the traffic as it is sent over the network between them.

To mitigate this concern, MariaDB allows you to encrypt data in transit between the server and clients using the Transport Layer Security (TLS) protocol. TLS was formerly known as Secure Socket Layer (SSL), but strictly speaking the SSL protocol is a predecessor to TLS and, that version of the protocol is now considered insecure. The documentation still uses the term SSL often and for compatibility reasons TLS-related server system and status variables still use the prefix `ssl_`, but internally, MariaDB only supports its secure successors.

See [Secure Connections Overview](#) for more information about how to determine whether your MariaDB server has TLS support.

You can set certain TLS-related restrictions for specific user accounts. For instance, you might use this with user accounts that require access to sensitive data while sending it across networks that you do not control. These restrictions can be enabled for a user account with the [CREATE USER](#), [ALTER USER](#), or [GRANT](#) statements. The following options are available:

Option	Description
REQUIRE NONE	TLS is not required for this account, but can still be used.
REQUIRE SSL	The account must use TLS, but no valid X509 certificate is required. This option cannot be combined with other TLS options.

REQUIRE X509	The account must use TLS and must have a valid X509 certificate. This option implies REQUIRE SSL . This option cannot be combined with other TLS options.
REQUIRE ISSUER 'issuer'	The account must use TLS and must have a valid X509 certificate. Also, the Certificate Authority must be the one specified via the string issuer . This option implies REQUIRE X509 . This option can be combined with the SUBJECT , and CIPHER options in any order.
REQUIRE SUBJECT 'subject'	The account must use TLS and must have a valid X509 certificate. Also, the certificate's Subject must be the one specified via the string subject . This option implies REQUIRE X509 . This option can be combined with the ISSUER , and CIPHER options in any order.
REQUIRE CIPHER 'cipher'	The account must use TLS, but no valid X509 certificate is required. Also, the encryption used for the connection must use a specific cipher method specified in the string cipher . This option implies REQUIRE SSL . This option can be combined with the ISSUER , and SUBJECT options in any order.

The

REQUIRE  
keyword must be used only once for all specified options, and the  
AND  
keyword can be used to separate individual options, but it is not required.

For example, you can create a user account that requires these TLS options with the following:

```
CREATE USER 'alice'@'%'  
REQUIRE SUBJECT '/CN=alice/0=My Dom, Inc./C=US/ST=Oregon/L=Portland'  
AND ISSUER '/C=FI/ST=Somewhere/L=City/ O=Some Company/CN=Peter Parker/emailAddress=p.parker@marvel.com'  
AND CIPHER 'SHA-DES-CBC3-EDH-RSA';
```

If any of these options are set for a specific user account, then any client who tries to connect with that user account will have to be configured to connect with TLS.

See [Securing Connections for Client and Server](#) for information on how to enable TLS on the client and server.

## Resource Limit Options

MariaDB starting with 10.2.0

MariaDB 10.2.0 introduced a number of resource limit options.

It is possible to set per-account limits for certain server resources. The following table shows the values that can be set per account:

Limit Type	Description
MAX_QUERIES_PER_HOUR	Number of statements that the account can issue per hour (including updates)
MAX_UPDATES_PER_HOUR	Number of updates (not queries) that the account can issue per hour

MAX_CONNECTIONS_PER_HOUR	Number of connections that the account can start per hour
MAX_USER_CONNECTIONS	Number of simultaneous connections that can be accepted from the same account; if it is 0, max_connections will be used instead; if max_connections is 0, there is no limit for this account's simultaneous connections.
MAX_STATEMENT_TIME	Timeout, in seconds, for statements executed by the user. See also <a href="#">Aborting Statements that Exceed a Certain Time to Execute</a> .

If any of these limits are set to

0

, then there is no limit for that resource for that user.

Here is an example showing how to create a user with resource limits:

```
CREATE USER 'someone'@'localhost' WITH
  MAX_USER_CONNECTIONS 10
  MAX_QUERIES_PER_HOUR 200;
```

The resources are tracked per account, which means

'user'@'server'  
; not per user name or per connection.

The count can be reset for all users using [FLUSH USER\\_RESOURCES](#), [FLUSH PRIVILEGES](#) or [mysqladmin reload](#).

Per account resource limits are stored in the `user` table, in the `mysql` database. Columns used for resources limits are named

max\_questions  
,  
max\_updates  
,  
max\_connections  
(for  
MAX\_CONNECTIONS\_PER\_HOUR  
, and  
max\_user\_connections  
(for  
MAX\_USER\_CONNECTIONS  
)�.

## Account Names

Account names have both a user name component and a host name component, and are specified as

'user\_name'@'host\_name'

The user name and host name may be unquoted, quoted as strings using double quotes (

"

) or single quotes (

'), or quoted as identifiers using backticks (

). You must use quotes when using special characters (such as a hyphen) or wildcard characters. If you quote, you must quote the user name and host name separately (for example

'user\_name'@'host\_name'  
).

## Host Name Component

If the host name is not provided, it is assumed to be

'%'

Host names may contain the wildcard characters

%  
and  
\_

. They are matched as if by the [LIKE](#) clause. If you need to use a wildcard character literally (for example, to match a domain name with an underscore), prefix the character with a backslash. See

[LIKE](#)

for more information on escaping wildcard characters.

Host name matches are case-insensitive. Host names can match either domain names or IP addresses. Use

'localhost'

as the host name to allow only local client connections.

You can use a netmask to match a range of IP addresses using

'base\_ip/netmask'

as the host name. A user with an IP address *ip\_addr* will be allowed to connect if the following condition is true:

```
ip_addr & netmask = base_ip
```

For example, given a user:

```
CREATE USER 'maria'@'247.150.130.0/255.255.255.0';
```

the IP addresses satisfying this condition range from 247.150.130.0 to 247.150.130.255.

Using

255.255.255.255

is equivalent to not using a netmask at all. Netmasks cannot be used for IPv6 addresses.

Note that the credentials added when creating a user with the

'%'

wildcard host will not grant access in all cases. For example, some systems come with an anonymous localhost user, and when connecting from localhost this will take precedence.

Before [MariaDB 10.6](#), the host name component could be up to 60 characters in length. Starting from [MariaDB 10.6](#), it can be up to 255 characters.

## User Name Component

User names must match exactly, including case. A user name that is empty is known as an anonymous account and is allowed to match a login attempt with any user name component. These are described more in the next section.

For valid identifiers to use as user names, see [Identifier Names](#).

It is possible for more than one account to match when a user connects. MariaDB selects the first matching account after sorting according to the following criteria:

- Accounts with an exact host name are sorted before accounts using a wildcard in the host name. Host names using a netmask are considered to be exact for sorting.
- Accounts with a wildcard in the host name are sorted according to the position of the first wildcard character. Those with a wildcard character later in the host name sort before those with a wildcard character earlier in the host name.
- Accounts with a non-empty user name sort before accounts with an empty user name.
- Accounts with an empty user name are sorted last. As mentioned previously, these are known as anonymous accounts. These are described more in the next section.

The following table shows a list of example account as sorted by these criteria:

User	Host
joffrey	192.168.0.3
	192.168.0.%
joffrey	192.168.%
	192.168.%

Once connected, you only have the privileges granted to the account that matched, not all accounts that could have matched. For example, consider the following commands:

```
CREATE USER 'joffrey'@'192.168.0.3';
CREATE USER 'joffrey'@'%';
GRANT SELECT ON test.t1 TO 'joffrey'@'192.168.0.3';
GRANT SELECT ON test.t2 TO 'joffrey'@'%';
```

If you connect as joffrey from

192.168.0.3

, you will have the

SELECT

privilege on the table

```
test.t1
, but not on the table
test.t2
. If you connect as joffrey from any other IP address, you will have the
SELECT
privilege on the table
test.t2
, but not on the table
test.t1
.
```

Usernames can be up to 80 characters long before 10.6 and starting from 10.6 it can be 128 characters long.

## Anonymous Accounts

Anonymous accounts are accounts where the user name portion of the account name is empty. These accounts act as special catch-all accounts. If a user attempts to log into the system from a host, and an anonymous account exists with a host name portion that matches the user's host, then the user will log in as the anonymous account if there is no more specific account match for the user name that the user entered.

For example, here are some anonymous accounts:

```
CREATE USER ''@'localhost';
CREATE USER ''@'192.168.0.3';
```

### Fixing a Legacy Default Anonymous Account

On some systems, the `mysql.db` table has some entries for the

`'@'%'`

anonymous account by default. Unfortunately, there is no matching entry in the `mysql.user` / `mysql.global_priv_table` table, which means that this anonymous account doesn't exactly exist, but it does have privileges--usually on the default

`test`

database created by `mysql_install_db`. These account-less privileges are a legacy that is leftover from a time when MySQL's privilege system was less advanced.

This situation means that you will run into errors if you try to create a

`'@'%'`

account. For example:

```
CREATE USER ''@'%';
ERROR 1396 (HY000): Operation CREATE USER failed for ''@'%'
```

The fix is to `DELETE` the row in the `mysql.db` table and then execute `FLUSH PRIVILEGES`:

```
DELETE FROM mysql.db WHERE User=' ' AND Host='';
FLUSH PRIVILEGES;
```

And then the account can be created:

```
CREATE USER ''@'%';
Query OK, 0 rows affected (0.01 sec)
```

See [MDEV-13486](#) for more information.

## Password Expiry

MariaDB starting with 10.4.3

Besides automatic password expiry, as determined by `default_password_lifetime`, password expiry times can be set on an individual user basis, overriding the global setting, for example:

```
CREATE USER 'monty'@'localhost' PASSWORD EXPIRE INTERVAL 120 DAY;
```

See [User Password Expiry](#) for more details.

## Account Locking

MariaDB starting with 10.4.2

Account locking permits privileged administrators to lock/unlock user accounts. No new client connections will be permitted if an account is locked

(existing connections are not affected). For example:

```
CREATE USER 'marijn'@'localhost' ACCOUNT LOCK;
```

See [Account Locking](#) for more details.

From [MariaDB 10.4.7](#) and [MariaDB 10.5.8](#), the *lock\_option* and *password\_option* clauses can occur in either order.

## 1.1.1.2 ALTER USER

MariaDB starting with [10.2.0](#)

The ALTER USER statement was introduced in [MariaDB 10.2.0](#).

## Syntax

```

ALTER USER [IF EXISTS]
  user_specification [,user_specification] ...
  [REQUIRE {NONE | tls_option [[AND] tls_option] ...}]
  [WITH resource_option [resource_option] ...]
  [lock_option] [password_option]

  user_specification:
    username [authentication_option]

  authentication_option:
    IDENTIFIED BY 'password'
    | IDENTIFIED BY PASSWORD 'password_hash'
    | IDENTIFIED {VIA|WITH} authentication_rule [OR authentication_rule] ...

  authentication_rule:
    authentication_plugin
    | authentication_plugin {USING|AS} 'authentication_string'
    | authentication_plugin {USING|AS} PASSWORD('password')

  tls_option
    SSL
    | X509
    | CIPHER 'cipher'
    | ISSUER 'issuer'
    | SUBJECT 'subject'

  resource_option
    MAX_QUERIES_PER_HOUR count
    | MAX_UPDATES_PER_HOUR count
    | MAX_CONNECTIONS_PER_HOUR count
    | MAX_USER_CONNECTIONS count
    | MAX_STATEMENT_TIME time

  password_option:
    PASSWORD EXPIRE
    | PASSWORD EXPIRE DEFAULT
    | PASSWORD EXPIRE NEVER
    | PASSWORD EXPIRE INTERVAL N DAY

  lock_option:
    ACCOUNT LOCK
    | ACCOUNT UNLOCK
}

```

## Contents

1. [Syntax](#)
2. [Description](#)
3. [IF EXISTS](#)
4. [Account Names](#)
5. [Authentication Options](#)
  1. [IDENTIFIED BY 'password'](#)
  2. [IDENTIFIED BY PASSWORD 'password\\_hash'](#)

10. [See Also](#)

## Description

The

`ALTER USER`

statement modifies existing MariaDB accounts. To use it, you must have the global `CREATE USER` privilege or the `UPDATE` privilege for the `mysql` database. The global `SUPER` privilege is also required if the `read_only` system variable is enabled.

If any of the specified user accounts do not yet exist, an error results. If an error occurs,

`ALTER USER`

will still modify the accounts that do not result in an error. Only one error is produced for all users which have not been modified.

# IF EXISTS

When the

IF EXISTS

clause is used, MariaDB will return a warning instead of an error for each specified user that does not exist.

## Account Names

For

ALTER USER  
statements, account names are specified as the  
username  
argument in the same way as they are for [CREATE USER](#) statements. See [account names](#) from the  
[CREATE USER](#)  
page for details on how account names are specified.

[CURRENT\\_USER](#) or

[CURRENT\\_USER\(\)](#)  
can also be used to alter the account logged into the current session. For example, to change the current user's password to  
mariadb  
:

```
ALTER USER CURRENT_USER() IDENTIFIED BY 'mariadb';
```

## Authentication Options

MariaDB starting with [10.4](#)

From [MariaDB 10.4](#), it is possible to use more than one authentication plugin for each user account. For example, this can be useful to slowly migrate users to the more secure ed25519 authentication plugin over time, while allowing the old mysql\_native\_password authentication plugin as an alternative for the transitional period. See [Authentication from MariaDB 10.4](#) for more.

When running

ALTER USER  
, not specifying an authentication option in the IDENTIFIED VIA clause will remove that authentication method. (However this was not the case before [MariaDB 10.4.13](#), see [MDEV-21928](#))

For example, a user is created with the ability to authenticate via both a password and unix\_socket:

```
CREATE USER 'bob'@'localhost'  
IDENTIFIED VIA mysql_native_password USING PASSWORD('pwd')  
OR unix_socket;  
  
SHOW CREATE USER 'bob'@'localhost'  
***** 1. row *****  
CREATE USER for bob@localhost: CREATE USER `bob`@`localhost`  
IDENTIFIED VIA mysql_native_password USING '*975B2CD4FF9AE554FE8AD33168FBFC326D2021DD'  
OR unix_socket
```

If the user's password is updated, but unix\_socket authentication is not specified in the

IDENTIFIED VIA  
clause, unix\_socket authentication will no longer be permitted.

```
ALTER USER 'bob'@'localhost' IDENTIFIED VIA mysql_native_password USING PASSWORD('pwd2');  
  
SHOW CREATE USER 'bob'@'localhost'  
***** 1. row *****  
CREATE USER for bob@localhost: CREATE USER `bob`@`localhost`  
IDENTIFIED BY PASSWORD '*38366FDA01695B6A5A9DD4E428D9FB8F7EB75512'
```

## IDENTIFIED BY 'password'

The optional

IDENTIFIED BY

clause can be used to provide an account with a password. The password should be specified in plain text. It will be hashed by the [PASSWORD](#) function prior to being stored to the [mysql.user](#) table.

For example, if our password is

mariadb

, then we can set the account's password with:

```
ALTER USER foo2@test IDENTIFIED BY 'mariadb';
```

If you do not specify a password with the  
IDENTIFIED BY  
clause, the user will be able to connect without a password. A blank password is not a wildcard to match any password. The user must connect without providing a password if no password is set.

The only [authentication plugins](#) that this clause supports are [mysql\\_native\\_password](#) and [mysql\\_old\\_password](#).

## IDENTIFIED BY PASSWORD 'password\_hash'

The optional  
IDENTIFIED BY PASSWORD  
clause can be used to provide an account with a password that has already been hashed. The password should be specified as a hash that was provided by the [PASSWORD](#) #function. It will be stored to the [mysql.user](#) table as-is.

For example, if our password is

mariadb

, then we can find the hash with:

```
SELECT PASSWORD('mariadb');
+-----+
| PASSWORD('mariadb') |
+-----+
| *54958E764CE10E50764C2EECB71D01F08549980 |
+-----+
```

And then we can set an account's password with the hash:

```
ALTER USER foo2@test IDENTIFIED BY PASSWORD '*54958E764CE10E50764C2EECB71D01F08549980';
```

If you do not specify a password with the  
IDENTIFIED BY  
clause, the user will be able to connect without a password. A blank password is not a wildcard to match any password. The user must connect without providing a password if no password is set.

The only [authentication plugins](#) that this clause supports are [mysql\\_native\\_password](#) and [mysql\\_old\\_password](#).

## IDENTIFIED {VIA|WITH} authentication\_plugin

The optional

IDENTIFIED VIA authentication\_plugin

allows you to specify that the account should be authenticated by a specific [authentication plugin](#). The plugin name must be an active authentication plugin as per [SHOW PLUGINS](#). If it doesn't show up in that output, then you will need to install it with [INSTALL PLUGIN](#) or [INSTALL SONAME](#).

For example, this could be used with the [PAM authentication plugin](#):

```
ALTER USER foo2@test IDENTIFIED VIA pam;
```

Some authentication plugins allow additional arguments to be specified after a

USING

or

AS

keyword. For example, the [PAM authentication plugin](#) accepts a [service name](#):

```
ALTER USER foo2@test IDENTIFIED VIA pam USING 'mariadb';
```

The exact meaning of the additional argument would depend on the specific authentication plugin.

In [MariaDB 10.4](#) and later, the

USING

or

AS

keyword can also be used to provide a plain-text password to a plugin if it's provided as an argument to the [PASSWORD\(\)](#) function. This is only valid for [authentication plugins](#) that have implemented a hook for the [PASSWORD\(\)](#) function. For example, the [ed25519](#) authentication plugin supports this:

```
ALTER USER safe@'%' IDENTIFIED VIA ed25519 USING PASSWORD('secret');
```

# TLS Options

By default, MariaDB transmits data between the server and clients without encrypting it. This is generally acceptable when the server and client run on the same host or in networks where security is guaranteed through other means. However, in cases where the server and client exist on separate networks or they are in a high-risk network, the lack of encryption does introduce security concerns as a malicious actor could potentially eavesdrop on the traffic as it is sent over the network between them.

To mitigate this concern, MariaDB allows you to encrypt data in transit between the server and clients using the Transport Layer Security (TLS) protocol. TLS was formerly known as Secure Socket Layer (SSL), but strictly speaking the SSL protocol is a predecessor to TLS and, that version of the protocol is now considered insecure. The documentation still uses the term SSL often and for compatibility reasons TLS-related server system and status variables still use the prefix `ssl_`, but internally, MariaDB only supports its secure successors.

See [Secure Connections Overview](#) for more information about how to determine whether your MariaDB server has TLS support.

You can set certain TLS-related restrictions for specific user accounts. For instance, you might use this with user accounts that require access to sensitive data while sending it across networks that you do not control. These restrictions can be enabled for a user account with the `CREATE USER`, `ALTER USER`, or `GRANT` statements. The following options are available:

Option	Description
<code>REQUIRE NONE</code>	TLS is not required for this account, but can still be used.
<code>REQUIRE SSL</code>	The account must use TLS, but no valid X509 certificate is required. This option cannot be combined with other TLS options.
<code>REQUIRE X509</code>	The account must use TLS and must have a valid X509 certificate. This option implies <code>REQUIRE SSL</code> . This option cannot be combined with other TLS options.
<code>'issuer' REQUIRE ISSUER</code>	The account must use TLS and must have a valid X509 certificate. Also, the Certificate Authority must be the one specified via the string <code>issuer</code> . This option implies <code>REQUIRE X509</code> . This option can be combined with the <code>SUBJECT</code> , and <code>CIPHER</code> options in any order.
<code>SUBJECT 'subject' REQUIRE</code>	The account must use TLS and must have a valid X509 certificate. Also, the certificate's Subject must be the one specified via the string <code>subject</code> . This option implies <code>REQUIRE X509</code> . This option can be combined with the <code>ISSUER</code> , and <code>CIPHER</code> options in any order.
<code>'cipher' REQUIRE CIPHER</code>	The account must use TLS, but no valid X509 certificate is required. Also, the encryption used for the connection must use a specific cipher method specified in the string <code>cipher</code> . This option implies <code>REQUIRE SSL</code> . This option can be combined with the <code>ISSUER</code> , and <code>SUBJECT</code> options in any order.

The

`REQUIRE`  
keyword must be used only once for all specified options, and the  
`AND`  
keyword can be used to separate individual options, but it is not required.

For example, you can alter a user account to require these TLS options with the following:

```

ALTER USER 'alice'@'%'
REQUIRE SUBJECT '/CN=alice/O=My Dom, Inc./C=US/ST=Oregon/L=Portland'
AND ISSUER '/C=FI/ST=Somewhere/L=City/ O=Some Company/CN=Peter Parker/emailAddress=p.parker@marvel.com'
AND CIPHER 'SHA-DES-CBC3-EDH-RSA';

```

If any of these options are set for a specific user account, then any client who tries to connect with that user account will have to be configured to connect with TLS.

See [Securing Connections for Client and Server](#) for information on how to enable TLS on the client and server.

## Resource Limit Options

MariaDB starting with 10.2.0

MariaDB 10.2.0 introduced a number of resource limit options.

It is possible to set per-account limits for certain server resources. The following table shows the values that can be set per account:

Limit Type	Description
MAX_QUERIES_PER_HOUR	Number of statements that the account can issue per hour (including updates)
MAX_UPDATES_PER_HOUR	Number of updates (not queries) that the account can issue per hour
MAX_CONNECTIONS_PER_HOUR	Number of connections that the account can start per hour
MAX_USER_CONNECTIONS	Number of simultaneous connections that can be accepted from the same account; if it is 0, <code>max_connections</code> will be used instead; if <code>max_connections</code> is 0, there is no limit for this account's simultaneous connections.
MAX_STATEMENT_TIME	Timeout, in seconds, for statements executed by the user. See also <a href="#">Aborting Statements that Exceed a Certain Time to Execute</a> .

If any of these limits are set to

0

, then there is no limit for that resource for that user.

Here is an example showing how to set an account's resource limits:

```

ALTER USER 'someone'@'localhost' WITH
  MAX_USER_CONNECTIONS 10
  MAX_QUERIES_PER_HOUR 200;

```

The resources are tracked per account, which means

'user'@'server'  
; not per user name or per connection.

The count can be reset for all users using [FLUSH USER\\_RESOURCES](#), [FLUSH PRIVILEGES](#) or [mysqladmin reload](#).

Per account resource limits are stored in the `user` table, in the `mysql` database. Columns used for resources limits are named

`max_questions`  
,  
`max_updates`  
,  
`max_connections`  
(for  
`MAX_CONNECTIONS_PER_HOUR`  
, and  
`max_user_connections`  
(for  
`MAX_USER_CONNECTIONS`  
).

# Password Expiry

MariaDB starting with 10.4.3

Besides automatic password expiry, as determined by `default_password_lifetime`, password expiry times can be set on an individual user basis, overriding the global setting, for example:

```
ALTER USER 'monty'@'localhost' PASSWORD EXPIRE INTERVAL 120 DAY;
ALTER USER 'monty'@'localhost' PASSWORD EXPIRE NEVER;
ALTER USER 'monty'@'localhost' PASSWORD EXPIRE DEFAULT;
```

See [User Password Expiry](#) for more details.

# Account Locking

MariaDB starting with 10.4.2

Account locking permits privileged administrators to lock/unlock user accounts. No new client connections will be permitted if an account is locked (existing connections are not affected). For example:

```
ALTER USER 'marijn'@'localhost' ACCOUNT LOCK;
```

See [Account Locking](#) for more details.

From MariaDB 10.4.7 and MariaDB 10.5.8, the `lock_option` and `password_option` clauses can occur in either order.

## See Also

- [Authentication from MariaDB 10.4](#)
- [GRANT](#)
- [CREATE USER](#)
- [DROP USER](#)
- [SET PASSWORD](#)
- [SHOW CREATE USER](#)
- [mysql.user table](#)
- [Password Validation Plugins](#) - permits the setting of basic criteria for passwords
- [Authentication Plugins](#) - allow various authentication methods to be used, and new ones to be developed.

## 1.1.1.3 DROP USER

### Syntax

```
DROP USER [IF EXISTS] user_name [, user_name] ...
```

### Contents

1. [Syntax](#)
2. [Description](#)
  - 1. [IF EXISTS](#)
3. [Examples](#)
4. [See Also](#)

### Description

The

```
DROP USER
```

statement removes one or more MariaDB accounts. It removes privilege rows for the account from all grant tables. To use this statement, you must have the global `CREATE USER` privilege or the `DELETE` privilege for the `mysql` database. Each account is named using the same format as for the

```
CREATE USER
statement; for example,
'jeffrey'@'localhost'
. If you specify only the user name part of the account name, a host name part of
'%'
is used. For additional information about specifying account names, see CREATE USER.
```

Note that, if you specify an account that is currently connected, it will not be deleted until the connection is closed. The connection will not be automatically

closed.

If any of the specified user accounts do not exist,

```
ERROR 1396 (HY000)
results. If an error occurs,
DROP USER
```

will still drop the accounts that do not result in an error. Only one error is produced for all users which have not been dropped:

```
ERROR 1396 (HY000): Operation DROP USER failed for 'u1'@'%','u2'@'%'
```

Failed

```
CREATE
or
DROP
operations, for both users and roles, produce the same error code.
```

## IF EXISTS

If the

```
IF EXISTS
clause is used, MariaDB will return a note instead of an error if the user does not exist.
```

## Examples

```
DROP USER bob;
```

```
IF EXISTS
:
DROB USER bob;
ERROR 1396 (HY000): Operation DROB USER failed for 'bob'@'%'

DROB USER IF EXISTS bob;
Query OK, 0 rows affected, 1 warning (0.00 sec)

SHOW WARNINGS;
+-----+-----+
| Level | Code | Message |
+-----+-----+
| Note  | 1974 | Can't drop user 'bob'@'%'; it doesn't exist |
+-----+-----+
```

## Syntax

```

GRANT
  priv_type [(column_list)]
  [, priv_type [(column_list)]] ...
  ON [object_type] priv_level
  TO user_specification [ user_options ...]

user_specification:
  username [authentication_option]

authentication_option:
  IDENTIFIED BY 'password'
  | IDENTIFIED BY PASSWORD 'password_hash'
  | IDENTIFIED {VIA|WITH} authentication_rule [OR authentication_rule ...]

authentication_rule:
  authentication_plugin
  | authentication_plugin {USING|AS} 'authentication_string'
  | authentication_plugin {USING|AS} PASSWORD('password')

GRANT PROXY ON username
  TO user_specification [, user_specification ...]
  [WITH GRANT OPTION]

GRANT rolename TO grantee [, grantee ...]
  [WITH ADMIN OPTION]

grantee:
  rolename
  username [authentication_option]

user_options:
  [REQUIRE {NONE | tls_option [[AND] tls_option] ...}]
  [WITH with_option [with_option] ...]

object_type:
  TABLE
  | FUNCTION
  | PROCEDURE
  | PACKAGE

priv_level:
  *
  | *.*
  | db_name.*
  | db_name.tbl_name
  | tbl_name
  | db_name.routine_name

with_option:
  GRANT OPTION
  | resource_option

resource_option:
  MAX_QUERIES_PER_HOUR count
  | MAX_UPDATES_PER_HOUR count
  | MAX_CONNECTIONS_PER_HOUR count
  | MAX_USER_CONNECTIONS count
  | MAX_STATEMENT_TIME time

tls_option:
  SSL
  | X509
  | CIPHER 'cipher'
  | ISSUER 'issuer'
  | SUBJECT 'subject'

```

## Description

The

```

GRANT
statement allows you to grant privileges or roles to accounts. To use
GRANT
, you must have the
GRANT OPTION

```

privilege, and you must have the privileges that you are granting.

Use the [REVOKE](#) statement to revoke privileges granted with the  
GRANT  
statement.

Use the [SHOW GRANTS](#) statement to determine what privileges an account has.

## Account Names

For

GRANT  
statements, account names are specified as the  
username  
argument in the same way as they are for [CREATE USER](#) statements. See [account names](#) from the  
[CREATE USER](#)  
page for details on how account names are specified.

## Implicit Account Creation

The

GRANT  
statement also allows you to implicitly create accounts in some cases.

If the account does not yet exist, then

GRANT  
can implicitly create it. To implicitly create an account with  
GRANT  
, a user is required to have the same privileges that would be required to explicitly create the account with the  
[CREATE USER](#)  
statement.

If the

NO\_AUTO\_CREATE\_USER  
[SQL\\_MODE](#) is set, then accounts can only be created if authentication information is specified, or with a [CREATE USER](#) statement. If no authentication information is provided,  
GRANT  
will produce an error when the specified account does not exist, for example:

```
show variables like '%sql_mode' ;
+-----+-----+
| Variable_name | Value           |
+-----+-----+
| sql_mode      | NO_AUTO_CREATE_USER,NO_ENGINE_SUBSTITUTION |
+-----+-----+

GRANT USAGE ON *.* TO 'user123'@'%' IDENTIFIED BY '';
ERROR 1133 (28000): Can't find any matching row in the user table

GRANT USAGE ON *.* TO 'user123'@'%' IDENTIFIED VIA PAM using 'mariadb' require ssl ;
Query OK, 0 rows affected (0.00 sec)

select host, user from mysql.user where user='user123' ;

+-----+-----+
| host | user   |
+-----+-----+
| %    | user123 |
+-----+-----+
```

## Privilege Levels

Privileges can be set globally, for an entire database, for a table or routine, or for individual columns in a table. Certain privileges can only be set at certain levels.

- Global privileges *priv\_type* are granted using  
\*.\*  
for *priv\_level*. Global privileges include privileges to administer the database and manage user accounts, as well as privileges for all tables, functions, and procedures. Global privileges are stored in the [mysql.user table](#).
- Database privileges *priv\_type* are granted using  
db\_name.\*  
for *priv\_level*, or using just

- \* to use default database. Database privileges include privileges to create tables and functions, as well as privileges for all tables, functions, and procedures in the database. Database privileges are stored in the [mysql.db table](#) .
- **Table privileges *priv\_type*** are granted using
 

```
db_name.tbl_name
for priv_level, or using just
tbl_name
to specify a table in the default database. The
TABLE
keyword is optional. Table privileges include the ability to select and change data in the table. Certain table privileges can be granted for individual columns.
```
- **Column privileges *priv\_type*** are granted by specifying a table for *priv\_level* and providing a column list after the privilege type. They allow you to control exactly which columns in a table users can select and change.
- **Function privileges *priv\_type*** are granted using
 

```
FUNCTION db_name.routine_name
for priv_level, or using just
FUNCTION routine_name
to specify a function in the default database.
```
- **Procedure privileges *priv\_type*** are granted using
 

```
PROCEDURE db_name.routine_name
for priv_level, or using just
PROCEDURE routine_name
to specify a procedure in the default database.
```

## The

### USAGE Privilege

The

```
USAGE
privilege grants no real privileges. The SHOW GRANTS statement will show a global
USAGE
privilege for a newly-created user. You can use
USAGE
with the
GRANT
statement to change options like
GRANT OPTION
and
MAX_USER_CONNECTIONS
without changing any account privileges.
```

## The

### ALL PRIVILEGES Privilege

The

```
ALL PRIVILEGES
privilege grants all available privileges. Granting all privileges only affects the given privilege level. For example, granting all privileges on a
table does not grant any privileges on the database or globally.
```

Using

```
ALL PRIVILEGES
does not grant the special
GRANT OPTION
privilege.
```

You can use

```
ALL
instead of
ALL PRIVILEGES
```

## The

### GRANT OPTION Privilege

Use the

```
WITH GRANT OPTION
```

clause to give users the ability to grant privileges to other users at the given privilege level. Users with the GRANT OPTION privilege can only grant privileges they have. They cannot grant privileges at a higher privilege level than they have the GRANT OPTION privilege.

The

GRANT OPTION  
privilege cannot be set for individual columns. If you use  
WITH GRANT OPTION  
when specifying [column privileges](#), the  
GRANT OPTION  
privilege will be granted for the entire table.

Using the

WITH GRANT OPTION  
clause is equivalent to listing  
GRANT OPTION  
as a privilege.

## Global Privileges

The following table lists the privileges that can be granted globally. You can also grant all database, table, and function privileges globally. When granted globally, these privileges apply to all databases, tables, or functions, including those created later.

To set a global privilege, use

\*.\*  
for *priv\_level*.

## BINLOG ADMIN

Enables administration of the [binary log](#), including the [PURGE BINARY LOGS](#) statement and setting the [binlog\\_annotation\\_row\\_events](#), [binlog\\_cache\\_size](#), [binlog\\_commit\\_wait\\_count](#), [binlog\\_commit\\_wait\\_usec](#), [binlog\\_direct\\_non\\_transactional\\_updates](#), [binlog\\_expire\\_logs\\_seconds](#), [binlog\\_file\\_cache\\_size](#), [binlog\\_format](#), [binlog\\_row\\_image](#), [binlog\\_row\\_metadata](#), [binlog\\_stmt\\_cache\\_size](#), [expire\\_logs\\_days](#), [log\\_bin\\_compress](#), [log\\_bin\\_compress\\_min\\_len](#), [log\\_bin\\_trust\\_function\\_creators](#), [max\\_binlog\\_cache\\_size](#), [max\\_binlog\\_size](#), [max\\_binlog\\_stmt\\_cache\\_size](#), [sql\\_log\\_bin](#) and [sync\\_binlog](#) system variables. Added in [MariaDB 10.5.2](#).

## BINLOG MONITOR

New name for [REPLICATION CLIENT](#) from [MariaDB 10.5.2](#),

REPLICATION CLIENT  
still supported as an alias for compatibility purposes). Permits running SHOW commands related to the [binary log](#), in particular the [SHOW BINLOG STATUS](#), [SHOW REPLICA STATUS](#) and [SHOW BINARY LOGS](#) statements.

## BINLOG REPLAY

Enables replaying the binary log with the [BINLOG](#) statement (generated by [mariadb-binlog](#)), executing [SET timestamp](#) when [secure\\_timestamp](#) is set to

replication  
, and setting the session values of system variables usually included in BINLOG output, in particular [gtid\\_domain\\_id](#), [gtid\\_seq\\_no](#), [pseudo\\_thread\\_id](#) and [server\\_id](#). Added in [MariaDB 10.5.2](#).

## CONNECTION ADMIN

Enables administering connection resource limit options. This includes ignoring the limits specified by [max\\_connections](#), [max\\_user\\_connections](#) and [max\\_password\\_errors](#), not executing the statements specified in [init\\_connect](#), [killing\\_connections\\_and\\_queries](#) owned by other users as well as setting the following connection-related system variables: [connect\\_timeout](#), [disconnect\\_on\\_expired\\_password](#), [extra\\_max\\_connections](#), [init\\_connect](#), [max\\_connections](#), [max\\_connect\\_errors](#), [max\\_password\\_errors](#), [proxy\\_protocol\\_networks](#), [secure\\_auth](#), [slow\\_launch\\_time](#), [thread\\_pool\\_exact\\_stats](#), [thread\\_pool\\_dedicated\\_listener](#), [thread\\_pool\\_idle\\_timeout](#), [thread\\_pool\\_max\\_threads](#), [thread\\_pool\\_min\\_threads](#), [thread\\_pool\\_mode](#), [thread\\_pool\\_oversubscribe](#), [thread\\_pool\\_prio\\_kickup\\_timer](#), [thread\\_pool\\_priority](#), [thread\\_pool\\_size](#), [thread\\_pool\\_stall\\_limit](#). Added in [MariaDB 10.5.2](#).

## CREATE USER

Create a user using the [CREATE USER](#) statement, or implicitly create a user with the  
GRANT  
statement.

## FEDERATED ADMIN

Execute [CREATE SERVER](#), [ALTER SERVER](#), and [DROP SERVER](#) statements. Added in [MariaDB 10.5.2](#).

## FILE

Read and write files on the server, using statements like [LOAD DATA INFILE](#) or functions like [LOAD\\_FILE\(\)](#). Also needed to create [CONNECT](#) outward tables. MariaDB server must have the permissions to access those files.

## GRANT OPTION

Grant global privileges. You can only grant privileges that you have.

## PROCESS

Show information about the active processes, for example via [SHOW PROCESSLIST](#) or [mysqladmin processlist](#). If you have the PROCESS privilege, you can see all threads. Otherwise, you can see only your own threads (that is, threads associated with the MariaDB account that you are using).

## READ\_ONLY ADMIN

User can set the [read\\_only](#) system variable and allows the user to perform write operations, even when the `read_only` option is active. Added in [MariaDB 10.5.2](#).

## RELOAD

Execute [FLUSH](#) statements or equivalent [mariadb-admin/mysqladmin](#) commands.

## REPLICATION CLIENT

Execute [SHOW MASTER STATUS](#), [SHOW SLAVE STATUS](#) and [SHOW BINARY LOGS](#) informative statements. Renamed to [BINLOG MONITOR](#) in [MariaDB 10.5.2](#) (but still supported as an alias for compatibility reasons).

## REPLICATION MASTER ADMIN

Permits administration of primary servers, including the [SHOW REPLICHOSTS](#) statement, and setting the [gtid\\_binlog\\_state](#), [gtid\\_domain\\_id](#), [master\\_verify\\_checksum](#) and [server\\_id](#) system variables. Added in [MariaDB 10.5.2](#).

## REPLICA MONITOR

Permit [SHOW REPLICASTATUS](#) and [SHOW RELAYLOG EVENTS](#). From [MariaDB 10.5.9](#).

When a user would upgrade from an older major release to a [MariaDB 10.5](#) minor release prior to [MariaDB 10.5.9](#), certain user accounts would lose capabilities. For example, a user account that had the REPLICATION CLIENT privilege in older major releases could run [SHOW REPLICASTATUS](#), but after upgrading to a [MariaDB 10.5](#) minor release prior to [MariaDB 10.5.9](#), they could no longer run [SHOW REPLICASTATUS](#), because that statement was changed to require the REPLICATION REPLICA ADMIN privilege.

This issue is fixed in [MariaDB 10.5.9](#) with this new privilege, which now grants the user the ability to execute `SHOW [ALL] (SLAVE | REPLICA) STATUS`.

When a database is upgraded from an older major release to MariaDB Server 10.5.9 or later, any user accounts with the REPLICATION CLIENT or REPLICATION SLAVE privileges will automatically be granted the new REPLICA MONITOR privilege. The privilege fix occurs when the server is started up, not when mariadb-upgrade is performed.

However, when a database is upgraded from an early 10.5 minor release to 10.5.9 and later, the user will have to fix any user account privileges manually.

## REPLICATION REPLICA

Synonym for [REPLICATION SLAVE](#). From [MariaDB 10.5.1](#).

## REPLICATION SLAVE

Accounts used by replica servers on the primary need this privilege. This is needed to get the updates made on the master. From [MariaDB 10.5.1](#), [REPLICATION REPLICA](#) is an alias for

`REPLICATION SLAVE`

## REPLICATION SLAVE ADMIN

Permits administering replica servers, including [START REPLICASLAVE](#), [STOP REPLICASLAVE](#), [CHANGE MASTER](#), [SHOW REPLICASLAVE STATUS](#), [SHOW RELAYLOG EVENTS](#) statements, replaying the binary log with the [BINLOG](#) statement (generated by [mariadb-binlog](#)), and setting the [gtid\\_cleanup\\_batch\\_size](#), [gtid\\_ignore\\_duplicates](#), [gtid\\_pos\\_auto\\_engines](#), [gtid\\_slave\\_pos](#), [gtid\\_strict\\_mode](#), [init\\_slave](#), [read\\_binlog\\_speed\\_limit](#), [relay\\_log\\_purge](#), [relay\\_log\\_recovery](#), [replicate\\_do\\_db](#), [replicate\\_do\\_table](#), [replicate\\_events\\_marked\\_for\\_skip](#), [replicate\\_ignore\\_db](#), [replicate\\_ignore\\_table](#), [replicate\\_wild\\_do\\_table](#), [replicate\\_wild\\_ignore\\_table](#), [slave\\_compressed\\_protocol](#), [slave\\_ddl\\_exec\\_mode](#), [slave\\_domain\\_parallel\\_threads](#), [slave\\_exec\\_mode](#), [slave\\_max\\_allowed\\_packet](#), [slave\\_net\\_timeout](#), [slave\\_parallel\\_max\\_queued](#), [slave\\_parallel\\_mode](#), [slave\\_parallel\\_threads](#), [slave\\_parallel\\_workers](#), [slave\\_run\\_triggers\\_for\\_rbr](#), [slave\\_sql\\_verify\\_checksum](#), [slave\\_transaction\\_retry\\_interval](#), [slave\\_type\\_conversions](#), [sync\\_master\\_info](#), [sync\\_relay\\_log](#) and [sync\\_relay\\_log\\_info](#) system variables. Added in

## SET USER

Enables setting the  
DEFINER  
when creating triggers , views , stored functions and stored procedures . Added in MariaDB 10.5.2 .

## SHOW DATABASES

List all databases using the SHOW DATABASES statement. Without the

```
SHOW DATABASES
privilege, you can still issue the
SHOW DATABASES
statement, but it will only list databases containing tables on which you have privileges.
```

## SHUTDOWN

Shut down the server using SHUTDOWN or the mysqladmin shutdown command.

## SUPER

Execute superuser statements: CHANGE MASTER TO , KILL (users who do not have this privilege can only  
KILL  
their own threads), PURGE LOGS , SET global system variables , or the mysqladmin debug command. Also, this permission allows the user to  
write data even if the read\_only startup option is set, enable or disable logging, enable or disable replication on replica, specify a  
DEFINER  
for statements that support that clause, connect once after reaching the  
MAX\_CONNECTIONS  
. If a statement has been specified for the init-connect  
mysqld  
option, that command will not be executed when a user with  
SUPER  
privileges connects to the server.

The SUPER privilege has been split into multiple smaller privileges from MariaDB 10.5.2 to allow for more fine-grained privileges, although it remains an alias for these smaller privileges.

## Database Privileges

The following table lists the privileges that can be granted at the database level. You can also grant all table and function privileges at the database level. Table and function privileges on a database apply to all tables or functions in that database, including those created later.

To set a privilege for a database, specify the database using

```
db_name.*  
for priv_level , or just use  
*  
to specify the default database.
```

Privilege	Description
CREATE	Create a database using the CREATE DATABASE statement, when the privilege is granted for a database. You can grant the CREATE privilege on databases that do not yet exist. This also grants the CREATE privilege on all tables in the database.
CREATE ROUTINE	Create Stored Programs using the CREATE PROCEDURE and CREATE FUNCTION statements.
CREATE TEMPORARY TABLES	Create temporary tables with the CREATE TEMPORARY TABLE statement. This privilege enables writing and dropping those temporary tables
DROP	Drop a database using the DROP DATABASE statement, when the privilege is granted for a database. This also grants the DROP privilege on all tables in the database.

EVENT	Create, drop and alter EVENT S.
GRANT OPTION	Grant database privileges. You can only grant privileges that you have.
LOCK TABLES	Acquire explicit locks using the <a href="#">LOCK TABLES</a> statement; you also need to have the SELECT privilege on a table, in order to lock it.

## Table Privileges

Privilege	Description
ALTER	Change the structure of an existing table using the <a href="#">ALTER TABLE</a> statement.
CREATE	Create a table using the <a href="#">CREATE TABLE</a> statement. You can grant the CREATE privilege on tables that do not yet exist.
CREATE VIEW	Create a view using the <a href="#">CREATE_VIEW</a> statement.
DELETE	Remove rows from a table using the <a href="#">DELETE</a> statement.
DELETE HISTORY	Remove <a href="#">historical rows</a> from a table using the <a href="#">DELETE HISTORY</a> statement. Displays as DELETE VERSIONING ROWS when running <a href="#">SHOW GRANTS</a> until MariaDB 10.3.15 and until MariaDB 10.4.5 ( MDEV-17655 ), or when running <a href="#">SHOW PRIVILEGES</a> until MariaDB 10.5.2 , MariaDB 10.4.13 and MariaDB 10.3.23 ( MDEV-20382 ). From MariaDB 10.3.4 . From MariaDB 10.3.5 , if a user has the SUPER privilege but not this privilege, running <a href="#">mysql_upgrade</a> will grant this privilege as well.
DROP	Drop a table using the <a href="#">DROP TABLE</a> statement or a view using the <a href="#">DROP VIEW</a> statement. Also required to execute the <a href="#">TRUNCATE TABLE</a> statement.
GRANT OPTION	Grant table privileges. You can only grant privileges that you have.
INDEX	Create an index on a table using the <a href="#">CREATE INDEX</a> statement. Without the INDEX privilege, you can still create indexes when creating a table using the <a href="#">CREATE TABLE</a> statement if the you have the CREATE privilege, and you can create indexes using the <a href="#">ALTER TABLE</a> statement if you have the ALTER privilege.
INSERT	Add rows to a table using the <a href="#">INSERT</a> statement. The INSERT privilege can also be set on individual columns; see <a href="#">Column Privileges</a> below for details.
REFERENCES	Unused.

SELECT	Read data from a table using the <a href="#">SELECT</a> statement. The <a href="#">SELECT</a> privilege can also be set on individual columns; see <a href="#">Column Privileges</a> below for details.
SHOW VIEW	Show the <a href="#">CREATE VIEW</a> statement to create a view using the <a href="#">SHOW CREATE VIEW</a> statement.
TRIGGER	Execute triggers associated to tables you update, execute the <a href="#">CREATE TRIGGER</a> and <a href="#">DROP TRIGGER</a> statements. You will still be able to see triggers.
UPDATE	Update existing rows in a table using the <a href="#">UPDATE</a> statement. UPDATE statements usually include a WHERE clause to update only certain rows. You must have SELECT privileges on the table or the appropriate columns for the WHERE clause. The UPDATE privilege can also be set on individual columns; see <a href="#">Column Privileges</a> below for details.

## Column Privileges

Some table privileges can be set for individual columns of a table. To use column privileges, specify the table explicitly and provide a list of column names after the privilege type. For example, the following statement would allow the user to read the names and positions of employees, but not other information from the same table, such as salaries.

```
GRANT SELECT (name, position) ON Employee TO 'jeffrey'@'localhost';
```

Privilege	Description
INSERT (column_list)	Add rows specifying values in columns using the <a href="#">INSERT</a> statement. If you only have column-level INSERT privileges, you must specify the columns you are setting in the <a href="#">INSERT</a> statement. All other columns will be set to their default values, or NULL.
REFERENCES (column_list)	Unused.
SELECT (column_list)	Read values in columns using the <a href="#">SELECT</a> statement. You cannot access or query any columns for which you do not have SELECT privileges, including in WHERE, , ON, , GROUP BY, , and ORDER BY clauses.
UPDATE (column_list)	Update values in columns of existing rows using the <a href="#">UPDATE</a> statement. UPDATE statements usually include a WHERE clause to update only certain rows. You must have SELECT privileges on the table or the appropriate columns for the WHERE clause.

## Function Privileges

Privilege	Description
ALTER ROUTINE	Change the characteristics of a stored function using the <a href="#">ALTER FUNCTION</a> statement.
EXECUTE	Use a stored function. You need SELECT privileges for any tables or columns accessed by the function.
GRANT OPTION	Grant function privileges. You can only grant privileges that you have.

## Procedure Privileges

Privilege	Description
ALTER ROUTINE	Change the characteristics of a stored procedure using the <a href="#">ALTER PROCEDURE</a> statement.
EXECUTE	Execute a <a href="#">stored procedure</a> using the <a href="#">CALL</a> statement. The privilege to call a procedure may allow you to perform actions you wouldn't otherwise be able to do, such as insert rows into a table.
GRANT OPTION	Grant procedure privileges. You can only grant privileges that you have.

## Proxy Privileges

Privilege	Description
PROXY	Permits one user to be a proxy for another.

The

PROXY

privilege allows one user to proxy as another user, which means their privileges change to that of the proxy user, and the [CURRENT\\_USER\(\)](#) function returns the user name of the proxy user.

The

PROXY

privilege only works with authentication plugins that support it. The default [mysql\\_native\\_password](#) authentication plugin does not support proxy users.

The [pam](#) authentication plugin is the only plugin included with MariaDB that currently supports proxy users. The

PROXY

privilege is commonly used with the [pam](#) authentication plugin to enable [user and group mapping with PAM](#).

For example, to grant the

PROXY

privilege to an [anonymous account](#) that authenticates with the [pam](#) authentication plugin, you could execute the following:

```
CREATE USER 'dba'@'%' IDENTIFIED BY 'strongpassword';
GRANT ALL PRIVILEGES ON *.* TO 'dba'@'%';
```

```
CREATE USER ''@'%' IDENTIFIED VIA pam USING 'mariadb';
GRANT PROXY ON 'dba'@'%' TO ''@'%';
```

A user account can only grant the

PROXY

privilege for a specific user account if the grantor also has the

PROXY

privilege for that specific user account, and if that privilege is defined

WITH GRANT OPTION

. For example, the following example fails because the grantee does not have the PROXY privilege for that specific user account at all:

```
SELECT USER(), CURRENT_USER();
+-----+-----+
| USER()          | CURRENT_USER()   |
+-----+-----+
| alice@localhost | alice@localhost |
+-----+-----+

SHOW GRANTS;
+-----+
| Grants for alice@localhost                                |
+-----+
| GRANT ALL PRIVILEGES ON *.* TO 'alice'@'localhost' IDENTIFIED BY PASSWORD '*2470C0C06DEE42FD1618BB99005ADCA2EC9D1E19' |
+-----+

GRANT PROXY ON 'dba'@'localhost' TO 'bob'@'localhost';
ERROR 1698 (28000): Access denied for user 'alice'@'localhost'
```

And the following example fails because the grantee does have the

PROXY  
privilege for that specific user account, but it is not defined  
WITH GRANT OPTION

```
SELECT USER(), CURRENT_USER();
+-----+-----+
| USER()          | CURRENT_USER()   |
+-----+-----+
| alice@localhost | alice@localhost |
+-----+-----+

SHOW GRANTS;
+-----+
| Grants for alice@localhost
+-----+
| GRANT ALL PRIVILEGES ON *.* TO 'alice'@'localhost' IDENTIFIED BY PASSWORD '*2470C0C06DEE42FD1618BB99005ADCA2EC9D1E19'
| GRANT PROXY ON 'dba'@'localhost' TO 'alice'@'localhost'
+-----+

GRANT PROXY ON 'dba'@'localhost' TO 'bob'@'localhost';
ERROR 1698 (28000): Access denied for user 'alice'@'localhost'
```

But the following example succeeds because the grantee does have the

PROXY  
privilege for that specific user account, and it is defined  
WITH GRANT OPTION

```
SELECT USER(), CURRENT_USER();
+-----+-----+
| USER() | CURRENT_USER() |
+-----+-----+
| alice@localhost | alice@localhost |
+-----+-----+

SHOW GRANTS;
+-----+
| Grants for alice@localhost
+
| GRANT ALL PRIVILEGES ON *.* TO 'alice'@'localhost' IDENTIFIED BY PASSWORD '*2470C0C06DEE42FD1618BB99005ADCA2EC9D1E19' WITH GRANTEE
| GRANT PROXY ON 'dba'@'localhost' TO 'alice'@'localhost' WITH GRANT OPTION
+
| GRANT PROXY ON 'dba'@'localhost' TO 'bob'@'localhost';
```

A user account can grant the

account can grant the  
PROXY  
privilege for any other user account if the grantor has the  
PROXY  
privilege for the

```
' '%'@'
```

anonymous user account, like this:

```
GRANT PROXY ON ''@''%'' TO 'dba'@'localhost' WITH GRANT OPTION;
```

For example, the following example succeeds because the user can grant the PROXY privilege for any other user account:

```
SELECT USER(), CURRENT_USER();
+-----+-----+
| USER() | CURRENT_USER() |
+-----+-----+
| alice@localhost | alice@localhost |
+-----+-----+

SHOW GRANTS;
+-----+
| Grants for alice@localhost
+-----+
| GRANT ALL PRIVILEGES ON *.* TO 'alice'@'localhost' IDENTIFIED BY PASSWORD '*2470C0C06DEE42FD1618BB99005ADCA2EC9D1E9' WITH GRANT OPTION
| GRANT PROXY ON ''@''%'' TO 'alice'@'localhost' WITH GRANT OPTION
+-----+

GRANT PROXY ON 'app1_dba'@'localhost' TO 'bob'@'localhost';
Query OK, 0 rows affected (0.004 sec)

GRANT PROXY ON 'app2_dba'@'localhost' TO 'carol'@'localhost';
Query OK, 0 rows affected (0.004 sec)
```

The default

root

user accounts created by `mysql_install_db` have this privilege. For example:

```
GRANT ALL PRIVILEGES ON *.* TO 'root'@'localhost' WITH GRANT OPTION;
GRANT PROXY ON ''@''%'' TO 'root'@'localhost' WITH GRANT OPTION;
```

This allows the default

root

user accounts to grant the

PROXY

privilege for any other user account, and it also allows the default

root

user accounts to grant others the privilege to do the same.

## Authentication Options

The authentication options for the

`GRANT`

statement are the same as those for the `CREATE USER` statement.

### IDENTIFIED BY 'password'

The optional

`IDENTIFIED BY`

clause can be used to provide an account with a password. The password should be specified in plain text. It will be hashed by the `PASSWORD` function prior to being stored to the `mysql.user` table.

For example, if our password is

`mariadb`

, then we can create the user with:

```
GRANT USAGE ON *.* TO foo2@test IDENTIFIED BY 'mariadb';
```

If you do not specify a password with the

`IDENTIFIED BY`

clause, the user will be able to connect without a password. A blank password is not a wildcard to match any password. The user must connect without providing a password if no password is set.

If the user account already exists and if you provide the

IDENTIFIED BY  
clause, then the user's password will be changed. You must have the privileges needed for the [SET PASSWORD](#) statement to change a user's password with  
GRANT

The only [authentication plugins](#) that this clause supports are [mysql\\_native\\_password](#) and [mysql\\_old\\_password](#).

## IDENTIFIED BY PASSWORD 'password\_hash'

The optional

IDENTIFIED BY PASSWORD

clause can be used to provide an account with a password that has already been hashed. The password should be specified as a hash that was provided by the [PASSWORD](#) function. It will be stored to the [mysql.user](#) table as-is.

For example, if our password is

mariadb

, then we can find the hash with:

```
SELECT PASSWORD('mariadb');
+-----+
| PASSWORD('mariadb') |
+-----+
| *54958E764CE10E50764C2EECBB71D01F08549980 |
+-----+
1 row in set (0.00 sec)
```

And then we can create a user with the hash:

```
GRANT USAGE ON *.* TO foo2@test IDENTIFIED BY PASSWORD '*54958E764CE10E50764C2EECBB71D01F08549980';
```

If you do not specify a password with the

IDENTIFIED BY

clause, the user will be able to connect without a password. A blank password is not a wildcard to match any password. The user must connect without providing a password if no password is set.

If the user account already exists and if you provide the

IDENTIFIED BY

clause, then the user's password will be changed. You must have the privileges needed for the [SET PASSWORD](#) statement to change a user's password with

GRANT

The only [authentication plugins](#) that this clause supports are [mysql\\_native\\_password](#) and [mysql\\_old\\_password](#).

## IDENTIFIED {VIA|WITH} authentication\_plugin

The optional

IDENTIFIED VIA authentication\_plugin

allows you to specify that the account should be authenticated by a specific [authentication plugin](#). The plugin name must be an active authentication plugin as per [SHOW PLUGINS](#). If it doesn't show up in that output, then you will need to install it with [INSTALL PLUGIN](#) or [INSTALL SONAME](#).

For example, this could be used with the [PAM authentication plugin](#):

```
GRANT USAGE ON *.* TO foo2@test IDENTIFIED VIA pam;
```

Some authentication plugins allow additional arguments to be specified after a

USING

or

AS

keyword. For example, the [PAM authentication plugin](#) accepts a [service name](#):

```
GRANT USAGE ON *.* TO foo2@test IDENTIFIED VIA pam USING 'mariadb';
```

The exact meaning of the additional argument would depend on the specific authentication plugin.

MariaDB starting with 10.4.0

The

USING

or

AS

keyword can also be used to provide a plain-text password to a plugin if it's provided as an argument to the `PASSWORD()` function. This is only valid for [authentication plugins](#) that have implemented a hook for the `PASSWORD()` function. For example, the `ed25519` authentication plugin supports this:

```
CREATE USER safe@'%' IDENTIFIED VIA ed25519 USING PASSWORD('secret');
```

MariaDB starting with 10.4.3

One can specify many authentication plugins, they all work as alternatives ways of authenticating a user:

```
CREATE USER safe@'%' IDENTIFIED VIA ed25519 USING PASSWORD('secret') OR unix_socket;
```

By default, when you create a user without specifying an authentication plugin, MariaDB uses the `mysql_native_password` plugin.

## Resource Limit Options

MariaDB starting with 10.2.0

[MariaDB 10.2.0](#) introduced a number of resource limit options.

It is possible to set per-account limits for certain server resources. The following table shows the values that can be set per account:

Limit Type	Description
MAX_QUERIES_PER_HOUR	Number of statements that the account can issue per hour (including updates)
MAX_UPDATES_PER_HOUR	Number of updates (not queries) that the account can issue per hour
MAX_CONNECTIONS_PER_HOUR	Number of connections that the account can start per hour
MAX_USER_CONNECTIONS	Number of simultaneous connections that can be accepted from the same account; if it is 0, <code>max_connections</code> will be used instead; if <code>max_connections</code> is 0, there is no limit for this account's simultaneous connections.
MAX_STATEMENT_TIME	Timeout, in seconds, for statements executed by the user. See also <a href="#">Aborting Statements that Exceed a Certain Time to Execute</a> .

If any of these limits are set to

0

, then there is no limit for that resource for that user.

To set resource limits for an account, if you do not want to change that account's privileges, you can issue a

```
GRANT USAGE ON *.* TO 'someone'@'localhost' WITH  
  MAX_USER_CONNECTIONS 0  
  MAX_QUERIES_PER_HOUR 200;
```

The resources are tracked per account, which means

'user'@'server'  
; not per user name or per connection.

The count can be reset for all users using `FLUSH USER_RESOURCES`, `FLUSH PRIVILEGES` or `mysqladmin reload`.

Users with the  
CONNECTION ADMIN

```

privilege (in MariaDB 10.5.2 and later) or the
SUPER
privilege are not restricted by
max_user_connections
,
max_connections
, or
max_password_errors
.

```

Per account resource limits are stored in the `user` table, in the `mysql` database. Columns used for resources limits are named

```

max_questions
,
max_updates
,
max_connections
(for
MAX_CONNECTIONS_PER_HOUR
), and
max_user_connections
(for
MAX_USER_CONNECTIONS
).

```

## TLS Options

By default, MariaDB transmits data between the server and clients without encrypting it. This is generally acceptable when the server and client run on the same host or in networks where security is guaranteed through other means. However, in cases where the server and client exist on separate networks or they are in a high-risk network, the lack of encryption does introduce security concerns as a malicious actor could potentially eavesdrop on the traffic as it is sent over the network between them.

To mitigate this concern, MariaDB allows you to encrypt data in transit between the server and clients using the Transport Layer Security (TLS) protocol. TLS was formerly known as Secure Socket Layer (SSL), but strictly speaking the SSL protocol is a predecessor to TLS and, that version of the protocol is now considered insecure. The documentation still uses the term SSL often and for compatibility reasons TLS-related server system and status variables still use the prefix `ssl_`, but internally, MariaDB only supports its secure successors.

See [Secure Connections Overview](#) for more information about how to determine whether your MariaDB server has TLS support.

You can set certain TLS-related restrictions for specific user accounts. For instance, you might use this with user accounts that require access to sensitive data while sending it across networks that you do not control. These restrictions can be enabled for a user account with the `CREATE USER`, `ALTER USER`, or `GRANT` statements. The following options are available:

Option	Description
REQUIRE NONE	TLS is not required for this account, but can still be used.
REQUIRE SSL	The account must use TLS, but no valid X509 certificate is required. This option cannot be combined with other TLS options.
REQUIRE X509	The account must use TLS and must have a valid X509 certificate. This option implies REQUIRE SSL . This option cannot be combined with other TLS options.
'issuer' REQUIRE ISSUER	The account must use TLS and must have a valid X509 certificate. Also, the Certificate Authority must be the one specified via the string issuer . This option implies REQUIRE X509 . This option can be combined with the SUBJECT , and CIPHER options in any order.

<pre>REQUIRE SUBJECT 'subject'</pre>	<p>The account must use TLS and must have a valid X509 certificate. Also, the certificate's Subject must be the one specified via the string</p> <pre>    subject     . This option implies REQUIRE X509     . This option can be combined with the ISSUER , and CIPHER options in any order.</pre>
<pre>REQUIRE CIPHER 'cipher'</pre>	<p>The account must use TLS, but no valid X509 certificate is required. Also, the encryption used for the connection must use a specific cipher method specified in the string</p> <pre>    cipher     . This option implies REQUIRE SSL     . This option can be combined with the ISSUER , and SUBJECT options in any order.</pre>

The

```
REQUIRE
keyword must be used only once for all specified options, and the
AND
keyword can be used to separate individual options, but it is not required.
```

For example, you can create a user account that requires these TLS options with the following:

```
GRANT USAGE ON *.* TO 'alice'@'%'
REQUIRE SUBJECT '/CN=alice/O=My Dom, Inc./C=US/ST=Oregon/L=Portland'
AND ISSUER '/C=FI/ST=Somewhere/L=City/ O=Some Company/CN=Peter Parker/emailAddress=p.parker@marvel.com'
AND CIPHER 'SHA-DES-CBC3-EDH-RSA';
```

If any of these options are set for a specific user account, then any client who tries to connect with that user account will have to be configured to connect with TLS.

See [Securing Connections for Client and Server](#) for information on how to enable TLS on the client and server.

## Roles

### Syntax

```
GRANT role TO grantee [, grantee ... ]
[ WITH ADMIN OPTION ]

grantee:
  rolename
  username [authentication_option]
```

The GRANT statement is also used to grant the use a [role](#) to one or more users or other roles. In order to be able to grant a role, the grantor doing so must have permission to do so (see WITH ADMIN in the [CREATE ROLE](#) article).

Specifying the

```
WITH ADMIN OPTION
permits the grantee to in turn grant the role to another.
```

For example, the following commands show how to grant the same role to a couple different users.

```
GRANT journalist TO hulda;
GRANT journalist TO berengar WITH ADMIN OPTION;
```

If a user has been granted a role, they do not automatically obtain all permissions associated with that role. These permissions are only in use when the user activates the role with the [SET ROLE](#) statement.

## Grant Examples

### Granting Root-like Privileges

You can create a user that has privileges similar to the default

root

accounts by executing the following:

```
CREATE USER 'alexander'@'localhost';
GRANT ALL PRIVILEGES ON *.* TO 'alexander'@'localhost' WITH GRANT OPTION;
```

## See Also

- [Troubleshooting Connection Issues](#)
- [--skip-grant-tables](#) allows you to start MariaDB without  
GRANT  
. This is useful if you lost your root password.

- [Password Validation Plugins](#) - permits the setting of basic criteria for passwords
- [Authentication Plugins](#) - allow various authentication methods to be used, and new ones to be developed.

## 1.1.1.5 RENAME USER

### Syntax

```
RENAME USER old_user TO new_user
[, old_user TO new_user] ...
```

### Description

The RENAME USER statement renames existing MariaDB accounts. To use it, you must have the global

[CREATE\\_USER](#)

privilege or the

[UPDATE](#)

privilege for the

[mysql](#)

database. Each account is named using the same format as for the

[CREATE\\_USER](#)

statement; for example,

'jeffrey'@'localhost'

. If you specify only the user name part of the account name, a host name part of

'%'

is used.

If any of the old user accounts do not exist or any of the new user accounts already exist,

[ERROR 1396 \(HY000\)](#)

results. If an error occurs,

[RENAME\\_USER](#)

will still rename the accounts that do not result in an error.

### Examples

```
CREATE USER 'donald', 'mickey';
RENAME USER 'donald' TO 'duck'@'localhost', 'mickey' TO 'mouse'@'localhost';
```

## 1.1.1.6 REVOKE

## Contents

- 1. Privileges
  - 1. Syntax
  - 2. Description
  - 3. Examples
- 2. Roles
  - 1. Syntax
  - 2. Description
  - 3. Example

# Privileges

## Syntax

```
REVOKE  
    priv_type [(column_list)]  
    [, priv_type [(column_list)]] ...  
ON [object_type] priv_level  
FROM user [, user] ...  
  
REVOKE ALL PRIVILEGES, GRANT OPTION  
    FROM user [, user] ...
```

## Description

The

```
REVOKE
```

statement enables system administrators to revoke privileges (or roles - see [section below](#)) from MariaDB accounts. Each account is named using the same format as for the

```
GRANT
```

statement; for example,

```
jeffrey'@'localhost
```

'. If you specify only the user name part of the account name, a host name part of '

```
%
```

' is used. For details on the levels at which privileges exist, the allowable

```
priv_type
```

and

```
priv_level
```

values, and the syntax for specifying users and passwords, see [GRANT](#).

To use the first

```
REVOKE
```

syntax, you must have the

```
GRANT OPTION
```

privilege, and you must have the privileges that you are revoking.

To revoke all privileges, use the second syntax, which drops all global, database, table, column, and routine privileges for the named user or users:

```
REVOKE ALL PRIVILEGES, GRANT OPTION FROM user [, user] ...
```

To use this

```
REVOKE
```

syntax, you must have the global [CREATE USER](#) privilege or the [UPDATE](#) privilege for the mysql database. See [GRANT](#).

## Examples

```
REVOKE SUPER ON *.* FROM 'alexander'@'localhost';
```

# Roles

## Syntax

```
REVOKE role [, role ...]
  FROM grantee [, grantee2 ... ]

REVOKE ADMIN OPTION FOR role FROM grantee [, grantee2]
```

## Description

REVOKE

is also used to remove a [role](#) from a user or another role that it's previously been assigned to. If a role has previously been set as a [default role](#), REVOKE

does not remove the record of the default role from the [mysql.user](#) table. If the role is subsequently granted again, it will again be the user's default. Use [SET DEFAULT ROLE NONE](#) to explicitly remove this.

Before [MariaDB 10.1.13](#), the

```
REVOKE role
statement was not permitted in prepared statements.
```

## Example

```
REVOKE journalist FROM hulda
```

## 1.1.1.7 SET PASSWORD

### Syntax

```
SET PASSWORD [FOR user] =
{
  PASSWORD('some password')
  | OLD_PASSWORD('some password')
  | 'encrypted password'
}
```

### Contents

1. [Syntax](#)
2. [Description](#)
3. [Authentication Plugin Support](#)
4. [Passwordless User Accounts](#)
5. [Example](#)
6. [See Also](#)

## Description

The

```
SET PASSWORD
```

statement assigns a password to an existing MariaDB user account.

If the password is specified using the

```
PASSWORD()
```

or

```
OLD_PASSWORD()
```

function, the literal text of the password should be given. If the password is specified without using either function, the password should be the already-encrypted password value as returned by

```
PASSWORD()
```

```
OLD_PASSWORD()
```

should only be used if your MariaDB/MySQL clients are very old (< 4.0.0).

With no

FOR

clause, this statement sets the password for the current user. Any client that has connected to the server using a non-anonymous account can change the password for that account.

With a

FOR

clause, this statement sets the password for a specific account on the current server host. Only clients that have the

UPDATE

privilege for the

mysql

database can do this. The user value should be given in

user\_name@host\_name

format, where

user\_name

and

host\_name

are exactly as they are listed in the User and Host columns of the

mysql.user

table entry.

The argument to

PASSWORD()

and the password given to MariaDB clients can be of arbitrary length.

## Authentication Plugin Support

MariaDB starting with 10.4

In MariaDB 10.4 and later,

SET PASSWORD

(with or without

PASSWORD()

) works for accounts authenticated via any [authentication plugin](#) that supports passwords stored in the

mysql.global\_priv

table.

The

ed25519

,

mysql\_native\_password

, and

mysql\_old\_password

authentication plugins store passwords in the

mysql.global\_priv

table.

If you run

SET PASSWORD

on an account that authenticates with one of these authentication plugins that stores passwords in the

mysql.global\_priv

table, then the

PASSWORD()

function is evaluated by the specific authentication plugin used by the account. The authentication plugin hashes the password with a method that is compatible with that specific authentication plugin.

The

`unix_socket`  
,

`named_pipe`  
,

`gssapi`

, and

`pam`

authentication plugins do **not** store passwords in the

`mysql.global_priv`

table. These authentication plugins rely on other methods to authenticate the user.

If you attempt to run

`SET PASSWORD`

on an account that authenticates with one of these authentication plugins that doesn't store a password in the

`mysql.global_priv`

table, then MariaDB Server will raise a warning like the following:

```
SET PASSWORD is ignored for users authenticating via unix_socket plugin
```

See [Authentication from MariaDB 10.4](#) for an overview of authentication changes in [MariaDB 10.4](#).

#### MariaDB until 10.3

In [MariaDB 10.3](#) and before,

`SET PASSWORD`

(with or without

`PASSWORD()`

) only works for accounts authenticated via

`mysql_native_password`

or

`mysql_old_password`

authentication plugins

## Passwordless User Accounts

User accounts do not always require passwords to login.

The

`unix_socket`

,

`named_pipe`

and

`gssapi`

authentication plugins do not require a password to authenticate the user.

The

`pam`

authentication plugin may or may not require a password to authenticate the user, depending on the specific configuration.

The

`mysql_native_password`

and

`mysql_old_password`

authentication plugins require passwords for authentication, but the password can be blank. In that case, no password is required.

If you provide a password while attempting to log into the server as an account that doesn't require a password, then MariaDB server will simply ignore the password.

MariaDB starting with 10.4

In MariaDB 10.4 and later, a user account can be defined to use multiple authentication plugins in a specific order of preference. This specific scenario may be more noticeable in these versions, since an account could be associated with some authentication plugins that require a password, and some that do not.

## Example

For example, if you had an entry with User and Host column values of '

bob

' and '

.loc.gov

', you would write the statement like this:

```
SET PASSWORD FOR 'bob'@'%loc.gov' = PASSWORD('newpass');
```

If you want to delete a password for a user, you would do:

```
SET PASSWORD FOR 'bob'@localhost = PASSWORD("");
```

## See Also

- [Password Validation Plugins](#) - permits the setting of basic criteria for passwords
- 

[ALTER USER](#)

## 1.1.1.8 CREATE ROLE

### Syntax

```
CREATE [OR REPLACE] ROLE [IF NOT EXISTS] role  
[WITH ADMIN  
{CURRENT_USER | CURRENT_ROLE | user | role}]
```

### Contents

1. [Syntax](#)
2. [Description](#)
  1. [WITH ADMIN](#)
  2. [OR REPLACE](#)
  3. [IF NOT EXISTS](#)
3. [Examples](#)
4. [See Also](#)

### Description

The

`CREATE ROLE`

statement creates one or more MariaDB [roles](#). To use it, you must have the global [CREATE USER](#) privilege or the [INSERT](#) privilege for the

mysql database. For each account,

```
CREATE ROLE  
creates a new row in the mysql.user table that has no privileges, and with the corresponding  
is_role  
field set to  
Y  
. It also creates a record in the mysql.roles_mapping table.
```

If any of the specified roles already exist,

```
ERROR 1396 (HY000)  
results. If an error occurs,  
CREATE ROLE  
will still create the roles that do not result in an error. The maximum length for a role is 128 characters. Role names can be quoted, as explained  
in the Identifier names page. Only one error is produced for all roles which have not been created:
```

```
ERROR 1396 (HY000): Operation CREATE ROLE failed for 'a','b','c'
```

Failed

```
CREATE  
or  
DROP  
operations, for both users and roles, produce the same error code.
```

```
PUBLIC  
and  
NONE  
are reserved, and cannot be used as role names.  
NONE  
is used to unset a role and  
PUBLIC  
has a special use in other systems, such as Oracle, so is reserved for compatibility purposes.
```

Before MariaDB 10.1.13 , the

```
CREATE ROLE  
statement was not permitted in prepared statements .
```

For valid identifiers to use as role names, see Identifier Names .

## WITH ADMIN

The optional

```
WITH ADMIN  
clause determines whether the current user, the current role or another user or role has use of the newly created role. If the clause is omitted,  
WITH ADMIN CURRENT_USER  
is treated as the default, which means that the current user will be able to GRANT this role to users.
```

## OR REPLACE

If the optional

```
OR REPLACE  
clause is used, it acts as a shortcut for:
```

```
DROP ROLE IF EXISTS name;  
CREATE ROLE name ...;
```

## IF NOT EXISTS

When the

```
IF NOT EXISTS  
clause is used, MariaDB will return a warning instead of an error if the specified role already exists. Cannot be used together with the  
OR REPLACE  
clause.
```

# Examples

```
CREATE ROLE journalist;  
  
CREATE ROLE developer WITH ADMIN lorinda@localhost;
```

Granting the role to another user. Only user

lorinda@localhost  
has permission to grant the  
developer  
role:

```
SELECT USER();
+-----+
| USER() |
+-----+
| henning@localhost |
+-----+
...
GRANT developer TO ian@localhost;
Access denied for user 'henning'@'localhost'

SELECT USER();
+-----+
| USER() |
+-----+
| lorinda@localhost |
+-----+

GRANT m_role TO ian@localhost;
```

The

OR REPLACE  
and  
IF NOT EXISTS  
clauses. The  
journalist  
role already exists:

```
CREATE ROLE journalist;
ERROR 1396 (HY000): Operation CREATE ROLE failed for 'journalist'

CREATE OR REPLACE ROLE journalist;
Query OK, 0 rows affected (0.00 sec)

CREATE ROLE IF NOT EXISTS journalist;
Query OK, 0 rows affected, 1 warning (0.00 sec)
```

```
SHOW WARNINGS;
+-----+-----+
| Level | Code | Message |
+-----+-----+
| Note  | 1975 | Can't create role 'journalist'; it already exists |
+-----+-----+
```

## See Also

- [Identifier Names](#)
- [Roles Overview](#)
- [DROP ROLE](#)

### 1.1.1.9 DROP ROLE

#### Syntax

```
DROP ROLE [IF EXISTS] role_name [,role_name ...]
```

## Contents

1. [Syntax](#)
2. [Description](#)
  1. [IF EXISTS](#)
3. [Examples](#)
4. [See Also](#)

## Description

The

```
DROP ROLE
```

statement removes one or more MariaDB [roles](#). To use this statement, you must have the global [CREATE USER](#) privilege or the [DELETE](#) privilege for the `mysql` database.

```
DROP ROLE
```

does not disable roles for connections which selected them with [SET ROLE](#). If a role has previously been set as a [default role](#),

```
DROP ROLE
```

does not remove the record of the default role from the `mysql.user` table. If the role is subsequently recreated and granted, it will again be the user's default. Use [SET DEFAULT ROLE NONE](#) to explicitly remove this.

If any of the specified user accounts do not exist,

```
ERROR 1396 (HY000)
```

results. If an error occurs,

```
DROP ROLE
```

will still drop the roles that do not result in an error. Only one error is produced for all roles which have not been dropped:

```
ERROR 1396 (HY000): Operation DROP ROLE failed for 'a','b','c'
```

Failed

```
CREATE
```

or

```
DROP
```

operations, for both users and roles, produce the same error code.

Before [MariaDB 10.1.13](#), the

```
DROP ROLE
```

statement was not permitted in [prepared statements](#).

## IF EXISTS

If the

```
IF EXISTS
```

clause is used, MariaDB will return a warning instead of an error if the role does not exist.

## Examples

```
DROP ROLE journalist;
```

The same thing using the optional

```
IF EXISTS
```

clause:

```
DROP ROLE journalist;
ERROR 1396 (HY000): Operation DROP ROLE failed for 'journalist'
```

```
DROP ROLE IF EXISTS journalist;
Query OK, 0 rows affected, 1 warning (0.00 sec)
```

```
Note (Code 1975): Can't drop role 'journalist'; it doesn't exist
```

## See Also

- [Roles Overview](#)
- [CREATE ROLE](#)

## 1.1.1.10 SET ROLE

# Syntax

```
SET ROLE { role | NONE }
```

## Contents

1. [Syntax](#)
2. [Description](#)
3. [Example](#)

## Description

The

```
SET ROLE
```

statement enables a [role](#), along with all of its associated permissions, for the current session. To unset a role, use [NONE](#).

If a role that doesn't exist, or to which the user has not been assigned, is specified, an

```
ERROR 1959 (OP000): Invalid role specification
```

error occurs.

An automatic SET ROLE is implicitly performed when a user connects if that user has been assigned a default role. See [SET DEFAULT ROLE](#).

## Example

```
SELECT CURRENT_ROLE;
+-----+
| CURRENT_ROLE |
+-----+
| NULL         |
+-----+

SET ROLE staff;

SELECT CURRENT_ROLE;
+-----+
| CURRENT_ROLE |
+-----+
| staff        |
+-----+

SET ROLE NONE;

SELECT CURRENT_ROLE();
+-----+
| CURRENT_ROLE() |
+-----+
| NULL          |
+-----+
```

## 1.1.1.11 SET DEFAULT ROLE

## Contents

1. [Syntax](#)
2. [Description](#)
3. [Examples](#)

## Syntax

```
SET DEFAULT ROLE { role | NONE } [ FOR user@host ]
```

## Description

The

```
SET DEFAULT ROLE
```

statement sets a [default role](#) for a specified (or current) user. A default role is automatically enabled when a user connects (an implicit [SET ROLE](#) statement is executed immediately after a connection is established).

To be able to set a role as a default, the role must already have been granted to that user, and one needs the privileges to enable this role (if you cannot do

```
SET ROLE X
, you won't be able to do
SET DEFAULT ROLE X
). To set a default role for another user one needs to have write access to the
mysql
database.
```

To remove a user's default role, use

```
SET DEFAULT ROLE NONE [ FOR user@host ]
```

. The record of the default role is not removed if the role is [dropped](#) or [revoked](#), so if the role is subsequently re-created or granted, it will again be the user's default role.

The default role is stored in the

```
default_role
column in the mysql.user table/view, as well as in the Information Schema APPLICABLE\_ROLES table, so these can be viewed to see which role has been assigned to a user as the default.
```

## Examples

Setting a default role for the current user:

```
SET DEFAULT ROLE journalist;
```

Removing a default role from the current user:

```
SET DEFAULT ROLE NONE;
```

Setting a default role for another user. The role has to have been granted to the user before it can be set as default:

```
CREATE ROLE journalist;
CREATE USER taniel;

SET DEFAULT ROLE journalist FOR taniel;
ERROR 1959 (OP000): Invalid role specification `journalist'

GRANT journalist TO taniel;
SET DEFAULT ROLE journalist FOR taniel;
```

Viewing mysql.user:

```
select * from mysql.user where user='taniel'\G
***** 1. row *****
      Host: %
      User: taniel
...
      is_role: N
      default_role: journalist
...
```

Removing a default role for another user

```
SET DEFAULT ROLE NONE FOR taniel;
```

## 1.1.1.12 SHOW GRANTS

### Contents

- 1. [Syntax](#)
- 2. [Description](#)
  - 1. [Users](#)
  - 2. [Roles](#)
    - 1. [Example](#)
- 3. [See Also](#)

### Syntax

```
SHOW GRANTS [FOR user|role]
```

# Description

The

```
SHOW GRANTS  
statement lists privileges granted to a particular user or role.
```

## Users

The statement lists the [GRANT](#) statement or statements that must be issued to duplicate the privileges that are granted to a MariaDB user account. The account is named using the same format as for the

```
GRANT  
statement; for example, '  
jeffrey'@'localhost'  
. If you specify only the user name part of the account name, a host name part of '  
' is used. For additional information about specifying account names, see GRANT.
```

```
SHOW GRANTS FOR 'root'@'localhost';  
+-----+  
| Grants for root@localhost |  
+-----+  
| GRANT ALL PRIVILEGES ON *.* TO 'root'@'localhost' WITH GRANT OPTION |  
+-----+
```

To list the privileges granted to the account that you are using to connect to the server, you can use any of the following statements:

```
SHOW GRANTS;  
SHOW GRANTS FOR CURRENT_USER;  
SHOW GRANTS FOR CURRENT_USER();
```

If

```
SHOW GRANTS FOR CURRENT_USER  
(or any of the equivalent syntaxes) is used in  
DEFINER  
context (such as within a stored procedure that is defined with  
SQL SECURITY DEFINER  
, the grants displayed are those of the definer and not the invoker.
```

Note that the

```
DELETE HISTORY  
privilege, introduced in MariaDB 10.3.4, was displayed as  
DELETE VERSIONING ROWS  
when running  
SHOW GRANTS  
until MariaDB 10.3.15 (MDEV-17655).
```

## Roles

```
SHOW GRANTS  
can also be used to view the privileges granted to a role.
```

### Example

```
SHOW GRANTS FOR journalist;  
+-----+  
| Grants for journalist |  
+-----+  
| GRANT USAGE ON *.* TO 'journalist' |  
| GRANT DELETE ON `test`.* TO 'journalist' |  
+-----+
```

- [SHOW PRIVILEGES](#) shows the privileges supported by MariaDB.
- [Roles](#)

## 1.1.1.13 SHOW CREATE USER

MariaDB starting with 10.2.0

```
SHOW CREATE USER  
was introduced in MariaDB 10.2.0
```

### Syntax

```
SHOW CREATE USER user_name
```

### Description

Shows the [CREATE USER](#) statement that created the given user. The statement requires the [SELECT](#) privilege for the [mysql](#) database, except for the current user.

### Examples

```
CREATE USER foo4@test require cipher 'text'  
    issuer 'foo_issuer' subject 'foo_subject';  
  
SHOW CREATE USER foo4@testG  
*****  
***** 1. row *****  
CREATE USER 'foo4'@'test'  
  REQUIRE ISSUER 'foo_issuer'  
  SUBJECT 'foo_subject'  
  CIPHER 'text'
```

User Password Expiry :

```
CREATE USER 'monty'@'localhost' PASSWORD EXPIRE INTERVAL 120 DAY;  
  
SHOW CREATE USER 'monty'@'localhost';  
+-----+  
| CREATE USER for monty@localhost |  
+-----+  
| CREATE USER 'monty'@'localhost' PASSWORD EXPIRE INTERVAL 120 DAY |  
+-----+
```

### See Also

16. [See Also](#)

## Description

### ALTER TABLE

enables you to change the structure of an existing table. For example, you can add or delete columns, create or destroy indexes, change the type of existing columns, or rename columns or the table itself. You can also change the comment for the table and the storage engine of the table.

If another connection is using the table, a [metadata lock](#) is active, and this statement will wait until the lock is released. This is also true for non-transactional tables.

When adding a  
UNIQUE  
index on a column (or a set of columns) which have duplicated values, an error will be produced and the statement will be stopped. To suppress the error and force the creation of  
UNIQUE  
indexes, discarding duplicates, the [IGNORE](#) option can be specified. This can be useful if a column (or a set of columns) should be UNIQUE but it contains duplicate values; however, this technique provides no control on which rows are preserved and which are deleted. Also, note that  
IGNORE  
is accepted but ignored in  
ALTER TABLE ... EXCHANGE PARTITION  
statements.

This statement can also be used to rename a table. For details see [RENAME TABLE](#).

When an index is created, the storage engine may use a configurable buffer in the process. Incrementing the buffer speeds up the index creation. [Aria](#) and [MyISAM](#) allocate a buffer whose size is defined by [aria\\_sort\\_buffer\\_size](#) or [myisam\\_sort\\_buffer\\_size](#), also used for [REPAIR TABLE](#). [InnoDB](#) allocates three buffers whose size is defined by [innodb\\_sort\\_buffer\\_size](#).

## Privileges

Executing the

```
ALTER TABLE
```

statement generally requires at least the [ALTER](#) privilege for the table or the database..

If you are renaming a table, then it also requires the [DROP](#), [CREATE](#) and [INSERT](#) privileges for the table or the database as well.

## Online DDL

Online DDL is supported with the [ALGORITHM](#) and [LOCK](#) clauses.

See [InnoDB Online DDL Overview](#) for more information on online DDL with [InnoDB](#).

### ALTER ONLINE TABLE

ALTER ONLINE TABLE also works for partitioned tables.

Online

```
ALTER TABLE
```

is available by executing the following:

```
ALTER ONLINE TABLE ...;
```

This statement has the following semantics:

This statement is equivalent to the following:

```
ALTER TABLE ... LOCK=NONE;
```

See the [LOCK](#) alter specification for more information. <>

This statement is equivalent to the following:

```
ALTER TABLE ... ALGORITHM=INPLACE;
```

See the [ALGORITHM](#) alter specification for more information. <>

## WAIT/NOWAIT

MariaDB starting with 10.3.0

Set the lock wait timeout. See [WAIT](#) and [NOWAIT](#).

## IF EXISTS

The

```
IF EXISTS
```

and

```
IF NOT EXISTS
```

clauses are available for the following:

```
ADD COLUMN      [IF NOT EXISTS]
ADD INDEX       [IF NOT EXISTS]
ADD FOREIGN KEY [IF NOT EXISTS]
ADD PARTITION   [IF NOT EXISTS]
CREATE INDEX    [IF NOT EXISTS]

DROP COLUMN     [IF EXISTS]
DROP INDEX      [IF EXISTS]
DROP FOREIGN KEY [IF EXISTS]
DROP PARTITION   [IF EXISTS]
CHANGE COLUMN   [IF EXISTS]
MODIFY COLUMN   [IF EXISTS]
DROP INDEX      [IF EXISTS]
```

When

IF EXISTS  
and  
IF NOT EXISTS

are used in clauses, queries will not report errors when the condition is triggered for that clause. A warning with the same message text will be issued and the ALTER will move on to the next clause in the statement (or end if finished). <>/product>>

MariaDB starting with 10.5.2

If this is directive is used after

```
ALTER ... TABLE
, one will not get an error if the table doesn't exist.
```

## Column Definitions

See [CREATE TABLE: Column Definitions](#) for information about column definitions.

## Index Definitions

See [CREATE TABLE: Index Definitions](#) for information about index definitions.

The [CREATE INDEX](#) and [DROP INDEX](#) statements can also be used to add or remove an index.

## Character Sets and Collations

```
CONVERT TO CHARACTER SET charset_name [COLLATE collation_name]
[DEFAULT] CHARACTER SET [=] charset_name
[DEFAULT] COLLATE [=] collation_name
```

See [Setting Character Sets and Collations](#) for details on setting the character sets and collations .

## Alter Specifications

### Table Options

See [CREATE TABLE: Table Options](#) for information about table options.

### ADD COLUMN

```
... ADD COLUMN [IF NOT EXISTS] (col_name column_definition,...)
```

Adds a column to the table. The syntax is the same as in [CREATE TABLE](#) . If you are using

IF NOT\_EXISTS  
the column will not be added if it was not there already. This is very useful when doing scripts to modify tables.

The

FIRST  
and  
AFTER  
clauses affect the physical order of columns in the datafile. Use  
FIRST

to add a column in the first (leftmost) position, or

AFTER

followed by a column name to add the new column in any other position. Note that, nowadays, the physical position of a column is usually irrelevant.

See also [Instant ADD COLUMN for InnoDB](#).

## DROP COLUMN

```
... DROP COLUMN [IF EXISTS] col_name [CASCADE|RESTRICT]
```

Drops the column from the table. If you are using

IF EXISTS

you will not get an error if the column didn't exist. If the column is part of any index, the column will be dropped from them, except if you add a new column with identical name at the same time. The index will be dropped if all columns from the index were dropped. If the column was used in a view or trigger, you will get an error next time the view or trigger is accessed.

MariaDB starting with 10.2.8

Dropping a column that is part of a multi-column

UNIQUE

constraint is not permitted. For example:

```
CREATE TABLE a (
    a int,
    b int,
    primary key (a,b)
);

ALTER TABLE x DROP COLUMN a;
[42000][1072] Key column 'A' doesn't exist in table
```

The reason is that dropping column

a

would result in the new constraint that all values in column

b

be unique. In order to drop the column, an explicit

DROP PRIMARY KEY

and

ADD PRIMARY KEY

would be required. Up until [MariaDB 10.2.7](#), the column was dropped and the additional constraint applied, resulting in the following structure:

```
ALTER TABLE x DROP COLUMN a;
Query OK, 0 rows affected (0.46 sec)
```

```
DESC x;
```

Field	Type	Null	Key	Default	Extra
b	int(11)	NO	PRI	NULL	

MariaDB starting with 10.4.0

[MariaDB 10.4.0](#) supports instant DROP COLUMN. DROP COLUMN of an indexed column would imply [DROP INDEX](#) (and in the case of a non-UNIQUE multi-column index, possibly ADD INDEX). These will not be allowed with [ALGORITHM=INSTANT](#), but unlike before, they can be allowed with [ALGORITHM=NOCOPY](#)

RESTRICT

and

CASCADE

are allowed to make porting from other database systems easier. In MariaDB, they do nothing.

## MODIFY COLUMN

Allows you to modify the type of a column. The column will be at the same place as the original column and all indexes on the column will be kept. Note that when modifying column, you should specify all attributes for the new column.

```
CREATE TABLE t1 (a INT UNSIGNED AUTO_INCREMENT, PRIMARY KEY((a));
ALTER TABLE t1 MODIFY a BIGINT UNSIGNED AUTO_INCREMENT;
```

## CHANGE COLUMN

Works like

MODIFY COLUMN

except that you can also change the name of the column. The column will be at the same place as the original column and all index on the column will be kept.

```
CREATE TABLE t1 (a INT UNSIGNED AUTO_INCREMENT, PRIMARY KEY(a));
ALTER TABLE t1 CHANGE a b BIGINT UNSIGNED AUTO_INCREMENT;
```

## ALTER COLUMN

This lets you change column options.

```
CREATE TABLE t1 (a INT UNSIGNED AUTO_INCREMENT, b varchar(50), PRIMARY KEY(a));
ALTER TABLE t1 ALTER b SET DEFAULT 'hello';
```

## RENAME INDEX/KEY

MariaDB starting with 10.5.2

From MariaDB 10.5.2 , it is possible to rename an index using the

RENAME INDEX

(or

RENAME KEY

) syntax, for example:

```
ALTER TABLE t1 RENAME INDEX i_old TO i_new;
```

## RENAME COLUMN

MariaDB starting with 10.5.2

From MariaDB 10.5.2 , it is possible to rename a column using the

RENAME COLUMN

syntax, for example:

```
ALTER TABLE t1 RENAME COLUMN c_old TO c_new;
```

## ADD PRIMARY KEY

Add a primary key.

For

PRIMARY KEY

indexes, you can specify a name for the index, but it is silently ignored, and the name of the index is always

PRIMARY

See [Getting Started with Indexes: Primary Key](#) for more information.

## DROP PRIMARY KEY

Drop a primary key.

For

PRIMARY KEY

indexes, you can specify a name for the index, but it is silently ignored, and the name of the index is always

PRIMARY

See [Getting Started with Indexes: Primary Key](#) for more information.

## ADD FOREIGN KEY

Add a foreign key.

For

FOREIGN KEY  
indexes, a reference definition must be provided.

For

FOREIGN KEY  
indexes, you can specify a name for the constraint, using the  
CONSTRAINT  
keyword. That name will be used in error messages.

First, you have to specify the name of the target (parent) table and a column or a column list which must be indexed and whose values must match to the foreign key's values. The

MATCH  
clause is accepted to improve the compatibility with other DBMS's, but has no meaning in MariaDB. The  
ON DELETE  
and  
ON UPDATE  
clauses specify what must be done when a  
DELETE  
(or a  
REPLACE  
) statements attempts to delete a referenced row from the parent table, and when an  
UPDATE  
statement attempts to modify the referenced foreign key columns in a parent table row, respectively. The following options are allowed:

- RESTRICT  
: The delete/update operation is not performed. The statement terminates with a 1451 error (SQLSTATE '2300').
- NO ACTION  
: Synonym for  
RESTRICT
- CASCADE  
: The delete/update operation is performed in both tables.
- SET NULL  
: The update or delete goes ahead in the parent table, and the corresponding foreign key fields in the child table are set to  
NULL  
. (They must not be defined as  
NOT NULL  
for this to succeed).
- SET DEFAULT  
: This option is implemented only for the legacy PBXT storage engine, which is disabled by default and no longer maintained. It sets the  
child table's foreign key fields to their  
DEFAULT  
values when the referenced parent table key entries are updated or deleted.

If either clause is omitted, the default behavior for the omitted clause is

RESTRICT

See [Foreign Keys](#) for more information.

## DROP FOREIGN KEY

Drop a foreign key.

See [Foreign Keys](#) for more information.

## ADD INDEX

Add a plain index.

Plain indexes are regular indexes that are not unique, and are not acting as a primary key or a foreign key. They are also not the "specialized"

FULLTEXT  
or  
SPATIAL

indexes.

See [Getting Started with Indexes: Plain Indexes](#) for more information.

## DROP INDEX

Drop a plain index.

Plain indexes are regular indexes that are not unique, and are not acting as a primary key or a foreign key. They are also not the "specialized"

FULLTEXT  
or  
SPATIAL  
indexes.

See [Getting Started with Indexes: Plain Indexes](#) for more information.

## ADD UNIQUE INDEX

Add a unique index.

The

UNIQUE  
keyword means that the index will not accept duplicated values, except for NULLs. An error will raise if you try to insert duplicate values in a  
UNIQUE index.

For

UNIQUE  
indexes, you can specify a name for the constraint, using the  
CONSTRAINT  
keyword. That name will be used in error messages.

See [Getting Started with Indexes: Unique Index](#) for more information.

## DROP UNIQUE INDEX

Drop a unique index.

The

UNIQUE  
keyword means that the index will not accept duplicated values, except for NULLs. An error will raise if you try to insert duplicate values in a  
UNIQUE index.

For

UNIQUE  
indexes, you can specify a name for the constraint, using the  
CONSTRAINT  
keyword. That name will be used in error messages.

See [Getting Started with Indexes: Unique Index](#) for more information.

## ADD FULLTEXT INDEX

Add a

FULLTEXT  
index.

See [Full-Text Indexes](#) for more information.

## DROP FULLTEXT INDEX

Drop a

FULLTEXT  
index.

See [Full-Text Indexes](#) for more information.

## ADD SPATIAL INDEX

Add a SPATIAL index.

See [SPATIAL INDEX](#) for more information.

## DROP SPATIAL INDEX

Drop a SPATIAL index.

See [SPATIAL INDEX](#) for more information.

## ENABLE/ DISABLE KEYS

DISABLE KEYS

will disable all non unique keys for the table for storage engines that support this (at least MyISAM and Aria). This can be used to speed up [inserts](#) into empty tables.

ENABLE KEYS

will enable all disabled keys.

## RENAME TO

Renames the table. See also [RENAME TABLE](#).

## ADD CONSTRAINT

Modifies the table adding a [constraint](#) on a particular column or columns.

MariaDB starting with 10.2.1

MariaDB 10.2.1 introduced new ways to define a constraint.

Note: Before MariaDB 10.2.1 , constraint expressions were accepted in syntax, but ignored.

```
ALTER TABLE table_name  
ADD CONSTRAINT [constraint_name] CHECK(expression);
```

Before a row is inserted or updated, all constraints are evaluated in the order they are defined. If any constraint fails, then the row will not be updated. One can use most deterministic functions in a constraint, including [UDF's](#).

```
CREATE TABLE account_ledger (  
    id INT PRIMARY KEY AUTO_INCREMENT,  
    transaction_name VARCHAR(100),  
    credit_account VARCHAR(100),  
    credit_amount INT,  
    debit_account VARCHAR(100),  
    debit_amount INT);  
  
ALTER TABLE account_ledger  
ADD CONSTRAINT is_balanced  
    CHECK((debit_amount + credit_amount) = 0);
```

The

constraint\_name  
is optional. If you don't provide one in the  
ALTER TABLE  
statement, MariaDB auto-generates a name for you. This is done so that you can remove it later using [DROP CONSTRAINT](#) clause.

You can disable all constraint expression checks by setting the variable [check\\_constraint\\_checks](#) to

OFF

. You may find this useful when loading a table that violates some constraints that you want to later find and fix in SQL.

To view constraints on a table, query [information\\_schema.TABLE\\_CONSTRAINTS](#) :

```
SELECT CONSTRAINT_NAME, TABLE_NAME, CONSTRAINT_TYPE  
FROM information_schema.TABLE_CONSTRAINTS  
WHERE TABLE_NAME = 'account_ledger';  
  
+-----+-----+  
| CONSTRAINT_NAME | TABLE_NAME | CONSTRAINT_TYPE |  
+-----+-----+  
| is_balanced | account_ledger | CHECK |  
+-----+-----+
```

## DROP CONSTRAINT

MariaDB starting with 10.2.22

```
DROP CONSTRAINT
for
UNIQUE
and
FOREIGN KEY
constraints was introduced in MariaDB 10.2.22 and MariaDB 10.3.13.
```

MariaDB starting with 10.2.1

```
DROP CONSTRAINT
for
CHECK
constraints was introduced in MariaDB 10.2.1
```

Modifies the table, removing the given constraint.

```
ALTER TABLE table_name
DROP CONSTRAINT constraint_name;
```

When you add a constraint to a table, whether through a `CREATE TABLE` or `ALTER TABLE...ADD CONSTRAINT` statement, you can either set a `constraint_name` yourself, or allow MariaDB to auto-generate one for you. To view constraints on a table, query `information_schema.TABLE_CONSTRAINTS`. For instance,

```
CREATE TABLE t (
    a INT,
    b INT,
    c INT,
    CONSTRAINT CHECK(a > b),
    CONSTRAINT check_equals CHECK(a = c);

SELECT CONSTRAINT_NAME, TABLE_NAME, CONSTRAINT_TYPE
FROM information_schema.TABLE_CONSTRAINTS
WHERE TABLE_NAME = 't';

+-----+-----+
| CONSTRAINT_NAME | TABLE_NAME      | CONSTRAINT_TYPE |
+-----+-----+
| check_equals   | t              | CHECK           |
| CONSTRAINT_1   | t              | CHECK           |
+-----+-----+
```

To remove a constraint from the table, issue an

```
ALTER TABLE...DROP CONSTRAINT
statement. For example,
```

```
ALTER TABLE t DROP CONSTRAINT is_unique;
```

## ADD SYSTEM VERSIONING

MariaDB starting with 10.3.4

`System-versioned tables` was added in MariaDB 10.3.4 .

Add system versioning.

## DROP SYSTEM VERSIONING

MariaDB starting with 10.3.4

`System-versioned tables` was added in MariaDB 10.3.4 .

Drop system versioning.

## ADD PERIOD FOR SYSTEM\_TIME

MariaDB starting with 10.3.4

System-versioned tables was added in MariaDB 10.3.4 .

## FORCE

```
ALTER TABLE ... FORCE  
can force MariaDB to re-build the table.
```

In MariaDB 5.5 and before, this could only be done by setting the [ENGINE](#) table option to its old value. For example, for an InnoDB table, one could execute the following:

```
ALTER TABLE tab_name ENGINE = InnoDB;
```

The

```
FORCE  
option can be used instead. For example, :
```

```
ALTER TABLE tab_name FORCE;
```

With InnoDB, the table rebuild will only reclaim unused space (i.e. the space previously used for deleted rows) if the [innodb\\_file\\_per\\_table](#) system variable is set to

```
ON  
. If the system variable is  
OFF  
, then the space will not be reclaimed, but it will be-re-used for new data that's later added.
```

## EXCHANGE PARTITION

This is used to exchange the tablespace files between a partition and another table.

See [copying InnoDB's transportable tablespaces](#) for more information.

## DISCARD TABLESPACE

This is used to discard an InnoDB table's tablespace.

See [copying InnoDB's transportable tablespaces](#) for more information.

## IMPORT TABLESPACE

This is used to import an InnoDB table's tablespace. The tablespace should have been copied from its original server after executing [FLUSH TABLES FOR EXPORT](#).

See [copying InnoDB's transportable tablespaces](#) for more information.

```
ALTER TABLE ... IMPORT  
only applies to InnoDB tables. Most other popular storage engines, such as Aria and MyISAM, will recognize their data files as soon as they've  
been placed in the proper directory under the datadir, and no special DDL is required to import them.
```

## ALGORITHM

The

```
ALTER TABLE  
statement supports the  
ALGORITHM  
clause. This clause is one of the clauses that is used to implement online DDL.  
ALTER TABLE  
supports several different algorithms. An algorithm can be explicitly chosen for an  
ALTER TABLE  
operation by setting the  
ALGORITHM  
clause. The supported values are:  
  
•  
    ALGORITHM=DEFAULT
```

- This implies the default behavior for the specific statement, such as if no `ALGORITHM` clause is specified.
- `ALGORITHM=COPY`
- `ALGORITHM=INPLACE`
- `ALGORITHM=NOCOPY`
  - This was added in [MariaDB 10.3.7](#).
- `ALGORITHM=INSTANT`
  - This was added in [MariaDB 10.3.7](#).

See [InnoDB Online DDL Overview: ALGORITHM](#) for information on how the `ALGORITHM` clause affects InnoDB.

## `ALGORITHM=DEFAULT`

The default behavior, which occurs if

```
ALGORITHM=DEFAULT
is specified, or if
ALGORITHM
```

is not specified at all, usually only makes a copy if the operation doesn't support being done in-place at all. In this case, the most efficient available algorithm will usually be used.

However, in [MariaDB 10.3.6](#) and before, if the value of the `old_alter_table` system variable is set to

```
ON
, then the default behavior is to perform
ALTER TABLE
operations by making a copy of the table using the old algorithm.
```

In [MariaDB 10.3.7](#) and later, the `old_alter_table` system variable is deprecated. Instead, the `alter_algorithm` system variable defines the default algorithm for

```
ALTER TABLE
operations.
```

## `ALGORITHM=COPY`

```
ALGORITHM=COPY
is the name for the original ALTER TABLE algorithm from early MariaDB versions.
```

When

```
ALGORITHM=COPY
is set, MariaDB essentially does the following operations:
```

```
-- Create a temporary table with the new definition
CREATE TEMPORARY TABLE tmp_tab (
  ...
);

-- Copy the data from the original table
INSERT INTO tmp_tab
  SELECT * FROM original_tab;

-- Drop the original table
DROP TABLE original_tab;

-- Rename the temporary table, so that it replaces the original one
RENAME TABLE tmp_tab TO original_tab;
```

This algorithm is very inefficient, but it is generic, so it works for all storage engines.

If

```
ALGORITHM=COPY
is specified, then the copy algorithm will be used even if it is not necessary. This can result in a lengthy table copy. If multiple ALTER TABLE operations are required that each require the table to be rebuilt, then it is best to specify all operations in a single ALTER TABLE statement, so that the table is only rebuilt once.
```

## `ALGORITHM=INPLACE`

`ALGORITHM=COPY`

can be incredibly slow, because the whole table has to be copied and rebuilt.

`ALGORITHM=INPLACE`

was introduced as a way to avoid this by performing operations in-place and avoiding the table copy and rebuild, when possible.

When

`ALGORITHM=INPLACE`

is set, the underlying storage engine uses optimizations to perform the operation while avoiding the table copy and rebuild. However, `INPLACE`

is a bit of a misnomer, since some operations may still require the table to be rebuilt for some storage engines. Regardless, several operations can be performed without a full copy of the table for some storage engines.

A more accurate name would have been

`ALGORITHM=ENGINE`

, where

`ENGINE`

refers to an "engine-specific" algorithm.

If an [ALTER TABLE](#) operation supports

`ALGORITHM=INPLACE`

, then it can be performed using optimizations by the underlying storage engine, but it may rebuilt.

See [InnoDB Online DDL Operations with ALGORITHM=INPLACE](#) for more.

## ALGORITHM=NOCOPY

`ALGORITHM=NOCOPY`

was introduced in [MariaDB 10.3.7](#).

`ALGORITHM=INPLACE`

can sometimes be surprisingly slow in instances where it has to rebuild the clustered index, because when the clustered index has to be rebuilt, the whole table has to be rebuilt.

`ALGORITHM=NOCOPY`

was introduced as a way to avoid this.

If an

`ALTER TABLE`

operation supports

`ALGORITHM=NOCOPY`

, then it can be performed without rebuilding the clustered index.

If

`ALGORITHM=NOCOPY`

is specified for an

`ALTER TABLE`

operation that does not support

`ALGORITHM=NOCOPY`

, then an error will be raised. In this case, raising an error is preferable, if the alternative is for the operation to rebuild the clustered index, and perform unexpectedly slowly.

See [InnoDB Online DDL Operations with ALGORITHM=NOCOPY](#) for more.

## ALGORITHM=INSTANT

`ALGORITHM=INSTANT`

was introduced in [MariaDB 10.3.7](#).

`ALGORITHM=INPLACE`

can sometimes be surprisingly slow in instances where it has to modify data files.

`ALGORITHM=INSTANT`

was introduced as a way to avoid this.

If an

`ALTER TABLE`

operation supports

`ALGORITHM=INSTANT`

, then it can be performed without modifying any data files.

If

`ALGORITHM=INSTANT`

is specified for an

```
ALTER TABLE
operation that does not support
ALGORITHM=INSTANT
, then an error will be raised. In this case, raising an error is preferable, if the alternative is for the operation to modify data files, and perform
unexpectedly slowly.
```

See [InnoDB Online DDL Operations with ALGORITHM=INSTANT](#) for more.

## LOCK

The

```
ALTER TABLE
statement supports the
LOCK
clause. This clause is one of the clauses that is used to implement online DDL.
```

```
ALTER TABLE
supports several different locking strategies. A locking strategy can be explicitly chosen for an
ALTER TABLE
operation by setting the
LOCK
clause. The supported values are:
```

- **DEFAULT**  
: Acquire the least restrictive lock on the table that is supported for the specific operation. Permit the maximum amount of concurrency that is supported for the specific operation.
- **NONE**  
: Acquire no lock on the table. Permit **all** concurrent DML. If this locking strategy is not permitted for an operation, then an error is raised.
- **SHARED**  
: Acquire a read lock on the table. Permit **read-only** concurrent DML. If this locking strategy is not permitted for an operation, then an error is raised.
- **EXCLUSIVE**  
: Acquire a write lock on the table. Do **not** permit concurrent DML.

Different storage engines support different locking strategies for different operations. If a specific locking strategy is chosen for an

```
ALTER TABLE
operation, and that table's storage engine does not support that locking strategy for that specific operation, then an error will be raised.
```

If the

```
LOCK
clause is not explicitly set, then the operation uses
LOCK=DEFAULT
```

[ALTER ONLINE TABLE](#) is equivalent to

```
LOCK=NONE
. Therefore, the ALTER ONLINE TABLE statement can be used to ensure that your
ALTER TABLE
operation allows all concurrent DML.
```

See [InnoDB Online DDL Overview: LOCK](#) for information on how the

```
LOCK
clause affects InnoDB.
```

## Progress Reporting

MariaDB provides progress reporting for

```
ALTER TABLE
statement for clients that support the new progress reporting protocol. For example, if you were using the mysql client, then the progress report
might look like this::
```

```
ALTER TABLE test ENGINE=Aria;
Stage: 1 of 2 'copy to tmp table'    46% of stage
```

The progress report is also shown in the output of the `SHOW PROCESSLIST` statement and in the contents of the `information_schema.PROCESSLIST` table.

See [Progress Reporting](#) for more information.

# Aborting ALTER TABLE Operations

If an

```
ALTER TABLE
```

operation is being performed and the connection is killed, the changes will be rolled back in a controlled manner. The rollback can be a slow operation as the time it takes is relative to how far the operation has progressed.

MariaDB starting with 10.2.13

Aborting

```
ALTER TABLE ... ALGORITHM=COPY
```

was made faster by removing excessive undo logging ( [MDEV-11415](#) ). This significantly shortens the time it takes to abort a running ALTER TABLE operation.

# Atomic ALTER TABLE

MariaDB starting with 10.6.1

From [MariaDB 10.6](#),

```
ALTER TABLE
```

is atomic for most engines, including InnoDB, MyRocks, MyISAM and Aria ( [MDEV-25180](#) ). This means that if there is a crash (server down or power outage) during an

```
ALTER TABLE
```

operation, after recovery, either the old table and associated triggers and status will be intact, or the new table will be active.

In older MariaDB versions one could get leftover #sql-alter..', '#sql-backup..' or 'table\_name.frm" files if the system crashed during the

```
ALTER TABLE
```

operation.

See [Atomic DDL](#) for more information.

# Replication

MariaDB starting with 10.8.0

Before [MariaDB 10.8.0](#), ALTER TABLE got fully executed on the primary first, and only then was it replicated and started executing on replicas. From [MariaDB 10.8.0](#), ALTER TABLE gets replicated and starts executing on replicas when it *starts* executing on the primary, not when it *finishes*. This way the replication lag caused by a heavy ALTER TABLE can be completely eliminated ( [MDEV-11675](#) ).

# Examples

Adding a new column:

```
ALTER TABLE t1 ADD x INT;
```

Dropping a column:

```
ALTER TABLE t1 DROP x;
```

Modifying the type of a column:

```
ALTER TABLE t1 MODIFY x bigint unsigned;
```

Changing the name and type of a column:

```
ALTER TABLE t1 CHANGE a b bigint unsigned auto_increment;
```

Combining multiple clauses in a single ALTER TABLE statement, separated by commas:

```
ALTER TABLE t1 DROP x, ADD x2 INT, CHANGE y y2 INT;
```

Changing the storage engine and adding a comment:

```
ALTER TABLE t1
  ENGINE = InnoDB
  COMMENT = 'First of three tables containing usage info';
```

Rebuilding the table (the previous example will also rebuild the table if it was already InnoDB):

```
ALTER TABLE t1 FORCE;
```

Dropping an index:

```
ALTER TABLE rooms DROP INDEX u;
```

Adding a unique index:

```
ALTER TABLE rooms ADD UNIQUE INDEX u(room_number);
```

From [MariaDB 10.5.3](#), adding a primary key for an [application-time period table](#) with a [WITHOUT OVERLAPS](#) constraint:

```
ALTER TABLE rooms ADD PRIMARY KEY(room_number, p WITHOUT OVERLAPS);
```

- [DROP TABLE](#)
- [Character Sets and Collations](#)
- [SHOW CREATE TABLE](#)
- [Instant ADD COLUMN for InnoDB](#)

## 1.1.2.1.1.2 ALTER DATABASE

Modifies a database, changing its overall characteristics.

## Syntax

```
ALTER {DATABASE | SCHEMA} [db_name]
    alter_specification ...
ALTER {DATABASE | SCHEMA} db_name
    UPGRADE DATA DIRECTORY NAME

alter_specification:
    [DEFAULT] CHARACTER SET [=] charset_name
    | [DEFAULT] COLLATE [=] collation_name
    | COMMENT [=] 'comment'
```

## Contents

1. [Syntax](#)
2. [Description](#)
3. [Examples](#)
4. [See Also](#)

## Description

ALTER DATABASE  
enables you to change the overall characteristics of a database. These characteristics are stored in the db.opt file in the database directory. To use  
ALTER DATABASE , you need the  
ALTER privilege on the database.  
ALTER SCHEMA is a synonym for ALTER DATABASE.

The

CHARACTER SET clause changes the default database character set. The  
COLLATE clause changes the default database collation. See [Character Sets and Collations](#) for more.

You can see what character sets and collations are available using, respectively, the [SHOW CHARACTER SET](#) and [SHOW COLLATION](#) statements.

Changing the default character set/collation of a database does not change the character set/collation of any [stored procedures](#) or [stored functions](#) that were previously created, and relied on the defaults. These need to be dropped and recreated in order to apply the character set/collation changes.

The database name can be omitted from the first syntax, in which case the statement applies to the default database.

The syntax that includes the

```
UPGRADE DATA DIRECTORY NAME
```

clause was added in MySQL 5.1.23. It updates the name of the directory associated with the database to use the encoding implemented in MySQL 5.1 for mapping database names to database directory names (see [Identifier to File Name Mapping](#)). This clause is for use under these conditions:

- It is intended when upgrading MySQL to 5.1 or later from older versions.
- It is intended to update a database directory name to the current encoding format if the name contains special characters that need encoding.
- The statement is used by

```
mysqlcheck  
(as invoked by  
mysql_upgrade  
).
```

For example, if a database in MySQL 5.0 has a name of a-b-c, the name contains instance of the '-' character. In 5.0, the database directory is also named a-b-c, which is not necessarily safe for all file systems. In MySQL 5.1 and up, the same database name is encoded as a@002db@002dc to produce a file system-neutral directory name.

When a MySQL installation is upgraded to MySQL 5.1 or later from an older version, the server displays a name such as a-b-c (which is in the old format) as #mysql50#a-b-c, and you must refer to the name using the #mysql50# prefix. Use

```
UPGRADE DATA DIRECTORY NAME
```

in this case to explicitly tell the server to re-encode the database directory name to the current encoding format:

```
ALTER DATABASE `#mysql50#a-b-c` UPGRADE DATA DIRECTORY NAME;
```

After executing this statement, you can refer to the database as a-b-c without the special #mysql50# prefix.

## COMMENT

MariaDB starting with [10.5.0](#)

From [MariaDB 10.5.0](#), it is possible to add a comment of a maximum of 1024 bytes. If the comment length exceeds this length, an error/warning code 4144 is thrown. The database comment is also added to the db.opt file, as well as to the [information\\_schema.schemata table](#).

## Examples

```
ALTER DATABASE test CHARACTER SET='utf8' COLLATE='utf8_bin';
```

From [MariaDB 10.5.0](#):

```
ALTER DATABASE p COMMENT='Presentations';
```

## See Also

- [CREATE DATABASE](#)
- [DROP DATABASE](#)
- [SHOW CREATE DATABASE](#)
- [SHOW DATABASES](#)
- [Character Sets and Collations](#)
- [Information Schema SCHEMATA Table](#)

## 1.1.2.1.1.3 ALTER EVENT

Modifies one or more characteristics of an existing event.

## Syntax

```
ALTER
[DEFINER = { user | CURRENT_USER }]
EVENT event_name
[ON SCHEDULE schedule]
[ON COMPLETION [NOT] PRESERVE]
[RENAME TO new_event_name]
[ENABLE | DISABLE | DISABLE ON SLAVE]
[COMMENT 'comment']
[DO sql_statement]
```

## Contents

1. [Syntax](#)
2. [Description](#)
3. [Examples](#)
4. [See Also](#)

## Description

The

ALTER EVENT

statement is used to change one or more of the characteristics of an existing [event](#) without the need to drop and recreate it. The syntax for each of the

DEFINER

,

ON SCHEDULE

,

ON COMPLETION

,

COMMENT

,

ENABLE

/

DISABLE

, and

DO

clauses is exactly the same as when used with

[CREATE EVENT](#)

This statement requires the

[EVENT](#)

privilege. When a user executes a successful

ALTER EVENT

statement, that user becomes the definer for the affected event.

(In MySQL 5.1.11 and earlier, an event could be altered only by its definer, or by a user having the

[SUPER](#)

privilege.)

ALTER EVENT

works only with an existing event:

```
ALTER EVENT no_such_event ON SCHEDULE EVERY '2:3' DAY_HOUR;
ERROR 1539 (HY000): Unknown event 'no_such_event'
```

## Examples

```
ALTER EVENT myevent
ON SCHEDULE AT CURRENT_TIMESTAMP + INTERVAL 2 HOUR
DO
    UPDATE myschema.mytable SET mycol = mycol + 1;
```

## See Also

- [Events Overview](#)
- [CREATE EVENT](#)
- [SHOW CREATE EVENT](#)
- [DROP EVENT](#)

### 1.1.2.1.1.4 ALTER FUNCTION

#### Syntax

```
ALTER FUNCTION func_name [characteristic ...]

characteristic:
  { CONTAINS SQL | NO SQL | READS SQL DATA | MODIFIES SQL DATA }
  | SQL SECURITY { DEFINER | INVOKER }
  | COMMENT 'string'
```

#### Contents

1. [Syntax](#)
2. [Description](#)
3. [Example](#)
4. [See Also](#)

#### Description

This statement can be used to change the characteristics of a stored function. More than one change may be specified in an

ALTER FUNCTION

statement. However, you cannot change the parameters or body of a stored function using this statement; to make such changes, you must drop and re-create the function using [DROP FUNCTION](#) and [CREATE FUNCTION](#).

You must have the

ALTER ROUTINE

privilege for the function. (That privilege is granted automatically to the function creator.) If binary logging is enabled, the

ALTER FUNCTION

statement might also require the

SUPER

privilege, as described in [Binary Logging of Stored Routines](#).

#### Example

```
ALTER FUNCTION hello SQL SECURITY INVOKER;
```

#### See Also

- [CREATE FUNCTION](#)
- [SHOW CREATE FUNCTION](#)
- [DROP FUNCTION](#)
- [SHOW FUNCTION STATUS](#)
- [Information Schema ROUTINES Table](#)

### 1.1.2.1.1.5 ALTER LOGFILE GROUP

#### Syntax

```
ALTER LOGFILE GROUP logfile_group
  ADD UNDOFILE 'file_name'
  [INITIAL_SIZE [=] size]
  [WAIT]
  ENGINE [=] engine_name
```

The

ALTER LOGFILE GROUP

statement is not supported by MariaDB. It was originally inherited from MySQL NDB Cluster. See [MDEV-19295](#) for more information.

## 1.1.2.1.1.6 ALTER PROCEDURE

### Syntax

```
ALTER PROCEDURE proc_name [characteristic ...]

characteristic:
  { CONTAINS SQL | NO SQL | READS SQL DATA | MODIFIES SQL DATA }
  | SQL SECURITY { DEFINER | INVOKER }
  | COMMENT 'string'
```

### Description

This statement can be used to change the characteristics of a [stored procedure](#). More than one change may be specified in an

ALTER PROCEDURE

statement. However, you cannot change the parameters or body of a stored procedure using this statement. To make such changes, you must drop and re-create the procedure using either [CREATE OR REPLACE PROCEDURE](#) (since [MariaDB 10.1.3](#)) or [DROP PROCEDURE](#) and [CREATE PROCEDURE](#) ([MariaDB 10.1.2](#) and before).

You must have the

ALTER ROUTINE

privilege for the procedure. By default, that privilege is granted automatically to the procedure creator. See [Stored Routine Privileges](#).

### Example

```
ALTER PROCEDURE simpleproc SQL SECURITY INVOKER;
```

### See Also

- [Stored Procedure Overview](#)
- [CREATE PROCEDURE](#)

- [DROP PROCEDURE](#)
- [SHOW CREATE PROCEDURE](#)
- [SHOW PROCEDURE STATUS](#)
- [Stored Routine Privileges](#)
- [Information Schema ROUTINES Table](#)

## 1.1.2.1.1.7 ALTER SEQUENCE

MariaDB starting with [10.3.1](#)

```
ALTER SEQUENCE
was introduced in MariaDB 10.3.
```

### Syntax

```

ALTER SEQUENCE [IF EXISTS] sequence_name
[ INCREMENT [ BY | = ] increment ]
[ MINVALUE [=] minvalue | NO MINVALUE | NOMINVALUE ]
[ MAXVALUE [=] maxvalue | NO MAXVALUE | NOMAXVALUE ]
[ START [ WITH | = ] start ] [ CACHE [=] cache ] [ [ NO ] CYCLE ]
[ RESTART [[WITH | =] restart]

```

## Contents

1. [Syntax](#)
2. [Description](#)
  1. [Arguments to ALTER SEQUENCE](#)
  2. [INSERT](#)
  3. [Notes](#)
3. [See Also](#)

ALTER SEQUENCE  
 allows one to change any values for a  
 SEQUENCE  
 created with [CREATE SEQUENCE](#).

The options for

ALTER SEQUENCE  
 can be given in any order.

## Description

ALTER SEQUENCE  
 changes the parameters of an existing sequence generator. Any parameters not specifically set in the  
 ALTER SEQUENCE  
 command retain their prior settings.

ALTER SEQUENCE  
 requires the [ALTER](#) privilege.

## Arguments to ALTER SEQUENCE

The following options may be used:

Option	Default value	Description
INCREMENT	1	Increment to use for values. May be negative.
MINVALUE	1 if INCREMENT > 0 and - 9223372036854775807 if INCREMENT < 0	Minimum value for the sequence.
MAXVALUE	9223372036854775806 if INCREMENT > 0 and -1 if INCREMENT < 0	Max value for sequence.

START	<pre> MINVALUE if INCREMENT &gt; 0 and MAX_VALUE if INCREMENT &lt; 0 </pre>	First value that the sequence will generate.
CACHE	1000	Number of values that should be cached. 0 if no CACHE . The underlying table will be updated first time a new sequence number is generated and each time the cache runs out.
CYCLE	0 (= NO CYCLE )	1 if the sequence should start again from MINVALUE # after it has run out of values.
RESTART	<pre> START if restart value not is given </pre>	If RESTART option is used, NEXT VALUE will return the restart value.

The optional clause

```

RESTART [ WITH restart ]
sets the next value for the sequence. This is equivalent to calling the SETVAL() function with the
is_used
argument as 0. The specified value will be returned by the next call of nextval. Using
RESTART
with no restart value is equivalent to supplying the start value that was recorded by CREATE SEQUENCE or last set by
ALTER SEQUENCE START WITH

```

```

ALTER SEQUENCE
will not allow you to change the sequence so that it's inconsistent. For example:

```

```

CREATE SEQUENCE s1;
ALTER SEQUENCE s1 MINVALUE 10;
ERROR 4061 (HY000): Sequence 'test.t1' values are conflicting

ALTER SEQUENCE s1 MINVALUE 10 RESTART 10;
ERROR 4061 (HY000): Sequence 'test.t1' values are conflicting

ALTER SEQUENCE s1 MINVALUE 10 START 10 RESTART 10;

```

## INSERT

To allow

```

SEQUENCE
objects to be backed up by old tools, like mysqldump , one can use
SELECT
to read the current state of a
SEQUENCE
object and use an
INSERT
to update the
SEQUENCE
object.
INSERT
is only allowed if all fields are specified:

```

```
CREATE SEQUENCE s1;
INSERT INTO s1 VALUES(1000,10,2000,1005,1,1000,0,0);
SELECT * FROM s1;

+-----+-----+-----+-----+-----+-----+
| next_value | min_value | max_value | start | increment | cache |
+-----+-----+-----+-----+-----+-----+
|          1000 |         10 |        2000 |    1005 |          1 |     1000 |
+-----+-----+-----+-----+-----+-----+
SHOW CREATE SEQUENCE s1;
+-----+
| Table | Create Table |
+-----+
| s1   | CREATE SEQUENCE `s1` start with 1005 minvalue 10 maxvalue 2000 increment by 1 cache 1000 nocycle ENGINE=Aria |
+-----+
```

## Notes

**ALTER SEQUENCE**  
will instantly affect all future  
**SEQUENCE**  
operations. This is in contrast to some other databases where the changes requested by  
**ALTER SEQUENCE**  
will not be seen until the sequence cache has run out.

ALTER SEQUENCE  
will take a full table lock of the sequence object during its (brief) operation. This ensures that  
ALTER SEQUENCE  
is replicated correctly. If you only want to set the next sequence value to a higher value than current, then you should use [SETVAL\(\)](#) instead, as this is not blocking.

If you want to change storage engine, sequence comment or rename the sequence, you can use `ALTER TABLE` for this.

## 1.1.2.1.1.8 ALTER SERVER

## Syntax

```
ALTER SERVER server_name  
    OPTIONS (option [, option] ...)
```

## Contents

1. Syntax
  2. Description
  3. Examples
  4. See Also

## Description

Alters the server information for `server_name`, adjusting the specified options as per the [CREATE SERVER](#) command. The corresponding fields in the [mysql.servers](#) table are updated accordingly. This statement requires the [SUPER](#) privilege or, from MariaDB 10.5.2, the [FEDERATED ADMIN](#) privilege.

ALTER SERVER is not written to the [binary log](#), irrespective of the [binary log format](#) being used. From MariaDB 10.1.13, Galera replicates the [CREATE SERVER](#), [ALTER SERVER](#) and [DROP SERVER](#) statements.

## Examples

```
ALTER SERVER s OPTIONS (USER 'sally');
```

## See Also

- [CREATE SERVER](#)
- [DROP SERVER](#)
- [Spider Storage Engine](#)

## 1.1.2.1.1.9 ALTER TABLESPACE

The

ALTER TABLESPACE

statement is not supported by MariaDB. It was originally inherited from MySQL NDB Cluster. In MySQL 5.7 and later, the statement is also supported for InnoDB. However, MariaDB has chosen not to include that specific feature. See [MDEV-19294](#) for more information.

## 1.1.2.1.1.10 ALTER USER

## 1.1.2.1.2 ALTER VIEW

### Syntax

```
ALTER
[ALGORITHM = {UNDEFINED | MERGE | TEMPTABLE}]
[DEFINER = { user | CURRENT_USER }]
[SQL SECURITY { DEFINER | INVOKER }]
VIEW view_name [(column_list)]
AS select_statement
[WITH [CASCADED | LOCAL] CHECK OPTION]
```

### Contents

1. [Syntax](#)
2. [Description](#)
3. [Example](#)
4. [See Also](#)

### Description

This statement changes the definition of a [view](#), which must exist. The syntax is similar to that for [CREATE VIEW](#) and the effect is the same as for

CREATE OR REPLACE VIEW  
if the view exists. This statement requires the  
CREATE VIEW  
and  
DROP  
[privileges](#) for the view, and some privilege for each column referred to in the  
SELECT  
statement.  
ALTER VIEW  
is allowed only to the definer or users with the [SUPER](#) privilege.

### Example

```
ALTER VIEW v AS SELECT a, a*3 AS a2 FROM t;
```

## See Also

- [CREATE VIEW](#)
- [DROP VIEW](#)
- [SHOW CREATE VIEW](#)
- [INFORMATION SCHEMA VIEWS Table](#)

## 1.1.2.1.3 ANALYZE TABLE

### Syntax

```
ANALYZE [NO_WRITE_TO_BINLOG | LOCAL] TABLE tbl_name [,tbl_name ...]
[PERSISTENT FOR [ALL|COLUMNS ([col_name [,col_name ...]])]
[INDEXES ([index_name [,index_name ...]])]]
```

### Contents

1. [Syntax](#)
2. [Description](#)
3. [Engine-Independent Statistics](#)
4. [See Also](#)

### Description

#### ANALYZE TABLE

analyzes and stores the key distribution for a table ( [index statistics](#) ). This statement works with [MyISAM](#) , [Aria](#) and [InnoDB](#) tables. During the analysis, InnoDB will allow reads/writes, and MyISAM/Aria reads/inserts. For MyISAM tables, this statement is equivalent to using `myisamchk --analyze` .

For more information on how the analysis works within InnoDB, see [InnoDB Limitations](#) .

MariaDB uses the stored key distribution to decide the order in which tables should be joined when you perform a join on something other than a constant. In addition, key distributions can be used when deciding which indexes to use for a specific table within a query.

This statement requires [SELECT](#) and [INSERT](#) privileges for the table.

By default, ANALYZE TABLE statements are written to the [binary log](#) and will be [replicated](#) . The

```
NO_WRITE_TO_BINLOG
keyword (
LOCAL
is an alias) will ensure the statement is not written to the binary log.
```

From [MariaDB 10.3.19](#) ,

```
ANALYZE TABLE
statements are not logged to the binary log if read\_only is set. See also Read-Only Replicas .
```

#### ANALYZE TABLE

is also supported for partitioned tables. You can use

#### ALTER TABLE

```
... ANALYZE PARTITION
to analyze one or more partitions.
```

The [Aria](#) storage engine supports [progress reporting](#) for the

```
ANALYZE TABLE
statement.
```

## Engine-Independent Statistics

#### ANALYZE TABLE

supports [engine-independent statistics](#) . See [Engine-Independent Table Statistics: Collecting Statistics with the ANALYZE TABLE Statement](#) for more information.

### See Also

- [Index Statistics](#)
- [InnoDB Persistent Statistics](#)

## 1.1.2.1.4 CHECK TABLE

# Syntax

```
CHECK TABLE tbl_name [, tbl_name] ... [option] ...
option = {FOR UPGRADE | QUICK | FAST | MEDIUM | EXTENDED | CHANGED}
```

## Description

**CHECK TABLE**  
checks a table or tables for errors.  
**CHECK TABLE**  
works for [Archive](#) , [Aria](#) , [CSV](#) , [InnoDB](#) , and [MyISAM](#) tables. For Aria and MyISAM tables, the key statistics are updated as well. For CSV, see also [Checking and Repairing CSV Tables](#) .

As an alternative, [myisamchk](#) is a commandline tool for checking MyISAM tables when the tables are not being accessed.

For checking [dynamic columns](#) integrity,

[COLUMN\\_CHECK\(\)](#)

can be used.

**CHECK TABLE**  
can also check views for problems, such as tables that are referenced in the view definition that no longer exist.

**CHECK TABLE**  
is also supported for partitioned tables. You can use

[ALTER TABLE](#)

... [CHECK PARTITION](#)  
to check one or more partitions.

The meaning of the different options are as follows - note that this can vary a bit between storage engines:

FOR UPGRADE	Do a very quick check if the storage format for the table has changed so that one needs to do a REPAIR. This is only needed when one upgrades between major versions of MariaDB or MySQL. This is usually done by <a href="#">running mysql_upgrade</a> .
FAST	Only check tables that has not been closed properly or are marked as corrupt. Only supported by the MyISAM and Aria engines. For other engines the table is checked normally
CHANGED	Check only tables that has changed since last REPAIR / CHECK. Only supported by the MyISAM and Aria engines. For other engines the table is checked normally.
QUICK	Do a fast check. For MyISAM and Aria engine this means we skip checking the delete link chain which may take some time.
MEDIUM	Scan also the data files. Checks integrity between data and index files with checksums. In most cases this should find all possible errors.
EXTENDED	Does a full check to verify every possible error. For MyISAM and Aria we verify for each row that all it keys exists and points to the row. This may take a long time on big tables!

For most cases running

**CHECK TABLE**  
without options or  
**MEDIUM**  
should be good enough.

The [Aria](#) storage engine supports [progress reporting](#) for this statement.

If you want to know if two tables are identical, take a look at

[CHECKSUM TABLE](#)

## InnoDB

If

**CHECK TABLE**  
finds an error in an InnoDB table, MariaDB might shutdown to prevent the error propagation. In this case, the problem will be reported in the error log. Otherwise the table or an index might be marked as corrupted, to prevent use. This does not happen with some minor problems, like a wrong

number of entries in a secondary index. Those problems are reported in the output of  
CHECK TABLE

Each tablespace contains a header with metadata. This header is not checked by this statement.

During the execution of

CHECK TABLE  
, other threads may be blocked.

## 1.1.2.1.5 CHECK VIEW

### Syntax

```
CHECK VIEW view_name
```

### Description

The

CHECK VIEW

statement was introduced in [MariaDB 10.0.18](#) to assist with fixing [MDEV-6916](#) , an issue introduced in [MariaDB 5.2](#) where the view algorithms were swapped. It checks whether the view algorithm is correct. It is run as part of [mysql\\_upgrade](#) , and should not normally be required in regular use.

### See Also

- [REPAIR VIEW](#)

## 1.1.2.1.6 CHECKSUM TABLE

### Syntax

```
CHECKSUM TABLE tbl_name [, tbl_name] ... [ QUICK | EXTENDED ]
```

### Contents

1. [Syntax](#)
2. [Description](#)
3. [Differences Between MariaDB and MySQL](#)

### Description

CHECKSUM TABLE  
reports a table checksum. This is very useful if you want to know if two tables are the same (for example on a master and slave).

With

QUICK  
, the live table checksum is reported if it is available, or  
NULL  
otherwise. This is very fast. A live checksum is enabled by specifying the  
CHECKSUM=1  
table option when you [create the table](#) ; currently, this is supported only for [Aria](#) and [MyISAM](#) tables.

With

EXTENDED  
, the entire table is read row by row and the checksum is calculated. This can be very slow for large tables.

If neither

QUICK  
nor  
EXTENDED  
is specified, MariaDB returns a live checksum if the table storage engine supports it and scans the table otherwise.

CHECKSUM TABLE  
requires the [SELECT privilege](#) for the table.

For a nonexistent table,

```
CHECKSUM TABLE
returns
NULL
and generates a warning.
```

The table row format affects the checksum value. If the row format changes, the checksum will change. This means that when a table created with a MariaDB/MySQL version is upgraded to another version, the checksum value will probably change.

Two identical tables should always match to the same checksum value; however, also for non-identical tables there is a very slight chance that they will return the same value as the hashing algorithm is not completely collision-free.

## Differences Between MariaDB and MySQL

```
CHECKSUM TABLE
may give a different result as MariaDB doesn't ignore
NULL
s in the columns as MySQL 5.1 does (Later MySQL versions should calculate checksums the same way as MariaDB). You can get the 'old style'
checksum in MariaDB by starting mysqld with the
--old
option. Note however that the MyISAM and Aria storage engines in MariaDB are using the new checksum internally, so if you are using
--old
, the
CHECKSUM
command will be slower as it needs to calculate the checksum row by row.
```

### 1.1.2.1.7 CREATE TABLE

#### Syntax

```
CREATE [OR REPLACE] [TEMPORARY] TABLE [IF NOT EXISTS] tbl_name
  [(create_definition,...)] [table_options] ... [partition_options]
CREATE [OR REPLACE] [TEMPORARY] TABLE [IF NOT EXISTS] tbl_name
  [(create_definition,...)] [table_options] ... [partition_options]
  select_statement
CREATE [OR REPLACE] [TEMPORARY] TABLE [IF NOT EXISTS] tbl_name
  { LIKE old_table_name | (LIKE old_table_name) }

select_statement:
  [IGNORE | REPLACE] [AS] SELECT ...  (Some legal select statement)
```

## Description

Use the

```
CREATE TABLE
statement to create a table with the given name.
```

In its most basic form, the

```
CREATE TABLE
statement provides a table name followed by a list of columns, indexes, and constraints. By default, the table is created in the default database.
```

Specify a database with

*db\_name*

*tbl\_name*

. If you quote the table name, you must quote the database name and table name separately as

*db\_name*

*tbl\_name*

. This is particularly useful for `CREATE TABLE ... SELECT`, because it allows to create a table into a database, which contains data from other databases. See [Identifier Qualifiers](#).

If a table with the same name exists, error 1050 results. Use `IF NOT EXISTS` to suppress this error and issue a note instead. Use `SHOW WARNINGS` to see notes.

The

`CREATE TABLE`

statement automatically commits the current transaction, except when using the `TEMPORARY` keyword.

For valid identifiers to use as table names, see [Identifier Names](#).

**Note:** if the `default_storage_engine` is set to ColumnStore then it needs setting on all UMs. Otherwise when the tables using the default engine are replicated across UMs they will use the wrong engine. You should therefore not use this option as a session variable with ColumnStore.

`Microsecond precision` can be between 0-6. If no precision is specified it is assumed to be 0, for backward compatibility reasons.

## Privileges

Executing the

`CREATE TABLE`

statement requires the `CREATE` privilege for the table or the database.

## CREATE OR REPLACE

If the

`OR REPLACE`

clause is used and the table already exists, then instead of returning an error, the server will drop the existing table and replace it with the newly defined table.

This syntax was originally added to make `replication` more robust if it has to rollback and repeat statements such as

`CREATE ... SELECT`

on replicas.

```
CREATE OR REPLACE TABLE table_name (a int);
```

is basically the same as:

```
DROP TABLE IF EXISTS table_name;
CREATE TABLE table_name (a int);
```

with the following exceptions:

- If  
*table\_name*  
was locked with `LOCK TABLES` it will continue to be locked after the statement.
- Temporary tables are only dropped if the  
`TEMPORARY`  
keyword was used. (With `DROP TABLE`, temporary tables are preferred to be dropped before normal tables).

## Things to be Aware of With CREATE OR REPLACE

- The table is dropped first (if it existed), after that the  
`CREATE`  
is done. Because of this, if the

- CREATE  
fails, then the table will not exist anymore after the statement. If the table was used with  
LOCK TABLES  
it will be unlocked.
- One can't use  
OR REPLACE  
together with  
IF EXISTS
  - Slaves in replication will by default use  
CREATE OR REPLACE  
when replicating  
CREATE  
statements that don't use  
IF EXISTS  
. This can be changed by setting the variable [slave-ddl-exec-mode](#) to  
STRICT

## CREATE TABLE IF NOT EXISTS

If the  
IF NOT EXISTS  
clause is used, then the table will only be created if a table with the same name does not already exist. If the table already exists, then a warning will be triggered by default.

## CREATE TEMPORARY TABLE

Use the  
TEMPORARY  
keyword to create a temporary table that is only available to the current session. Temporary tables are dropped when the session ends. Temporary table names are specific to the session. They will not conflict with other temporary tables from other sessions even if they share the same name. They will shadow names of non-temporary tables or views, if they are identical. A temporary table can have the same name as a non-temporary table which is located in the same database. In that case, their name will reference the temporary table when used in SQL statements. You must have the [CREATE TEMPORARY TABLES](#) privilege on the database to create temporary tables. If no storage engine is specified, the [default\\_tmp\\_storage\\_engine](#) setting will determine the engine.

[ROCKSDB](#) temporary tables cannot be created by setting the [default\\_tmp\\_storage\\_engine](#) system variable, or using  
CREATE TEMPORARY TABLE LIKE  
. Before [MariaDB 10.7](#), they could be specified, but would silently fail, and a MyISAM table would be created instead. From [MariaDB 10.7](#) an error is returned. Explicitly creating a temporary table with  
ENGINE=ROCKSDB  
has never been permitted.

## CREATE TABLE ... LIKE

Use the  
LIKE  
clause instead of a full table definition to create a table with the same definition as another table, including columns, indexes, and table options. Foreign key definitions, as well as any DATA DIRECTORY or INDEX DIRECTORY table options specified on the original table, will not be created.

## CREATE TABLE ... SELECT

You can create a table containing data from other tables using the

```
CREATE ... SELECT  

statement. Columns will be created in the table for each field returned by the  

SELECT  

query.
```

You can also define some columns normally and add other columns from a

```
SELECT  

. You can also create columns in the normal way and assign them some values using the query, this is done to force a certain type or other field characteristics. The columns that are not named in the query will be placed before the others. For example:
```

```
CREATE TABLE test (a INT NOT NULL, b CHAR(10)) ENGINE=MyISAM  

SELECT 5 AS b, c, d FROM another_table;
```

Remember that the query just returns data. If you want to use the same indexes, or the same columns attributes ( [NOT] NULL

```

,
DEFAULT
,
AUTO_INCREMENT
) in the new table, you need to specify them manually. Types and sizes are not automatically preserved if no data returned by the
SELECT
requires the full size, and
VARCHAR
could be converted into
CHAR
. The CAST\(\) function can be used to forcee the new table to use certain types.

```

Aliases (

```

AS
) are taken into account, and they should always be used when you
SELECT
an expression (function, arithmetical operation, etc).

```

If an error occurs during the query, the table will not be created at all.

If the new table has a primary key or

```

UNIQUE
indexes, you can use the IGNORE or
REPLACE
keywords to handle duplicate key errors during the query.
IGNORE
means that the newer values must not be inserted an identical value exists in the index.
REPLACE
means that older values must be overwritten.

```

If the columns in the new table are more than the rows returned by the query, the columns populated by the query will be placed after other columns. Note that if the strict

```

SQL_MODE
is on, and the columns that are not names in the query do not have a
DEFAULT
value, an error will raise and no rows will be copied.

```

[Concurrent inserts](#) are not used during the execution of a

```
CREATE ... SELECT
```

If the table already exists, an error similar to the following will be returned:

```
ERROR 1050 (42S01): Table 't' already exists
```

If the

```
IF NOT EXISTS
clause is used and the table exists, a note will be produced instead of an error.
```

To insert rows from a query into an existing table, [INSERT ... SELECT](#) can be used.

## Column Definitions

```

create_definition:
{ col_name column_definition | index\_definition | period\_definition | CHECK (expr) }

column_definition:
data\_type
[NOT NULL | NULL] [DEFAULT default_value | (expression)]
[ON UPDATE [NOW | CURRENT_TIMESTAMP] [(precision)]]
[AUTO_INCREMENT] [ZEROFILL] [UNIQUE [KEY] | [PRIMARY] KEY]
[INVISIBLE] [{WITH|WITHOUT} SYSTEM VERSIONING]
[COMMENT 'string'] [REF_SYSTEM_ID = value]
[reference\_definition]
| data\_type [GENERATED ALWAYS]
AS { { ROW {START|END} } | { (expression) [VIRTUAL | PERSISTENT | STORED] } }
[UNIQUE [KEY]] [COMMENT 'string']

constraint_definition:
CONSTRAINT [constraint_name] CHECK (expression)

```

**Note:** Until MariaDB 10.4 , MariaDB accepts the shortcut format with a REFERENCES clause only in ALTER TABLE and CREATE TABLE

statements, but that syntax does nothing. For example:

```
CREATE TABLE b(for_key INT REFERENCES a(not_key));
```

MariaDB simply parses it without returning any error or warning, for compatibility with other DBMS's. Before MariaDB 10.2.1 this was also true for  
CHECK  
constraints. However, only the syntax described below creates foreign keys.

From MariaDB 10.5 , MariaDB will attempt to apply the constraint. See [Foreign Keys examples](#) .

Each definition either creates a column in the table or specifies and index or constraint on one or more columns. See [Indexes](#) below for details on creating indexes.

Create a column by specifying a column name and a data type, optionally followed by column options. See [Data Types](#) for a full list of data types allowed in MariaDB.

## NULL and NOT NULL

Use the

NULL

or

NOT NULL

options to specify that values in the column may or may not be

NULL

, respectively. By default, values may be

NULL

. See also [NULL Values in MariaDB](#) .

## DEFAULT Column Option

MariaDB starting with 10.2.1

The

DEFAULT

clause was enhanced in MariaDB 10.2.1 . Some enhancements include

- BLOB and TEXT columns now support

DEFAULT

- The

DEFAULT

clause can now be used with an expression or function.

Specify a default value using the

DEFAULT

clause. If you don't specify

DEFAULT

then the following rules apply:

- If the column is not defined with

NOT NULL

,

AUTO\_INCREMENT

or

TIMESTAMP

, an explicit

DEFAULT NULL

will be added. Note that in MySQL and in MariaDB before 10.1.6, you may get an explicit

DEFAULT

for primary key parts, if not specified with NOT NULL.

The default value will be used if you [INSERT](#) a row without specifying a value for that column, or if you specify [DEFAULT](#) for that column. Before MariaDB 10.2.1 you couldn't usually provide an expression or function to evaluate at insertion time. You had to provide a constant default value instead. The one exception is that you may use [CURRENT\\_TIMESTAMP](#) as the default value for a [TIMESTAMP](#) column to use the current timestamp at insertion time.

[CURRENT\\_TIMESTAMP](#) may also be used as the default value for a [DATETIME](#)

From MariaDB 10.2.1 you can use most functions in

DEFAULT

. Expressions should have parentheses around them. If you use a non deterministic function in

DEFAULT

then all inserts to the table will be [replicated](#) in [row mode](#) . You can even refer to earlier columns in the

DEFAULT

expression (excluding  
AUTO\_INCREMENT  
columns):

```
CREATE TABLE t1 (a int DEFAULT (1+1), b int DEFAULT (a+1));  
CREATE TABLE t2 (a bigint primary key DEFAULT UUID_SHORT());
```

The  
DEFAULT  
clause cannot contain any [stored functions](#) or [subqueries](#), and a column used in the clause must already have been defined earlier in the statement.

Since [MariaDB 10.2.1](#), it is possible to assign [BLOB](#) or [TEXT](#) columns a  
DEFAULT  
value. In earlier versions, assigning a default to these columns was not possible.

MariaDB starting with [10.3.3](#)

Starting from 10.3.3 you can also use [DEFAULT \( NEXT VALUE FOR sequence \)](#)

## AUTO\_INCREMENT Column Option

Use [AUTO\\_INCREMENT](#) to create a column whose value can be set automatically from a simple counter. You can only use

AUTO\_INCREMENT  
on a column with an integer type. The column must be a key, and there can only be one  
AUTO\_INCREMENT  
column in a table. If you insert a row without specifying a value for that column (or if you specify

0

,

NULL

, or [DEFAULT](#) as the value), the actual value will be taken from the counter, with each insertion incrementing the counter by one. You can still insert a value explicitly. If you insert a value that is greater than the current counter value, the counter is set based on the new value. An

AUTO\_INCREMENT  
column is implicitly  
NOT NULL

. Use [LAST\\_INSERT\\_ID](#) to get the [AUTO\\_INCREMENT](#) value most recently used by an [INSERT](#) statement.

## ZEROFILL Column Option

If the

ZEROFILL  
column option is specified for a column using a [numeric](#) data type, then the column will be set to  
UNSIGNED  
and the spaces used by default to pad the field are replaced with zeros.  
ZEROFILL  
is ignored in expressions or as part of a [UNION](#).  
ZEROFILL  
is a non-standard MySQL and MariaDB enhancement.

## PRIMARY KEY Column Option

Use  
PRIMARY KEY  
to make a column a primary key. A primary key is a special type of a unique key. There can be at most one primary key per table, and it is implicitly  
NOT NULL

Specifying a column as a unique key creates a unique index on that column. See the [Index Definitions](#) section below for more information.

## UNIQUE KEY Column Option

Use  
UNIQUE KEY  
(or just  
UNIQUE  
) to specify that all values in the column must be distinct from each other. Unless the column is  
NOT NULL  
, there may be multiple rows with

NULL  
in the column.

Specifying a column as a unique key creates a unique index on that column. See the [Index Definitions](#) section below for more information.

## COMMENT Column Option

You can provide a comment for each column using the

COMMENT  
clause. The maximum length is 1024 characters. Use the [SHOW FULL COLUMNS](#) statement to see column comments.

## REF\_SYSTEM\_ID

REF\_SYSTEM\_ID  
can be used to specify Spatial Reference System IDs for spatial data type columns.

## Generated Columns

A generated column is a column in a table that cannot explicitly be set to a specific value in a [DML query](#). Instead, its value is automatically generated based on an expression. This expression might generate the value based on the values of other columns in the table, or it might generate the value by calling [built-in functions](#) or [user-defined functions \(UDFs\)](#).

There are two types of generated columns:

- PERSISTENT  
or  
STORED  
: This type's value is actually stored in the table.
- VIRTUAL  
: This type's value is not stored at all. Instead, the value is generated dynamically when the table is queried. This type is the default.

Generated columns are also sometimes called computed columns or virtual columns.

For a complete description about generated columns and their limitations, see [Generated \(Virtual and Persistent/Stored\) Columns](#).

## COMPRESSED

MariaDB starting with 10.3.3

Certain columns may be compressed. See [Storage-Engine Independent Column Compression](#).

## INVISIBLE

MariaDB starting with 10.3.3

Columns may be made invisible, and hidden in certain contexts. See [Invisible Columns](#).

## WITH SYSTEM VERSIONING Column Option

MariaDB starting with 10.3.4

Columns may be explicitly marked as included from system versioning. See [System-versioned tables](#) for details.

## WITHOUT SYSTEM VERSIONING Column Option

MariaDB starting with 10.3.4

Columns may be explicitly marked as excluded from system versioning. See [System-versioned tables](#) for details.

## Index Definitions

```

index_definition:
  {INDEX|KEY} [index_name] [index_type] (index_col_name,...) [index_option] ...
  | {FULLTEXT|SPATIAL} [INDEX|KEY] [index_name] (index_col_name,...) [index_option] ...
  | [CONSTRAINT [symbol]] PRIMARY KEY [index_type] (index_col_name,...) [index_option] ...
  | [CONSTRAINT [symbol]] UNIQUE [INDEX|KEY] [index_name] [index_type] (index_col_name,...) [index_option] ...
  | [CONSTRAINT [symbol]] FOREIGN KEY [index_name] (index_col_name,...) reference_definition

index_col_name:
  col_name [(length)] [ASC | DESC]

index_type:
  USING {BTREE | HASH | RTREE}

index_option:
  [ KEY_BLOCK_SIZE [=] value
  | index_type
  | WITH PARSER parser_name
  | COMMENT 'string'
  | CLUSTERING={YES| NO} ]
  [ IGNORED | NOT IGNORED ]

reference_definition:
  REFERENCES tbl_name (index_col_name,...)
  [MATCH FULL | MATCH PARTIAL | MATCH SIMPLE]
  [ON DELETE reference_option]
  [ON UPDATE reference_option]

reference_option:
  RESTRICT | CASCADE | SET NULL | NO ACTION

```

INDEX  
and  
KEY  
are synonyms.

Index names are optional, if not specified an automatic name will be assigned. Index name are needed to drop indexes and appear in error messages when a constraint is violated.

## Index Categories

### Plain Indexes

Plain indexes are regular indexes that are not unique, and are not acting as a primary key or a foreign key. They are also not the "specialized"

FULLTEXT  
or  
SPATIAL  
indexes.

See [Getting Started with Indexes: Plain Indexes](#) for more information.

### PRIMARY KEY

For

PRIMARY KEY  
indexes, you can specify a name for the index, but it is ignored, and the name of the index is always  
PRIMARY  
. From [MariaDB 10.3.18](#) and [MariaDB 10.4.8](#), a warning is explicitly issued if a name is specified. Before then, the name was silently ignored.

See [Getting Started with Indexes: Primary Key](#) for more information.

### UNIQUE

The

UNIQUE  
keyword means that the index will not accept duplicated values, except for NULLs. An error will raise if you try to insert duplicate values in a  
UNIQUE index.

For

UNIQUE  
indexes, you can specify a name for the constraint, using the  
CONSTRAINT

keyword. That name will be used in error messages.

See [Getting Started with Indexes: Unique Index](#) for more information.

## FOREIGN KEY

For

FOREIGN KEY  
indexes, a reference definition must be provided.

For

FOREIGN KEY  
indexes, you can specify a name for the constraint, using the  
CONSTRAINT  
keyword. That name will be used in error messages.

First, you have to specify the name of the target (parent) table and a column or a column list which must be indexed and whose values must match to the foreign key's values. The

MATCH  
clause is accepted to improve the compatibility with other DBMS's, but has no meaning in MariaDB. The  
ON DELETE  
and  
ON UPDATE  
clauses specify what must be done when a  
DELETE  
(or a  
REPLACE  
) statements attempts to delete a referenced row from the parent table, and when an  
UPDATE  
statement attempts to modify the referenced foreign key columns in a parent table row, respectively. The following options are allowed:

- RESTRICT  
: The delete/update operation is not performed. The statement terminates with a 1451 error (SQLSTATE '2300').
- NO ACTION  
: Synonym for  
RESTRICT
- CASCADE  
: The delete/update operation is performed in both tables.
- SET NULL  
: The update or delete goes ahead in the parent table, and the corresponding foreign key fields in the child table are set to  
NULL  
. (They must not be defined as  
NOT NULL  
for this to succeed).
- SET DEFAULT  
: This option is currently implemented only for the PBXT storage engine, which is disabled by default and no longer maintained. It sets the  
child table's foreign key fields to their  
DEFAULT  
values when the referenced parent table key entries are updated or deleted.

If either clause is omitted, the default behavior for the omitted clause is

RESTRICT

See [Foreign Keys](#) for more information.

## FULLTEXT

Use the

FULLTEXT  
keyword to create full-text indexes.

See [Full-Text Indexes](#) for more information.

## SPATIAL

Use the

SPATIAL

keyword to create geometric indexes.

See [SPATIAL INDEX](#) for more information.

## Index Options

### KEY\_BLOCK\_SIZE Index Option

The

KEY\_BLOCK\_SIZE  
index option is similar to the [KEY\\_BLOCK\\_SIZE](#) table option.

With the [InnoDB](#) storage engine, if you specify a non-zero value for the

KEY\_BLOCK\_SIZE  
table option for the whole table, then the table will implicitly be created with the [ROW\\_FORMAT](#) table option set to  
COMPRESSED

. However, this does not happen if you just set the

KEY\_BLOCK\_SIZE  
index option for one or more indexes in the table. The [InnoDB](#) storage engine ignores the  
KEY\_BLOCK\_SIZE  
index option. However, the [SHOW CREATE TABLE](#) statement may still report it for the index.

For information about the

KEY\_BLOCK\_SIZE  
index option, see the [KEY\\_BLOCK\\_SIZE](#) table option below.

### Index Types

Each storage engine supports some or all index types. See [Storage Engine Index Types](#) for details on permitted index types for each storage engine.

Different index types are optimized for different kind of operations:

- BTREE  
is the default type, and normally is the best choice. It is supported by all storage engines. It can be used to compare a column's value with a value using the =, >, >=, <, <=,  
BETWEEN  
, and  
LIKE  
operators.  
BTREE  
can also be used to find  
NULL  
values. Searches against an index prefix are possible.
- HASH  
is only supported by the MEMORY storage engine.  
HASH  
indexes can only be used for =, <=, and >= comparisons. It can not be used for the  
ORDER BY  
clause. Searches against an index prefix are not possible.
- RTREE  
is the default for  
SPATIAL  
indexes, but if the storage engine does not support it  
BTREE  
can be used.

Index columns names are listed between parenthesis. After each column, a prefix length can be specified. If no length is specified, the whole column will be indexed.

ASC  
and  
DESC  
can be specified for compatibility with are DBMS's, but have no meaning in MariaDB.

### WITH PARSER Index Option

The

WITH PARSER  
index option only applies to [FULLTEXT](#) indexes and contains the fulltext parser name. The fulltext parser must be an installed plugin.

### COMMENT Index Option

A comment of up to 1024 characters is permitted with the

```
COMMENT  
index option.
```

The

```
COMMENT  
index option allows you to specify a comment with user-readable text describing what the index is for. This information is not used by the server itself.
```

## CLUSTERING Index Option

The

```
CLUSTERING  
index option is only valid for tables using the Tokudb storage engine.
```

## IGNORED / NOT IGNORED

MariaDB starting with [10.6.0](#)

From [MariaDB 10.6.0](#), indexes can be specified to be ignored by the optimizer. See [Ignored Indexes](#).

## Periods

MariaDB starting with [10.3.4](#)

```
period_definition:  
    PERIOD FOR SYSTEM_TIME (start_column_name, end_column_name)
```

MariaDB supports a subset of the standard syntax for periods. At the moment it's only used for creating [System-versioned tables](#). Both columns must be created, must be either of a

```
TIMESTAMP(6)  
or  
BIGINT UNSIGNED  
type, and be generated as  
ROW START  
and  
ROW END  
accordingly. See System-versioned tables for details.
```

The table must also have the

```
WITH SYSTEM VERSIONING  
clause.
```

## Constraint Expressions

MariaDB starting with [10.2.1](#)

[MariaDB 10.2.1](#) introduced new ways to define a constraint.

Note: Before [MariaDB 10.2.1](#), constraint expressions were accepted in the syntax but ignored.

[MariaDB 10.2.1](#) introduced two ways to define a constraint:

- ```
CHECK(expression)  
given as part of a column definition.
```
- ```
CONSTRAINT [constraint_name] CHECK (expression)
```

Before a row is inserted or updated, all constraints are evaluated in the order they are defined. If any constraints fails, then the row will not be updated. One can use most deterministic functions in a constraint, including [UDFs](#).

```
create table t1 (a int check(a>0) ,b int check (b> 0), constraint abc check (a>b));
```

If you use the second format and you don't give a name to the constraint, then the constraint will get a auto generated name. This is done so that you can later delete the constraint with [ALTER TABLE DROP constraint\\_name](#).

One can disable all constraint expression checks by setting the variable  
`check_constraint_checks`

to  
OFF  
. This is useful for example when loading a table that violates some constraints that you want to later find and fix in SQL.

See [CONSTRAINT](#) for more information.

## Table Options

For each individual table you create (or alter), you can set some table options. The general syntax for setting options is:

```
<OPTION_NAME> = <option_value>, [<OPTION_NAME> = <option_value> ...]
```

The equal sign is optional.

Some options are supported by the server and can be used for all tables, no matter what storage engine they use; other options can be specified for all storage engines, but have a meaning only for some engines. Also, engines can [extend](#)

```
CREATE TABLE  
  with new options .
```

If the

```
IGNORE_BAD_TABLE_OPTIONS  
SQL_MODE is enabled, wrong table options generate a warning; otherwise, they generate an error.
```

```
table_option:  
  [STORAGE] ENGINE [=] engine_name  
  | AUTO_INCREMENT [=] value  
  | AVG_ROW_LENGTH [=] value  
  | [DEFAULT] CHARACTER SET [=] charset_name  
  | CHECKSUM [=] {0 | 1}  
  | [DEFAULT] COLLATE [=] collation_name  
  | COMMENT [=] 'string'  
  | CONNECTION [=] 'connect_string'  
  | DATA DIRECTORY [=] 'absolute path to directory'  
  | DELAY_KEY_WRITE [=] {0 | 1}  
  | ENCRYPTED [=] {YES | NO}  
  | ENCRYPTION_KEY_ID [=] value  
  | IETF_QUOTES [=] {YES | NO}  
  | INDEX DIRECTORY [=] 'absolute path to directory'  
  | INSERT_METHOD [=] {NO | FIRST | LAST}  
  | KEY_BLOCK_SIZE [=] value  
  | MAX_ROWS [=] value  
  | MIN_ROWS [=] value  
  | PACK_KEYS [=] {0 | 1 | DEFAULT}  
  | PAGE_CHECKSUM [=] {0 | 1}  
  | PAGE_COMPRESSED [=] {0 | 1}  
  | PAGE_COMPRESSION_LEVEL [=] {0 .. 9}  
  | PASSWORD [=] 'string'  
  | ROW_FORMAT [=] {DEFAULT|DYNAMIC|FIXED|COMPRESSED|REDUNDANT|COMPACT|PAGE}  
  | SEQUENCE [=] {0|1}  
  | STATS_AUTO_RECALC [=] {DEFAULT|0|1}  
  | STATS_PERSISTENT [=] {DEFAULT|0|1}  
  | STATS_SAMPLE_PAGES [=] {DEFAULT|value}  
  | TABLESPACE tablespace_name  
  | TRANSACTIONAL [=] {0 | 1}  
  | UNION [=] (tbl_name[,tbl_name]...)  
  | WITH SYSTEM VERSIONING
```

## [STORAGE] ENGINE

```
[STORAGE] ENGINE
```

specifies a [storage engine](#) for the table. If this option is not used, the default storage engine is used instead. That is, the [default\\_storage\\_engine](#) session option value if it is set, or the value specified for the

```
--default-storage-engine
```

[mysqld startup option](#), or the default storage engine, [InnoDB](#). If the specified storage engine is not installed and active, the default value will be used, unless the

```
NO_ENGINE_SUBSTITUTION
```

[SQL MODE](#) is set (default). This is only true for

```
CREATE TABLE
```

, not for

```
ALTER TABLE
```

. For a list of storage engines that are present in your server, issue a [SHOW ENGINES](#).

## AUTO\_INCREMENT

AUTO\_INCREMENT  
specifies the initial value for the  
AUTO\_INCREMENT  
primary key. This works for MyISAM, Aria, InnoDB/XtraDB, MEMORY, and ARCHIVE tables. You can change this option with  
ALTER TABLE  
, but in that case the new value must be higher than the highest value which is present in the  
AUTO\_INCREMENT  
column. If the storage engine does not support this option, you can insert (and then delete) a row having the wanted value - 1 in the  
AUTO\_INCREMENT  
column.

## AVG\_ROW\_LENGTH

AVG\_ROW\_LENGTH  
is the average rows size. It only applies to tables using [MyISAM](#) and [Aria](#) storage engines that have the ROW\_FORMAT table option set to  
FIXED  
format.

MyISAM uses

MAX\_ROWS  
and  
AVG\_ROW\_LENGTH  
to decide the maximum size of a table (default: 256TB, or the maximum file size allowed by the system).

## [DEFAULT] CHARACTER SET/CHARSET

[DEFAULT] CHARACTER SET  
(or  
[DEFAULT] CHARSET  
) is used to set a default character set for the table. This is the character set used for all columns where an explicit character set is not specified.  
If this option is omitted or  
DEFAULT  
is specified, database's default character set will be used. See [Setting Character Sets and Collations](#) for details on setting the character sets .

## CHECKSUM/TABLE\_CHECKSUM

CHECKSUM  
(or  
TABLE\_CHECKSUM  
) can be set to 1 to maintain a live checksum for all table's rows. This makes write operations slower, but  
CHECKSUM TABLE  
will be very fast. This option is only supported for [MyISAM](#) and [Aria tables](#) .

## [DEFAULT] COLLATE

[DEFAULT] COLLATE  
is used to set a default collation for the table. This is the collation used for all columns where an explicit character set is not specified. If this option is omitted or  
DEFAULT  
is specified, database's default option will be used. See [Setting Character Sets and Collations](#) for details on setting the collations

## COMMENT

COMMENT  
is a comment for the table. The maximum length is 2048 characters. Also used to define table parameters when creating a [Spider](#) table.

## CONNECTION

CONNECTION

is used to specify a server name or a connection string for a [Spider](#) , [CONNECT](#) , [Federated](#) or [FederatedX](#) table .

## DATA DIRECTORY/INDEX DIRECTORY

DATA DIRECTORY  
and  
INDEX DIRECTORY

are supported for MyISAM and Aria, and DATA DIRECTORY is also supported by InnoDB if the `innodb_file_per_table` server system variable is enabled, but only in CREATE TABLE, not in [ALTER TABLE](#) . So, carefully choose a path for InnoDB tables at creation time, because it cannot be changed without dropping and re-creating the table. These options specify the paths for data files and index files, respectively. If these options are omitted, the database's directory will be used to store data files and index files. Note that these table options do not work for [partitioned](#) tables (use the partition options instead), or if the server has been invoked with the

```
--skip-symbolic-links  
startup option . To avoid the overwriting of old files with the same name that could be present in the directories, you can use the  
--keep_files_on_create  
option (an error will be issued if files already exist). These options are ignored if the  
NO_DIR_IN_CREATE  
SQL_MODE is enabled (useful for replication slaves). Also note that symbolic links cannot be used for InnoDB tables.
```

DATA DIRECTORY

works by creating symlinks from where the table would normally have been (inside the `datadir` ) to where the option specifies. For security reasons, to avoid bypassing the privilege system, the server does not permit symlinks inside the datadir. Therefore,

DATA DIRECTORY

cannot be used to specify a location inside the datadir. An attempt to do so will result in an error

1210 (HY000) Incorrect arguments to DATA DIRECTORY

## DELAY\_KEY\_WRITE

DELAY\_KEY\_WRITE

is supported by MyISAM and Aria, and can be set to 1 to speed up write operations. In that case, when data are modified, the indexes are not updated until the table is closed. Writing the changes to the index file altogether can be much faster. However, note that this option is applied only if the `delay_key_write` server variable is set to 'ON'. If it is 'OFF' the delayed index writes are always disabled, and if it is 'ALL' the delayed index writes are always used, disregarding the value of

DELAY\_KEY\_WRITE

## ENCRYPTED

The

ENCRYPTED

table option can be used to manually set the encryption status of an InnoDB table. See [InnoDB Encryption](#) for more information.

Aria does not support the

ENCRYPTED

table option. See [MDEV-18049](#) .

See [Data-at-Rest Encryption](#) for more information.

## ENCRYPTION\_KEY\_ID

The

ENCRYPTION\_KEY\_ID

table option can be used to manually set the encryption key of an InnoDB table. See [InnoDB Encryption](#) for more information.

Aria does not support the

ENCRYPTION\_KEY\_ID

table option. See [MDEV-18049](#) .

See [Data-at-Rest Encryption](#) for more information.

## IETF\_QUOTES

For the `CSV` storage engine, the

IETF\_QUOTES

option, when set to

YES

, enables IETF-compatible parsing of embedded quote and comma characters. Enabling this option for a table improves compatibility with other tools that use CSV, but is not compatible with MySQL CSV tables, or MariaDB CSV tables created without this option. Disabled by default.

## INSERT\_METHOD

INSERT\_METHOD

is only used with [MERGE](#) tables. This option determines in which underlying table the new rows should be inserted. If you set it to 'NO' (which is the default) no new rows can be added to the table (but you will still be able to perform

INSERT

s directly against the underlying tables).

FIRST

means that the rows are inserted into the first table, and

LAST

means that they are inserted into the last table.

## KEY\_BLOCK\_SIZE

KEY\_BLOCK\_SIZE

is used to determine the size of key blocks, in bytes or kilobytes. However, this value is just a hint, and the storage engine could modify or ignore it. If

KEY\_BLOCK\_SIZE

is set to 0, the storage engine's default value will be used.

With the [InnoDB](#) storage engine, if you specify a non-zero value for the

KEY\_BLOCK\_SIZE

table option for the whole table, then the table will implicitly be created with the [ROW\\_FORMAT](#) table option set to COMPRESSED

## MIN\_ROWS/MAX\_ROWS

MIN\_ROWS

and

MAX\_ROWS

let the storage engine know how many rows you are planning to store as a minimum and as a maximum. These values will not be used as real limits, but they help the storage engine to optimize the table.

MIN\_ROWS

is only used by [MEMORY](#) storage engine to decide the minimum memory that is always allocated.

MAX\_ROWS

is used to decide the minimum size for indexes.

## PACK\_KEYS

PACK\_KEYS

can be used to determine whether the indexes will be compressed. Set it to 1 to compress all keys. With a value of 0, compression will not be used. With the

DEFAULT

value, only long strings will be compressed. Uncompressed keys are faster.

## PAGE\_CHECKSUM

PAGE\_CHECKSUM

is only applicable to [Aria](#) tables, and determines whether indexes and data should use page checksums for extra safety.

## PAGE\_COMPRESSED

PAGE\_COMPRESSED

is used to enable [InnoDB](#) page compression for [InnoDB](#) tables.

## PAGE\_COMPRESSION\_LEVEL

#### PAGE\_COMPRESSION\_LEVEL

is used to set the compression level for [InnoDB page compression](#) for [InnoDB](#) tables. The table must also have the [PAGE\\_COMPRESSED](#) table option set to

1

Valid values for

#### PAGE\_COMPRESSION\_LEVEL

are 1 (the best speed) through 9 (the best compression), .

## PASSWORD

#### PASSWORD

is unused.

## RAID\_TYPE

#### RAID\_TYPE

is an obsolete option, as the raid support has been disabled since MySQL 5.0.

## ROW\_FORMAT

The

#### ROW\_FORMAT

table option specifies the row format for the data file. Possible values are engine-dependent.

### Supported MyISAM Row Formats

For [MyISAM](#), the supported row formats are:

- FIXED
- DYNAMIC
- COMPRESSED

The

#### COMPRESSED

row format can only be set by the [myisampack](#) command line tool.

See [MyISAM Storage Formats](#) for more information.

### Supported Aria Row Formats

For [Aria](#), the supported row formats are:

- PAGE
- FIXED
- DYNAMIC

See [Aria Storage Formats](#) for more information.

### Supported InnoDB Row Formats

For [InnoDB](#), the supported row formats are:

- COMPACT
- REDUNDANT

- COMPRESSED
- DYNAMIC

If the

`ROW_FORMAT`

table option is set to

`FIXED`

for an InnoDB table, then the server will either return an error or a warning depending on the value of the `innodb_strict_mode` system variable. If the `innodb_strict_mode` system variable is set to

`OFF`

, then a warning is issued, and MariaDB will create the table using the default row format for the specific MariaDB server version. If the `innodb_strict_mode` system variable is set to

`ON`

, then an error will be raised.

See [InnoDB Storage Formats](#) for more information.

## Other Storage Engines and ROW\_FORMAT

Other storage engines do not support the

`ROW_FORMAT`

table option.

## SEQUENCE

MariaDB starting with [10.3](#)

If the table is a `sequence`, then it will have the

`SEQUENCE`

set to

`1`

## STATS\_AUTO\_RECALC

`STATS_AUTO_RECALC`

indicates whether to automatically recalculate persistent statistics (see

`STATS_PERSISTENT`

, below) for an InnoDB table. If set to

`1`

, statistics will be recalculated when more than 10% of the data has changed. When set to

`0`

, stats will be recalculated only when an `ANALYZE TABLE` is run. If set to

`DEFAULT`

, or left out, the value set by the `innodb_stats_auto_recalc` system variable applies. See [InnoDB Persistent Statistics](#).

## STATS\_PERSISTENT

`STATS_PERSISTENT`

indicates whether the InnoDB statistics created by `ANALYZE TABLE` will remain on disk or not. It can be set to

`1`

(on disk),

`0`

(not on disk, the pre-MariaDB 10 behavior), or

`DEFAULT`

(the same as leaving out the option), in which case the value set by the `innodb_stats_persistent` system variable will apply. Persistent statistics stored on disk allow the statistics to survive server restarts, and provide better query plan stability. See [InnoDB Persistent Statistics](#).

## STATS\_SAMPLE\_PAGES

`STATS_SAMPLE_PAGES`

indicates how many pages are used to sample index statistics. If 0 or DEFAULT, the default value, the `innodb_stats_sample_pages` value is used. See [InnoDB Persistent Statistics](#).

## TRANSACTIONAL

TRANSACTIONAL

is only applicable for Aria tables. In future Aria tables created with this option will be fully transactional, but currently this provides a form of crash protection. See [Aria Storage Engine](#) for more details.

## UNION

UNION

must be specified when you create a MERGE table. This option contains a comma-separated list of MyISAM tables which are accessed by the new table. The list is enclosed between parenthesis. Example:

```
UNION = (t1,t2)
```

## WITH SYSTEM VERSIONING

WITH SYSTEM VERSIONING

is used for creating [System-versioned tables](#).

## Partitions

```
partition_options:  
  PARTITION BY  
    { [LINEAR] HASH(expr)  
    | [LINEAR] KEY(column_list)  
    | RANGE(expr)  
    | LIST(expr)  
    | SYSTEM_TIME [INTERVAL time_quantity time_unit] [LIMIT num] }  
  [PARTITIONS num]  
  [SUBPARTITION BY  
    { [LINEAR] HASH(expr)  
    | [LINEAR] KEY(column_list) }  
    [SUBPARTITIONS num]  
  ]  
  [(partition_definition [, partition_definition] ...)]  
  
partition_definition:  
  PARTITION partition_name  
    [VALUES {LESS THAN {(expr) | MAXVALUE} | IN (value_list)}]  
    [[STORAGE] ENGINE [=] engine_name]  
    [COMMENT [=] 'comment_text']  
    [DATA DIRECTORY [=] 'data_dir']  
    [INDEX DIRECTORY [=] 'index_dir']  
    [MAX_ROWS [=] max_number_of_rows]  
    [MIN_ROWS [=] min_number_of_rows]  
    [TABLESPACE [=] tablespace_name]  
    [NODEGROUP [=] node_group_id]  
    [(subpartition_definition [, subpartition_definition] ...)]  
  
subpartition_definition:  
  SUBPARTITION logical_name  
    [[STORAGE] ENGINE [=] engine_name]  
    [COMMENT [=] 'comment_text']  
    [DATA DIRECTORY [=] 'data_dir']  
    [INDEX DIRECTORY [=] 'index_dir']  
    [MAX_ROWS [=] max_number_of_rows]  
    [MIN_ROWS [=] min_number_of_rows]  
    [TABLESPACE [=] tablespace_name]  
    [NODEGROUP [=] node_group_id]
```

If the

PARTITION BY

clause is used, the table will be [partitioned](#). A partition method must be explicitly indicated for partitions and subpartitions. Partition methods are:

- [LINEAR] HASH  
creates a hash key which will be used to read and write rows. The partition function can be any valid SQL expression which returns an INTEGER  
number. Thus, it is possible to use the HASH  
method on an integer column, or on functions which accept integer columns as an argument. However, VALUES LESS THAN  
and  
VALUES IN  
clauses can not be used with HASH  
. An example:

```
CREATE TABLE t1 (a INT, b CHAR(5), c DATETIME)
PARTITION BY HASH ( YEAR(c) );
```

[LINEAR] HASH  
can be used for subpartitions, too.

- [LINEAR] KEY  
is similar to  
HASH  
, but the index has an even distribution of data. Also, the expression can only be a column or a list of columns.  
VALUES LESS THAN  
and  
VALUES IN  
clauses can not be used with  
KEY

- RANGE partitions the rows using on a range of values, using the  
VALUES LESS THAN  
operator.  
VALUES IN  
is not allowed with  
RANGE  
. The partition function can be any valid SQL expression which returns a single value.
- LIST assigns partitions based on a table's column with a restricted set of possible values. It is similar to  
RANGE  
, but  
VALUES IN  
must be used for at least 1 columns, and  
VALUES LESS THAN  
is disallowed.

- SYSTEM\_TIME  
partitioning is used for [System-versioned tables](#) to store historical data separately from current data.

Only

HASH  
and  
KEY  
can be used for subpartitions, and they can be  
[LINEAR]

It is possible to define up to 1024 partitions and subpartitions.

The number of defined partitions can be optionally specified as

PARTITION count  
. This can be done to avoid specifying all partitions individually. But you can also declare each individual partition and, additionally, specify a PARTITIONS count  
clause; in the case, the number of PARTITION  
s must equal count.

Also see [Partitioning Types Overview](#).

## Sequences

MariaDB starting with [10.3](#)

```
CREATE TABLE  
can also be used to create a SEQUENCE . See CREATE SEQUENCE and Sequence Overview .
```

## Atomic DDL

MariaDB starting with [10.6.1](#)

[MariaDB 10.6.1](#) supports [Atomic DDL](#) .

```
CREATE TABLE  
is atomic, except for  
CREATE OR REPLACE  
, which is only crash safe.
```

## Examples

```
create table if not exists test (  
a bigint auto_increment primary key,  
name varchar(128) charset utf8,  
key name (name(32))  
) engine=InnoDB default charset latin1;
```

This example shows a couple of things:

- Usage of
  - IF NOT EXISTS
    - ; If the table already existed, it will not be created. There will not be any error for the client, just a warning.
- How to create a
  - PRIMARY KEY
    - that is [automatically generated](#) .
- How to specify a table-specific [character set](#) and another for a column.
- How to create an index (
  - name
    - ) that is only partly indexed (to save space).

The following clauses will work from [MariaDB 10.2.1](#) only.

```
CREATE TABLE t1(  
a int DEFAULT (1+1),  
b int DEFAULT (a+1),  
expires DATETIME DEFAULT(NOW() + INTERVAL 1 YEAR),  
x BLOB DEFAULT USER()  
);
```

## 1.1.2.1.8 DELETE

## Contents

1. [Syntax](#)
2. [Description](#)
  1. [PARTITION](#)
  2. [FOR PORTION OF](#)
  3. [RETURNING](#)
  4. [Same Source and Target Table](#)
  5. [DELETE HISTORY](#)
3. [Examples](#)
  1. [Deleting from the Same Source and Target](#)
  4. [See Also](#)

## Syntax

Single-table syntax:

```
DELETE [LOW_PRIORITY] [QUICK] [IGNORE]
  FROM tbl_name [PARTITION (partition_list)]
  [FOR PORTION OF period FROM expr1 TO expr2]
  [WHERE where_condition]
  [ORDER BY ...]
  [LIMIT row_count]
  [RETURNING select_expr
   [, select_expr ...]]
```

Multiple-table syntax:

```
DELETE [LOW_PRIORITY] [QUICK] [IGNORE]
  tbl_name[.*] [, tbl_name[.*]] ...
  FROM table_references
  [WHERE where_condition]
```

Or:

```
DELETE [LOW_PRIORITY] [QUICK] [IGNORE]
  FROM tbl_name[.*] [, tbl_name[.*]] ...
  USING table_references
  [WHERE where_condition]
```

Trimming history:

```
DELETE HISTORY
  FROM tbl_name [PARTITION (partition_list)]
  [BEFORE SYSTEM_TIME [TIMESTAMP|TRANSACTION] expression]
```

## Description

Option	Description
LOW_PRIORITY	Wait until all SELECT's are done before starting the statement. Used with storage engines that uses table locking (MyISAM, Aria etc). See <a href="#">HIGH_PRIORITY and LOW_PRIORITY clauses</a> for details.
QUICK	Signal the storage engine that it should expect that a lot of rows are deleted. The storage engine can do things to speed up the DELETE like ignoring merging of data blocks until all rows are deleted from the block (instead of when a block is half full). This speeds up things at the expense of lost space in data blocks. At least <a href="#">MyISAM</a> and <a href="#">Aria</a> support this feature.
IGNORE	Don't stop the query even if a not-critical error occurs (like data overflow). See <a href="#">How IGNORE works</a> for a full description.

For the single-table syntax, the

```
DELETE
  statement deletes rows from tbl_name and returns a count of the number of deleted rows. This count can be obtained by calling the
ROW_COUNT() function. The
  WHERE
  clause, if given, specifies the conditions that identify which rows to delete. With no
  WHERE
  clause, all rows are deleted. If the ORDER BY clause is specified, the rows are deleted in the order that is specified. The LIMIT clause places a
  limit on the number of rows that can be deleted.
```

For the multiple-table syntax,

```
DELETE
```

deletes from each  
tbl\_name  
the rows that satisfy the conditions. In this case, [ORDER BY](#) and [LIMIT](#) > cannot be used. A  
[DELETE](#)  
can also reference tables which are located in different databases; see [Identifier Qualifiers](#) for the syntax.

where\_condition  
is an expression that evaluates to true for each row to be deleted. It is specified as described in [SELECT](#).

Currently, you cannot delete from a table and select from the same table in a subquery.

You need the

[DELETE](#)  
privilege on a table to delete rows from it. You need only the  
[SELECT](#)  
privilege for any columns that are only read, such as those named in the  
[WHERE](#)  
clause. See [GRANT](#).

As stated, a

[DELETE](#)  
statement with no  
[WHERE](#)  
clause deletes all rows. A faster way to do this, when you do not need to know the number of deleted rows, is to use  
[TRUNCATE TABLE](#)  
. However, within a transaction or if you have a lock on the table,  
[TRUNCATE TABLE](#)  
cannot be used whereas

[DELETE](#)

can. See

[TRUNCATE TABLE](#)

, and

[LOCK](#)

## PARTITION

See [Partition Pruning and Selection](#) for details.

## FOR PORTION OF

MariaDB starting with [10.4.3](#)

See [Application Time Periods - Deletion by Portion](#).

## RETURNING

It is possible to return a resultset of the deleted rows for a single table to the client by using the syntax

`DELETE ... RETURNING select_expr [, select_expr2 ...]`

Any of SQL expression that can be calculated from a single row fields is allowed. Subqueries are allowed. The AS keyword is allowed, so it is possible to use aliases.

The use of aggregate functions is not allowed. RETURNING cannot be used in multi-table DELETEs.

MariaDB starting with [10.3.1](#)

## Same Source and Target Table

Until [MariaDB 10.3.1](#), deleting from a table with the same source and target was not possible. From [MariaDB 10.3.1](#), this is now possible. For example:

```
DELETE FROM t1 WHERE c1 IN (SELECT b.c1 FROM t1 b WHERE b.c2=0);
```

MariaDB starting with 10.3.4

## DELETE HISTORY

One can use

```
DELETE HISTORY  
to delete historical information from System-versioned tables .
```

## Examples

How to use the ORDER BY and LIMIT clauses:

```
DELETE FROM page_hit ORDER BY timestamp LIMIT 1000000;
```

How to use the RETURNING clause:

```
DELETE FROM t RETURNING f1;  
+-----+  
| f1 |  
+-----+  
| 5 |  
| 50 |  
| 500 |  
+-----+
```

The following statement joins two tables: one is only used to satisfy a WHERE condition, but no row is deleted from it; rows from the other table are deleted, instead.

```
DELETE post FROM blog INNER JOIN post WHERE blog.id = post.blog_id;
```

## Deleting from the Same Source and Target

```
CREATE TABLE t1 (c1 INT, c2 INT);  
DELETE FROM t1 WHERE c1 IN (SELECT b.c1 FROM t1 b WHERE b.c2=0);
```

Until MariaDB 10.3.1 , this returned:

```
ERROR 1093 (HY000): Table 't1' is specified twice, both as a target for 'DELETE'  
and as a separate source for
```

From MariaDB 10.3.1 :

```
Query OK, 0 rows affected (0.00 sec)
```

## 1.1.2.1.9 DROP TABLE

### Syntax

```
DROP [TEMPORARY] TABLE [IF EXISTS] /*COMMENT TO SAVE*/  
tbl_name [, tbl_name] ...  
[WAIT n|NOWAIT]  
[RESTRICT | CASCADE]
```

## Contents

1. [Syntax](#)
2. [Description](#)
  1. [WAIT/NOWAIT](#)
3. [DROP TABLE in replication](#)
4. [Dropping an Internal #sql... Table](#)
5. [Dropping All Tables in a Database](#)
6. [Atomic DROP TABLE](#)
7. [Examples](#)
8. [Notes](#)
9. [See Also](#)

## Description

DROP TABLE

removes one or more tables. You must have the

DROP

privilege for each table. All table data and the table definition are removed, as well as [triggers](#) associated to the table, so be careful with this statement! If any of the tables named in the argument list do not exist, MariaDB returns an error indicating by name which non-existing tables it was unable to drop, but it also drops all of the tables in the list that do exist.

**Important** : When a table is dropped, user privileges on the table are not automatically dropped. See [GRANT](#).

If another thread is using the table in an explicit transaction or an autocommit transaction, then the thread acquires a [metadata lock \(MDL\)](#) on the table. The

DROP TABLE

statement will wait in the "Waiting for table metadata lock" [thread state](#) until the MDL is released. MDLs are released in the following cases:

- If an MDL is acquired in an explicit transaction, then the MDL will be released when the transaction ends.
- If an MDL is acquired in an autocommit transaction, then the MDL will be released when the statement ends.
- Transactional and non-transactional tables are handled the same.

Note that for a partitioned table,

DROP TABLE

permanently removes the table definition, all of its partitions, and all of the data which was stored in those partitions. It also removes the partitioning definition (.par) file associated with the dropped table.

For each referenced table,

DROP TABLE

drops a temporary table with that name, if it exists. If it does not exist, and the

TEMPORARY

keyword is not used, it drops a non-temporary table with the same name, if it exists. The

TEMPORARY

keyword ensures that a non-temporary table will not accidentally be dropped.

Use

IF EXISTS

to prevent an error from occurring for tables that do not exist. A

NOTE

is generated for each non-existent table when using

IF EXISTS

. See [SHOW WARNINGS](#).

If a [foreign key](#) references this table, the table cannot be dropped. In this case, it is necessary to drop the foreign key first.

RESTRICT

and

CASCADE

are allowed to make porting from other database systems easier. In MariaDB, they do nothing.

The comment before the table names (

/\*COMMENT TO SAVE\*/

) is stored in the [binary log](#). That feature can be used by replication tools to send their internal messages.

It is possible to specify table names as

db\_name

.

tab\_name

. This is useful to delete tables from multiple databases with one statement. See [Identifier Qualifiers](#) for details.

The [DROP privilege](#) is required to use

DROP TABLE

on non-temporary tables. For temporary tables, no privilege is required, because such tables are only visible for the current session.

#### Note:

```
DROP TABLE  
automatically commits the current active transaction, unless you use the  
TEMPORARY  
keyword.
```

MariaDB starting with 10.5.4

From MariaDB 10.5.4 ,

```
DROP TABLE  
reliably deletes table remnants inside a storage engine even if the  
.frm  
file is missing. Before then, a missing  
.frm  
file would result in the statement failing.
```

MariaDB starting with 10.3.1

## WAIT/NOWAIT

Set the lock wait timeout. See [WAIT and NOWAIT](#) .

## DROP TABLE in replication

DROP TABLE  
has the following characteristics in [replication](#) :

- DROP TABLE IF EXISTS  
are always logged.
- DROP TABLE  
without  
IF EXISTS  
for tables that don't exist are not written to the [binary log](#) .
- Dropping of  
TEMPORARY  
tables are prefixed in the log with  
TEMPORARY  
. These drops are only logged when running [statement](#) or [mixed mode](#) replication.
- One  
DROP TABLE  
statement can be logged with up to 3 different  
DROP  
statements:
  - DROP TEMPORARY TABLE list\_of\_non\_transactional\_temporary\_tables
  - DROP TEMPORARY TABLE list\_of\_transactional\_temporary\_tables
  - DROP TABLE list\_of\_normal\_tables

DROP TABLE  
on the primary is treated on the replica as  
DROP TABLE IF EXISTS  
. You can change that by setting [slave-ddl-exec-mode](#) to  
STRICT

## Dropping an Internal #sql-... Table

From MariaDB 10.6 , [DROP TABLE](#) is [atomic](#) and the following does not apply. Until MariaDB 10.5 , if the [mariadb/mysqld process](#) is killed during an [ALTER TABLE](#) you may find a table named #sql... in your data directory. In MariaDB 10.3 , InnoDB tables with this prefix will be deleted automatically during startup. From MariaDB 10.4 , these temporary tables will always be deleted automatically.

If you want to delete one of these tables explicitly you can do so by using the following syntax:

```
DROP TABLE `#mysql150##sql-...`;
```

When running an

```
ALTER TABLE..ALGORITHM=INPLACE  
that rebuilds the table, InnoDB will create an internal  
#sql-ib  
table. Until MariaDB 10.3.2 , for these tables, the  
.frm  
file will be called something else. In order to drop such a table after a server crash, you must rename the  
#sql*.frm  
file to match the  
#sql-ib*.ibd  
file.
```

From MariaDB 10.3.3 , the same name as the .frm file is used for the intermediate copy of the table. The #sql-ib names are used by TRUNCATE and delayed DROP.

From MariaDB 10.2.19 and MariaDB 10.3.10 , the #sql-ib tables will be deleted automatically.

## Dropping All Tables in a Database

The best way to drop all tables in a database is by executing

```
DROP DATABASE
```

, which will drop the database itself, and all tables in it.

However, if you want to drop all tables in the database, but you also want to keep the database itself and any other non-table objects in it, then you would need to execute

```
DROP TABLE  
to drop each individual table. You can construct these  
DROP TABLE  
commands by querying the
```

```
TABLES
```

table in the

```
information_schema
```

database. For example:

```
SELECT CONCAT('DROP TABLE IF EXISTS `', TABLE_SCHEMA, '`.', TABLE_NAME, '`;')  
FROM information_schema.TABLES  
WHERE TABLE_SCHEMA = 'mydb';
```

## Atomic DROP TABLE

MariaDB starting with 10.6.1

From MariaDB 10.6 ,

```
DROP TABLE  
for a single table is atomic ( MDEV-25180 ) for most engines, including InnoDB, MyRocks, MyISAM and Aria.
```

This means that if there is a crash (server down or power outage) during

```
DROP TABLE  
, all tables that have been processed so far will be completely dropped, including related trigger files and status entries, and the binary log will include a
```

```
DROP TABLE  
statement for the dropped tables. Tables for which the drop had not started will be left intact.
```

In older MariaDB versions, there was a small chance that, during a server crash happening in the middle of

```
DROP TABLE  
, some storage engines that were using multiple storage files, like MyISAM , could have only a part of its internal files dropped.
```

In MariaDB 10.5 ,

```
DROP TABLE  
was extended to be able to delete a table that was only partly dropped ( MDEV-11412 ) as explained above. Atomic  
DROP TABLE  
is the final piece to make
```

```
DROP TABLE  
    fully reliable.  
  
Dropping multiple tables is crash-safe.  
See Atomic DDL for more information.
```

## Examples

```
DROP TABLE Employees, Customers;
```

## Notes

Beware that

```
DROP TABLE  
can drop both tables and sequences. This is mainly done to allow old tools like mysqldump to work with sequences.
```

## See Also

- Variable [slave-ddl-exec-mode](#).

## 1.1.2.1.10 Installing System Tables (`mysql_install_db`)

`mysql_install_db`  
initializes the MariaDB data directory and creates the [system tables](#) in the

`mysql`

database, if they do not exist. MariaDB uses these tables to manage [privileges](#), [roles](#), and [plugins](#). It also uses them to provide the data for the

`help`

command in the

`mysql`

client.

`mysql_install_db`

works by starting MariaDB Server's  
`mysqld`  
process in

`--bootstrap`

mode and sending commands to create the [system tables](#) and their content.

There is a version specifically for Windows,

`mysql_install_db.exe`

To invoke

`mysql_install_db`  
, use the following syntax:

```
mysql_install_db --user=mysql
```

For the options supported by

`mysql_install_db`

, see [mysql\\_install\\_db: Options](#) .

For the option groups read by

`mysql_install_db`

, see [mysql\\_install\\_db: Option Groups](#) .

See [mysql\\_install\\_db: Installing System Tables](#) for information on the installation process.

See [mysql\\_install\\_db: Troubleshooting Issues](#) for information on how to troubleshoot the installation process.

## See also:

- [mysql\\_install\\_db](#)
- The Windows version of  
`mysql_install_db`  
:

`mysql_install_db.exe`

## 1.1.2.1.11 mysqlcheck

MariaDB starting with 10.4.6

From [MariaDB 10.4.6](#),

`mariadb-check`  
is a symlink to  
`mysqlcheck`

.

MariaDB starting with 10.5.2

From [MariaDB 10.5.2](#),

`mariadb-check`  
is the name of the tool, with  
`mysqlcheck`  
a symlink .

### Contents

1. [Using mysqlcheck](#)
  1. [Options](#)
  2. [Option Files](#)
    1. [Option Groups](#)
2. [Notes](#)
  1. [Default Values](#)
  2. [mysqlcheck and auto-repair](#)
  3. [mysqlcheck and all-databases](#)
  4. [mysqlcheck and verbose](#)

`mysqlcheck`

is a maintenance tool that allows you to check, repair, analyze and optimize multiple tables from the command line.

It is essentially a commandline interface to the [CHECK TABLE](#) , [REPAIR TABLE](#) , [ANALYZE TABLE](#) and [OPTIMIZE TABLE](#) commands, and so, unlike [myisamchk](#) and [aria\\_chk](#) , requires the server to be running.

This tool does not work with partitioned tables.

## Using mysqlcheck

```
./client/mysqlcheck [OPTIONS] database [tables]
```

OR

```
./client/mysqlcheck [OPTIONS] --databases DB1 [DB2 DB3...]
```

OR

```
./client/mysqlcheck [OPTIONS] --all-databases
```

#### mysqlcheck

can be used to CHECK (-c, -m, -C), REPAIR (-r), ANALYZE (-a), or OPTIMIZE (-o) tables. Some of the options (like -e or -q) can be used at the same time. Not all options are supported by all storage engines.

The -c, -r, -a and -o options are exclusive to each other.

The option

--check

will be used by default, if no other options were specified. You can change the default behavior by making a symbolic link to the binary, or copying it somewhere with another name, the alternatives are:

mysqlrepair	The default option will be -r ( --repair )
mysqlanalyze	The default option will be -a ( --analyze )
mysqloptimize	The default option will be -o ( --optimize )

## Options

#### mysqlcheck

supports the following options:

Option	Description
-A ,-- all-databases	Check all the databases. This is the same as --databases with all databases selected.
-1 ,-- all-in-1	Instead of issuing one query for each table, use one query per database, naming all tables in the database in a comma-separated list.
-a ,-- analyze	Analyze given tables.
-- auto-repair	If a checked table is corrupted, automatically fix it. Repairing will be done after all tables have been checked.

--character-sets-dir=name	Directory where <b>character set</b> files are installed.
-c , --check	Check table for errors.
-C , --check-only-changed	Check only tables that have changed since last check or haven't been closed properly.
-g , --check-upgrade	Check tables for version-dependent changes. May be used with --auto-repair to correct tables requiring version-dependent updates. Automatically enables the --fix-db-names and --fix-table-names options. Used <a href="#">when upgrading</a>
--compress	Compress all information sent between the client and server if both support compression.
-B , --databases	Check several databases. Note that normally <i>mysqlcheck</i> treats the first argument as a database name, and following arguments as table names. With this option, no tables are given, and all name arguments are regarded as database names.
-# , --debug[=name]	Output debug log. Often this is 'd:t:o,filename'.
--debug-check	Check memory and open file usage at exit.
--debug-info	Print some debug info at exit.
--default-auth=plugin	Default authentication client-side plugin to use.
--default-character-set=name	Set the default <b>character set</b> .

	<code>-e</code> , <code>--</code>	If you are using this option with <code>--check</code> , it will ensure that the table is 100 percent consistent, but will take a long time. If you are using this option with <code>--repair</code> , it will force using the old, slow, repair with keycache method, instead of the much faster repair by sorting.
	<code>-F</code> , <code>--</code>	Check only tables that haven't been closed properly.
	<code>--fix-db-names</code>	Convert database names to the format used since MySQL 5.1. Only database names that contain special characters are affected. Used <a href="#">when upgrading</a> from an old MySQL version.
	<code>--fix-table-names</code>	Convert table names (including <a href="#">views</a> ) to the format used since MySQL 5.1. Only table names that contain special characters are affected. Used <a href="#">when upgrading</a> from an old MySQL version.
	<code>--flush</code>	Flush each table after check. This is useful if you don't want to have the checked tables take up space in the caches after the check.
	<code>-f</code> , <code>--</code>	Continue even if we get an SQL error.
	<code>-?</code> , <code>--</code>	Display this help message and exit.
	<code>-h</code> , <code>--host=name</code>	Connect to the given host.
	<code>-m</code> , <code>--</code>	Faster than extended-check, but only finds 99.99 percent of all errors. Should be good enough for most cases.
	<code>-o</code> , <code>--</code>	Optimize tables.
	<code>-p</code> , <code>--password[=name]</code>	Password to use when connecting to the server. If you use the short option form ( <code>-p</code> ), you cannot have a space between the option and the password. If you omit the password value following the <code>--password</code> or <code>-p</code> option on the command line, mysqlcheck prompts for one. Specifying a password on the command line should be considered insecure. You can use an option file to avoid giving the password on the command line.

	<b>-z</b> ,--	When using ANALYZE TABLE ( --analyze ), uses the PERSISTENT FOR ALL option, which forces <a href="#">Engine-independent Statistics</a> for this table to be updated. Added in <a href="#">MariaDB 10.1.10</a>
	<b>-W</b> ,--	On Windows, connect to the server via a named pipe. This option applies only if the server supports named-pipe connections.
	<b>--plugin-dir</b>	Directory for client-side plugins.
<b>num</b>  <b>port=num</b>	<b>-P</b> ,--	Port number to use for connection or 0 for default to, in order of preference, my.cnf, \$MYSQL_TCP_PORT, /etc/services, built-in default (3306).
	<b>--process-tables</b>	Perform the requested operation (check, repair, analyze, optimize) on tables. Enabled by default. Use --skip-process-tables to disable.
<b>process-views[=val]</b>	<b>--</b>	Perform the requested operation (only <a href="#">CHECK VIEW</a> or <a href="#">REPAIR VIEW</a> ). Possible values are NO, YES (correct the checksum, if necessary, add the mariadb-version field), UPGRADE_FROM_MYSQL (same as YES and toggle the algorithm MERGE->TEMPTABLE).
	<b>--protocol=name</b>	The connection protocol (tcp, socket, pipe, memory) to use for connecting to the server. Useful when other connection parameters would cause a protocol to be used other than the one you want.
<b>quick</b>	<b>-q</b> ,--	If you are using this option with CHECK TABLE, it prevents the check from scanning the rows to check for wrong links. This is the fastest check. If you are using this option with REPAIR TABLE, it will try to repair only the index tree. This is the fastest repair method for a table.
<b>repair</b>	<b>-r</b> ,--	Can fix almost anything except unique keys that aren't unique.
<b>shared-memory-base-name</b>	<b>--</b>	Shared-memory name to use for Windows connections using shared memory to a local server (started with the --shared-memory option). Case-sensitive.
<b>silent</b>	<b>-s</b> ,--	Print only error messages.
<b>--skip-database</b>	<b>--</b>	Don't process the database (case-sensitive) specified as argument.

name -S , --socket=name	For connections to localhost, the Unix socket file to use, or, on Windows, the name of the named pipe to use.
ssl --ssl	Enables <a href="#">TLS</a> . TLS is also enabled even without setting this option when certain other TLS options are set. Starting with <a href="#">MariaDB 10.2</a> , the <code>--ssl</code> option will not enable <a href="#">verifying the server certificate</a> by default. In order to verify the server certificate, the user must specify the <code>--ssl-verify-server-cert</code> option.
ssl-ca=name --ssl-ca=name	Defines a path to a PEM file that should contain one or more X509 certificates for trusted Certificate Authorities (CAs) to use for <a href="#">TLS</a> . This option requires that you use the absolute path, not a relative path. See <a href="#">Secure Connections Overview: Certificate Authorities (CAs)</a> for more information. This option implies the <code>--ssl</code> option.
ssl-capath=name --ssl-capath=name	Defines a path to a directory that contains one or more PEM files that should each contain one X509 certificate for a trusted Certificate Authority (CA) to use for <a href="#">TLS</a> . This option requires that you use the absolute path, not a relative path. The directory specified by this option needs to be run through the <code>openssl rehash</code> command. See <a href="#">Secure Connections Overview: Certificate Authorities (CAs)</a> for more information. This option is only supported if the client was built with OpenSSL or yaSSL. If the client was built with GnuTLS or Schannel, then this option is not supported. See <a href="#">TLS and Cryptography Libraries Used by MariaDB</a> for more information about which libraries are used on which platforms. This option implies the <code>--ssl</code> option.
ssl-cert=name --ssl-cert=name	Defines a path to the X509 certificate file to use for <a href="#">TLS</a> . This option requires that you use the absolute path, not a relative path. This option implies the <code>--ssl</code> option.
ssl-cipher=name --ssl-cipher=name	List of permitted ciphers or cipher suites to use for <a href="#">TLS</a> . This option implies the <code>--ssl</code> option.
ssl-crl=name --ssl-crl=name	Defines a path to a PEM file that should contain one or more revoked X509 certificates to use for <a href="#">TLS</a> . This option requires that you use the absolute path, not a relative path. See <a href="#">Secure Connections Overview: Certificate Revocation Lists (CRLs)</a> for more information. This option is only supported if the client was built with OpenSSL or Schannel. If the client was built with yaSSL or GnuTLS, then this option is not supported. See <a href="#">TLS and Cryptography Libraries Used by MariaDB</a> for more information about which libraries are used on which platforms.
ssl-crlpath=name --ssl-crlpath=name	Defines a path to a directory that contains one or more PEM files that should each contain one revoked X509 certificate to use for <a href="#">TLS</a> . This option requires that you use the absolute path, not a relative path. The directory specified by this option needs to be run through the <code>openssl rehash</code> command. See <a href="#">Secure Connections Overview: Certificate Revocation Lists (CRLs)</a> for more information. This option is only supported if the client was built with OpenSSL. If the client was built with yaSSL, GnuTLS, or Schannel, then this option is not supported. See <a href="#">TLS and Cryptography Libraries Used by MariaDB</a> for more information about which libraries are used on which platforms.
ssl-key=name --ssl-key=name	Defines a path to a private key file to use for <a href="#">TLS</a> . This option requires that you use the absolute path, not a relative path. This option implies the <code>--ssl</code> option.
ssl-verify-server-cert --ssl-verify-server-cert	Enables <a href="#">server certificate verification</a> . This option is disabled by default.

tables	--	Overrides the --databases or -B option such that all name arguments following the option are regarded as table names.
usefrm	--	For repair operations on MyISAM tables, get table structure from .frm file, so the table can be repaired even if the .MYI header is corrupted.
username	-u ,	User for login if not current user.
verbose	-v ,	Print info about the various stages. You can give this option several times to get even more information. See <a href="#">mysqlcheck and verbose</a> , below.
version	-V ,	Output version information and exit.
write-binlog	--	Write ANALYZE, OPTIMIZE and REPAIR TABLE commands to the <a href="#">binary log</a> . Enabled by default; use --skip-write-binlog when commands should not be sent to replication slaves.

## Option Files

In addition to reading options from the command-line,

```
mysqlcheck
can also read options from option files. If an unknown option is provided to
mysqlcheck
in an option file, then it is ignored.
```

The following options relate to how MariaDB command-line tools handles option files. They must be given as the first argument on the command-line:

Option	Description
--print-defaults	Print the program argument list and exit.
--no-defaults	Don't read default options from any option file.
--defaults-file=#	Only read default options from the given file #.
--defaults-extra-file=#	Read this file after the global files are read.
--defaults-group-suffix=#	In addition to the default option groups, also read option groups with this suffix.

In [MariaDB 10.2](#) and later,

```
mysqlcheck
is linked with MariaDB Connector/C. However, MariaDB Connector/C does not yet handle the parsing of option files for this client. That is still
performed by the server option file parsing code. See MDEV-19035 for more information.
```

## Option Groups

`mysqlcheck`  
reads options from the following [option groups](#) from [option files](#) :

Group	Description
[mysqlcheck]	Options read by <code>mysqlcheck</code> , which includes both MariaDB Server and MySQL Server.
[mariadb-check]	Options read by <code>mysqlcheck</code> . Available starting with <a href="#">MariaDB 10.4.6</a> .
[client]	Options read by all MariaDB and MySQL <a href="#">client programs</a> , which includes both MariaDB and MySQL clients. For example, <code>mysqldump</code>
[client-server]	Options read by all MariaDB <a href="#">client programs</a> and the MariaDB Server. This is useful for options like socket and port, which is common between the server and the clients.
[client-mariadb]	Options read by all MariaDB <a href="#">client programs</a> .

## Notes

### Default Values

To see the default values for the options and also to see the arguments you get from configuration files you can do:

```
./client/mysqlcheck --print-defaults
./client/mysqlcheck --help
```

### mysqlcheck and auto-repair

When running

```
mysqlcheck
with
--auto-repair
(as done by mysql\_upgrade),
mysqlcheck
will first check all tables and then in a separate phase repair those that failed the check.
```

### mysqlcheck and all-databases

```
mysqlcheck --all-databases
will ignore the internal log tables general\_log and slow\_log as these can't be checked, repaired or optimized.
```

### mysqlcheck and verbose

Using one

```
--verbose
option will give you more information about what mysqlcheck is doing.
```

Using two

```
--verbose
options will also give you connection information.
```

If you use three

```
--verbose
options you will also get, on stdout, all ALTER , RENAME , and CHECK commands that mysqlcheck executes.
```

## 1.1.2.1.12 OPTIMIZE TABLE

# Syntax

```
OPTIMIZE [NO_WRITE_TO_BINLOG | LOCAL] TABLE
  tbl_name [, tbl_name] ...
  [WAIT n | NOWAIT]
```

## Contents

1. [Syntax](#)
2. [Description](#)
  1. [WAIT/NOWAIT](#)
  2. [Defragmenting](#)
  3. [Updating an InnoDB fulltext index](#)
  4. [Defragmenting InnoDB tablespaces](#)
3. [See Also](#)

## Description

OPTIMIZE TABLE

has two main functions. It can either be used to defragment tables, or to update the InnoDB fulltext index.

MariaDB starting with [10.3.0](#)

### WAIT/NOWAIT

Set the lock wait timeout. See [WAIT and NOWAIT](#).

## Defragmenting

OPTIMIZE TABLE

works for [InnoDB](#) (before [MariaDB 10.1.1](#), only if the `innodb_file_per_table` server system variable is set), [Aria](#), [MyISAM](#) and [ARCHIVE](#) tables, and should be used if you have deleted a large part of a table or if you have made many changes to a table with variable-length rows (tables that have `VARCHAR`, `VARBINARY`, `BLOB`, or `TEXT` columns). Deleted rows are maintained in a linked list and subsequent

`INSERT`

operations reuse old row positions.

This statement requires [SELECT](#) and [INSERT](#) privileges for the table.

By default,

OPTIMIZE TABLE

statements are written to the [binary log](#) and will be [replicated](#). The

`NO_WRITE_TO_BINLOG`

keyword (

`LOCAL`

is an alias) will ensure the statement is not written to the binary log.

From [MariaDB 10.3.19](#),

OPTIMIZE TABLE

statements are not logged to the binary log if `read_only` is set. See also [Read-Only Replicas](#).

OPTIMIZE TABLE

is also supported for partitioned tables. You can use

[ALTER TABLE](#)

... `OPTIMIZE PARTITION`

to optimize one or more partitions.

You can use

OPTIMIZE TABLE

to reclaim the unused space and to defragment the data file. With other storage engines,

OPTIMIZE TABLE

does nothing by default, and returns this message: "The storage engine for the table doesn't support optimize". However, if the server has been started with the

`--skip-new`

option,

OPTIMIZE TABLE

is linked to [ALTER TABLE](#), and recreates the table. This operation frees the unused space and updates index statistics.

The [Aria](#) storage engine supports [progress reporting](#) for this statement.

If a [MyISAM](#) table is fragmented, [concurrent inserts](#) will not be performed until an

```
OPTIMIZE TABLE  
statement is executed on that table, unless the concurrent\_insert server system variable is set to  
ALWAYS
```

## Updating an InnoDB fulltext index

When rows are added or deleted to an InnoDB [fulltext index](#), the index is not immediately re-organized, as this can be an expensive operation. Change statistics are stored in a separate location. The fulltext index is only fully re-organized when an

```
OPTIMIZE TABLE  
statement is run.
```

By default, an OPTIMIZE TABLE will defragment a table. In order to use it to update fulltext index statistics, the [innodb\\_optimize\\_fulltext\\_only](#) system variable must be set to

```
1  
. This is intended to be a temporary setting, and should be reset to  
0  
once the fulltext index has been re-organized.
```

Since fulltext re-organization can take a long time, the [innodb\\_ft\\_num\\_word\\_optimize](#) variable limits the re-organization to a number of words (2000 by default). You can run multiple OPTIMIZE statements to fully re-organize the index.

## Defragmenting InnoDB tablespaces

[MariaDB 10.1.1](#) merged the Facebook/Kakao defragmentation patch, allowing one to use

```
OPTIMIZE TABLE  
to defragment InnoDB tablespaces. For this functionality to be enabled, the innodb\_defragment system variable must be enabled. No new tables  
are created and there is no need to copy data from old tables to new tables. Instead, this feature loads  
n  
pages (determined by innodb-defragment-n-pages) and tries to move records so that pages would be full of records and then frees pages that  
are fully empty after the operation. Note that tablespace files (including ibdata1) will not shrink as the result of defragmentation, but one will get better  
memory utilization in the InnoDB buffer pool as there are fewer data pages in use.
```

See [Defragmenting InnoDB Tablespaces](#) for more details.

- [Optimize Table in InnoDB with ALGORITHM set to INSTANT](#)

## 1.1.2.1.13 RENAME TABLE

### Syntax

```
RENAME TABLE[S] [IF EXISTS] tbl_name  
[WAIT n | NOWAIT]  
TO new_tbl_name  
[, tbl_name2 TO new_tbl_name2] ...
```

### Contents

1. [Syntax](#)
2. [Description](#)
  1. [IF EXISTS](#)
  2. [WAIT/NOWAIT](#)
  3. [Privileges](#)
  4. [Atomic RENAME TABLE](#)

### Description

This statement renames one or more tables or [views](#), but not the privileges associated with them.

#### IF EXISTS

MariaDB starting with [10.5.2](#)

If this directive is used, one will not get an error if the table to be renamed doesn't exist.

The rename operation is done atomically, which means that no other session can access any of the tables while the rename is running. For example, if you have an existing table

```
old_table  
, you can create another table  
new_table  
that has the same structure but is empty, and then replace the existing table with the empty one as follows (assuming that  
backup_table  
does not already exist):
```

```
CREATE TABLE new_table (...);  
RENAME TABLE old_table TO backup_table, new_table TO old_table;
```

tbl\_name  
can optionally be specified as  
db\_name  
. .  
tbl\_name  
. See [Identifier Qualifiers](#). This allows to use  
RENAME  
to move a table from a database to another (as long as they are on the same filesystem):

```
RENAME TABLE db1.t TO db2.t;
```

Note that moving a table to another database is not possible if it has some [triggers](#). Trying to do so produces the following error:

```
ERROR 1435 (HY000): Trigger in wrong schema
```

Also, views cannot be moved to another database:

```
ERROR 1450 (HY000): Changing schema from 'old_db' to 'new_db' is not allowed.
```

Multiple tables can be renamed in a single statement. The presence or absence of the optional

```
S  
(  
RENAME TABLE  
or  
RENAME TABLES  
) has no impact, whether a single or multiple tables are being renamed.
```

If a

```
RENAME TABLE  
renames more than one table and one renaming fails, all renames executed by the same statement are rolled back.
```

Renames are always executed in the specified order. Knowing this, it is also possible to swap two tables' names:

```
RENAME TABLE t1 TO tmp_table,  
t2 TO t1,  
tmp_table TO t2;
```

## WAIT/NOWAIT

MariaDB starting with [10.3.0](#)

Set the lock wait timeout. See [WAIT](#) and [NOWAIT](#).

## Privileges

Executing the

```
RENAME TABLE  
statement requires the DROP, CREATE and INSERT privileges for the table or the database.
```

## Atomic RENAME TABLE

MariaDB starting with [10.6.1](#)

From MariaDB 10.6 ,  
 RENAME TABLE  
 is atomic for most engines, including InnoDB, MyRocks, MyISAM and Aria ( [MDEV-23842](#) ). This means that if there is a crash (server down or power outage) during  
 RENAME TABLE  
 , all tables will revert to their original names and any changes to trigger files will be reverted.  
 In older MariaDB version there was a small chance that, during a server crash happening in the middle of  
 RENAME TABLE  
 , some tables could have been renamed (in the worst case partly) while others would not be renamed.  
 See [Atomic DDL](#) for more information.

## 1.1.2.1.14 REPAIR TABLE

### Syntax

```
REPAIR [NO_WRITE_TO_BINLOG | LOCAL] TABLE
tbl_name [, tbl_name] ...
[QUICK] [EXTENDED] [USE_FRM]
```

### Description

`REPAIR TABLE`  
 repairs a possibly corrupted table. By default, it has the same effect as

```
myisamchk --recover tbl_name
```

or

```
aria_chk --recover tbl_name
```

See [aria\\_chk](#) and [myisamchk](#) for more.

`REPAIR TABLE`  
 works for [Archive](#) , [Aria](#) , [CSV](#) and [MyISAM](#) tables. For [InnoDB](#) , see [recovery modes](#) . For CSV, see also [Checking and Repairing CSV Tables](#) . For Archive, this statement also improves compression. If the storage engine does not support this statement, a warning is issued.

This statement requires [SELECT](#) and [INSERT](#) privileges for the table.

By default,

```
REPAIR TABLE
statements are written to the binary log and will be replicated . The
NO_WRITE_TO_BINLOG
keyword (
LOCAL
is an alias) will ensure the statement is not written to the binary log.
```

From MariaDB 10.3.19 ,

```
REPAIR TABLE
statements are not logged to the binary log if read\_only is set. See also Read-Only Replicas .
```

When an index is recreated, the storage engine may use a configurable buffer in the process. Incrementing the buffer speeds up the index creation. [Aria](#) and [MyISAM](#) allocate a buffer whose size is defined by

```
aria_sort_buffer_size
```

or

```
myisam_sort_buffer_size
```

, also used for

```
ALTER TABLE
```

```
.
```

```
REPAIR TABLE
```

is also supported for partitioned tables. However, the `USE_FRM` option cannot be used with this statement on a partitioned table.

```
ALTER TABLE ... REPAIR PARTITION
```

can be used to repair one or more partitions.

The [Aria](#) storage engine supports [progress reporting](#) for this statement.

## 1.1.2.1.15 REPAIR VIEW

### Syntax

```
REPAIR [NO_WRITE_TO_BINLOG | LOCAL] VIEW view_name[, view_name] ... [FROM MYSQL]
```

### Contents

1. [Syntax](#)
2. [Description](#)
3. [See Also](#)

### Description

The

```
REPAIR VIEW
```

statement was introduced to assist with fixing [MDEV-6916](#), an issue introduced in [MariaDB 5.2](#) where the view algorithms were swapped compared to their MySQL on disk representation. It checks whether the view algorithm is correct. It is run as part of [mysql\\_upgrade](#), and should not normally be required in regular use.

By default it corrects the checksum and if necessary adds the mariadb-version field. If the optional

```
FROM MYSQL
```

clause is used, and no mariadb-version field is present, the MERGE and TEMPTABLE algorithms are toggled.

By default,

```
REPAIR VIEW  
statements are written to the binary log and will be replicated. The  
NO_WRITE_TO_BINLOG  
keyword (  
LOCAL  
is an alias) will ensure the statement is not written to the binary log.
```

### See Also

- [CHECK VIEW](#)

## 1.1.2.1.16 REPLACE

### Syntax

```
REPLACE [LOW_PRIORITY | DELAYED]  
[INTO] tbl_name [PARTITION (partition_list)] [(col,...)]  
{VALUES | VALUE} ({expr | DEFAULT},...),(...),...  
[RETURNING select_expr  
[, select_expr ...]]
```

Or:

```
REPLACE [LOW_PRIORITY | DELAYED]  
[INTO] tbl_name [PARTITION (partition_list)]  
SET col={expr | DEFAULT}, ...  
[RETURNING select_expr  
[, select_expr ...]]
```

Or:

```
REPLACE [LOW_PRIORITY | DELAYED]
[INTO] tbl_name [PARTITION (partition_list)] [(col,...)]
SELECT ...
[RETURNING select_expr
[, select_expr ...]]
```

## Contents

1. [Syntax](#)
2. [Description](#)
  1. [PARTITION](#)
  2. [REPLACE RETURNING](#)
    1. [Examples](#)
3. [Examples](#)
4. [See Also](#)

## Description

REPLACE  
works exactly like

[INSERT](#)

, except that if an old row in the table has the same value as a new row for a  
PRIMARY KEY  
or a  
UNIQUE  
index, the old row is deleted before the new row is inserted. If the table has more than one  
UNIQUE  
keys, it is possible that the new row conflicts with more than one row. In this case, all conflicting rows will be deleted.

The table name can be specified in the form

db\_name  
.tbl\_name  
or, if a default database is selected, in the form  
tbl\_name  
(see [Identifier Qualifiers](#)). This allows to use

[REPLACE ... SELECT](#)

to copy rows between different databases.

MariaDB starting with [10.5.0](#)

The RETURNING clause was introduced in [MariaDB 10.5.0](#)

Basically it works like this:

```
BEGIN;
SELECT 1 FROM t1 WHERE key=# FOR UPDATE;
IF found-row
  DELETE FROM t1 WHERE key=# ;
ENDIF
INSERT INTO t1 VALUES (...);
END;
```

The above can be replaced with:

```
REPLACE INTO t1 VALUES (...)
```

REPLACE  
is a MariaDB/MySQL extension to the SQL standard. It either inserts, or deletes and inserts. For other MariaDB/MySQL extensions to standard SQL --- that also handle duplicate values --- see [IGNORE](#) and [INSERT ON DUPLICATE KEY UPDATE](#).

Note that unless the table has a

PRIMARY KEY  
or

UNIQUE  
index, using a  
REPLACE  
statement makes no sense. It becomes equivalent to  
INSERT  
, because there is no index to be used to determine whether a new row duplicates another.

Values for all columns are taken from the values specified in the

REPLACE  
statement. Any missing columns are set to their default values, just as happens for  
INSERT  
. You cannot refer to values from the current row and use them in the new row. If you use an assignment such as  
'SET col = col + 1'  
, the reference to the column name on the right hand side is treated as  
DEFAULT(col)  
, so the assignment is equivalent to  
'SET col = DEFAULT(col) + 1'

To use

REPLACE  
, you must have both the  
INSERT  
and  
DELETE  
privileges for the table.

There are some gotchas you should be aware of, before using

REPLACE  
:

- If there is an

[AUTO\\_INCREMENT](#)

field, a new value will be generated.

- If there are foreign keys,

ON DELETE  
action will be activated by  
REPLACE

- Triggers on

DELETE  
and  
INSERT  
will be activated by  
REPLACE

To avoid some of these behaviors, you can use

INSERT ... ON DUPLICATE KEY UPDATE

This statement activates INSERT and DELETE triggers. See [Trigger Overview](#) for details.

## PARTITION

See [Partition Pruning and Selection](#) for details.

## REPLACE RETURNING

REPLACE ... RETURNING  
returns a resultset of the replaced rows.

This returns the listed columns for all the rows that are replaced, or alternatively, the specified SELECT expression. Any SQL expressions which can be calculated can be used in the select expression for the RETURNING clause, including virtual columns and aliases, expressions which use various operators such as bitwise, logical and arithmetic operators, string functions, date-time functions, numeric functions, control flow functions, secondary functions and stored functions. Along with this, statements which have subqueries and prepared statements can also be used.

### Examples

Simple REPLACE statement

```

REPLACE INTO t2 VALUES (1,'Leopard'),(2,'Dog') RETURNING id2, id2+id2
as Total ,id2|id2, id2&&id2;
+-----+-----+-----+
| id2 | Total | id2|id2 | id2&&id2 |
+-----+-----+-----+
|  1 |     2 |     1 |     1 |
|  2 |     4 |     2 |     1 |
+-----+-----+-----+

```

Using stored functions in RETURNING

```

DELIMITER |
CREATE FUNCTION f(arg INT) RETURNS INT
BEGIN
    RETURN (SELECT arg+arg);
END |

DELIMITER ;
PREPARE stmt FROM "REPLACE INTO t2 SET id2=3, animal2='Fox' RETURNING f2(id2),
UPPER(animal2)";

EXECUTE stmt;
+-----+
| f2(id2) | UPPER(animal2) |
+-----+
|      6 | FOX             |
+-----+

```

Subqueries in the statement

```

REPLACE INTO t1 SELECT * FROM t2 RETURNING (SELECT id2 FROM t2 WHERE
id2 IN (SELECT id2 FROM t2 WHERE id2=1)) AS new_id;
+-----+
| new_id |
+-----+
|   1 |
|   1 |
|   1 |
|   1 |
+-----+

```

Subqueries in the RETURNING clause that return more than one row or column cannot be used..

Aggregate functions cannot be used in the RETURNING clause. Since aggregate functions work on a set of values and if the purpose is to get the row count, ROW\_COUNT() with SELECT can be used, or it can be used in REPLACE...SEL== Description

```

REPLACE ... RETURNING
returns a resultset of the replaced rows.

```

This returns the listed columns for all the rows that are replaced, or alternatively, the specified SELECT expression. Any SQL expressions which can be calculated can be used in the select expression for the RETURNING clause, including virtual columns and aliases, expressions which use various operators such as bitwise, logical and arithmetic operators, string functions, date-time functions, numeric functions, control flow functions, secondary functions and stored functions. Along with this, statements which have subqueries and prepared statements can also be used.

## Examples

Simple REPLACE statement

```

REPLACE INTO t2 VALUES (1,'Leopard'),(2,'Dog') RETURNING id2, id2+id2
as Total ,id2|id2, id2&&id2;
+-----+-----+-----+
| id2 | Total | id2|id2 | id2&&id2 |
+-----+-----+-----+
|  1 |     2 |     1 |     1 |
|  2 |     4 |     2 |     1 |
+-----+-----+-----+

```

Using stored functions in RETURNING

```

DELIMITER |
CREATE FUNCTION f(arg INT) RETURNS INT
BEGIN
    RETURN (SELECT arg+arg);
END |

DELIMITER ;
PREPARE stmt FROM "REPLACE INTO t2 SET id2=3, animal2='Fox' RETURNING f2(id2),
UPPER(animal2)";

EXECUTE stmt;
+-----+
| f2(id2) | UPPER(animal2) |
+-----+
|      6   | FOX           |
+-----+

```

Subqueries in the statement

```

REPLACE INTO t1 SELECT * FROM t2 RETURNING (SELECT id2 FROM t2 WHERE
id2 IN (SELECT id2 FROM t2 WHERE id2=1)) AS new_id;
+-----+
| new_id |
+-----+
|      1  |
|      1  |
|      1  |
|      1  |
+-----+

```

Subqueries in the RETURNING clause that return more than one row or column cannot be used..

Aggregate functions cannot be used in the RETURNING clause. Since aggregate functions work on a set of values and if the purpose is to get the row count, ROW\_COUNT() with SELECT can be used, or it can be used in REPLACE...SELECT...RETURNING if the table in the RETURNING clause is not the same as the REPLACE table. ECT...RETURNING if the table in the RETURNING clause is not the same as the REPLACE table.

- [INSERT DELAYED](#) for details on the  
DELAYED  
clause

### 1.1.2.1.17 SHOW COLUMNS

#### Syntax

```

SHOW [FULL] {COLUMNS | FIELDS} FROM tbl_name [FROM db_name]
[LIKE 'pattern' | WHERE expr]

```

#### Contents

1. [Syntax](#)
2. [Description](#)
3. [Examples](#)
4. [See Also](#)

#### Description

SHOW COLUMNS  
 displays information about the columns in a given table. It also works for views. The  
 LIKE  
 clause, if present on its own, indicates which column names to match. The  
 WHERE  
 and  
 LIKE  
 clauses can be given to select rows using more general conditions, as discussed in [Extended SHOW](#).

If the data types differ from what you expect them to be based on a

CREATE TABLE

statement, note that MariaDB sometimes changes data types when you create or alter a table. The conditions under which this occurs are described in the [Silent Column Changes](#) article.

The

FULL

keyword causes the output to include the column collation and comments, as well as the privileges you have for each column.

You can use

db\_name.tbl\_name

as an alternative to the

tbl\_name FROM db\_name

syntax. In other words, these two statements are equivalent:

```
SHOW COLUMNS FROM mytable FROM mydb;
SHOW COLUMNS FROM mydb.mytable;
```

SHOW COLUMNS

displays the following values for each table column:

**Field** indicates the column name.

**Type** indicates the column data type.

**Collation** indicates the collation for non-binary string columns, or NULL for other columns. This value is displayed only if you use the FULL keyword.

The **Null** field contains YES if NULL values can be stored in the column, NO if not.

The **Key** field indicates whether the column is indexed:

- If **Key** is empty, the column either is not indexed or is indexed only as a secondary column in a multiple-column, non-unique index.
- If **Key** is **PRI**, the column is a

PRIMARY KEY

or is one of the columns in a multiple-column

PRIMARY KEY

- If **Key** is **UNI**, the column is the first column of a unique-valued index that cannot contain

NULL

values.

- If **Key** is **MUL**, multiple occurrences of a given value are allowed within the column. The column is the first column of a non-unique index or a unique-valued index that can contain

NULL

values.

If more than one of the **Key** values applies to a given column of a table, **Key** displays the one with the highest priority, in the order PRI, UNI, MUL.

A

UNIQUE

index may be displayed as

PRI

if it cannot contain

NULL

values and there is no

PRIMARY KEY

in the table. A

UNIQUE

index may display as

MUL

if several columns form a composite

UNIQUE

index; although the combination of the columns is unique, each column can still hold multiple occurrences of a given value.

The **Default** field indicates the default value that is assigned to the column.

The **Extra** field contains any additional information that is available about a given column.

Value	Description
AUTO_INCREMENT	The column was created with the AUTO_INCREMENT keyword.
PERSISTENT	The column was created with the PERSISTENT keyword. (New in 5.3)

VIRTUAL	The column was created with the VIRTUAL keyword. (New in 5.3)
on update CURRENT_TIMESTAMP	The column is a TIMESTAMP column that is automatically updated on INSERT and UPDATE.

**Privileges** indicates the privileges you have for the column. This value is displayed only if you use the FULL keyword.

**Comment** indicates any comment the column has. This value is displayed only if you use the FULL keyword.

SHOW FIELDS  
is a synonym for  
SHOW COLUMNS  
. Also

[DESCRIBE](#)

and

[EXPLAIN](#)

can be used as shortcuts.

You can also list a table's columns with:

```
mysqlshow db_name tbl_name
```

See the

[mysqlshow](#)

command for more details.

The

[DESCRIBE](#)

statement provides information similar to  
SHOW COLUMNS  
. The

[information\\_schema.COLUMNS](#)

table provides similar, but more complete, information.

The

[SHOW CREATE TABLE](#)

,

[SHOW TABLE STATUS](#)

, and

[SHOW INDEX](#)

statements also provide information about tables.

## Examples

```
SHOW COLUMNS FROM city;
+-----+-----+-----+-----+
| Field | Type | Null | Key | Default | Extra |
+-----+-----+-----+-----+
| Id | int(11) | NO | PRI | NULL | auto_increment |
| Name | char(35) | NO | | | |
| Country | char(3) | NO | UNI | | |
| District | char(20) | YES | MUL | | |
| Population | int(11) | NO | | 0 | |
+-----+-----+-----+-----+
```

```
SHOW COLUMNS FROM employees WHERE Type LIKE 'Varchar%';
+-----+-----+-----+-----+
| Field | Type | Null | Key | Default | Extra |
+-----+-----+-----+-----+
| first_name | varchar(30) | NO | MUL | NULL | |
| last_name | varchar(40) | NO | | NULL | |
| position | varchar(25) | NO | | NULL | |
| home_address | varchar(50) | NO | | NULL | |
| home_phone | varchar(12) | NO | | NULL | |
| employee_code | varchar(25) | NO | UNI | NULL | |
+-----+-----+-----+-----+
```

## See Also

- [SHOW CREATE TABLE](#)
- [SHOW TABLE STATUS](#)
- [SHOW INDEX](#)
- [Extended SHOW](#)
- [Silent Column Changes](#)

### 1.1.2.1.18 SHOW CREATE TABLE

#### Syntax

```
SHOW CREATE TABLE tbl_name
```

#### Contents

1. [Syntax](#)
2. [Description](#)
3. [Examples](#)
4. [See Also](#)

#### Description

Shows the [CREATE TABLE](#) statement that created the given table. The statement requires the [SELECT](#) privilege for the table. This statement also works with [views](#) and [SEQUENCE](#).

```
SHOW CREATE TABLE
quotes table and column names according to the value of the sql_quote_show_create server system variable.
```

Certain [SQL\\_MODE](#) values can result in parts of the original [CREATE](#) statement not being included in the output. MariaDB-specific table options, column options, and index options are not included in the output of this statement if the [NO\\_TABLE\\_OPTIONS](#), [NO\\_FIELD\\_OPTIONS](#) and [NO\\_KEY\\_OPTIONS](#) [SQL\\_MODE](#) flags are used. All MariaDB-specific table attributes are also not shown when a non-MariaDB/MySQL emulation mode is used, which includes [ANSI](#), [DB2](#), [POSTGRESQL](#), [MSSQL](#), [MAXDB](#) or [ORACLE](#).

Invalid table options, column options and index options are normally commented out (note, that it is possible to create a table with invalid options, by altering a table of a different engine, where these options were valid). To have them uncommented, enable the [IGNORE\\_BAD\\_TABLE\\_OPTIONS](#) [SQL\\_MODE](#). Remember that replaying a [CREATE TABLE](#) statement with uncommented invalid options will fail with an error, unless the [IGNORE\\_BAD\\_TABLE\\_OPTIONS](#) [SQL\\_MODE](#) is in effect.

Note that

```
SHOW CREATE TABLE
is not meant to provide metadata about a table. It provides information about how the table was declared, but the real table structure could differ
```

a bit. For example, if an index has been declared as

```
HASH
, the
CREATE TABLE
statement returned by
SHOW CREATE TABLE
will declare that index as
HASH
; however, it is possible that the index is in fact a
BTREE
, because the storage engine does not support
HASH
```

#### MariaDB starting with 10.2.1

MariaDB 10.2.1 permits TEXT and BLOB data types to be assigned a DEFAULT value. As a result, from MariaDB 10.2.1 ,

```
SHOW CREATE TABLE
will append a
DEFAULT NULL
to nullable TEXT or BLOB fields if no specific default is provided.
```

#### MariaDB starting with 10.2.2

From MariaDB 10.2.2 , numbers are no longer quoted in the

```
DEFAULT
clause in
SHOW CREATE
statement. Previously, MariaDB quoted numbers.
```

## Examples

```
SHOW CREATE TABLE t\G
***** 1. row *****
Table: t
Create Table: CREATE TABLE `t` (
  `id` int(11) NOT NULL AUTO_INCREMENT,
  `s` char(60) DEFAULT NULL,
  PRIMARY KEY (`id`)
) ENGINE=InnoDB DEFAULT CHARSET=latin1
```

With `sql_quote_show_create` off:

```
SHOW CREATE TABLE t\G
***** 1. row *****
Table: t
Create Table: CREATE TABLE t (
  id int(11) NOT NULL AUTO_INCREMENT,
  s char(60) DEFAULT NULL,
  PRIMARY KEY (id)
) ENGINE=InnoDB DEFAULT CHARSET=latin1
```

Unquoted numeric DEFAULTs, from MariaDB 10.2.2 :

```
CREATE TABLE td (link TINYINT DEFAULT 1);

SHOW CREATE TABLE td\G
***** 1. row *****
Table: td
Create Table: CREATE TABLE `td` (
  `link` tinyint(4) DEFAULT 1
) ENGINE=InnoDB DEFAULT CHARSET=latin1
```

Quoted numeric DEFAULTs, until MariaDB 10.2.1 :

```

CREATE TABLE td (link TINYINT DEFAULT 1);

SHOW CREATE TABLE td\G
***** 1. row *****
    Table: td
Create Table: CREATE TABLE `td` (
  `link` tinyint(4) DEFAULT '1'
) ENGINE=InnoDB DEFAULT CHARSET=latin1

```

[SQL\\_MODE](#) impacting the output:

```

SELECT @@sql_mode;
+-----+
| @@sql_mode |
+-----+
| STRICT_TRANS_TABLES,ERROR_FOR_DIVISION_BY_ZERO,NO_AUTO_CREATE_USER,NO_ENGINE_SUBSTITUTION |
+-----+

CREATE TABLE `t1` (
  `id` int(11) NOT NULL AUTO_INCREMENT,
  `msg` varchar(100) DEFAULT NULL,
  PRIMARY KEY (`id`)
) ENGINE=InnoDB DEFAULT CHARSET=latin1
;

SHOW CREATE TABLE t1\G
***** 1. row *****
    Table: t1
Create Table: CREATE TABLE `t1` (
  `id` int(11) NOT NULL AUTO_INCREMENT,
  `msg` varchar(100) DEFAULT NULL,
  PRIMARY KEY (`id`)
) ENGINE=InnoDB DEFAULT CHARSET=latin1

SET SQL_MODE=ORACLE;

SHOW CREATE TABLE t1\G
***** 1. row *****
    Table: t1
Create Table: CREATE TABLE "t1" (
  "id" int(11) NOT NULL,
  "msg" varchar(100) DEFAULT NULL,
  PRIMARY KEY ("id")
)

```

- [SHOW CREATE VIEW](#)

## 1.1.2.1.19 SHOW INDEX

### Syntax

```

SHOW {INDEX | INDEXES | KEYS}
  FROM tbl_name [FROM db_name]
  [WHERE expr]

```

### Contents

1. [Syntax](#)
2. [Description](#)
3. [Examples](#)
4. [See Also](#)

### Description

```

SHOW INDEX
returns table index information. The format resembles that of the SQLStatistics call in ODBC.

```

You can use

db\_name.tbl\_name  
as an alternative to the  
tbl\_name FROM db\_name  
syntax. These two statements are equivalent:

```
SHOW INDEX FROM mytable FROM mydb;
SHOW INDEX FROM mydb.mytable;
```

SHOW KEYS  
and  
SHOW INDEXES  
are synonyms for  
SHOW INDEX

You can also list a table's indexes with the [mariadb-show/mysqlshow](#) command:

```
mysqlshow -k db_name tbl_name
```

The `information_schema.STATISTICS` table stores similar information.

The following fields are returned by

```
SHOW INDEX
```

Field	Description
Table	Table name
Non_unique	1 if the index permits duplicate values, 0 if values must be unique.
Key_name	Index name. The primary key is always named PRIMARY
Seq_in_index	The column's sequence in the index, beginning with 1
Column_name	Column name.
Collation	Either A , if the column is sorted in ascending order in the index, or NULL if it's not sorted.
Cardinality	Estimated number of unique values in the index. The cardinality statistics are calculated at various times, and can help the optimizer make improved decisions.
Sub_part	NULL if the entire column is included in the index, or the number of included characters if not.
Packed	NULL if the index is not packed, otherwise how the index is packed.

Null	<p>NULL if NULL values are permitted in the column, an empty string if NULL 's are not permitted.</p>
Index_type	<p>The index type, which can be</p> <p>BTREE , FULLTEXT , HASH or RTREE . See <a href="#">Storage Engine Index Types</a> .</p>
Comment	Other information, such as whether the index is disabled.
Index_comment	Contents of the COMMENT attribute when the index was created.
Ignored	Whether or not an index will be ignored by the optimizer. See <a href="#">Ignored Indexes</a> . From <a href="#">MariaDB 10.6.0</a> .

The

WHERE  
and  
LIKE

clauses can be given to select rows using more general conditions, as discussed in [Extended SHOW](#) .

## Examples

```

CREATE TABLE IF NOT EXISTS `employees_example` (
`id` int(11) NOT NULL AUTO_INCREMENT,
`first_name` varchar(30) NOT NULL,
`last_name` varchar(40) NOT NULL,
`position` varchar(25) NOT NULL,
`home_address` varchar(50) NOT NULL,
`home_phone` varchar(12) NOT NULL,
`employee_code` varchar(25) NOT NULL,
PRIMARY KEY (`id`),
UNIQUE KEY `employee_code` (`employee_code`),
KEY `first_name` (`first_name`,`last_name`)
) ENGINE=Aria;

INSERT INTO `employees_example`(`first_name`, `last_name`, `position`, `home_address`, `home_phone`, `employee_code`)
VALUES
('Mustapha', 'Mond', 'Chief Executive Officer', '692 Promiscuous Plaza', '326-555-3492', 'MM1'),
('Henry', 'Foster', 'Store Manager', '314 Savage Circle', '326-555-3847', 'HF1'),
('Bernard', 'Marx', 'Cashier', '1240 Ambient Avenue', '326-555-8456', 'BM1'),
('Lenina', 'Crowne', 'Cashier', '281 Bumblepuppy Boulevard', '328-555-2349', 'LC1'),
('Fanny', 'Crowne', 'Restocker', '1023 Bokanovsky Lane', '326-555-6329', 'FC1'),
('Helmholtz', 'Watson', 'Janitor', '944 Soma Court', '329-555-2478', 'HW1');

```

```

SHOW INDEXES FROM employees_example\G
***** 1. row *****

## 1.1.2.1.20 TRUNCATE TABLE

### Syntax

```

TRUNCATE [TABLE] tbl_name
[WAIT n | NOWAIT]

```

## Contents

1. [Syntax](#)
2. [Description](#)
  1. [WAIT/NOWAIT](#)
  2. [Oracle-mode](#)
  3. [Performance](#)
3. [See Also](#)

## Description

TRUNCATE TABLE  
empties a table completely. It requires the  
DROP  
privilege. See [GRANT](#).

tbl\_name  
can also be specified in the form  
db\_name.  
  
tbl\_name  
(see [Identifier Qualifiers](#)).

Logically,

TRUNCATE TABLE  
is equivalent to a [DELETE](#) statement that deletes all rows, but there are practical differences under some circumstances.

TRUNCATE TABLE  
will fail for an [InnoDB table](#) if any FOREIGN KEY constraints from other tables reference the table, returning the error:

ERROR 1701 (42000): Cannot truncate a table referenced in a foreign key constraint

Foreign Key constraints between columns in the same table are permitted.

For an InnoDB table, if there are no

FOREIGN KEY  
constraints, InnoDB performs fast truncation by dropping the original table and creating an empty one with the same definition, which is much faster than deleting rows one by one. The [AUTO\\_INCREMENT](#) counter is reset by

TRUNCATE TABLE  
, regardless of whether there is a  
FOREIGN KEY  
constraint.

The count of rows affected by

TRUNCATE TABLE  
is accurate only when it is mapped to a  
DELETE  
statement.

For other storage engines,

TRUNCATE TABLE  
differs from  
DELETE  
in the following ways:

- Truncate operations drop and re-create the table, which is much faster than deleting rows one by one, particularly for large tables.
- Truncate operations cause an implicit commit.
- Truncation operations cannot be performed if the session holds an active table lock.
- Truncation operations do not return a meaningful value for the number of deleted rows. The usual result is "0 rows affected," which should be interpreted as "no information."
- As long as the table format file  
  
tbl\_name.frm  
is valid, the table can be re-created as an empty table with  
  
TRUNCATE TABLE  
, even if the data or index files have become corrupted.
- The table handler does not remember the last used [AUTO\\_INCREMENT](#) value, but starts counting from the beginning. This is true even for MyISAM and InnoDB, which normally do not reuse sequence values.
- When used with partitioned tables,  
  
TRUNCATE TABLE  
preserves the partitioning; that is, the data and index files are dropped and re-created, while the partition definitions (.par) file is unaffected.

- Since truncation of a table does not make any use of
 

```
DELETE
, the
TRUNCATE
```

 statement does not invoke
 

```
ON DELETE
```

 triggers.
- ```
TRUNCATE TABLE
```

 will only reset the values in the [Performance Schema summary tables](#) to zero or null, and will not remove the rows.

For the purposes of binary logging and [replication](#) ,

```
TRUNCATE TABLE
```

is treated as [DROP TABLE](#) followed by [CREATE TABLE](#) (DDL rather than DML).

```
TRUNCATE TABLE
does not work on views . Currently,
TRUNCATE TABLE
drops all historical records from a system-versioned table .
```

MariaDB starting with [10.3.0](#)

#### [WAIT/NOWAIT](#)

Set the lock wait timeout. See [WAIT](#) and [NOWAIT](#) .

#### Oracle-mode

[Oracle-mode](#) from [MariaDB 10.3](#) permits the optional keywords REUSE STORAGE or DROP STORAGE to be used.

```
TRUNCATE [TABLE] tbl_name [{DROP | REUSE} STORAGE] [WAIT n | NOWAIT]
```

These have no effect on the operation.

## Performance

```
TRUNCATE TABLE
is faster than DELETE , because it drops and re-creates a table.
```

With [InnoDB](#) ,

```
TRUNCATE TABLE
is slower if innodb\_file\_per\_table=ON is set (the default). This is because
TRUNCATE TABLE
unlinks the underlying tablespace file, which can be an expensive operation. See MDEV-8069 for more details.
```

The performance issues with [innodb\\_file\\_per\\_table=ON](#) can be exacerbated in cases where the [InnoDB buffer pool](#) is very large and [innodb\\_adaptive\\_hash\\_index=ON](#) is set. In that case, using [DROP TABLE](#) followed by [CREATE TABLE](#) instead of

```
TRUNCATE TABLE
may perform better. Setting innodb\_adaptive\_hash\_index=OFF (it defaults to ON before MariaDB 10.5 ) can also help. In MariaDB 10.2 only, from MariaDB 10.2.19 , this performance can also be improved by setting innodb\_safe\_truncate=OFF . See MDEV-9459 for more details.
```

Setting [innodb\\_adaptive\\_hash\\_index=OFF](#) can also improve

```
TRUNCATE TABLE
performance in general. See MDEV-16796 for more details.
```

## See Also

- [TRUNCATE function](#)
- [innodb\\_safe\\_truncate](#) system variable
- [Oracle mode from MariaDB 10.3](#)

## 1.1.2.1.21 UPDATE

### Syntax

Single-table syntax:

```

UPDATE [LOW_PRIORITY] [IGNORE] table_reference
[PARTITION (partition_list)]
[FOR PORTION OF period FROM expr1 TO expr2]
SET col1={expr1|DEFAULT} [,col2={expr2|DEFAULT}] ...
[WHERE where_condition]
[ORDER BY ...]
[LIMIT row_count]

```

Multiple-table syntax:

```

UPDATE [LOW_PRIORITY] [IGNORE] table_references
      SET col1={expr1|DEFAULT} [, col2={expr2|DEFAULT}] ...
      [WHERE where_condition]

```

## Contents

1. [Syntax](#)
2. [Description](#)
  1. [PARTITION](#)
  2. [FOR PORTION OF](#)
  3. [UPDATE Statements With the Same Source and Target](#)
3. [Example](#)
4. [See Also](#)

## Description

For the single-table syntax, the

```

UPDATE
statement updates columns of existing rows in the named table with new values. The
SET
clause indicates which columns to modify and the values they should be given. Each value can be given as an expression, or the keyword
DEFAULT
to set a column explicitly to its default value. The
WHERE
clause, if given, specifies the conditions that identify which rows to update. With no
WHERE
clause, all rows are updated. If the ORDER BY clause is specified, the rows are updated in the order that is specified. The LIMIT clause places a
limit on the number of rows that can be updated.

```

Until [MariaDB 10.3.2](#), for the multiple-table syntax,

```

UPDATE
updates rows in each table named in table_references that satisfy the conditions. In this case, ORDER BY and LIMIT cannot be used. This
restriction was lifted in MariaDB 10.3.2 and both clauses can be used with multiple-table updates. An
UPDATE
can also reference tables which are located in different databases; see Identifier Qualifiers for the syntax.

```

where\_condition  
is an expression that evaluates to true for each row to be updated.

```

table_references
and
where_condition
are as specified as described in SELECT.

```

For single-table updates, assignments are evaluated in left-to-right order, while for multi-table updates, there is no guarantee of a particular order. If the SIMULTANEOUS\_ASSIGNMENT sql\_mode (available from [MariaDB 10.3.5](#)) is set, UPDATE statements evaluate all assignments simultaneously.

You need the

```

UPDATE
privilege only for columns referenced in an
UPDATE
that are actually updated. You need only the SELECT privilege for any columns that are read but not modified. See GRANT.

```

The

```

UPDATE
statement supports the following modifiers:

```

- If you use the  
LOW\_PRIORITY

keyword, execution of the  
UPDATE  
is delayed until no other clients are reading from the table. This affects only storage engines that use only table-level locking (MyISAM, MEMORY, MERGE). See [HIGH\\_PRIORITY](#) and [LOW\\_PRIORITY](#) clauses for details.

- If you use the  
IGNORE  
keyword, the update statement does not abort even if errors occur during the update. Rows for which duplicate-key conflicts occur are not updated. Rows for which columns are updated to values that would cause data conversion errors are updated to the closest valid values instead.

## PARTITION

See [Partition Pruning and Selection](#) for details.

## FOR PORTION OF

MariaDB starting with 10.4.3  
See [Application Time Periods - Updating by Portion](#).

## UPDATE Statements With the Same Source and Target

MariaDB starting with 10.3.2  
From MariaDB 10.3.2 , UPDATE statements may have the same source and target.

For example, given the following table:

```
DROP TABLE t1;
CREATE TABLE t1 (c1 INT, c2 INT);
INSERT INTO t1 VALUES (10,10), (20,20);
```

Until MariaDB 10.3.1 , the following UPDATE statement would not work:

```
UPDATE t1 SET c1=c1+1 WHERE c2=(SELECT MAX(c2) FROM t1);
ERROR 1093 (HY000): Table 't1' is specified twice,
both as a target for 'UPDATE' and as a separate source for data
```

From MariaDB 10.3.2 , the statement executes successfully:

```
UPDATE t1 SET c1=c1+1 WHERE c2=(SELECT MAX(c2) FROM t1);

SELECT * FROM t1;
+-----+
| c1 | c2 |
+-----+
| 10 | 10 |
| 21 | 20 |
+-----+
```

## Example

Single-table syntax:

```
UPDATE table_name SET column1 = value1, column2 = value2 WHERE id=100;
```

Multiple-table syntax:

```
UPDATE tab1, tab2 SET tab1.column1 = value1, tab1.column2 = value2 WHERE tab1.id = tab2.id;
```

## See Also

- [How IGNORE works](#)
- [SELECT](#)
- [ORDER BY](#)
- [LIMIT](#)
- [Identifier Qualifiers](#)

## 1.1.2.1.22 IGNORE

The

IGNORE

option tells the server to ignore some common errors.

IGNORE

can be used with the following statements:

- [DELETE](#)
- [INSERT](#) (see also [INSERT IGNORE](#) )
- [LOAD DATA INFILE](#)
- [UPDATE](#)
- [ALTER TABLE](#)
- [CREATE TABLE ... SELECT](#)
- [INSERT ... SELECT](#)

The logic used:

- Variables out of ranges are replaced with the maximum/minimum value.

- [SQL\\_MODEs](#)

```
STRICT_TRANS_TABLES  
,  
STRICT_ALL_TABLES  
,  
NO_ZERO_IN_DATE  
,  
NO_ZERO_DATE  
are ignored.
```

- Inserting

```
NULL  
in a  
NOT NULL  
field will insert 0 ( in a numerical field), 0000-00-00 ( in a date field) or an empty string ( in a character field).
```

- Rows that cause a duplicate key error or break a foreign key constraint are not inserted, updated, or deleted.

The following errors are ignored:

| Error number | Symbolic error name                | Description                                   |
|--------------|------------------------------------|-----------------------------------------------|
| 1022         | ER_DUP_KEY                         | Can't write; duplicate key in table '%s'      |
| 1048         | ER_BAD_NULL_ERROR                  | Column '%s' cannot be null                    |
| 1062         | ER_DUP_ENTRY                       | Duplicate entry '%s' for key %d               |
| 1242         | ER_SUBQUERY_NO_1_ROW               | Subquery returns more than 1 row              |
| 1264         | ER_WARN_DATA_OUT_OF_RANGE          | Out of range value for column '%s' at row %ld |
| 1265         | WARN_DATA_TRUNCATED                | Data truncated for column '%s' at row %ld     |
| 1292         | ER_TRUNCATED_WRONG_VALUE           | Truncated incorrect %s value: '%s'            |

| 1748 | ER_ROW_DOES_NOT_MATCH_GIVEN_PARTITION_SET | Found a row not matching the given partition set                      |

Ignored errors normally generate a warning.

A property of the

IGNORE

clause consists in causing transactional engines and non-transactional engines (like XtraDB and Aria) to behave the same way. For example, normally a multi-row insert which tries to violate a

UNIQUE

constraint is completely rolled back on XtraDB/InnoDB, but might be partially executed on Aria. With the

IGNORE

clause, the statement will be partially executed in both engines.

Duplicate key errors also generate warnings. The `OLD_MODE` server variable can be used to prevent this.

## 1.1.2.1.23 System-Versioned Tables

### 1.1.2.2 ANALYZE and EXPLAIN Statements

#### 1.1.2.2.1 ANALYZE FORMAT=JSON

##### Contents

- 1. Basic Execution Data
- 2. Advanced Execution Data
- 3. Data About Individual Query Plan Nodes
- 4. Use Cases

`ANALYZE FORMAT=JSON` is a mix of the `EXPLAIN FORMAT=JSON` and `ANALYZE` statement features. The `ANALYZE FORMAT=JSON $statement` will execute `$statement`, and then print the output of `EXPLAIN FORMAT=JSON`, amended with data from the query execution.

## Basic Execution Data

You can get the following also from tabular

`ANALYZE`

statement form:

- `r_rows` is provided for any node that reads rows. It shows how many rows were read, on average
- `r_filtered` is provided whenever there is a condition that is checked. It shows the percentage of rows left after checking the condition.

# Advanced Execution Data

The most important data not available in the regular tabula

ANALYZE  
statement are:

- **r\_loops**  
field. This shows how many times the node was executed. Most query plan elements have this field.
- **r\_total\_time\_ms**  
field. It shows how much time in total was spent executing this node. If the node has subnodes, their execution time is included.
- **r\_buffer\_size**  
field. Query plan nodes that make use of buffers report the size of buffer that was used.

## Data About Individual Query Plan Nodes

- **filesort**  
node reports whether sorting was done with  
`LIMIT n`  
parameter, and how many rows were in the sort result.
- **block-nl-join**  
node has  
**r\_loops**  
field, which allows to tell whether  
Using join buffer  
was efficient
- **range-checked-for-each-record**  
reports counters that show the result of the check.
- **expression-cache**  
is used for subqueries, and it reports how many times the cache was used, and what cache hit ratio was.
- **union\_result**  
node has  
**r\_rows**  
so one can see how many rows were produced after UNION operation
- and so forth

## Use Cases

See [Examples of ANALYZE FORMAT=JSON](#).

### 1.1.2.2 ANALYZE FORMAT=JSON Examples

#### Example #1

Customers who have ordered more than 1M goods.

```
ANALYZE FORMAT=JSON
SELECT COUNT(*)
FROM customer
WHERE
  (SELECT SUM(o_totalprice) FROM orders WHERE o_custkey=c_custkey) > 1000*1000;
```

The query takes 40 seconds over cold cache

```

EXPLAIN: {
  "query_block": {
    "select_id": 1,
    "r_loops": 1,
    "r_total_time_ms": 39872,
    "table": {
      "table_name": "customer",
      "access_type": "index",
      "key": "i_c_nationkey",
      "key_length": "5",
      "used_key_parts": ["c_nationkey"],
      "r_loops": 1,
      "rows": 150303,
      "r_rows": 150000,
      "r_total_time_ms": 270.3,
      "filtered": 100,
      "r_filtered": 60.691,
      "attached_condition": "((subquery#2) > <cache>((1000 * 1000)))",
      "using_index": true
    },
    "subqueries": [
      {
        "query_block": {
          "select_id": 2,
          "r_loops": 150000,
          "r_total_time_ms": 39531,
          "table": {
            "table_name": "orders",
            "access_type": "ref",
            "possible_keys": ["i_o_custkey"],
            "key": "i_o_custkey",
            "key_length": "5",
            "used_key_parts": ["o_custkey"],
            "ref": ["dbt3sf1.customer.c_custkey"],
            "r_loops": 150000,
            "rows": 7,
            "r_rows": 10,
            "r_total_time_ms": 39208,
            "filtered": 100,
            "r_filtered": 100
          }
        }
      }
    ]
  }
}

```

#### ANALYZE

shows that 39.2 seconds were spent in the subquery, which was executed 150K times (for every row of outer table).

### 1.1.2.2.3 ANALYZE Statement

#### Contents

1. [Description](#)
2. [Command Output](#)
3. [Interpreting the Output](#)
  1. [Joins](#)
  2. [Meaning of NULL in r\\_rows and r\\_filtered](#)
4. [ANALYZE FORMAT=JSON](#)
5. [Notes](#)
6. [See Also](#)

### Description

The

ANALYZE statement  
is similar to the  
EXPLAIN statement

```
ANALYZE statement  
will invoke the optimizer, execute the statement, and then produce  
EXPLAIN  
output instead of the result set. The  
EXPLAIN  
output will be annotated with statistics from statement execution.
```

This lets one check how close the optimizer's estimates about the query plan are to the reality.

```
ANALYZE  
produces an overview, while the
```

```
ANALYZE FORMAT=JSON
```

command provides a more detailed view of the query plan and the query execution.

The syntax is

```
ANALYZE explainable_statement;
```

where the statement is any statement for which one can run

```
EXPLAIN
```

## Command Output

Consider an example:

```
ANALYZE SELECT * FROM tbl1  
WHERE key1  
    BETWEEN 10 AND 200 AND  
col1 LIKE 'foo%'\\G
```

```
***** 1. row *****  
    id: 1  
select_type: SIMPLE  
    table: tbl1  
        type: range  
possible_keys: key1  
    key: key1  
key_len: 5  
    ref: NULL  
    rows: 181  
r_rows: 181  
filtered: 100.00  
r_filtered: 10.50  
Extra: Using index condition; Using where
```

Compared to

```
EXPLAIN  
,  
ANALYZE  
produces two extra columns:
```

- **r\_rows**  
is an observation-based counterpart of the **rows** column. It shows how many rows were actually read from the table.
- **r\_filtered**  
is an observation-based counterpart of the **filtered** column. It shows which fraction of rows was left after applying the WHERE condition.

## Interpreting the Output

### Joins

Let's consider a more complicated example.

```

ANALYZE SELECT *
FROM orders, customer
WHERE
customer.c_custkey=orders.o_custkey AND
customer.c_acctbal < 0 AND
orders.o_totalprice > 200*1000

```

| id   select_type   table   type   possible_keys   key   key_len   ref   rows   r_rows   filtered |
|--------------------------------------------------------------------------------------------------|
| 1   SIMPLE   customer   ALL   PRIMARY,...   NULL   NULL   NULL   149095   150000   18.08         |
| 1   SIMPLE   orders   ref   i_o_custkey   i_o_custkey   5   customer.c_custkey   7   10   100.00 |
|                                                                                                  |

Here, one can see that

- For table customer, **customer.rows=149095, customer.r\_rows=150000**. The estimate for number of rows we will read was fairly precise
- **customer.filtered=18.08, customer.r\_filtered=9.13**. The optimizer somewhat overestimated the number of records that will match selectivity of condition attached to `customer` table (in general, when you have a full scan and r\_filtered is less than 15%, it's time to consider adding an appropriate index).
- For table orders, **orders.rows=7, orders.r\_rows=10**. This means that on average, there are 7 orders for a given c\_custkey, but in our case there were 10, which is close to the expectation (when this number is consistently far from the expectation, it may be time to run ANALYZE TABLE, or even edit the table statistics manually to get better query plans).
- **orders.filtered=100, orders.r\_filtered=30.03**. The optimizer didn't have any way to estimate which fraction of records will be left after it checks the condition that is attached to table orders (it's orders.o\_totalprice > 200\*1000). So, it used 100%. In reality, it is 30%. 30% is typically not selective enough to warrant adding new indexes. For joins with many tables, it might be worth to collect and use [column statistics](#) for columns in question, this may help the optimizer to pick a better query plan.

## Meaning of NULL in r\_rows and r\_filtered

Let's modify the previous example slightly

```

ANALYZE SELECT *
FROM orders, customer
WHERE
customer.c_custkey=orders.o_custkey AND
customer.c_acctbal < -0 AND
customer.c_comment LIKE '%foo%' AND
orders.o_totalprice > 200*1000;

```

| id   select_type   table   type   possible_keys   key   key_len   ref   rows   r_rows   filtered   |
|----------------------------------------------------------------------------------------------------|
| 1   SIMPLE   customer   ALL   PRIMARY,...   NULL   NULL   NULL   149095   150000   18.08           |
| 1   SIMPLE   orders   ref   i_o_custkey   i_o_custkey   5   customer.c_custkey   7   NULL   100.00 |

Here, one can see that **orders.r\_rows=NULL** and **orders.r\_filtered=NULL**. This means that table orders was not scanned even once. Indeed, we can also see **customer.r\_filtered=0.00**. This shows that a part of WHERE attached to table `customer` was never satisfied (or, satisfied in less than 0.01% of cases).

## ANALYZE FORMAT=JSON

[ANALYZE FORMAT=JSON](#) produces JSON output. It produces much more information than tabular

ANALYZE

## Notes

- - ANALYZE UPDATE  
or
  - ANALYZE DELETE  
will actually make updates/deletes (
  - ANALYZE SELECT  
will perform the select operation and then discard the resultset).
- PostgreSQL has a similar command,  
EXPLAIN ANALYZE

- The [EXPLAIN in the slow query log](#) feature allows MariaDB to have  
ANALYZE  
output of slow queries printed into the [slow query log](#) (see [MDEV-6388](#) ).

## See Also

- [ANALYZE FORMAT=JSON](#)
- [ANALYZE TABLE](#)
- JIRA task for ANALYZE statement, [MDEV-406](#)

## 1.1.2.2.4 EXPLAIN

### Syntax

```
EXPLAIN tbl_name
```

Or

```
EXPLAIN [EXTENDED | PARTITIONS]
{SELECT select_options | UPDATE update_options | DELETE delete_options}
```

### Contents

- [Syntax](#)
- [Description](#)
- [Columns in EXPLAIN ... SELECT](#)
  - "Select\_type" Column
  - "Type" Column
  - "Extra" Column
- [EXPLAIN EXTENDED](#)
- [Examples](#)
  - [Example of ref\\_or\\_null Optimization](#)
- [See Also](#)

### Description

The

```
EXPLAIN
statement can be used either as a synonym for
DESCRIBE
or as a way to obtain information about how MariaDB executes a
SELECT
,
UPDATE
or
DELETE
statement:
```

- 'EXPLAIN tbl\_name'  
is synonymous with  
,

```
DESCRIBE
```

```
tbl_name'
or
'
```

```
SHOW COLUMNS
```

```
FROM tbl_name'
```

- When you precede a  
SELECT  
,
- UPDATE  
or a

DELETE  
statement with the keyword  
EXPLAIN  
, MariaDB displays information from the optimizer about the query execution plan. That is, MariaDB explains how it would process the  
SELECT  
,

UPDATE  
or  
DELETE  
, including information about how tables are joined and in which order.  
EXPLAIN EXTENDED  
can be used to provide additional information.

- EXPLAIN PARTITIONS  
is useful only when examining queries involving partitioned tables.

For details, see [Partition pruning and selection](#).

- **ANALYZE statement** performs the query as well as producing EXPLAIN output, and provides actual as well as estimated statistics.

- EXPLAIN  
output can be printed in the [slow query log](#). See [EXPLAIN in the Slow Query Log](#) for details.

**SHOW EXPLAIN** shows the output of a running statement. In some cases, its output can be closer to reality than

EXPLAIN

The **ANALYZE statement** runs a statement and returns information about its execution plan. It also shows additional columns, to check how much the optimizer's estimation about filtering and found rows are close to reality.

There is an online [EXPLAIN Analyzer](#) that you can use to share

EXPLAIN

and

EXPLAIN EXTENDED

output with others.

EXPLAIN  
can acquire metadata locks in the same way that  
SELECT  
does, as it needs to know table metadata and, sometimes, data as well.

## Columns in EXPLAIN ... SELECT

| Column name   | Description                                                                                         |
|---------------|-----------------------------------------------------------------------------------------------------|
| id            | Sequence number that shows in which order tables are joined.                                        |
| select_type   | What kind of<br>SELECT<br>the table comes from.                                                     |
| table         | Alias name of table. Materialized temporary tables for sub queries are named <subquery#>            |
| type          | How rows are found from the table (join type).                                                      |
| possible_keys | keys in table that could be used to find rows in the table                                          |
| key           | The name of the key that is used to retrieve rows.<br>NULL<br>is no key was used.                   |
| key_len       | How many bytes of the key that was used (shows if we are using only parts of the multi-column key). |

|       |                                                                             |
|-------|-----------------------------------------------------------------------------|
| ref   | The reference that is used as the key value.                                |
| rows  | An estimate of how many rows we will find in the table for each key lookup. |
| Extra | Extra information about this join.                                          |

Here are descriptions of the values for some of the more complex columns in

```
EXPLAIN ... SELECT
```

:

### "Select\_type" Column

The

`select_type`

column can have the following values:

| Value                 | Description                                            | Comment                                                                                                                                                                            |
|-----------------------|--------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| DEPENDENT<br>SUBQUERY | The<br>SUBQUERY<br>is<br>DEPENDENT                     |                                                                                                                                                                                    |
| DEPENDENT UNION       | The<br>UNION<br>is<br>DEPENDENT                        |                                                                                                                                                                                    |
| DERIVED               | The<br>SELECT<br>is<br>DERIVED<br>from the<br>PRIMARY  |                                                                                                                                                                                    |
| MATERIALIZED          | The<br>SUBQUERY<br>is<br><b>MATERIALIZED</b>           | Materialized tables will be populated at first access and will be accessed by the primary key (= one key lookup). Number of rows in EXPLAIN shows the cost of populating the table |
| PRIMARY               | The<br>SELECT<br>is a<br>PRIMARY<br>one.               |                                                                                                                                                                                    |
| SIMPLE                | The<br>SELECT<br>is a<br>SIMPLE<br>one.                |                                                                                                                                                                                    |
| SUBQUERY              | The<br>SELECT<br>is a<br>SUBQUERY<br>of the<br>PRIMARY |                                                                                                                                                                                    |

|                      |                                                |
|----------------------|------------------------------------------------|
| UNCACHEABLE SUBQUERY | The SUBQUERY is UNCACHEABLE                    |
| UNCACHEABLE UNION    | The UNION is UNCACHEABLE                       |
| UNION                | The SELECT is a UNION of the PRIMARY           |
| RESULT               | The result of the UNION                        |
| LATERAL DERIVED      | The SELECT uses a Lateral Derived optimization |

## "Type" Column

This column contains information on how the table is accessed.

| Value          | Description                                                                                                                                                                                                                      |
|----------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| ALL            | A full table scan is done for the table (all rows are read). This is bad if the table is large and the table is joined against a previous table! This happens when the optimizer could not find any usable index to access rows. |
| const          | There is only one possibly matching row in the table. The row is read before the optimization phase and all columns in the table are treated as constants.                                                                       |
| eq_ref         | A unique index is used to find the rows. This is the best possible plan to find the row.                                                                                                                                         |
| fulltext       | A fulltext index is used to access the rows.                                                                                                                                                                                     |
| index_merge    | A 'range' access is done for several index and the found rows are merged. The key column shows which keys are used.                                                                                                              |
| index_subquery | This is similar as ref, but used for sub queries that are transformed to key lookups.                                                                                                                                            |
| index          | A full scan over the used index. Better than ALL but still bad if index is large and the table is joined against a previous table.                                                                                               |
| range          | The table will be accessed with a key over one or more value ranges.                                                                                                                                                             |

|                 |                                                                                                                                                 |
|-----------------|-------------------------------------------------------------------------------------------------------------------------------------------------|
| ref_or_null     | Like 'ref' but in addition another search for the 'null' value is done if the first value was not found. This happens usually with sub queries. |
| ref             | A non unique index or prefix of an unique index is used to find the rows. Good if the prefix doesn't match many rows.                           |
| system          | The table has 0 or 1 rows.                                                                                                                      |
| unique_subquery | This is similar as eq_ref, but used for sub queries that are transformed to key lookups                                                         |

## "Extra" Column

This column consists of one or more of the following values, separated by ','

*Note that some of these values are detected after the optimization phase.*

The optimization phase can do the following changes to the

WHERE  
clause:

- Add the expressions from the  
ON  
and  
USING  
clauses to the  
WHERE  
clause.
- Constant propagation: If there is  
column=constant  
, replace all column instances with this constant.
- Replace all columns from '  
const  
' tables with their values.
- Remove the used key columns from the  
WHERE  
(as this will be tested as part of the key lookup).
- Remove impossible constant sub expressions. For example  
WHERE '(a=1 and a=2) OR b=1'  
becomes  
'b=1'
- Replace columns with other columns that has identical values: Example:  
WHERE  
  
a=b  
and  
a=c  
may be treated as  
'WHERE a=b and a=c and b=c'

- Add extra conditions to detect impossible row conditions earlier. This happens mainly with  
OUTER JOIN  
where we in some cases add detection of  
NULL  
values in the  
WHERE  
(Part of'  
Not exists  
'optimization). This can cause an unexpected'  
Using where  
' in the Extra column.
- For each table level we remove expressions that have already been tested when we read the previous row. Example: When joining tables  
t1  
with  
t2

using the following  
 WHERE 't1.a=1 and t1.a=t2.b'  
 , we don't have to test  
 't1.a=1'  
 when checking rows in  
 t2  
 as we already know that this expression is true.

| Value                                                               | Description                                                                                                                                                                                                                                                                         |
|---------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| const<br>row not found                                              | The table was a system table (a table with exactly one row), but no row was found.                                                                                                                                                                                                  |
| Distinct                                                            | If distinct optimization (remove duplicates) was used. This is marked only for the last table in the<br><pre>SELECT .</pre>                                                                                                                                                         |
| Full<br>scan on NULL key                                            | The table is a part of the sub query and if the value that is used to match the sub query will be<br><pre>NULL , we will do a full table scan.</pre>                                                                                                                                |
| Impossible HAVING                                                   | The used<br><pre>HAVING clause is always false so the SELECT will return no rows.</pre>                                                                                                                                                                                             |
| Impossible WHERE<br>noticed<br>after<br>reading<br>const<br>tables. | The used<br><pre>WHERE clause is always false so the SELECT will return no rows. This case was detected after we had read all 'const' tables and used the column values as constant in the WHERE clause. For example: WHERE const_column=5 and const_column had a value of 4.</pre> |
| Impossible WHERE                                                    | The used<br><pre>WHERE clause is always false so the SELECT will return no rows. For example: WHERE 1=2</pre>                                                                                                                                                                       |
| No<br>matching min/max<br>row                                       | During early optimization of<br><pre>MIN() / MAX() values it was detected that no row could match the WHERE clause. The MIN() / MAX() function will return NULL .</pre>                                                                                                             |

|                                                   |                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
|---------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| no matching row<br>in const table                 | The table was a const table (a table with only one possible matching row), but no row was found.                                                                                                                                                                                                                                                                                                                                                                     |
| No tables used                                    | The<br>SELECT<br>was a sub query that did not use any tables. For example a there was no<br>FROM<br>clause or a<br>FROM DUAL<br>clause.                                                                                                                                                                                                                                                                                                                              |
| Not exists                                        | Stop searching after more row if we find one single matching row. This optimization is used with<br>LEFT JOIN<br>where one is explicitly searching for rows that doesn't exists in the<br>LEFT JOIN TABLE<br>. Example:<br>SELECT * FROM t1 LEFT JOIN t2 on (...) WHERE t2.not_null_column IS NULL<br>. As<br>t2.not_null_column<br>can only be<br>NULL<br>if there was no matching row for on condition, we can stop searching if we find a single matching row.    |
| Open_frm_only                                     | For<br>information_schema<br>tables. Only the<br>frm<br>(table definition file was opened) was opened for each matching row.                                                                                                                                                                                                                                                                                                                                         |
| Open_full_table                                   | For<br>information_schema<br>tables. A full table open for each matching row is done to retrieve the requested information. (Slow)                                                                                                                                                                                                                                                                                                                                   |
| Open_trigger_only                                 | For<br>information_schema<br>tables. Only the trigger file definition was opened for each matching row.                                                                                                                                                                                                                                                                                                                                                              |
| Range checked for each record<br>(index map: ...) | This only happens when there was no good default index to use but there may some index that could be used when we can treat all columns from previous table as constants. For each row combination the optimizer will decide which index to use (if any) to fetch a row from this table. This is not fast, but faster than a full table scan that is the only other choice. The index map is a bitmask that shows which index are considered for each row condition. |
| Scanned 0/1/all databases                         | For<br>information_schema<br>tables. Shows how many times we had to do a directory scan.                                                                                                                                                                                                                                                                                                                                                                             |

|                              |                                                                                                                                                                                                                                                                                                                                                         |
|------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Select tables optimized away | All tables in the join was optimized away. This happens when we are only using COUNT(*) , MIN() and MAX() functions in the SELECT and we were able to replace all of these with constants.                                                                                                                                                              |
| Skip_open_table              | For information_schema tables. The queried table didn't need to be opened.                                                                                                                                                                                                                                                                              |
| unique row not found         | The table was detected to be a const table (a table with only one possible matching row) during the early optimization phase, but no row was found.                                                                                                                                                                                                     |
| Using filesort               | Filesort is needed to resolve the query. This means an extra phase where we first collect all columns to sort, sort them with a disk based merge sort and then use the sorted set to retrieve the rows in sorted order. If the column set is small, we store all the columns in the sort file to not have to go to the database to retrieve them again. |
| Using index                  | Only the index is used to retrieve the needed information from the table. There is no need to perform an extra seek to retrieve the actual record.                                                                                                                                                                                                      |
| Using index condition        | Like ' Using where ' but the where condition is pushed down to the table engine for internal optimization at the index level.                                                                                                                                                                                                                           |
| Using index condition(BKA)   | Like ' Using index condition ' but in addition we use batch key access to retrieve rows.                                                                                                                                                                                                                                                                |
| Using index for group-by     | The index is being used to resolve a GROUP BY or DISTINCT query. The rows are not read. This is very efficient if the table has a lot of identical index entries as duplicates are quickly jumped over.                                                                                                                                                 |
| Using intersect(...)         | For index_merge joins. Shows which index are part of the intersect.                                                                                                                                                                                                                                                                                     |
| Using join buffer            | We store previous row combinations in a row buffer to be able to match each row against all of the rows combinations in the join buffer at one go.                                                                                                                                                                                                      |
| Using sort_union(...)        | For index_merge joins. Shows which index are part of the union.                                                                                                                                                                                                                                                                                         |
| Using temporary              | A temporary table is created to hold the result. This typically happens if you are using GROUP BY , DISTINCT or ORDER BY .                                                                                                                                                                                                                              |

|                                      |                                                                                                                                                                                                                                               |
|--------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| where                                | Using<br>A<br>WHERE<br>expression (in additional to the possible key lookup) is used to check if the row should be accepted. If you don't have 'Using where' together with a join type of<br>ALL<br>, you are probably doing something wrong! |
| where<br>with<br>pushed<br>condition | Like '<br>Using where<br>' but the where condition is pushed down to the table engine for internal optimization at the row level.                                                                                                             |
| buffer                               | Using<br>The<br>UPDATE<br>statement will first buffer the rows, and then run the updates, rather than do updates on the fly. See <a href="#">Using Buffer UPDATE Algorithm</a> for a detailed explanation.                                    |

## EXPLAIN EXTENDED

The  
EXTENDED  
keyword adds another column, *filtered* , to the output. This is a percentage estimate of the table rows that will be filtered by the condition.

An  
EXPLAIN EXTENDED  
will always throw a warning, as it adds extra *Message* information to a subsequent

`SHOW WARNINGS`

statement. This includes what the  
`SELECT`  
query would look like after optimizing and rewriting rules are applied and how the optimizer qualifies columns and tables.

## Examples

As synonym for

`DESCRIBE`  
or  
`SHOW COLUMNS FROM`  
:

```
DESCRIBE city;
+-----+-----+-----+-----+-----+
| Field | Type   | Null | Key  | Default | Extra          |
+-----+-----+-----+-----+-----+
Id	int(11)	NO	PRI	NULL	auto_increment
Name	char(35)	YES		NULL	
Country	char(3)	NO	UNI		
District	char(20)	YES	MUL		
Population	int(11)	YES		NULL	
+-----+-----+-----+-----+-----+
```

A simple set of examples to see how

`EXPLAIN`  
can identify poor index usage:

```

CREATE TABLE IF NOT EXISTS `employees_example` (
  `id` int(11) NOT NULL AUTO_INCREMENT,
  `first_name` varchar(30) NOT NULL,
  `last_name` varchar(40) NOT NULL,
  `position` varchar(25) NOT NULL,
  `home_address` varchar(50) NOT NULL,
  `home_phone` varchar(12) NOT NULL,
  `employee_code` varchar(25) NOT NULL,
  PRIMARY KEY (`id`),
  UNIQUE KEY `employee_code` (`employee_code`),
  KEY `first_name` (`first_name`,`last_name`)
) ENGINE=Aria;

INSERT INTO `employees_example` (`first_name`, `last_name`, `position`, `home_address`, `home_phone`, `employee_code`)
VALUES
('Mustapha', 'Mond', 'Chief Executive Officer', '692 Promiscuous Plaza', '326-555-3492', 'MM1'),
('Henry', 'Foster', 'Store Manager', '314 Savage Circle', '326-555-3847', 'HF1'),
('Bernard', 'Marx', 'Cashier', '1240 Ambient Avenue', '326-555-8456', 'BM1'),
('Lenina', 'Crowne', 'Cashier', '281 Bumblepuppy Boulevard', '328-555-2349', 'LC1'),
('Fanny', 'Crowne', 'Restocker', '1023 Bokanovsky Lane', '326-555-6329', 'FC1'),
('Helmholtz', 'Watson', 'Janitor', '944 Soma Court', '329-555-2478', 'HW1');

```

```
SHOW INDEXES FROM employees_example;
```

| Table             | Non_unique | Key_name      | Seq_in_index | Column_name   | Collation | Cardinality | Sub_part | Packed |
|-------------------|------------|---------------|--------------|---------------|-----------|-------------|----------|--------|
| employees_example | 0          | PRIMARY       | 1            | id            | A         | 7           | NULL     | NULL   |
| employees_example | 0          | employee_code | 1            | employee_code | A         | 7           | NULL     | NULL   |
| employees_example | 1          | first_name    | 1            | first_name    | A         | NULL        | NULL     | NULL   |
| employees_example | 1          | first_name    | 2            | last_name     | A         | NULL        | NULL     | NULL   |

```
SELECT
```

```
on a primary key:
```

```
EXPLAIN SELECT * FROM employees_example WHERE id=1;
```

| id | select_type | table             | type  | possible_keys | key     | key_len | ref   | rows | Extra |
|----|-------------|-------------------|-------|---------------|---------|---------|-------|------|-------|
| 1  | SIMPLE      | employees_example | const | PRIMARY       | PRIMARY | 4       | const | 1    |       |

The type is `const`, which means that only one possible result could be returned. Now, returning the same record but searching by their phone number:

```
EXPLAIN SELECT * FROM employees_example WHERE home_phone='326-555-3492';
```

| id | select_type | table             | type | possible_keys | key  | key_len | ref  | rows | Extra       |
|----|-------------|-------------------|------|---------------|------|---------|------|------|-------------|
| 1  | SIMPLE      | employees_example | ALL  | NULL          | NULL | NULL    | NULL | 6    | Using where |

Here, the type is `All`, which means no index could be used. Looking at the rows count, a full table scan (all six rows) had to be performed in order to retrieve the record. If it's a requirement to search by phone number, an index will have to be created.

```
SHOW EXPLAIN
```

```
example:
```

```
SHOW EXPLAIN FOR 1;
```

| id | select_type | table | type  | possible_keys | key | key_len | ref  | rows    | Extra       |
|----|-------------|-------|-------|---------------|-----|---------|------|---------|-------------|
| 1  | SIMPLE      | tbl   | index | NULL          | a   | 5       | NULL | 1000107 | Using index |

```
1 row in set, 1 warning (0.00 sec)
```

## Example of

### ref\_or\_null

## Optimization

```
SELECT * FROM table_name
WHERE key_column=expr OR key_column IS NULL;
```

ref\_or\_null  
is something that often happens when you use subqueries with  
NOT IN  
as then one has to do an extra check for  
NULL  
values if the first value didn't have a matching row.

## 1.1.2.2.5 EXPLAIN ANALYZE

The syntax for the

EXPLAIN ANALYZE  
feature was changed to  
ANALYZE statement  
, available since MariaDB 10.1.0 . See [ANALYZE statement](#) .

## 1.1.2.2.6 EXPLAIN FORMAT=JSON

MariaDB starting with 10.1.2

Starting from version 10.1.2, MariaDB supports the EXPLAIN FORMAT=JSON syntax.

### Contents

1. [Synopsis](#)
2. [Output is different from MySQL](#)
3. [Output format](#)
4. [See also](#)

## Synopsis

EXPLAIN FORMAT=JSON  
is a variant of

[EXPLAIN](#)

command that produces output in JSON form. The output always has one row which has only one column titled "  
JSON  
". The contents are a JSON representation of the query plan, formatted for readability:

```
EXPLAIN FORMAT=JSON SELECT * FROM t1 WHERE col1=1\G
```

```
***** 1. row *****
EXPLAIN: {
  "query_block": {
    "select_id": 1,
    "table": {
      "table_name": "t1",
      "access_type": "ALL",
      "rows": 1000,
      "filtered": 100,
      "attached_condition": "(t1.col1 = 1)"
    }
  }
}
```

# Output is different from MySQL

The output of MariaDB's

`EXPLAIN FORMAT=JSON`

is different from

`EXPLAIN FORMAT=JSON`

in MySQL. The reasons for that are:

- MySQL's output has deficiencies. Some are listed here:

`EXPLAIN FORMAT=JSON in MySQL`

- The output of MySQL's

`EXPLAIN FORMAT=JSON`

is not defined. Even MySQL Workbench has trouble parsing it (see this [blog post](#)).

- MariaDB has query optimizations that MySQL does not have. Ergo, MariaDB generates query plans that MySQL does not generate.

A (as yet incomplete) list of how MariaDB's output is different from MySQL can be found here: [EXPLAIN FORMAT=JSON differences from MySQL](#).

## Output format

TODO: MariaDB's output format description.

## See also

- 

`ANALYZE FORMAT=JSON`

produces output like

`EXPLAIN FORMAT=JSON`

, but amended with the data from query execution.

## 1.1.2.2.7 SHOW EXPLAIN

### Contents

- [Syntax](#)
- [Description](#)
  - [Possible Errors](#)
  - [Differences Between SHOW EXPLAIN and EXPLAIN Outputs](#)
    - [Background](#)
    - [List of Recorded Differences](#)
    - [Required Permissions](#)
  - [See Also](#)

## Syntax

```
SHOW EXPLAIN FOR <thread_id>;
```

## Description

The

`SHOW EXPLAIN`

command allows one to get an [EXPLAIN](#) (that is, a description of a query plan) of a query running in a certain thread.

```
SHOW EXPLAIN FOR <thread_id>;
```

will produce an

`EXPLAIN`

output for the query that thread number

`thread_id`

is running. The thread id can be obtained with [SHOW PROCESSLIST](#).

```
SHOW EXPLAIN FOR 1;
+-----+-----+-----+-----+-----+-----+-----+-----+
| id | select_type | table | type | possible_keys | key | key_len | ref | rows | Extra |
+-----+-----+-----+-----+-----+-----+-----+-----+
| 1 | SIMPLE | tbl | index | NULL | a | 5 | NULL | 1000107 | Using index |
+-----+-----+-----+-----+-----+-----+-----+-----+
1 row in set, 1 warning (0.00 sec)
```

The output is always accompanied with a warning which shows the query the target thread is running (this shows what the EXPLAIN is for):

```
SHOW WARNINGS;
+-----+-----+
| Level | Code | Message |
+-----+-----+
| Note | 1003 | select sum(a) from tbl |
+-----+-----+
1 row in set (0.00 sec)
```

## Possible Errors

The output can be only produced if the target thread is *currently* running a query, which has a ready query plan. If this is not the case, the output will be:

```
SHOW EXPLAIN FOR 2;
ERROR 1932 (HY000): Target is not running an EXPLAINable command
```

You will get this error when:

- the target thread is not running a command for which one can run EXPLAIN
- the target thread is running a command for which one can run EXPLAIN, but
  - there is no query plan yet (for example, tables are open and locks are acquired before the query plan is produced)

## Differences Between SHOW EXPLAIN and EXPLAIN Outputs

### Background

In MySQL,

```
EXPLAIN
execution takes a slightly different route from the way the real query (typically the
SELECT
) is optimized. This is unfortunate, and has caused a number of bugs in
EXPLAIN
. (For example, see MDEV-326 , MDEV-410 , and lp:1013343 . lp:992942 is not directly about
EXPLAIN
, but it also would not have existed if MySQL didn't try to delete parts of a query plan in the middle of the query)
```

```
SHOW EXPLAIN
examines a running
SELECT
, and hence its output may be slightly different from what
EXPLAIN SELECT
would produce. We did our best to make sure that either the difference is negligible, or
SHOW EXPLAIN
's output is closer to reality than
EXPLAIN
's output.
```

### List of Recorded Differences

- SHOW EXPLAIN may have Extra='no matching row in const table ', where

- ```

EXPLAIN
would produce Extra=
Impossible WHERE ...
'

• For queries with subqueries,
SHOW EXPLAIN
may print
select_type==PRIMARY
where regular
EXPLAIN
used to print
select_type==SIMPLE
, or vice versa.

```

## Required Permissions

Running

```

SHOW EXPLAIN
requires the same permissions as running
SHOW PROCESSLIST
would.

```

## See Also

- [EXPLAIN ANALYZE](#) , which will perform a query and outputs enhanced EXPLAIN results.
- It is also possible to save EXPLAIN into the slow query log .

## 1.1.2.2.8 Using Buffer UPDATE Algorithm

This article explains the [UPDATE](#) statement's *Using Buffer* algorithm.

Take the following table and query:

Name	Salary
Babatunde	1000
Jolana	1050
Pankaja	1300

```
UPDATE employees SET salary = salary+100 WHERE salary < 2000;
```

Suppose the *employees* table has an index on the *salary* column, and the optimizer decides to use a range scan on that index.

The optimizer starts a range scan on the *salary* index. We find the first record *Babatunde, 1000* . If we do an on-the-fly update, we immediately instruct the storage engine to change this record to be *Babatunde, 1000+100=1100* .

Then we proceed to search for the next record, and find *Jolana, 1050* . We instruct the storage engine to update it to be *Jolana, 1050+100=1150* .

Then we proceed to search for the next record ... and what happens next depends on the storage engine. In some storage engines, data changes are visible immediately, so we will find the *Babatunde, 1100* record that we wrote at the first step, modifying it again, giving Babatunde an undeserved raise. Then we will see Babatunde again and again, looping continually.

In order to prevent such situations, the optimizer checks whether the UPDATE statement is going to change key values for the keys it is using. In that case, it will use a different algorithm:

1. Scan everyone with "salary<2000", remembering the rowids of the rows in a buffer.
2. Read the buffer and apply the updates.

This way, each row will be updated only once.

The

```

Using buffer
EXPLAIN output indicates that the buffer as described above will be used.

```

## 1.1.2.3 BACKUP Commands

### 1.1.2.3.1 BACKUP STAGE

MariaDB starting with [10.4.1](#)

The

BACKUP STAGE  
commands were introduced in [MariaDB 10.4.1](#).

## Contents

1. [Syntax](#)
2. [Goals with BACKUP STAGE Commands](#)
3. [BACKUP STAGE Commands](#)
  1. [BACKUP STAGE START](#)
  2. [BACKUP STAGE FLUSH](#)
  3. [BACKUP STAGE BLOCK\\_DDL](#)
  4. [BACKUP STAGE BLOCK\\_COMMIT](#)
  5. [BACKUP STAGE END](#)
4. [Using BACKUP STAGE Commands with Backup Tools](#)
  1. [Using BACKUP STAGE Commands with mariabackup](#)
  2. [Using BACKUP STAGE Commands with Storage Snapshots](#)
5. [Privileges](#)
6. [Notes](#)
7. [See Also](#)

The

BACKUP STAGE  
commands are a set of commands to make it possible to make an efficient external backup tool.

## Syntax

```
BACKUP STAGE [START | FLUSH | BLOCK_DDL | BLOCK_COMMIT | END ]
```

In the following text, a transactional table means InnoDB or "InnoDB-like engine with redo log that can lock redo purges and can be copied without locks by an outside process".

## Goals with BACKUP STAGE Commands

- To be able to do a majority of the backup with the minimum possible server locks. Especially for transactional tables (InnoDB, MyRocks etc) there is only need for a very short block of new commits while copying statistics and log tables.
- DDL are only needed to be blocked for a very short duration of the backup while [mariabackup](#) is copying the tables affected by DDL during the initial part of the backup.
- Most non transactional tables (those that are not in use) will be copied during
  - BACKUP STAGE START
    - . The exceptions are system statistic and log tables that are not blocked during the backup until
    - BLOCK\_COMMIT
  - Should work efficiently with backup tools that use disk snapshots.
  - Should work as efficiently as possible for all table types that store data on the local disks.
  - As little copying as possible under higher level stages/locks. For example, .frm (dictionary) and .trn (trigger) files should be copying while copying the table data.

## BACKUP STAGE Commands

### BACKUP STAGE START

The

START  
stage is designed for the following tasks:

- Blocks purge of redo files for storage engines that needs this (Aria)
- Start logging of DDL commands into 'datadir'/ddl.log. This may take a short time as the command has to wait until there are no active DDL commands.

## BACKUP STAGE FLUSH

The

FLUSH

stage is designed for the following tasks:

- FLUSH all changes for inactive non-transactional tables, except for statistics and log tables.
- Close all tables that are not in use, to ensure they are marked as closed for the backup.
- BLOCK all new write locks for all non transactional tables (except statistics and log tables). The command will not wait for tables that are in use by read-only transactions.

DDLs don't have to be blocked at this stage as they can't cause the table to be in an inconsistent state. This is true also for non-transactional tables.

## BACKUP STAGE BLOCK\_DDL

The

BLOCK\_DDL

stage is designed for the following tasks:

- Wait for all statements using write locked non-transactional tables to end.
- Blocks [CREATE TABLE](#), [DROP TABLE](#), [TRUNCATE TABLE](#), and [RENAME TABLE](#).
- Blocks also start off a new [ALTER TABLE](#) and the **final rename phase** of [ALTER TABLE](#). Running ALTER TABLES are not blocked.

## BACKUP STAGE BLOCK\_COMMIT

The

BLOCK\_COMMIT

stage is designed for the following tasks:

- Lock the binary log and commit/rollback to ensure that no changes are committed to any tables. If there are active commits or data to be copied to the binary log this will be allowed to finish. Active transactions will not affect

BLOCK\_COMMIT

- This doesn't lock temporary tables that are not used by replication. However these will be blocked when it's time to write to the binary log.
- Lock system log tables and statistics tables, flush them and mark them closed.

When the

BLOCK\_COMMIT

's stages return, this is the 'backup time'. Everything committed will be in the backup and everything not committed will roll back.

Transactional engines will continue to do changes to the redo log during the

BLOCK\_COMMIT

stage, but this is not important as all of these will roll back later as the changes will not be committed.

## BACKUP STAGE END

The

END

stage is designed for the following tasks:

- End DDL logging
- Free resources

## Using

### BACKUP STAGE Commands with Backup Tools

## Using

### BACKUP STAGE

## Commands with Mariabackup

The

`BACKUP STAGE`

commands are a set of commands to make it possible to make an efficient external backup tool. How [Mariabackup](#) uses these commands depends on whether you are using the version that is bundled with MariaDB Community Server or the version that is bundled with [MariaDB Enterprise Server](#). See [Mariabackup and BACKUP STAGE Commands](#) for some examples on how [Mariabackup](#) uses these commands.

If you would like to use a version of [Mariabackup](#) that uses the

`BACKUP STAGE`

commands in an efficient way, then one option is to use [MariaDB Enterprise Backup](#) that is bundled with [MariaDB Enterprise Server](#).

## Using

`BACKUP STAGE`

Commands with Storage Snapshots

The

`BACKUP STAGE`

commands are a set of commands to make it possible to make an efficient external backup tool. These commands could even be used by tools that perform backups by taking a snapshot of a file system, SAN, or some other kind of storage device. See [Storage Snapshots and BACKUP STAGE Commands](#) for some examples on how to use each

`BACKUP STAGE`

command in an efficient way.

## Privileges

`BACKUP STAGE`

requires the

`RELOAD`

privilege.

## Notes

- Only one connection can run

`BACKUP STAGE START`

. If a second connection tries, it will wait until the first one has executed

`BACKUP STAGE END`

- If the user skips a

`BACKUP STAGE`

, then all intermediate backup stages will automatically be run. This will allow us to add new stages within the

`BACKUP STAGE`

hierarchy in the future with even more precise locks without causing problems for tools using an earlier version of the

`BACKUP STAGE`

implementation.

- One can use the

`max_statement_time`

or

`lock_wait_timeout`

system variables to ensure that a

`BACKUP STAGE`

command doesn't block the server too long.

- DDL logging will only be available in [MariaDB Enterprise Server](#) 10.2 and later.

## See Also

- [BACKUP LOCK](#) Locking a table from DDL's.
- [MDEV-5336](#) . Implement BACKUP STAGE for safe external backups.

## 1.1.2.3.2 BACKUP LOCK

MariaDB starting with [10.4.2](#)

The BACKUP LOCK command was introduced in [MariaDB 10.4.2](#).

### Contents

1. [Syntax](#)
2. [Usage in a Backup Tool](#)
3. [Privileges](#)
4. [Notes](#)
5. [Implementation](#)
6. [See Also](#)

BACKUP LOCK blocks a table from DDL statements. This is mainly intended to be used by tools like [mariabackup](#) that need to ensure there are no DDLs on a table while the table files are opened. For example, for an Aria table that stores data in 3 files with extensions .frm, .MAI and .MAD. Normal read/write operations can continue as normal.

### Syntax

To lock a table:

```
BACKUP LOCK table_name
```

To unlock a table:

```
BACKUP UNLOCK
```

### Usage in a Backup Tool

```
BACKUP LOCK [database.]table_name;
- Open all files related to a table (for example, t.frm, t.MAI and t.MYD)
BACKUP UNLOCK;
- Copy data
- Close files
```

This ensures that all files are from the same generation, that is created at the same time by the MariaDB server. This works, because the open files will point to the original table files which will not be affected if there is any ALTER TABLE while copying the files.

### Privileges

BACKUP LOCK requires the

```
RELOAD
```

privilege.

### Notes

- The idea is that the  

```
BACKUP LOCK
```

should be held for as short a time as possible by the backup tool. The time to take an uncontested lock is very short! One can easily do 50,000 locks/unlocks per second on low end hardware.
- One should use different connections for [BACKUP STAGE](#) commands and  

```
BACKUP LOCK
```

### Implementation

- Internally, BACKUP LOCK is implemented by taking an  

```
MDL_SHARED_HIGH_PRIO
```

MDL lock on the table object, which protects the table from any DDL operations.

### See Also

- [BACKUP STAGE](#)
- [MDEV-17309](#) - BACKUP LOCK: DDL locking of tables during backup

## 1.1.2.3.3 Mariabackup and BACKUP STAGE Commands

MariaDB starting with [10.4.1](#)

The

[BACKUP STAGE](#)

commands were introduced in [MariaDB 10.4.1](#).

### Contents

1. [Mariabackup and BACKUP STAGE Commands in MariaDB Community Server](#)
  1. [Tasks Performed Prior to BACKUP STAGE in MariaDB Community Server](#)
  2. [BACKUP STAGE START in MariaDB Community Server](#)
  3. [BACKUP STAGE FLUSH in MariaDB Community Server](#)
  4. [BACKUP STAGE BLOCK\\_DDL in MariaDB Community Server](#)
  5. [BACKUP STAGE BLOCK\\_COMMIT in MariaDB Community Server](#)
  6. [BACKUP STAGE END in MariaDB Community Server](#)
2. [Mariabackup and BACKUP STAGE Commands in MariaDB Enterprise Server](#)
  1. [BACKUP STAGE START in MariaDB Enterprise Server](#)
  2. [BACKUP STAGE FLUSH in MariaDB Enterprise Server](#)
  3. [BACKUP STAGE BLOCK\\_DDL in MariaDB Enterprise Server](#)
  4. [BACKUP STAGE BLOCK\\_COMMIT in MariaDB Enterprise Server](#)
  5. [BACKUP STAGE END in MariaDB Enterprise Server](#)

The

[BACKUP STAGE](#)

commands are a set of commands to make it possible to make an efficient external backup tool. How Mariabackup uses these commands depends on whether you are using the version that is bundled with MariaDB Community Server or the version that is bundled with [MariaDB Enterprise Server](#).

## Mariabackup and BACKUP STAGE Commands in MariaDB Community Server

MariaDB starting with [10.4.1](#)

In MariaDB Community Server, Mariabackup first supported

[BACKUP STAGE](#)

commands in [MariaDB 10.4.1](#).

In [MariaDB 10.3](#) and before, the

[BACKUP STAGE](#)

commands are **not** supported, so Mariabackup executes the

## FLUSH TABLES WITH READ LOCK

command to lock the database. When the backup is complete, it executes the

## UNLOCK TABLES

command to unlock the database.

In [MariaDB 10.4](#) and later, the

## BACKUP STAGE

commands are supported. However, the version of Mariabackup that is bundled with MariaDB Community Server does not yet use the

## BACKUP STAGE

commands in the most efficient way. Mariabackup simply executes the following

## BACKUP STAGE

commands to lock the database:

```
BACKUP STAGE START;  
BACKUP STAGE BLOCK_COMMIT;
```

When the backup is complete, it executes the following

## BACKUP STAGE

command to unlock the database:

```
BACKUP STAGE END;
```

If you would like to use a version of Mariabackup that uses the

## BACKUP STAGE

commands in the most efficient way, then your best option is to use [MariaDB Enterprise Backup](#) that is bundled with [MariaDB Enterprise Server](#).

## Tasks Performed Prior to

### BACKUP STAGE in MariaDB Community Server

- Copy some transactional tables.
  - [InnoDB](#) (i.e.
    - ibdataN
    - and file extensions
    - .ibd
    - and
    - .isl
    - )
- Copy the tail of some transaction logs.
  - The tail of the [InnoDB redo log](#) (i.e.
    - ib\_logfileN
    - files) will be copied for [InnoDB](#) tables.

### BACKUP STAGE START in MariaDB Community Server

Mariabackup from MariaDB Community Server does not currently perform any tasks in the

START  
stage.

## BACKUP STAGE FLUSH in MariaDB Community Server

Mariabackup from MariaDB Community Server does not currently perform any tasks in the FLUSH stage.

## BACKUP STAGE BLOCK\_DDL in MariaDB Community Server

Mariabackup from MariaDB Community Server does not currently perform any tasks in the BLOCK\_DDL stage.

## BACKUP STAGE BLOCK\_COMMIT in MariaDB Community Server

Mariabackup from MariaDB Community Server performs the following tasks in the BLOCK\_COMMIT stage:

- Copy other files.
  - i.e. file extensions
    - .frm
    - ,
    - .isl
    - ,
    - .TRG
    - ,
    - .TRN
    - ,
    - .opt
    - ,
    - .par
- Copy some transactional tables.
  - [Aria](#) (i.e.
    - aria\_log\_control
    - and file extensions
    - .MAD
    - and
    - .MAI
    - )
- Copy the non-transactional tables.
  - [MyISAM](#) (i.e. file extensions
    - .MYD
    - and
    - .MYI
    - )
  - [MERGE](#) (i.e. file extensions
    - .MRG
    - )
  - [ARCHIVE](#) (i.e. file extensions
    - .ARM
    - and
    - .ARZ
    - )
  - [CSV](#) (i.e. file extensions
    - .CSM
    - and
    - .CSV
    - )
- Create a [MyRocks](#) checkpoint using the `rocksdb_create_checkpoint` system variable.
- Copy the tail of some transaction logs.

- The tail of the [InnoDB redo log](#) (i.e. `ib_logfileN` files) will be copied for [InnoDB](#) tables.
- Save the [binary log](#) position to

`xtrabackup_binlog_info`

- Save the [Galera Cluster](#) state information to

`xtrabackup_galera_info`

## BACKUP STAGE END in MariaDB Community Server

Mariabackup from MariaDB Community Server performs the following tasks in the

END  
stage:

- Copy the [MyRocks](#) checkpoint into the backup.

## Mariabackup and BACKUP STAGE Commands in MariaDB Enterprise Server

MariaDB starting with [10.2.25](#)

[MariaDB Enterprise Backup](#) first supported

`BACKUP STAGE`

commands in [MariaDB Enterprise Server 10.4.6-1](#) , [MariaDB Enterprise Server 10.3.16-1](#) , and [MariaDB Enterprise Server 10.2.25-1](#) .

The following sections describe how the [MariaDB Enterprise Backup](#) version of Mariabackup that is bundled with [MariaDB Enterprise Server](#) uses each

`BACKUP STAGE`

command in an efficient way.

## BACKUP STAGE START in MariaDB Enterprise Server

Mariabackup from MariaDB Enterprise Server performs the following tasks in the

START  
stage:

- Copy all transactional tables.
  - [InnoDB](#) (i.e.
    - `ibdataN`
    - and file extensions
    - `.ibd`
    - and
    - `.isl`
    - )
  - [Aria](#) (i.e.
    - `aria_log_control`
    - and file extensions
    - `.MAD`
    - and
    - `.MAI`
    - )
- Copy the tail of all transaction logs.
  - The tail of the [InnoDB redo log](#) (i.e. `ib_logfileN`)

- files) will be copied for [InnoDB](#) tables.
- The tail of the Aria redo log (i.e.  
aria\_log.N  
files) will be copied for [Aria](#) tables.

## BACKUP STAGE FLUSH in MariaDB Enterprise Server

Mariabackup from MariaDB Enterprise Server performs the following tasks in the

FLUSH

stage:

- Copy all non-transactional tables that are not in use. This list of used tables is found with

[SHOW OPEN TABLES](#)

- [MyISAM](#) (i.e. file extensions  
.MYD  
and  
.MYI  
)
- [MERGE](#) (i.e. file extensions  
.MRG  
)
- [ARCHIVE](#) (i.e. file extensions  
.ARM  
and  
.ARZ  
)
- [CSV](#) (i.e. file extensions  
.CSM  
and  
.CSV  
)
- Copy the tail of all transaction logs.
  - The tail of the [InnoDB redo log](#) (i.e.  
ib\_logfileN  
files) will be copied for [InnoDB](#) tables.
  - The tail of the Aria redo log (i.e.  
aria\_log.N  
files) will be copied for [Aria](#) tables.

## BACKUP STAGE BLOCK\_DDL in MariaDB Enterprise Server

Mariabackup from MariaDB Enterprise Server performs the following tasks in the

BLOCK\_DDL

stage:

- Copy other files.
  - i.e. file extensions  
.frm  
,  
.isl  
,  
.TRG  
,  
.TRN  
,  
.opt  
,  
.par
- Copy the non-transactional tables that were in use during  
BACKUP STAGE FLUSH
  - [MyISAM](#) (i.e. file extensions  
.MYD

- **MERGE** (i.e. file extensions
  - .MRG
  - )
- **ARCHIVE** (i.e. file extensions
  - .ARM
  - and
  - .ARZ
  - )
- **CSV** (i.e. file extensions
  - .CSM
  - and
  - .CSV
  - )

- Check

ddl.log  
for DDL executed before the  
BLOCK\_DDL  
stage.

- The file names of newly created tables can be read from

ddl.log

- The file names of dropped tables can also be read from

ddl.log

- The file names of renamed tables can also be read from

ddl.log

, so the files can be renamed instead of re-copying them.

- Copy changes to system log tables.

- 

## mysql.general\_log

○

## mysql.slow\_log

- This is easy as these are append only.
  - Copy the tail of all transaction logs.

- The tail of the InnoDB redo log (i.e.

ib logfileN

files) will be copied for InnoDB tables.

- The tail of the Aria redo log (i.e.

aria\_log.N

files) will be copied for [Aria](#) tables.

## BACKUP STAGE BLOCK\_COMMIT in MariaDB Enterprise Server

Mariabackup from MariaDB Enterprise Server performs the following tasks in the `BLOCK_COMMIT` stage:

- Create a `MyRocks` checkpoint using the

`rocksdb create_checkpoint`

system variable.

- Copy changes to system log tables.

8

## mysql.general log

8

`mysql.slow_log`

- This is easy as these are append only.
- Copy changes to statistics tables.
  -

`mysql.table_stats`

◦

`mysql.column_stats`

◦

`mysql.index_stats`

- Copy the tail of all transaction logs.

- The tail of the [InnoDB redo log](#) (i.e. `ib_logfileN` files) will be copied for [InnoDB](#) tables.
- The tail of the [Aria redo log](#) (i.e. `aria_log.N` files) will be copied for [Aria](#) tables.

- Save the [binary log](#) position to

`xtrabackup_binlog_info`

- Save the [Galera Cluster](#) state information to

`xtrabackup_galera_info`

## BACKUP STAGE END in MariaDB Enterprise Server

Mariabackup from MariaDB Enterprise Server performs the following tasks in the

`END`  
stage:

- Copy the [MyRocks](#) checkpoint into the backup.

### 1.1.2.3.4 Storage Snapshots and BACKUP STAGE Commands

MariaDB starting with [10.4.1](#)

The

`BACKUP STAGE`  
commands were introduced in [MariaDB 10.4.1](#).

## Contents

1. [Generic Backup Process with Storage Snapshots](#)

The

`BACKUP STAGE`

commands are a set of commands to make it possible to make an efficient external backup tool. These commands could even be used by tools that perform backups by taking a snapshot of a file system, SAN, or some other kind of storage device.

# Generic Backup Process with Storage Snapshots

A tool that backs up MariaDB by taking a snapshot of a file system, SAN, or some other kind of storage device could use each

```
BACKUP STAGE  
command in the following way:
```

- First, execute the following:

```
BACKUP STAGE START  
BACKUP STAGE BLOCK_COMMIT
```

- Then, take the snapshot.

- Then, execute the following:

```
BACKUP STAGE END
```

The above ensures that all non-transactional tables are properly flushed to disk before the snapshot is done. Using

```
BACKUP STAGE  
commands is also more efficient than using the
```

```
FLUSH TABLES WITH READ LOCK
```

command as the above set of commands will not block or be blocked by write operations to transactional tables.

Note that when the backup is completed, one should delete all files with the "#sql" prefix, as these are files used by concurrent running

```
ALTER TABLE  
. Note that InnoDB will on server restart automatically delete any tables with the "#sql" prefix.
```

## 1.1.2.4 FLUSH Commands

### 1.1.2.4.1 FLUSH

#### Syntax

```
FLUSH [NO_WRITE_TO_BINLOG | LOCAL]  
flush_option [, flush_option] ...
```

or when flushing tables:

```
FLUSH [NO_WRITE_TO_BINLOG | LOCAL] TABLES [table_list] [table_flush_option]
```

## Contents

1. Syntax
2. Description
3. FLUSH STATUS
4. Compatibility with MySQL
  1. Global Status Variables that Support FLUSH STATUS
5. The different usage of FLUSH TABLES
  1. The purpose of FLUSH TABLES
  2. The purpose of FLUSH TABLES WITH READ LOCK
  3. The purpose of FLUSH TABLES table\_list
  4. The purpose of FLUSH TABLES table\_list WITH READ LOCK
6. Implementation of FLUSH TABLES commands in MariaDB 10.4.8 and above
  1. Implementation of FLUSH TABLES
  2. Implementation of FLUSH TABLES WITH READ LOCK
  3. Implementation of FLUSH TABLES table\_list
  4. Implementation of FLUSH TABLES table\_list FOR EXPORT
7. FLUSH SSL
8. Reducing Memory Usage

where

table\_list  
is a list of tables separated by  
,

(comma).

## Description

The

FLUSH  
statement clears or reloads various internal caches used by MariaDB. To execute  
FLUSH  
, you must have the  
RELOAD  
privilege. See [GRANT](#).

The

RESET  
statement is similar to  
FLUSH  
. See [RESET](#).

You cannot issue a FLUSH statement from within a [stored function](#) or a [trigger](#). Doing so within a stored procedure is permitted, as long as it is not called by a stored function or trigger. See [Stored Routine Limitations](#), [Stored Function Limitations](#) and [Trigger Limitations](#).

If a listed table is a view, an error like the following will be produced:

```
ERROR 1347 (HY000): 'test.v' is not BASE TABLE
```

By default,

FLUSH  
statements are written to the [binary log](#) and will be [replicated](#). The  
NO\_WRITE\_TO\_BINLOG  
keyword (  
LOCAL  
is an alias) will ensure the statement is not written to the binary log.

The different flush options are:

Option	Description
CHANGED_PAGE_BITMAPS	Internal command used for backup purposes. See the <a href="#">Information Schema CHANGED_PAGE_BITMAPS Table</a> .

CLIENT_STATISTICS	Reset client statistics (see <a href="#">SHOW CLIENT_STATISTICS</a> ).
DES_KEY_FILE	Reloads the DES key file (Specified with the <a>--des-key-file</a> startup option ).
HOSTS	Flush the hostname cache (used for converting ip to host names and for unblocking blocked hosts. See <a>max_connect_errors</a> )
INDEX_STATISTICS	Reset index statistics (see <a>SHOW INDEX_STATISTICS</a> ).
[ERROR   ENGINE   GENERAL   SLOW   BINARY   RELAY] LOGS	<p>Close and reopen the specified log type, or all log types if none are specified.</p> <p><code>FLUSH RELAY LOGS [connection-name]</code>  can be used to flush the relay logs for a specific connection. Only one connection can be specified per <code>FLUSH</code> command. See <a>Multi-source replication</a> .</p> <p><code>FLUSH ENGINE LOGS</code>  will delete all unneeded Aria redo logs. Since MariaDB 10.1.30 and MariaDB 10.2.11 , <code>FLUSH BINARY LOGS DELETE_DOMAIN_ID=(list-of-domains)</code>  can be used to discard obsolete GTID domains from the server's <a>binary log</a> state. In order for this to be successful, no event group from the listed GTID domains can be present in existing <a>binary log</a> files. If some still exist, then they must be purged prior to executing this command. If the command completes successfully, then it also rotates the <a>binary log</a> .</p>
MASTER	Deprecated option, use <a>RESET MASTER</a> instead.
PRIVILEGES	Reload all privileges from the privilege tables in the mysql database. If the server is started with <code>--skip-grant-table</code> option, this will activate the privilege tables again.
QUERY CACHE	Defragment the <a>query cache</a> to better utilize its memory. If you want to reset the query cache, you can do it with <a>RESET QUERY CACHE</a> .
QUERY_RESPONSE_TIME	See the <a>QUERY_RESPONSE_TIME</a> plugin.
SLAVE	Deprecated option, use <a>RESET REPLICA</a> or <a>RESET SLAVE</a> instead.
SSL	Used to dynamically reinitialize the server's <a>TLS</a> context by reloading the files defined by several <a>TLS system variables</a> . See <a>FLUSH SSL</a> for more information. This command was first added in <a>MariaDB 10.4.1</a> .
STATUS	Resets all <a>server status variables</a> that can be reset to 0. Not all global status variables support this, so not all global values are reset. See <a>FLUSH STATUS</a> for more information.
TABLE	Close tables given as options or all open tables if no table list was used. From <a>MariaDB 10.4.1</a> , using without any table list will only close tables not in use, and tables not locked by the FLUSH TABLES connection. If there are no locked tables, FLUSH TABLES will be instant and will not cause any waits, as it no longer waits for tables in use. When a table list is provided, from <a>MariaDB 10.4.1</a> , the server will wait for the end of any transactions that are using the tables. Previously, FLUSH TABLES only waited for the statements to complete.
TABLES	Same as <code>FLUSH TABLE</code> -
TABLES ... FOR EXPORT	For InnoDB tables, flushes table changes to disk to permit binary table copies while the server is running. Introduced in <a>MariaDB 10.0.8</a> . See <a>FLUSH TABLES ... FOR EXPORT</a> for more.

TABLES WITH READ LOCK	Closes all open tables. New tables are only allowed to be opened with read locks until an <a href="#">UNLOCK TABLES</a> is given.
TABLES WITH READ LOCK AND DISABLE CHECKPOINT	As TABLES WITH READ LOCK but also disable all checkpoint writes by transactional table engines. This is useful when doing a disk snapshot of all tables.
TABLE_STATISTICS	Reset table statistics (see <a href="#">SHOW TABLE_STATISTICS</a> ).
USER_RESOURCES	Resets all per hour <a href="#">user resources</a> . This enables clients that have exhausted their resources to connect again.
USER_STATISTICS	Reset user statistics (see <a href="#">SHOW USER_STATISTICS</a> ).

You can also use the [mysqladmin](#) client to flush things. Use

```
mysqladmin --help
to examine what flush commands it supports.
```

## FLUSH STATUS

[Server status variables](#) can be reset by executing the following:

```
FLUSH STATUS;
```

## Compatibility with MySQL

MariaDB starting with [10.7.0](#)

The

```
FOR CHANNEL
```

keyword was added for MySQL compatibility. This is identical as using the channel\_name directly after the FLUSH command

For example, one can now use:

```
FLUSH RELAY LOGS 'connection_name';
FLUSH RELAY LOGS FOR CHANNEL 'connection_name';
```

## Global Status Variables that Support FLUSH STATUS

Not all global status variables support being reset by

```
FLUSH STATUS
. Currently, the following status variables are reset by
FLUSH STATUS
:
```

- [Aborted\\_clients](#)
- [Aborted\\_connects](#)

## The different usage of

# FLUSH TABLES

## The purpose of FLUSH TABLES

The purpose of

FLUSH TABLES

is to clean up the open table cache and table definition cache from not in use tables. This frees up memory and file descriptors. Normally this is not needed as the caches works on a FIFO bases, but can be useful if the server seams to use up to much memory for some reason.

## The purpose of FLUSH TABLES WITH READ LOCK

FLUSH TABLES WITH READ LOCK

is useful if you want to take a backup of some tables. When

FLUSH TABLES WITH READ LOCK

returns, all write access to tables are blocked and all tables are marked as 'properly closed' on disk. The tables can still be used for read operations.

## The purpose of FLUSH TABLES table\_list

FLUSH TABLES

table\_list is useful if you want to copy a table object/files to or from the server. This command puts a lock that stops new users of the table and will wait until everyone has stopped using the table. The table is then removed from the table definition and table cache.

Note that it's up to the user to ensure that no one is accessing the table between

FLUSH TABLES

and the table is copied to or from the server. This can be secured by using [LOCK TABLES](#).

If there are any tables locked by the connection that is using

FLUSH TABLES

all the locked tables will be closed as part of the flush and reopened and relocked before

FLUSH TABLES

returns. This allows one to copy the table after

FLUSH TABLES

returns without having any writes on the table. For now this works works with most tables, except InnoDB as InnoDB may do background purges on the table even while it's write locked.

## The purpose of FLUSH TABLES table\_list WITH READ LOCK

FLUSH TABLES table\_list WITH READ LOCK

should work as

FLUSH TABLES WITH READ LOCK

, but only those tables that are listed will be properly closed. However in practice this works exactly like

FLUSH TABLES WITH READ LOCK

as the

FLUSH

command has anyway to wait for all WRITE operations to end because we are depending on a global read lock for this code. In the future we should consider fixing this to instead use meta data locks.

## Implementation of FLUSH TABLES commands in MariaDB 10.4.8 and above

## Implementation of FLUSH TABLES

- Free memory and file descriptors not in use

## Implementation of FLUSH TABLES WITH READ LOCK

- Lock all tables read only for simple old style backup.
- All background writes are suspended and tables are marked as closed.
- No statement requiring table changes are allowed for any user until  
UNLOCK TABLES

Instead of using

FLUSH TABLE WITH READ LOCK  
one should in most cases instead use [BACKUP STAGE BLOCK\\_COMMIT](#).

## Implementation of FLUSH TABLES table\_list

- Free memory and file descriptors for tables not in use from table list.
- Lock given tables as read only.
- Wait until all translations has ended that uses any of the given tables.
- Wait until all background writes are suspended and tables are marked as closed.

## Implementation of FLUSH TABLES table\_list FOR EXPORT

- Free memory and file descriptors for tables not in use from table list
  - Lock given tables as read.
  - Wait until all background writes are suspended and tables are marked as closed.
  - Check that all tables supports  
FOR EXPORT
- No changes to these tables allowed until  
UNLOCK TABLES

This is basically the same behavior as in old MariaDB version if one first lock the tables, then do

FLUSH TABLES  
. The tables will be copyable until  
UNLOCK TABLES

## FLUSH SSL

MariaDB starting with [10.4](#)

The

FLUSH SSL  
command was first added in [MariaDB 10.4](#).

In [MariaDB 10.4](#) and later, the

FLUSH SSL  
command can be used to dynamically reinitialize the server's [TLS](#) context. This is most useful if you need to replace a certificate that is about to expire without restarting the server.

This operation is performed by reloading the files defined by the following [TLS system variables](#):

-

`ssl_cert`

`ssl_key`

`ssl_ca`

`ssl_capath`

`ssl_crl`

`ssl_crlpath`

These [TLS system variables](#) are not dynamic, so their values can **not** be changed without restarting the server.

If you want to dynamically reinitialize the server's [TLS](#) context, then you need to change the certificate and key files at the relevant paths defined by these [TLS system variables](#), without actually changing the values of the variables. See [MDEV-19341](#) for more information.

## Reducing Memory Usage

To flush some of the global caches that take up memory, you could execute the following command:

```
FLUSH LOCAL HOSTS,  
        QUERY CACHE,  
        TABLE_STATISTICS,  
        INDEX_STATISTICS,  
        USER_STATISTICS;
```

### 1.1.2.4.2 FLUSH QUERY CACHE

#### Description

You can defragment [the query cache](#) to better utilize its memory with the

```
FLUSH QUERY CACHE  
statement. The statement does not remove any queries from the cache.
```

The

```
RESET QUERY CACHE
```

statement removes all query results from the query cache. The

```
FLUSH TABLES
```

statement also does this.

### 1.1.2.4.3 FLUSH TABLES FOR EXPORT

#### Syntax

```
FLUSH TABLES table_name [, table_name] FOR EXPORT
```

## Contents

1. [Syntax](#)
2. [Description](#)
3. [Example](#)
4. [See Also](#)

## Description

`FLUSH TABLES ... FOR EXPORT`

flushes changes to the specified tables to disk so that binary copies can be made while the server is still running. This works for [Archive](#) , [Aria](#) , [CSV](#) , [InnoDB](#) , [MyISAM](#) , [MERGE](#) , and [XtraDB](#) tables.

The table is read locked until one has issued [UNLOCK TABLES](#) .

If a storage engine does not support

`FLUSH TABLES FOR EXPORT`

, a 1031 error ( [SQLSTATE](#) 'HY000') is produced.

If

`FLUSH TABLES ... FOR EXPORT`

is in effect in the session, the following statements will produce an error if attempted:

- `FLUSH TABLES WITH READ LOCK`
- `FLUSH TABLES ... WITH READ LOCK`
- `FLUSH TABLES ... FOR EXPORT`
- Any statement trying to update any table

If any of the following statements is in effect in the session, attempting

`FLUSH TABLES ... FOR EXPORT`

will produce an error.

- `FLUSH TABLES ... WITH READ LOCK`
- `FLUSH TABLES ... FOR EXPORT`
- `LOCK TABLES ... READ`
- `LOCK TABLES ... WRITE`

`FLUSH FOR EXPORT`

is not written to the [binary log](#) .

This statement requires the [RELOAD](#) and the [LOCK TABLES](#) privileges.

If one of the specified tables cannot be locked, none of the tables will be locked.

If a table does not exist, an error like the following will be produced:

```
ERROR 1146 (42S02): Table 'test.xxx' doesn't exist
```

If a table is a view, an error like the following will be produced:

```
ERROR 1347 (HY000): 'test.v' is not BASE TABLE
```

## Example

```
FLUSH TABLES test.t1 FOR EXPORT;
# Copy files related to the table (see below)
UNLOCK TABLES;
```

## 1.1.2.5 Replication Commands

### 1.1.2.5.1 CHANGE MASTER TO

The terms *master* and *slave* have historically been used in replication, but the terms *primary* and *replica* are now preferred. The old terms are used still used in parts of the documentation, and in MariaDB commands, although MariaDB 10.5 has begun the process of renaming. The documentation process is ongoing. See [MDEV-18777](#) to follow progress on this effort.

## Syntax

```
CHANGE MASTER ['connection_name'] TO master_def [, master_def] ... [FOR CHANNEL 'channel_name']

master_def:
  MASTER_BIND = 'interface_name'
  | MASTER_HOST = 'host_name'
  | MASTER_USER = 'user_name'
  | MASTER_PASSWORD = 'password'
  | MASTER_PORT = port_num
  | MASTER_CONNECT_RETRY = interval
  | MASTER_HEARTBEAT_PERIOD = interval
  | MASTER_LOG_FILE = 'master_log_name'
  | MASTER_LOG_POS = master_log_pos
  | RELAY_LOG_FILE = 'relay_log_name'
  | RELAY_LOG_POS = relay_log_pos
  | MASTER_DELAY = interval
  | MASTER_SSL = {0|1}
  | MASTER_SSL_CA = 'ca_file_name'
  | MASTER_SSL_CAPATH = 'ca_directory_name'
  | MASTER_SSL_CERT = 'cert_file_name'
  | MASTER_SSL_CRL = 'crl_file_name'
  | MASTER_SSL_CRLPATH = 'crl_directory_name'
  | MASTER_SSL_KEY = 'key_file_name'
  | MASTER_SSL_CIPHER = 'cipher_list'
  | MASTER_SSL_VERIFY_SERVER_CERT = {0|1}
  | MASTER_USE_GTID = {current_pos|slave_pos|no}
  | IGNORE_SERVER_IDS = (server_id_list)
  | DO_DOMAIN_IDS = ([N,...])
  | IGNORE_DOMAIN_IDS = ([N,...])
```

## Description

The

```
CHANGE MASTER  
statement sets the options that a replica uses to connect to and replicate from a primary.
```

MariaDB starting with 10.7.0

The

```
FOR CHANNEL  
keyword was added for MySQL compatibility. This is identical to using the channel_name directly after  
CHANGE MASTER
```

## Multi-Source Replication

If you are using `multi-source replication`, then you need to specify a connection name when you execute

```
CHANGE MASTER  
. There are two ways to do this:

- Setting the default_master_connection system variable prior to executing  
CHANGE MASTER
- Setting the

```

```
connection_name  
parameter when executing  
CHANGE MASTER
```

## default\_master\_connection

```
SET default_master_connection = 'gandalf';  
STOP SLAVE;  
CHANGE MASTER TO  
    MASTER_PASSWORD='new3cret';  
START SLAVE;
```

## connection\_name

```
STOP SLAVE 'gandalf';  
CHANGE MASTER 'gandalf' TO  
    MASTER_PASSWORD='new3cret';  
START SLAVE 'gandalf';
```

# Options

## Connection Options

### MASTER\_USER

The

```
MASTER_USER  
option for  
CHANGE MASTER  
defines the user account that the replica will use to connect to the primary.
```

This user account will need the [REPLICATION SLAVE](#) privilege (or, from [MariaDB 10.5.1](#), the [REPLICATION REPLICA](#) on the primary).

For example:

```
STOP SLAVE;  
CHANGE MASTER TO  
    MASTER_USER='rep1',  
    MASTER_PASSWORD='new3cret';  
START SLAVE;
```

The maximum length of the

```
MASTER_USER  
string is 96 characters until MariaDB 10.5, and 128 characters from MariaDB 10.6.
```

### MASTER\_PASSWORD

The

```
MASTER_USER  
option for  
CHANGE MASTER  
defines the password that the replica will use to connect to the primary as the user account defined by the MASTER\_USER option.
```

For example:

```
STOP SLAVE;  
CHANGE MASTER TO  
    MASTER_PASSWORD='new3cret';  
START SLAVE;
```

The maximum length of the  
MASTER\_PASSWORD  
string is 32 characters.

#### MASTER\_HOST

The  
MASTER\_HOST  
option for  
CHANGE MASTER  
defines the hostname or IP address of the primary .

If you set the value of the

MASTER\_HOST  
option to the empty string, then that is not the same as not setting the option's value at all. If you set the value of the  
MASTER\_HOST  
option to the empty string, then the  
CHANGE MASTER  
command will fail with an error. In MariaDB 5.3 and before, if you set the value of the  
MASTER\_HOST  
option to the empty string, then the  
CHANGE MASTER  
command would succeed, but the subsequent START SLAVE command would fail.

For example:

```
STOP SLAVE;  
CHANGE MASTER TO  
MASTER_HOST='dbserver1.example.com',  
MASTER_USER='rep1',  
MASTER_PASSWORD='new3cret',  
MASTER_USE_GTID=slave_pos;  
START SLAVE;
```

If you set the value of the

MASTER\_HOST  
option in a  
CHANGE MASTER  
command, then the replica assumes that the primary is different from before, even if you set the value of this option to the same value it had previously. In this scenario, the replica will consider the old values for the primary's binary log file name and position to be invalid for the new primary. As a side effect, if you do not explicitly set the values of the MASTER\_LOG\_FILE and MASTER\_LOG\_POS options in the statement, then the statement will be implicitly appended with  
MASTER\_LOG\_FILE=''  
and  
MASTER\_LOG\_POS=4  
. However, if you enable GTID mode for replication by setting the MASTER\_USE\_GTID option to some value other than  
no  
in the statement, then these values will effectively be ignored anyway.

Replicas cannot connect to primaries using Unix socket files or Windows named pipes. The replica must connect to the primary using TCP/IP.

The maximum length of the  
MASTER\_HOST  
string is 60 characters until MariaDB 10.5 , and 255 characters from MariaDB 10.6 .

#### MASTER\_PORT

The  
MASTER\_PORT  
option for  
CHANGE MASTER  
defines the TCP/IP port of the primary .

For example:

```
STOP SLAVE;
CHANGE MASTER TO
  MASTER_HOST='dbserver1.example.com',
  MASTER_PORT=3307,
  MASTER_USER='rep1',
  MASTER_PASSWORD='new3cret',
  MASTER_USE_GTID=slave_pos;
START SLAVE;
```

If you set the value of the

MASTER\_PORT  
option in a  
CHANGE MASTER

command, then the replica assumes that the primary is different from before, even if you set the value of this option to the same value it had previously. In this scenario, the replica will consider the old values for the primary's [binary log](#) file name and position to be invalid for the new primary. As a side effect, if you do not explicitly set the values of the [MASTER\\_LOG\\_FILE](#) and [MASTER\\_LOG\\_POS](#) options in the statement, then the statement will be implicitly appended with

MASTER\_LOG\_FILE=''  
and  
MASTER\_LOG\_POS=4  
. However, if you enable [GTID](#) mode for replication by setting the [MASTER\\_USE\\_GTID](#) option to some value other than no  
in the statement, then these values will effectively be ignored anyway.

Replicas cannot connect to primaries using Unix socket files or Windows named pipes. The replica must connect to the primary using TCP/IP.

#### MASTER\_CONNECT\_RETRY

The

MASTER\_CONNECT\_RETRY  
option for  
CHANGE MASTER  
defines how many seconds that the replica will wait between connection retries. The default is  
60

```
STOP SLAVE;
CHANGE MASTER TO
  MASTER_CONNECT_RETRY=20;
START SLAVE;
```

The number of connection attempts is limited by the [master\\_retry\\_count](#) option. It can be set either on the command-line or in a server [option group](#) in an [option file](#) prior to starting up the server. For example:

```
[mariadb]
...
master_retry_count=4294967295
```

#### MASTER\_BIND

The

MASTER\_BIND  
option for  
CHANGE MASTER

is only supported by MySQL 5.6.2 and later and by MySQL NDB Cluster 7.3.1 and later. This option is not supported by MariaDB. See [MDEV-19248](#) for more information.

The

MASTER\_BIND  
option for  
CHANGE MASTER

can be used on replicas that have multiple network interfaces to choose which network interface the replica will use to connect to the primary.

#### MASTER\_HEARTBEAT\_PERIOD

The

MASTER\_HEARTBEAT\_PERIOD

option for

CHANGE MASTER

can be used to set the interval in seconds between replication heartbeats. Whenever the primary's [binary log](#) is updated with an event, the waiting period for the next heartbeat is reset.

This option's *interval* argument has the following characteristics:

- It is a decimal value with a range of
  - 0
  - to
  - 4294967
  - seconds.
- It has a resolution of hundredths of a second.
- Its smallest valid non-zero value is
  - 0.001
- Its default value is the value of the [slave\\_net\\_timeout](#) system variable divided by 2.
- If it's set to
  - 0
  - , then heartbeats are disabled.

Heartbeats are sent by the primary only if there are no unsent events in the binary log file for a period longer than the interval.

If the [RESET SLAVE](#) statement is executed, then the heartbeat interval is reset to the default.

If the [slave\\_net\\_timeout](#) system variable is set to a value that is lower than the current heartbeat interval, then a warning will be issued.

## TLS Options

The TLS options are used for providing information about [TLS](#). The options can be set even on replicas that are compiled without TLS support. The TLS options are saved to either the default

master.info

file or the file that is configured by the [master\\_info\\_file](#) option, but these TLS options are ignored unless the replica supports TLS.

See [Replication with Secure Connections](#) for more information.

#### MASTER\_SSL

The

MASTER\_SSL

option for

CHANGE MASTER

tells the replica whether to force [TLS](#) for the connection. The valid values are

0

or

1

For example:

```
STOP SLAVE;  
CHANGE MASTER TO  
    MASTER_SSL=1;  
START SLAVE;
```

#### MASTER\_SSL\_CA

The

MASTER\_SSL\_CA

option for

CHANGE MASTER

defines a path to a PEM file that should contain one or more X509 certificates for trusted Certificate Authorities (CAs) to use for [TLS](#). This option requires that you use the absolute path, not a relative path. This option implies the [MASTER\\_SSL](#) option.

For example:

```
STOP SLAVE;
CHANGE MASTER TO
  MASTER_SSL_CERT='/etc/my.cnf.d/certificates/server-cert.pem',
  MASTER_SSL_KEY='/etc/my.cnf.d/certificates/server-key.pem',
  MASTER_SSL_CA='/etc/my.cnf.d/certificates/ca.pem',
  MASTER_SSL_VERIFY_SERVER_CERT=1;
START SLAVE;
```

See [Secure Connections Overview: Certificate Authorities \(CAs\)](#) for more information.

The maximum length of

MASTER\_SSL\_CA  
string is 511 characters.

#### MASTER\_SSL\_CAPATH

The

MASTER\_SSL\_CAPATH  
option for  
CHANGE MASTER

defines a path to a directory that contains one or more PEM files that should each contain one X509 certificate for a trusted Certificate Authority (CA) to use for [TLS](#). This option requires that you use the absolute path, not a relative path. The directory specified by this option needs to be run through the [openssl rehash](#) command. This option implies the [MASTER\\_SSL](#) option.

For example:

```
STOP SLAVE;
CHANGE MASTER TO
  MASTER_SSL_CERT='/etc/my.cnf.d/certificates/server-cert.pem',
  MASTER_SSL_KEY='/etc/my.cnf.d/certificates/server-key.pem',
  MASTER_SSL_CAPATH='/etc/my.cnf.d/certificates/ca/',
  MASTER_SSL_VERIFY_SERVER_CERT=1;
START SLAVE;
```

See [Secure Connections Overview: Certificate Authorities \(CAs\)](#) for more information.

The maximum length of

MASTER\_SSL\_CA\_PATH  
string is 511 characters.

#### MASTER\_SSL\_CERT

The

MASTER\_SSL\_CERT  
option for  
CHANGE MASTER

defines a path to the X509 certificate file to use for [TLS](#). This option requires that you use the absolute path, not a relative path. This option implies the [MASTER\\_SSL](#) option.

For example:

```
STOP SLAVE;
CHANGE MASTER TO
  MASTER_SSL_CERT='/etc/my.cnf.d/certificates/server-cert.pem',
  MASTER_SSL_KEY='/etc/my.cnf.d/certificates/server-key.pem',
  MASTER_SSL_CA='/etc/my.cnf.d/certificates/ca.pem',
  MASTER_SSL_VERIFY_SERVER_CERT=1;
START SLAVE;
```

The maximum length of

MASTER\_SSL\_CERT  
string is 511 characters.

## MASTER\_SSL\_CRL

The

MASTER\_SSL\_CRL  
option for  
CHANGE MASTER

defines a path to a PEM file that should contain one or more revoked X509 certificates to use for [TLS](#). This option requires that you use the absolute path, not a relative path.

This option is only supported if the server was built with OpenSSL. If the server was built with yaSSL, then this option is not supported. See [TLS and Cryptography Libraries Used by MariaDB](#) for more information about which libraries are used on which platforms.

For example:

```
STOP SLAVE;  
CHANGE MASTER TO  
MASTER_SSL_CERT='/etc/my.cnf.d/certificates/server-cert.pem',  
MASTER_SSL_KEY='/etc/my.cnf.d/certificates/server-key.pem',  
MASTER_SSL_CA='/etc/my.cnf.d/certificates/ca.pem',  
MASTER_SSL_VERIFY_SERVER_CERT=1,  
MASTER_SSL_CRL='/etc/my.cnf.d/certificates/crl.pem';  
START SLAVE;
```

See [Secure Connections Overview: Certificate Revocation Lists \(CRLs\)](#) for more information.

The maximum length of

MASTER\_SSL\_CRL  
string is 511 characters.

## MASTER\_SSL\_CRLPATH

The

MASTER\_SSL\_CRLPATH  
option for  
CHANGE MASTER

defines a path to a directory that contains one or more PEM files that should each contain one revoked X509 certificate to use for [TLS](#). This option requires that you use the absolute path, not a relative path. The directory specified by this variable needs to be run through the [openssl rehash](#) command.

This option is only supported if the server was built with OpenSSL. If the server was built with yaSSL, then this option is not supported. See [TLS and Cryptography Libraries Used by MariaDB](#) for more information about which libraries are used on which platforms.

For example:

```
STOP SLAVE;  
CHANGE MASTER TO  
MASTER_SSL_CERT='/etc/my.cnf.d/certificates/server-cert.pem',  
MASTER_SSL_KEY='/etc/my.cnf.d/certificates/server-key.pem',  
MASTER_SSL_CA='/etc/my.cnf.d/certificates/ca.pem',  
MASTER_SSL_VERIFY_SERVER_CERT=1,  
MASTER_SSL_CRLPATH='/etc/my.cnf.d/certificates/crl/';  
START SLAVE;
```

See [Secure Connections Overview: Certificate Revocation Lists \(CRLs\)](#) for more information.

The maximum length of

MASTER\_SSL\_CRL\_PATH  
string is 511 characters.

## MASTER\_SSL\_KEY

The

MASTER\_SSL\_KEY  
option for  
CHANGE MASTER

defines a path to a private key file to use for [TLS](#). This option requires that you use the absolute path, not a relative path. This option implies the [MASTER\\_SSL](#) option.

For example:

```

STOP SLAVE;
CHANGE MASTER TO
  MASTER_SSL_CERT='/etc/my.cnf.d/certificates/server-cert.pem',
  MASTER_SSL_KEY='/etc/my.cnf.d/certificates/server-key.pem',
  MASTER_SSL_CA='/etc/my.cnf.d/certificates/ca.pem',
  MASTER_SSL_VERIFY_SERVER_CERT=1;
START SLAVE;

```

The maximum length of

MASTER\_SSL\_KEY  
string is 511 characters.

#### MASTER\_SSL\_CIPHER

The

MASTER\_SSL\_CIPHER  
option for  
CHANGE MASTER

defines the list of permitted ciphers or cipher suites to use for [TLS](#). Besides cipher names, if MariaDB was compiled with OpenSSL, this option could be set to "SSLv3" or "TLSv1.2" to allow all SSLv3 or all TLSv1.2 ciphers. Note that the TLSv1.3 ciphers cannot be excluded when using OpenSSL, even by using this option. See [Using TLSv1.3](#) for details. This option implies the [MASTER\\_SSL](#) option.

For example:

```

STOP SLAVE;
CHANGE MASTER TO
  MASTER_SSL_CERT='/etc/my.cnf.d/certificates/server-cert.pem',
  MASTER_SSL_KEY='/etc/my.cnf.d/certificates/server-key.pem',
  MASTER_SSL_CA='/etc/my.cnf.d/certificates/ca.pem',
  MASTER_SSL_VERIFY_SERVER_CERT=1,
  MASTER_SSL_CIPHER='TLSv1.2';
START SLAVE;

```

The maximum length of

MASTER\_SSL\_CIPHER  
string is 511 characters.

#### MASTER\_SSL\_VERIFY\_SERVER\_CERT

The

MASTER\_SSL\_VERIFY\_SERVER\_CERT  
option for  
CHANGE MASTER  
enables [server certificate verification](#). This option is disabled by default.

For example:

```

STOP SLAVE;
CHANGE MASTER TO
  MASTER_SSL_CERT='/etc/my.cnf.d/certificates/server-cert.pem',
  MASTER_SSL_KEY='/etc/my.cnf.d/certificates/server-key.pem',
  MASTER_SSL_CA='/etc/my.cnf.d/certificates/ca.pem',
  MASTER_SSL_VERIFY_SERVER_CERT=1;
START SLAVE;

```

See [Secure Connections Overview: Server Certificate Verification](#) for more information.

## Binary Log Options

These options are related to the [binary log](#) position on the primary.

#### MASTER\_LOG\_FILE

The

MASTER\_LOG\_FILE

option for  
CHANGE MASTER  
can be used along with  
MASTER\_LOG\_POS  
to specify the coordinates at which the [replica's I/O thread](#) should begin reading from the primary's [binary logs](#) the next time the thread starts.

For example:

```
STOP SLAVE;  
CHANGE MASTER TO  
    MASTER_LOG_FILE='master2-bin.001',  
    MASTER_LOG_POS=4;  
START SLAVE;
```

The [MASTER\\_LOG\\_FILE](#) and [MASTER\\_LOG\\_POS](#) options cannot be specified if the [RELAY\\_LOG\\_FILE](#) and [RELAY\\_LOG\\_POS](#) options were also specified.

The [MASTER\\_LOG\\_FILE](#) and [MASTER\\_LOG\\_POS](#) options are effectively ignored if you enable [GTID](#) mode for replication by setting the [MASTER\\_USE\\_GTID](#) option to some value other than

no  
in the statement.

### MASTER\_LOG\_POS

The

MASTER\_LOG\_POS  
option for  
CHANGE MASTER  
can be used along with  
MASTER\_LOG\_FILE  
to specify the coordinates at which the [replica's I/O thread](#) should begin reading from the primary's [binary logs](#) the next time the thread starts.

For example:

```
STOP SLAVE;  
CHANGE MASTER TO  
    MASTER_LOG_FILE='master2-bin.001',  
    MASTER_LOG_POS=4;  
START SLAVE;
```

The [MASTER\\_LOG\\_FILE](#) and [MASTER\\_LOG\\_POS](#) options cannot be specified if the [RELAY\\_LOG\\_FILE](#) and [RELAY\\_LOG\\_POS](#) options were also specified.

The [MASTER\\_LOG\\_FILE](#) and [MASTER\\_LOG\\_POS](#) options are effectively ignored if you enable [GTID](#) mode for replication by setting the [MASTER\\_USE\\_GTID](#) option to some value other than

no  
in the statement.

## Relay Log Options

These options are related to the [relay log](#) position on the replica.

### RELAY\_LOG\_FILE

The

RELAY\_LOG\_FILE  
option for  
CHANGE MASTER  
can be used along with the [RELAY\\_LOG\\_POS](#) option to specify the coordinates at which the [replica's SQL thread](#) should begin reading from the [relay log](#) the next time the thread starts.

The

```
CHANGE MASTER  
statement usually deletes all relay log files. However, if the  
RELAY_LOG_FILE  
and/or  
RELAY_LOG_POS  
options are specified, then existing relay log files are kept.
```

When you want to change the [relay log](#) position, you only need to stop the [replica's SQL thread](#). The [replica's I/O thread](#) can continue running. The [STOP SLAVE](#) and [START SLAVE](#) statements support the

```
SQL_THREAD  
option for this scenario. For example:
```

```
STOP SLAVE SQL_THREAD;  
CHANGE MASTER TO  
    RELAY_LOG_FILE='slave-relay-bin.006',  
    RELAY_LOG_POS=4025;  
START SLAVE SQL_THREAD;
```

When the value of this option is changed, the metadata about the [replica's SQL thread's](#) position in the [relay logs](#) will also be changed in the [relay-log.info](#) file or the file that is configured by the [relay\\_log\\_info\\_file](#) system variable.

The [RELAY\\_LOG\\_FILE](#) and [RELAY\\_LOG\\_POS](#) options cannot be specified if the [MASTER\\_LOG\\_FILE](#) and [MASTER\\_LOG\\_POS](#) options were also specified.

### RELAY\_LOG\_POS

The

```
RELAY_LOG_POS  
option for  
CHANGE MASTER  
can be used along with the RELAY\_LOG\_FILE option to specify the coordinates at which the replica's SQL thread should begin reading from the  
relay log the next time the thread starts.
```

The

```
CHANGE MASTER  
statement usually deletes all relay log files. However, if the  
RELAY_LOG_FILE  
and/or  
RELAY_LOG_POS  
options are specified, then existing relay log files are kept.
```

When you want to change the [relay log](#) position, you only need to stop the [replica's SQL thread](#). The [replica's I/O thread](#) can continue running. The [STOP SLAVE](#) and [START SLAVE](#) statements support the

```
SQL_THREAD  
option for this scenario. For example:
```

```
STOP SLAVE SQL_THREAD;  
CHANGE MASTER TO  
    RELAY_LOG_FILE='slave-relay-bin.006',  
    RELAY_LOG_POS=4025;  
START SLAVE SQL_THREAD;
```

When the value of this option is changed, the metadata about the [replica's SQL thread's](#) position in the [relay logs](#) will also be changed in the [relay-log.info](#) file or the file that is configured by the [relay\\_log\\_info\\_file](#) system variable.

The [RELAY\\_LOG\\_FILE](#) and [RELAY\\_LOG\\_POS](#) options cannot be specified if the [MASTER\\_LOG\\_FILE](#) and [MASTER\\_LOG\\_POS](#) options were also specified.

## GTID Options

### MASTER\_USE\_GTID

The

MASTER\_USE\_GTID  
option for  
CHANGE MASTER  
can be used to configure the replica to use the [global transaction ID \(GTID\)](#) when connecting to a primary. The possible values are:

- current\_pos
  - Replicate in **GTID** mode and use [gtid\\_current\\_pos](#) as the position to start downloading transactions from the primary.
- slave\_pos
  - Replicate in **GTID** mode and use [gtid\\_slave\\_pos](#) as the position to start downloading transactions from the primary. From [MariaDB 10.5.1](#),
- replica\_pos
  - is an alias for
  - slave\_pos
- no
  - Don't replicate in **GTID** mode.

For example:

```
STOP SLAVE;  
CHANGE MASTER TO  
    MASTER_USE_GTID = current_pos;  
START SLAVE;
```

Or:

```
STOP SLAVE;  
SET GLOBAL gtid_slave_pos='0-1-153';  
CHANGE MASTER TO  
    MASTER_USE_GTID = slave_pos;  
START SLAVE;
```

## Replication Filter Options

Also see [Replication filters](#).

### IGNORE\_SERVER\_IDS

The

IGNORE\_SERVER\_IDS  
option for  
CHANGE MASTER  
can be used to configure a [replica](#) to ignore [binary log](#) events that originated from certain servers. Filtered [binary log](#) events will not get logged to the replica's [relay log](#), and they will not be applied by the replica.

The option's value can be specified by providing a comma-separated list of [server\\_id](#) values. For example:

```
STOP SLAVE;  
CHANGE MASTER TO  
    IGNORE_SERVER_IDS = (3,5);  
START SLAVE;
```

If you would like to clear a previously set list, then you can set the value to an empty list. For example:

```
STOP SLAVE;  
CHANGE MASTER TO  
    IGNORE_SERVER_IDS = ();  
START SLAVE;
```

### DO\_DOMAIN\_IDS

MariaDB starting with [10.1.2](#)

The

DO\_DOMAIN\_IDS

option for  
CHANGE MASTER  
was first added in [MariaDB 10.1.2](#).

The

DO\_DOMAIN\_IDS  
option for  
CHANGE MASTER  
can be used to configure a [replica](#) to only apply [binary log](#) events if the transaction's [GTID](#) is in a specific [gtid\\_domain\\_id](#) value. Filtered [binary log](#) events will not get logged to the replica's [relay log](#), and they will not be applied by the replica.

The option's value can be specified by providing a comma-separated list of [gtid\\_domain\\_id](#) values. Duplicate values are automatically ignored. For example:

```
STOP SLAVE;  
CHANGE MASTER TO  
    DO_DOMAIN_IDS = (1,2);  
START SLAVE;
```

If you would like to clear a previously set list, then you can set the value to an empty list. For example:

```
STOP SLAVE;  
CHANGE MASTER TO  
    DO_DOMAIN_IDS = ();  
START SLAVE;
```

The [DO\\_DOMAIN\\_IDS](#) option and the [IGNORE\\_DOMAIN\\_IDS](#) option cannot both be set to non-empty values at the same time. If you want to set the [DO\\_DOMAIN\\_IDS](#) option, and the [IGNORE\\_DOMAIN\\_IDS](#) option was previously set, then you need to clear the value of the [IGNORE\\_DOMAIN\\_IDS](#) option. For example:

```
STOP SLAVE;  
CHANGE MASTER TO  
    IGNORE_DOMAIN_IDS = (),  
    DO_DOMAIN_IDS = (1,2);  
START SLAVE;
```

The

DO\_DOMAIN\_IDS  
option can only be specified if the replica is replicating in [GTID](#) mode. Therefore, the [MASTER\\_USE\\_GTID](#) option must also be set to some value other than  
no  
in order to use this option.

## IGNORE\_DOMAIN\_IDS

MariaDB starting with [10.1.2](#)

The

IGNORE\_DOMAIN\_IDS  
option for  
CHANGE MASTER  
was first added in [MariaDB 10.1.2](#).

The

IGNORE\_DOMAIN\_IDS  
option for  
CHANGE MASTER  
can be used to configure a [replica](#) to ignore [binary log](#) events if the transaction's [GTID](#) is in a specific [gtid\\_domain\\_id](#) value. Filtered [binary log](#) events will not get logged to the replica's [relay log](#), and they will not be applied by the replica.

The option's value can be specified by providing a comma-separated list of [gtid\\_domain\\_id](#) values. Duplicate values are automatically ignored. For example:

```
STOP SLAVE;
CHANGE MASTER TO
  IGNORE_DOMAIN_IDS = (1,2);
START SLAVE;
```

If you would like to clear a previously set list, then you can set the value to an empty list. For example:

```
STOP SLAVE;
CHANGE MASTER TO
  IGNORE_DOMAIN_IDS = ();
START SLAVE;
```

The `DO_DOMAIN_IDS` option and the `IGNORE_DOMAIN_IDS` option cannot both be set to non-empty values at the same time. If you want to set the `IGNORE_DOMAIN_IDS` option, and the `DO_DOMAIN_IDS` option was previously set, then you need to clear the value of the `DO_DOMAIN_IDS` option. For example:

```
STOP SLAVE;
CHANGE MASTER TO
  DO_DOMAIN_IDS = (),
  IGNORE_DOMAIN_IDS = (1,2);
START SLAVE;
```

The

`IGNORE_DOMAIN_IDS` option can only be specified if the replica is replicating in `GTID` mode. Therefore, the `MASTER_USE_GTID` option must also be set to some value other than `no` in order to use this option.

## Delayed Replication Options

### `MASTER_DELAY`

MariaDB starting with 10.2.3

The

`MASTER_DELAY` option for `CHANGE MASTER` was first added in MariaDB 10.2.3 to enable `delayed replication`.

The

`MASTER_DELAY` option for `CHANGE MASTER` can be used to enable `delayed replication`. This option specifies the time in seconds (at least) that a replica should lag behind the primary up to a maximum value of 2147483647, or about 68 years. Before executing an event, the replica will first wait, if necessary, until the given time has passed since the event was created on the primary. The result is that the replica will reflect the state of the primary some time back in the past. The default is zero, no delay.

```
STOP SLAVE;
CHANGE MASTER TO
  MASTER_DELAY=3600;
START SLAVE;
```

## Changing Option Values

If you don't specify a given option when executing the

`CHANGE MASTER`

statement, then the option keeps its old value in most cases. Most of the time, there is no need to specify the options that do not need to change. For example, if the password for the user account that the replica uses to connect to its primary has changed, but no other options need to change, then you can just change the `MASTER_PASSWORD` option by executing the following commands:

```
STOP SLAVE;
CHANGE MASTER TO
    MASTER_PASSWORD='new3cret';
START SLAVE;
```

There are some cases where options are implicitly reset, such as when the `MASTER_HOST` and `MASTER_PORT` options are changed.

## Option Persistence

The values of the `MASTER_LOG_FILE` and `MASTER_LOG_POS` options (i.e. the `binary log` position on the primary) and most other options are written to either the default

`master.info`

file or the file that is configured by the `master_info_file` option. The replica's I/O thread keeps this `binary log` position updated as it downloads events only when `MASTER_USE_GTID` option is set to

`NO`

. Otherwise the file is not updated on a per event basis.

The `master_info_file` option can be set either on the command-line or in a server `option group` in an `option file` prior to starting up the server. For example:

```
[mariadb]
...
master_info_file=/mariadb/myserver1-master.info
```

The values of the `RELAY_LOG_FILE` and `RELAY_LOG_POS` options (i.e. the `relay log` position) are written to either the default

`relay-log.info`

file or the file that is configured by the `relay_log_info_file` system variable. The replica's SQL thread keeps this `relay log` position updated as it applies events.

The `relay_log_info_file` system variable can be set either on the command-line or in a server `option group` in an `option file` prior to starting up the server. For example:

```
[mariadb]
...
relay_log_info_file=/mariadb/myserver1-relay-log.info
```

## GTID Persistence

If the replica is replicating `binary log` events that contain `GTIDs`, then the replica's SQL thread will write every GTID that it applies to the `mysql.gtid_slave_pos` table. This GTID can be inspected and modified through the `gtid_slave_pos` system variable.

If the replica has the `log_slave_updates` system variable enabled and if the replica has the `binary log` enabled, then every write by the replica's SQL thread will also go into the replica's `binary log`. This means that `GTIDs` of replicated transactions would be reflected in the value of the `gtid_binlog_pos` system variable.

## Creating a Slave from a Backup

The

`CHANGE MASTER`

statement is useful for setting up a replica when you have a backup of the primary and you also have the `binary log` position or `GTID` position corresponding to the backup.

After restoring the backup on the replica, you could execute something like this to use the `binary log` position:

```
CHANGE MASTER TO
    MASTER_LOG_FILE='master2-bin.001',
    MASTER_LOG_POS=4;
START SLAVE;
```

Or you could execute something like this to use the `GTID` position:

```
SET GLOBAL gtid_slave_pos='0-1-153';
CHANGE MASTER TO
    MASTER_USE_GTID=slave_pos;
START SLAVE;
```

See [Setting up a Replication Slave with Mariabackup](#) for more information on how to do this with [Mariabackup](#).

## Example

The following example changes the primary and primary's binary log coordinates. This is used when you want to set up the replica to replicate the primary:

```
CHANGE MASTER TO
  MASTER_HOST='master2.mycompany.com',
  MASTER_USER='replication',
  MASTER_PASSWORD='bigs3cret',
  MASTER_PORT=3306,
  MASTER_LOG_FILE='master2-bin.001',
  MASTER_LOG_POS=4,
  MASTER_CONNECT_RETRY=10;
START SLAVE;
```

## See Also

- [Setting up replication](#)
- [START SLAVE](#)
- [Multi-source replication](#)
- [RESET SLAVE](#). Removes a connection created with  
CHANGE MASTER TO

- [Global Transaction ID](#)

## 1.1.2.5.2 START SLAVE

The terms *master* and *slave* have historically been used in replication, but the terms *primary* and *replica* are now preferred. The old terms are used still used in parts of the documentation, and in MariaDB commands, although MariaDB 10.5 has begun the process of renaming. The documentation process is ongoing. See [MDEV-18777](#) to follow progress on this effort.

## Syntax

```
START SLAVE ["connection_name"] [thread_type [, thread_type] ... ] [FOR CHANNEL "connection_name"]
START SLAVE ["connection_name"] [SQL_THREAD] UNTIL
  MASTER_LOG_FILE = 'log_name', MASTER_LOG_POS = log_pos [FOR CHANNEL "connection_name"]
START SLAVE ["connection_name"] [SQL_THREAD] UNTIL
  RELAY_LOG_FILE = 'log_name', RELAY_LOG_POS = log_pos [FOR CHANNEL "connection_name"]
START SLAVE ["connection_name"] [SQL_THREAD] UNTIL
  MASTER_GTID_POS = <GTID position> [FOR CHANNEL "connection_name"]
START ALL SLAVES [thread_type [, thread_type]]

START REPLICA ["connection_name"] [thread_type [, thread_type] ... ] -- from 10.5.1
START REPLICA ["connection_name"] [SQL_THREAD] UNTIL
  MASTER_LOG_FILE = 'log_name', MASTER_LOG_POS = log_pos -- from 10.5.1
START REPLICA ["connection_name"] [SQL_THREAD] UNTIL
  RELAY_LOG_FILE = 'log_name', RELAY_LOG_POS = log_pos -- from 10.5.1
START REPLICA ["connection_name"] [SQL_THREAD] UNTIL
  MASTER_GTID_POS = <GTID position> -- from 10.5.1
START ALL REPLICAS [thread_type [, thread_type]] -- from 10.5.1

thread_type: IO_THREAD | SQL_THREAD
```

## Contents

1. [Syntax](#)
2. [Description](#)
  1. [START SLAVE UNTIL](#)
  2. [connection\\_name](#)
  3. [START ALL SLAVES](#)
  4. [START REPLICA](#)
3. [See Also](#)

## Description

```
START SLAVE
(
START REPLICA
  from MariaDB 10.5.1 ) with no thread_type options starts both of the replica threads (see replication). The I/O thread reads events from the primary server and stores them in the relay log. The SQL thread reads events from the relay log and executes them.
```

START SLAVE

requires the [SUPER](#) privilege, or, from [MariaDB 10.5.2](#), the [REPLICATION SLAVE ADMIN](#) privilege.

If

START SLAVE

succeeds in starting the replica threads, it returns without any error. However, even in that case, it might be that the replica threads start and then later stop (for example, because they do not manage to connect to the primary or read its [binary log](#), or some other problem).

START SLAVE

does not warn you about this. You must check the replica's [error log](#) for error messages generated by the replica threads, or check that they are running satisfactorily with [SHOW SLAVE STATUS](#) ( [SHOW REPLICAS STATUS](#) from [MariaDB 10.5.1](#) ).

## START SLAVE UNTIL

START SLAVE UNTIL

refers to the

SQL\_THREAD

replica position at which the

SQL\_THREAD

replication will halt. If

SQL\_THREAD

isn't specified both threads are started.

START SLAVE UNTIL master\_gtid\_pos=xxx

is also supported. See [Global Transaction ID/START SLAVE UNTIL master\\_gtid\\_pos=xxx](#) for more details.

## connection\_name

If there is only one nameless primary, or the default primary (as specified by the [default\\_master\\_connection](#) system variable) is intended,

connection\_name

can be omitted. If provided, the

START SLAVE

statement will apply to the specified primary.

connection\_name

is case-insensitive.

MariaDB starting with [10.7.0](#)

The

FOR CHANNEL

keyword was added for MySQL compatibility. This is identical as using the channel\_name directly after

START SLAVE

## START ALL SLAVES

START ALL SLAVES

starts all configured replicas (replicas with master\_host not empty) that were not started before. It will give a

note

for all started connections. You can check the notes with [SHOW WARNINGS](#).

## START REPLICA

MariaDB starting with [10.5.1](#)

START REPLICA

is an alias for

START SLAVE

from [MariaDB 10.5.1](#).

## See Also

- [Setting up replication](#).
- [CHANGE MASTER TO](#) is used to create and change connections.
- [STOP SLAVE](#) is used to stop a running connection.
- [RESET SLAVE](#) is used to reset parameters for a connection and also to permanently delete a primary connection.

## 1.1.2.5.3 STOP SLAVE

The terms *master* and *slave* have historically been used in replication, but the terms *primary* and *replica* are now preferred. The old terms are used still used in parts of the documentation, and in MariaDB commands, although MariaDB 10.5 has begun the process of renaming. The documentation process is ongoing. See [MDEV-18777](#) to follow progress on this effort.

### Syntax

```
STOP SLAVE ["connection_name"] [thread_type [, thread_type] ... ] [FOR CHANNEL "connection_name"]

STOP ALL SLAVES [thread_type [, thread_type]]

STOP REPLICA ["connection_name"] [thread_type [, thread_type] ... ] -- from 10.5.1

STOP ALL REPLICAS [thread_type [, thread_type]] -- from 10.5.1

thread_type: IO_THREAD | SQL_THREAD
```

### Contents

1. [Syntax](#)
2. [Description](#)
  - 1. [STOP ALL SLAVES](#)
  - 2. [connection\\_name](#)
  - 3. [STOP REPLICA](#)
3. [See Also](#)

### Description

Stops the replica threads.

```
STOP SLAVE
requires the SUPER privilege, or, from MariaDB 10.5.2 , the REPLICATION SLAVE ADMIN privilege.
```

Like [START SLAVE](#) , this statement may be used with the

IO\_THREAD  
and  
SQL\_THREAD  
options to name the thread or threads to be stopped. In almost all cases, one never need to use the  
thread\_type  
options.

STOP SLAVE  
waits until any current replication event group affecting one or more non-transactional tables has finished executing (if there is any such replication group), or until the user issues a [KILL QUERY](#) or [KILL CONNECTION](#) statement.

Note that

```
STOP SLAVE
doesn't delete the connection permanently. Next time you execute START SLAVE or the MariaDB server restarts, the replica connection is
restored with it's original arguments . If you want to delete a connection, you should execute RESET SLAVE .
```

### STOP ALL SLAVES

```
STOP ALL SLAVES
stops all your running replicas. It will give you a
note
for every stopped connection. You can check the notes with SHOW WARNINGS .
```

### connection\_name

The

```
connection_name
option is used for multi-source replication .
```

If there is only one nameless master, or the default master (as specified by the [default\\_master\\_connection](#) system variable) is intended,  
connection\_name  
can be omitted. If provided, the  
STOP SLAVE  
statement will apply to the specified master.

`connection_name`  
is case-insensitive.

MariaDB starting with 10.7.0

The

`FOR CHANNEL`  
keyword was added for MySQL compatibility. This is identical as using the `channel_name` directly after  
`STOP SLAVE`

## STOP REPLICA

MariaDB starting with 10.5.1

`STOP REPLICA`  
is an alias for  
`STOP SLAVE`  
from MariaDB 10.5.1 .

## See Also

- [CHANGE MASTER TO](#) is used to create and change connections.
- [START SLAVE](#) is used to start a predefined connection.
- [RESET SLAVE](#) is used to reset parameters for a connection and also to permanently delete a master connection.

## 1.1.2.5.4 RESET SLAVE

The terms *master* and *slave* have historically been used in replication, but the terms *primary* and *replica* are now preferred. The old terms are used still used in parts of the documentation, and in MariaDB commands, although MariaDB 10.5 has begun the process of renaming. The documentation process is ongoing. See [MDEV-18777](#) to follow progress on this effort.

## Syntax

```
RESET SLAVE ["connection_name"] [ALL] [FOR CHANNEL "connection_name"]
```

### Contents

1. [Syntax](#)
2. [Description](#)
  1. [connection\\_name](#)
  2. [RESET REPLICA](#)
3. [See Also](#)

## Description

`RESET SLAVE` makes the slave forget its [replication](#) position in the master's [binary log](#). This statement is meant to be used for a clean start. It deletes the `master.info` and `relay-log.info` files, all the [relay log](#) files, and starts a new relay log file. To use `RESET SLAVE`, the slave replication threads must be stopped (use `STOP SLAVE` if necessary).

Note: All relay log files are deleted, even if they have not been completely executed by the slave SQL thread. (This is a condition likely to exist on a replication slave if you have issued a `STOP SLAVE` statement or if the slave is highly loaded.)

Note:

`RESET REPLICA`  
does not reset the global  
`gtid_slave_pos`  
variable. This means that a replica server configured with  
`CHANGE MASTER TO MASTER_USE_GTID=slave_pos`  
will not receive events with GTIDs occurring before the state saved in  
`gtid_slave_pos`  
. If the intent is to reprocess these events,  
`gtid_slave_pos`

```
must be manually reset, e.g. by executing  
set global gtid_slave_pos=""
```

Connection information stored in the master.info file is immediately reset using any values specified in the corresponding startup options. This information includes values such as master host, master port, master user, and master password. If the slave SQL thread was in the middle of replicating temporary tables when it was stopped, and RESET SLAVE is issued, these replicated temporary tables are deleted on the slave.

The

```
ALL  
also resets the  
PORT  
,  
HOST  
,  
USER  
and  
PASSWORD
```

parameters for the slave. If you are using a connection name, it will permanently delete it and it will not show up anymore in [SHOW ALL SLAVES STATUS](#).

`connection_name`

The

```
connection_name  
option is used for multi-source replication.
```

If there is only one nameless master, or the default master (as specified by the `default_master_connection` system variable) is intended,

```
connection_name  
can be omitted. If provided, the  
RESET SLAVE  
statement will apply to the specified master.  
connection_name  
is case-insensitive.
```

MariaDB starting with [10.7.0](#)

The

```
FOR CHANNEL  
keyword was added for MySQL compatibility. This is identical as using the channel_name directly after  
RESET SLAVE
```

**RESET REPLICA**

MariaDB starting with [10.5.1](#)

```
RESET REPLICA  
is an alias for  
RESET SLAVE  
from MariaDB 10.5.1.
```

## See Also

- [STOP SLAVE](#) stops the slave, but it can be restarted with [START SLAVE](#) or after next MariaDB server restart.

## 1.1.2.5.5 SET GLOBAL SQL\_SLAVE\_SKIP\_COUNTER

### Contents

1. [Syntax](#)
2. [Description](#)
3. [Example](#)
4. [Multiple Replication Domains](#)
5. [See Also](#)

## Syntax

```
SET GLOBAL sql_slave_skip_counter = N
```

## Description

This statement skips the next

*N*

events from the master. This is useful for recovering from [replication stops](#) caused by a statement.

If multi-source replication is used, this statement applies to the default connection. It could be necessary to change the value of the

[default\\_master\\_connection](#)

server system variable.

Note that, if the event is a [transaction](#), the whole transaction will be skipped. With non-transactional engines, an event is always a single statement.

This statement is valid only when the slave threads are not running. Otherwise, it produces an error.

The statement does not automatically restart the slave threads.

## Example

```
SHOW SLAVE STATUS \G
...
SET GLOBAL sql_slave_skip_counter = 1;
START SLAVE;
```

Multi-source replication:

```
SET @@default_master_connection = 'master_01';
SET GLOBAL SQL_SLAVE_SKIP_COUNTER = 1;
START SLAVE;
```

## Multiple Replication Domains

`sql_slave_skip_counter`  
can't be used to skip transactions on a slave if [GTID replication](#) is in use and if

[gtid\\_slave\\_pos](#)

contains multiple

[gtid\\_domain\\_id](#)

values. In that case, you'll get an error like the following:

```
ERROR 1966 (HY000): When using parallel replication and GTID with multiple
replication domains, @@sql_slave_skip_counter can not be used. Instead,
setting @@gtid_slave_pos explicitly can be used to skip to after a given GTID
position.
```

In order to skip transactions in cases like this, you will have to manually change

[gtid\\_slave\\_pos](#)

## See Also

- [Selectively Skipping Replication of Binlog Events](#)

## 1.1.2.5.6 SHOW RELAYLOG EVENTS

The terms *master* and *slave* have historically been used in replication, but the terms *primary* and *replica* are now preferred. The old terms are

used still used in parts of the documentation, and in MariaDB commands, although MariaDB 10.5 has begun the process of renaming. The documentation process is ongoing. See [MDEV-18777](#) to follow progress on this effort.

## Syntax

```
SHOW RELAYLOG ['connection_name'] EVENTS  
[IN 'log_name'] [FROM pos] [LIMIT [offset,] row_count]  
[ FOR CHANNEL 'channel_name']
```

## Description

On `replicas`, this command shows the events in the `relay log`. If  
`'log_name'`  
is not specified, the first relay log is shown.

Syntax for the

`LIMIT`  
clause is the same as for `SELECT ... LIMIT`.

Using the

`LIMIT`  
clause is highly recommended because the  
`SHOW RELAYLOG EVENTS`  
command returns the complete contents of the relay log, which can be quite large.

This command does not return events related to setting user and system variables. If you need those, use `mariadb-binlog/mysqlbinlog`.

On the primary, this command does nothing.

Requires the `REPLICA MONITOR` privilege (>= MariaDB 10.5.9), the `REPLICATION SLAVE ADMIN` privilege (>= MariaDB 10.5.2) or the `REPLICATION SLAVE` privilege (<= MariaDB 10.5.1).

`connection_name`

If there is only one nameless primary, or the default primary (as specified by the `default_master_connection` system variable) is intended,

`connection_name`  
can be omitted. If provided, the  
`SHOW RELAYLOG`  
statement will apply to the specified primary.  
`connection_name`  
is case-insensitive.

MariaDB starting with 10.7.0

The  
`FOR CHANNEL`  
keyword was added for MySQL compatibility. This is identical as using the `channel_name` directly after  
`SHOW RELAYLOG`

## 1.1.2.5.7 SHOW SLAVE STATUS

## Syntax

```
SHOW SLAVE ["connection_name"] STATUS [FOR CHANNEL "connection_name"]  
SHOW REPLICA ["connection_name"] STATUS -- From MariaDB 10.5.1
```

or

```
SHOW ALL SLAVES STATUS  
SHOW ALL REPLICAS STATUS -- From MariaDB 10.5.1
```

## Contents

1. [Syntax](#)
2. [Description](#)
  1. [Multi-Source](#)
  2. [Column Descriptions](#)
  3. [SHOW REPLICA STATUS](#)
3. [Examples](#)
4. [See Also](#)

## Description

This statement is to be run on a replica and provides status information on essential parameters of the `replica` threads.

This statement requires the `SUPER` privilege, the `REPLICATION_CLIENT` privilege, or, from MariaDB 10.5.2 , the `REPLICATION SLAVE ADMIN` privilege, or, from MariaDB 10.5.9 , the `REPLICA MONITOR` privilege.

### Multi-Source

The

```
FULL  
and  
"connection_name"  
options allow you to connect to many primaries at the same time .
```

```
ALL SLAVES  
(or  
ALL REPLICAS  
from MariaDB 10.5.1 ) gives you a list of all connections to the primary nodes.
```

The rows will be sorted according to

```
Connection_name
```

If you specify a

```
connection_name  
, you only get the information about that connection. If  
connection_name  
is not used, then the name set by  
default_master_connection  
is used. If the connection name doesn't exist you will get an error:  
There is no master connection for 'xxx'
```

MariaDB starting with 10.7.0

The

```
FOR CHANNEL  
keyword was added for MySQL compatibility. This is identical as using the channel_name directly after  
SHOW SLAVE
```

### Column Descriptions

Name	Description	Added
Connection_name	Name of the primary connection. Returned with <code>SHOW ALL SLAVES STATUS</code> (or <code>SHOW ALL REPLICAS STATUS</code> from MariaDB 10.5.1 ) only.	
Slave_SQL_State	State of SQL thread. Returned with <code>SHOW ALL SLAVES STATUS</code> (or <code>SHOW ALL REPLICAS STATUS</code> from MariaDB 10.5.1 ) only. See <a href="#">Slave SQL Thread States</a> .	
Slave_IO_State	State of I/O thread. See <a href="#">Slave I/O Thread States</a> .	
Master_host	Master host that the replica is connected to.	

Master_user	Account user name being used to connect to the primary.	
Master_port	The port being used to connect to the primary.	
Connect_Retry	Time in seconds between retries to connect. The default is 60. The <a href="#">CHANGE MASTER TO</a> statement can set this. The <a href="#">master-retry-count</a> option determines the maximum number of reconnection attempts.	
Master_Log_File	Name of the primary <a href="#">binary log</a> file that the I/O thread is currently reading from.	
Read_Master_Log_Pos	Position up to which the I/O thread has read in the current primary <a href="#">binary log</a> file.	
Relay_Log_File	Name of the relay log file that the SQL thread is currently processing.	
Relay_Log_Pos	Position up to which the SQL thread has finished processing in the current relay log file.	
Relay_Master_Log_File	Name of the primary <a href="#">binary log</a> file that contains the most recent event executed by the SQL thread.	
Slave_IO_Running	Whether the replica I/O thread is running and connected ( Yes ), running but not connected to a primary ( Connecting ) or not running ( No ).	
Slave_SQL_Running	Whether or not the SQL thread is running.	
Replicate_Do_DB	Databases specified for replicating with the  <a href="#">replicate_do_db</a>  option.	
Replicate_Ignore_DB	Databases specified for ignoring with the  <a href="#">replicate_ignore_db</a>  option.	
Replicate_Do_Table	Tables specified for replicating with the  <a href="#">replicate_do_table</a>  option.	
Replicate_Ignore_Table	Tables specified for ignoring with the  <a href="#">replicate_ignore_table</a>  option.	
Replicate_Wild_Do_Table	Tables specified for replicating with the  <a href="#">replicate_wild_do_table</a>  option.	
Replicate_Wild_Ignore_Table	Tables specified for ignoring with the  <a href="#">replicate_wild_ignore_table</a>  option.	
Last_Error	Alias for  Last_SQL_Error (see below)	
Skip_Counter	Number of events that a replica skips from the master, as recorded in the <a href="#">sql_slave_skip_counter</a> system variable.	
Exec_Master_Log_Pos	Position up to which the SQL thread has processed in the current master <a href="#">binary log</a> file. Can be used to start a new replica from a current replica with the <a href="#">CHANGE MASTER TO ... MASTER_LOG_POS</a> option.	
Relay_Log_Space	Total size of all relay log files combined.	

Until_Condition		
Until_Log_File	The MASTER_LOG_FILE value of the <b>START SLAVE UNTIL</b> condition.	
Until_Log_Pos	The MASTER_LOG_POS value of the <b>START SLAVE UNTIL</b> condition.	
Master_SSL_Allowed	Whether an SSL connection is permitted ( Yes , not permitted ( No ) or permitted but without the replica having SSL support enabled ( Ignored )	
Master_SSL_CA_File	The MASTER_SSL_CA option of the  <b>CHANGE MASTER TO</b>  statement.	
Master_SSL_CA_Path	The MASTER_SSL_CAPATH option of the  <b>CHANGE MASTER TO</b>  statement.	
Master_SSL_Cert	The MASTER_SSL_CERT option of the  <b>CHANGE MASTER TO</b>  statement.	
Master_SSL_Cipher	The MASTER_SSL_CIPHER option of the  <b>CHANGE MASTER TO</b>  statement.	
Master_SSL_Key	The MASTER_SSL_KEY option of the  <b>CHANGE MASTER TO</b>  statement.	
Seconds_Behind_Master	Difference between the timestamp logged on the master for the event that the replica is currently processing, and the current timestamp on the replica. Zero if the replica is not currently processing an event. With <a href="#">parallel replication</a> , seconds_behind_master is updated only after transactions commit.	
Master_SSL_Verify_Server_Cert	The MASTER_SSL_VERIFY_SERVER_CERT option of the  <b>CHANGE MASTER TO</b>  statement.	
Last_IO_Error	<a href="#">Error code</a> of the most recent error that caused the I/O thread to stop (also recorded in the replica's error log). 0 means no error. <b>RESET SLAVE</b> or <b>RESET MASTER</b> will reset this value.	

Last_IO_Error	<a href="#">Error message</a> of the most recent error that caused the I/O thread to stop (also recorded in the replica's error log). An empty string means no error. <a href="#">RESET SLAVE</a> or <a href="#">RESET MASTER</a> will reset this value.	
Last_SQL_Erno	<a href="#">Error code</a> of the most recent error that caused the SQL thread to stop (also recorded in the replica's error log). 0 means no error. <a href="#">RESET SLAVE</a> or <a href="#">RESET MASTER</a> will reset this value.	
Last_SQL_Error	<a href="#">Error message</a> of the most recent error that caused the SQL thread to stop (also recorded in the replica's error log). An empty string means no error. <a href="#">RESET SLAVE</a> or <a href="#">RESET MASTER</a> will reset this value.	
Replicate_Ignore_Server_Ids	List of <a href="#">server_ids</a> that are currently being ignored for replication purposes, or an empty string for none, as specified in the  IGNORE_SERVER_IDS option of the  CHANGE MASTER TO  statement.	
Master_Server_Id	The master's <a href="#">server_id</a> value.	
Master_SSL_Crl	The  MASTER_SSL_CRL option of the  CHANGE MASTER TO  statement.	
Master_SSL_Crlpath	The  MASTER_SSL_CRLPATH option of the  CHANGE MASTER TO  statement.	
Using_Gtid	Whether or not <a href="#">global transaction ID's</a> are being used for replication (can be No ,, Slave_Pos , or Current_Pos ).	
Gtid_IO_Pos	Current <a href="#">global transaction ID</a> value.	
Retried_transactions	Number of retried transactions for this connection. Returned with  SHOW ALL SLAVES STATUS only.	
Max_relay_log_size	Max <a href="#">relay log</a> size for this connection. Returned with  SHOW ALL SLAVES STATUS only.	
Executed_log_entries	How many log entries the replica has executed. Returned with  SHOW ALL SLAVES STATUS only.	
Slave_received_heartbeats	How many heartbeats we have got from the master. Returned with  SHOW ALL SLAVES STATUS only.	
Slave_heartbeat_period	How often to request a heartbeat packet from the master (in seconds). Returned with  SHOW ALL SLAVES STATUS only.	
Gtid_Slave_Pos	GTID of the last event group replicated on a replica server, for each replication domain, as stored in the <a href="#">gtid_slave_pos</a> system variable. Returned with  SHOW ALL SLAVES STATUS only.	

SQL_Delay	<p>Value specified by</p> <pre>MASTER_DELAY in  CHANGE MASTER</pre> <p>(or 0 if none).</p>	MariaDB 10.2.3
SQL_Remaining_Delay	<p>When the replica is delaying the execution of an event due to</p> <pre>MASTER_DELAY</pre> <p>, this is the number of seconds of delay remaining before the event will be applied.</p> <p>Otherwise, the value is</p> <pre>NULL</pre>	MariaDB 10.2.3
Slave_SQL_Running_State	<p>The state of the SQL driver threads, same as in</p> <pre>SHOW PROCESSLIST</pre> <p>. When the replica is delaying the execution of an event due to</p> <pre>MASTER_DELAY</pre> <p>, this field displays: "</p> <p>Waiting until MASTER_DELAY seconds after master executed event</p> <p>".</p>	MariaDB 10.2.3
Slave_DDL_Groups	This status variable counts the occurrence of DDL statements. This is a replica-side counter for optimistic parallel replication.	MariaDB 10.3.7
Slave_Non_Transactional_Groups	This status variable counts the occurrence of non-transactional event groups. This is a replica-side counter for optimistic parallel replication.	MariaDB 10.3.7
Slave_Transactional_Groups	This status variable counts the occurrence of transactional event groups. This is a replica-side counter for optimistic parallel replication.	MariaDB 10.3.7

## SHOW REPLICAS STATUS

MariaDB starting with 10.5.1

```
SHOW REPLICAS STATUS
is an alias for
SHOW SLAVE STATUS
from MariaDB 10.5.1 .
```

## Examples

If you issue this statement using the

`mysql`

client, you can use a

`\G`

statement terminator rather than a semicolon to obtain a more readable vertical layout.

```
SHOW SLAVE STATUS\G
***** 1. row *****
Slave_IO_State: Waiting for master to send event
Master_Host: db01.example.com
Master_User: replicant
Master_Port: 3306
Connect_Retry: 60
Master_Log_File: mariadb-bin.000010
Read_Master_Log_Pos: 548
Relay_Log_File: relay-bin.000004
Relay_Log_Pos: 837
Relay_Master_Log_File: mariadb-bin.000010
Slave_IO_Running: Yes
Slave_SQL_Running: Yes
Replicate_Do_DB:
Replicate_Ignore_DB:
Replicate_Do_Table:
Replicate_Ignore_Table:
Replicate_Wild_Do_Table:
Replicate_Wild_Ignore_Table:

### 1.1.2.5.8 SHOW MASTER STATUS

#### Syntax

```

SHOW MASTER STATUS
SHOW BINLOG STATUS -- From MariaDB 10.5.2

```

#### Description

Provides status information about the [binary log](#) files of the primary.

This statement requires the [SUPER](#) privilege, the [REPLICATION\\_CLIENT](#) privilege, or, from [MariaDB 10.5.2](#), the [BINLOG MONITOR](#) privilege.

To see information about the current GTIDs in the binary log, use the [gtid\\_binlog\\_pos](#) variable.

```

SHOW MASTER STATUS
was renamed to
SHOW BINLOG STATUS
in MariaDB 10.5.2 , but the old name remains an alias for compatibility purposes.

```

#### Example

```

SHOW MASTER STATUS;
+-----+-----+-----+-----+
| File          | Position | Binlog_Do_DB | Binlog_Ignore_DB |
+-----+-----+-----+-----+
| mariadb-bin.000016 |      475 |           |           |
+-----+-----+-----+-----+
SELECT @@global.gtid_binlog_pos;
+-----+
| @@global.gtid_binlog_pos |
+-----+
| 0-1-2           |
+-----+

```

## See Also

- [MariaDB replication](#)

- [The gtid\\_binlog\\_pos variable](#)

### 1.1.2.5.9 SHOW SLAVE HOSTS

## Contents

1. [Syntax](#)
2. [Description](#)
  1. [SHOW REPLICHOSTS](#)
3. [See Also](#)

## Syntax

```
SHOW SLAVE HOSTS  
SHOW REPLICHOSTS -- from MariaDB 10.5.1
```

## Description

This command is run on the primary and displays a list of replicas that are currently registered with it. Only replicas started with the `--report-host=host_name` option are visible in this list.

The list is displayed on any server (not just the primary server). The output looks like this:

```
SHOW SLAVE HOSTS;  
+-----+-----+-----+  
| Server_id | Host      | Port | Master_id |  
+-----+-----+-----+  
| 192168010 | iconnect2 | 3306 | 192168011 |  
| 1921680101 | athena     | 3306 | 192168011 |  
+-----+-----+-----+
```

- **Server\_id**  
: The unique server ID of the replica server, as configured in the server's option file, or on the command line with `--server-id=value`.
- **Host**  
: The host name of the replica server, as configured in the server's option file, or on the command line with `--report-host=host_name`. Note that this can differ from the machine name as configured in the operating system.
- **Port**  
: The port the replica server is listening on.
- **Master\_id**  
: The unique server ID of the primary server that the replica server is replicating from.

Some MariaDB and MySQL versions report another variable, `rpl_recovery_rank`. This variable was never used, and was eventually removed in [MariaDB 10.1.2](#).

Requires the [REPLICATION MASTER ADMIN](#) privilege (>= [MariaDB 10.5.2](#)) or the [REPLICATION SLAVE](#) privilege (<= [MariaDB 10.5.1](#)).

## SHOW REPLICHOSTS

MariaDB starting with [10.5.1](#)

```
SHOW REPLICHOSTS  
is an alias for  
SHOW SLAVE HOSTS  
from MariaDB 10.5.1.
```

## See Also

- [MariaDB replication](#)
- [Replication threads](#)
- [SHOW PROCESSLIST](#). In

[SHOW PROCESSLIST](#)

output, replica threads are identified by  
Binlog Dump

## 1.1.2.5.10 RESET MASTER

```
RESET MASTER [TO #]
```

Deletes all [binary log](#) files listed in the index file, resets the binary log index file to be empty, and creates a new binary log file with a suffix of .000001.

If

TO #

is given, then the first new binary log file will start from number #.

This statement is for use only when the master is started for the first time, and should never be used if any slaves are actively [replicating](#) from the binary log.

### See Also

- The [PURGE BINARY LOGS](#) statement is intended for use in active replication.

## 1.1.2.6 Plugin SQL Statements

### 1.1.2.6.1 SHOW PLUGINS

#### Syntax

```
SHOW PLUGINS;
```

#### Contents

1. [Syntax](#)
2. [Description](#)
3. [Examples](#)
4. [See Also](#)

#### Description

`SHOW PLUGINS`  
displays information about installed [plugins](#). The  
Library  
column indicates the plugin library - if it is  
NULL  
, the plugin is built-in and cannot be uninstalled.

The

[PLUGINS](#)  
table in the  
[information\\_schema](#)  
database contains more detailed information.

For specific information about storage engines (a particular type of plugin), see the

[information\\_schema.ENGINES](#)  
table and the  
[SHOW ENGINES](#)  
statement.

#### Examples

```
SHOW PLUGINS;
+-----+-----+-----+-----+-----+
| Name      | Status   | Type     | Library   | License  |
+-----+-----+-----+-----+-----+
| binlog    | ACTIVE   | STORAGE ENGINE | NULL      | GPL      |
| mysql_native_password | ACTIVE   | AUTHENTICATION | NULL      | GPL      |
| mysql_old_password | ACTIVE   | AUTHENTICATION | NULL      | GPL      |
| MRG_MyISAM | ACTIVE   | STORAGE ENGINE | NULL      | GPL      |
| MyISAM    | ACTIVE   | STORAGE ENGINE | NULL      | GPL      |
| CSV       | ACTIVE   | STORAGE ENGINE | NULL      | GPL      |
| MEMORY    | ACTIVE   | STORAGE ENGINE | NULL      | GPL      |
| FEDERATED | ACTIVE   | STORAGE ENGINE | NULL      | GPL      |
| PERFORMANCE_SCHEMA | ACTIVE   | STORAGE ENGINE | NULL      | GPL      |
| Aria      | ACTIVE   | STORAGE ENGINE | NULL      | GPL      |
| InnoDB    | ACTIVE   | STORAGE ENGINE | NULL      | GPL      |
| INNODB_TRX | ACTIVE   | INFORMATION SCHEMA | NULL      | GPL      |
...
| INNODB_SYS_FOREIGN | ACTIVE   | INFORMATION SCHEMA | NULL      | GPL      |
| INNODB_SYS_FOREIGN_COLS | ACTIVE   | INFORMATION SCHEMA | NULL      | GPL      |
| SPHINX    | ACTIVE   | STORAGE ENGINE  | NULL      | GPL      |
| ARCHIVE   | ACTIVE   | STORAGE ENGINE  | NULL      | GPL      |
| BLACKHOLE  | ACTIVE   | STORAGE ENGINE  | NULL      | GPL      |
| FEEDBACK  | DISABLED | INFORMATION SCHEMA | NULL      | GPL      |
| partition | ACTIVE   | STORAGE ENGINE  | NULL      | GPL      |
| pam       | ACTIVE   | AUTHENTICATION  | auth_pam.so | GPL      |
+-----+-----+-----+-----+-----+
```

## See Also

- [UNINSTALL SONAME](#)

### 1.1.2.6.2 SHOW PLUGINS SONAME

#### Syntax

```
SHOW PLUGINS SONAME { library | LIKE 'pattern' | WHERE expr };
```

#### Description

`SHOW PLUGINS SONAME`  
displays information about compiled-in and all server plugins in the

`plugin_dir`

directory, including plugins that haven't been installed.

#### Examples

```
SHOW PLUGINS SONAME 'ha_example.so';
+-----+-----+-----+-----+-----+
| Name      | Status   | Type     | Library   | License  |
+-----+-----+-----+-----+-----+
| EXAMPLE   | NOT INSTALLED | STORAGE ENGINE | ha_example.so | GPL      |
| UNUSABLE  | NOT INSTALLED | DAEMON      | ha_example.so | GPL      |
+-----+-----+-----+-----+-----+
```

There is also a corresponding

[information\\_schema](#)

table, called

#### [ALL\\_PLUGINS](#)

, which contains more complete information.

## 1.1.2.6.3 INSTALL PLUGIN

### Syntax

```
INSTALL PLUGIN [IF NOT EXISTS] plugin_name SONAME 'plugin_library'
```

### Contents

- 1. [Syntax](#)
- 2. [Description](#)
- 3. [IF NOT EXISTS](#)
- 4. [Examples](#)
- 5. [See Also](#)

### Description

This statement installs an individual [plugin](#) from the specified library. To install the whole library (which could be required), use [INSTALL SONAME](#). See also [Installing a Plugin](#).

`plugin_name`

is the name of the plugin as defined in the plugin declaration structure contained in the library file. Plugin names are not case sensitive. For maximal compatibility, plugin names should be limited to ASCII letters, digits, and underscore, because they are used in C source files, shell command lines, M4 and Bourne shell scripts, and SQL environments.

`plugin_library`

is the name of the shared library that contains the plugin code. The file name extension can be omitted (which makes the statement look the same on all architectures).

The shared library must be located in the plugin directory (that is, the directory named by the [plugin\\_dir](#) system variable). The library must be in the plugin directory itself, not in a subdirectory. By default,

```
plugin_dir  
is plugin directory under the directory named by the  
pkglibdir  
configuration variable, but it can be changed by setting the value of  
plugin_dir  
at server startup. For example, set its value in a  
my.cnf  
file:
```

```
[mysqld]  
plugin_dir=/path/to/plugin/directory
```

If the value of [plugin\\_dir](#) is a relative path name, it is taken to be relative to the MySQL base directory (the value of the [basedir](#) system variable).

```
INSTALL PLUGIN  
adds a line to the  
mysql.plugin  
table that describes the plugin. This table contains the plugin name and library file name.
```

```
INSTALL PLUGIN  
causes the server to read option (br/>  
my.cnf  
) files just as during server startup. This enables the plugin to pick up any relevant options from those files. It is possible to add plugin options to  
an option file even before loading a plugin (if the loose prefix is used). It is also possible to uninstall a plugin, edit  
my.cnf  
, and install the plugin again. Restarting the plugin this way enables it to the new option values without a server restart.
```

```
INSTALL PLUGIN  
also loads and initializes the plugin code to make the plugin available for use. A plugin is initialized by executing its initialization function, which
```

handles any setup that the plugin must perform before it can be used.

To use

```
INSTALL PLUGIN  
, you must have the INSERT privilege for the  
mysql.plugin  
table.
```

At server startup, the server loads and initializes any plugin that is listed in the

```
mysql.plugin  
table. This means that a plugin is installed with  
INSTALL PLUGIN  
only once, not every time the server starts. Plugin loading at startup does not occur if the server is started with the  
--skip-grant-tables  
option.
```

When the server shuts down, it executes the de-initialization function for each plugin that is loaded so that the plugin has a chance to perform any final cleanup.

If you need to load plugins for a single server startup when the

```
--skip-grant-tables  
option is given (which tells the server not to read system tables), use the  
--plugin-load  
mysqld option .
```

MariaDB starting with 10.4.0

## IF NOT EXISTS

When the

```
IF NOT EXISTS  
clause is used, MariaDB will return a note instead of an error if the specified plugin already exists. See SHOW WARNINGS .
```

## Examples

```
INSTALL PLUGIN sphinx SONAME 'ha_sphinx.so';
```

The extension can also be omitted:

```
INSTALL PLUGIN innodb SONAME 'ha_xtradb';
```

From MariaDB 10.4.0 :

```
INSTALL PLUGIN IF NOT EXISTS example SONAME 'ha_example';  
Query OK, 0 rows affected (0.104 sec)  
  
INSTALL PLUGIN IF NOT EXISTS example SONAME 'ha_example';  
Query OK, 0 rows affected, 1 warning (0.000 sec)  
  
SHOW WARNINGS;  
+-----+-----+  
| Level | Code | Message |  
+-----+-----+  
| Note  | 1968 | Plugin 'example' already installed |  
+-----+-----+
```

## 1.1.2.6.4 UNINSTALL PLUGIN

# Syntax

```
UNINSTALL PLUGIN [IF EXISTS] plugin_name
```

## Contents

1. [Syntax](#)
2. [Description](#)
  - 1. [IF EXISTS](#)
3. [Examples](#)
4. [See Also](#)

## Description

This statement removes a single installed plugin . To uninstall the whole library which contains the plugin, use [UNINSTALL SONAME](#) . You cannot uninstall a plugin if any table that uses it is open.

plugin\_name

must be the name of some plugin that is listed in the [mysql.plugin](#) table. The server executes the plugin's deinitialization function and removes the row for the plugin from the

[mysql.plugin](#)

table, so that subsequent server restarts will not load and initialize the plugin.

[UNINSTALL PLUGIN](#)

does not remove the plugin's shared library file.

To use

[UNINSTALL PLUGIN](#)

, you must have the [DELETE](#) privilege for the [mysql.plugin](#) table.

MariaDB starting with 10.4.0

### IF EXISTS

If the

[IF EXISTS](#)

clause is used, MariaDB will return a note instead of an error if the plugin does not exist. See [SHOW WARNINGS](#) .

## Examples

```
UNINSTALL PLUGIN example;
```

From [MariaDB 10.4.0](#) :

```
UNINSTALL PLUGIN IF EXISTS example;
Query OK, 0 rows affected (0.099 sec)

UNINSTALL PLUGIN IF EXISTS example;
Query OK, 0 rows affected, 1 warning (0.000 sec)

SHOW WARNINGS;
+-----+-----+
| Level | Code | Message |
+-----+-----+
| Note  | 1305 | PLUGIN example does not exist |
+-----+-----+
```

## 1.1.2.6.5 INSTALL SONAME

### Syntax

```
INSTALL SONAME 'plugin_library'
```

## Contents

1. [Syntax](#)
2. [Description](#)
3. [Examples](#)
4. [See Also](#)

## Description

This statement is a variant of [INSTALL PLUGIN](#). It installs **all** [plugins](#) from a given

`plugin_library`  
. See [INSTALL PLUGIN](#) for details.

`plugin_library`  
is the name of the shared library that contains the plugin code. The file name extension (for example,  
`libmyplugin.so`  
or  
`libmyplugin.dll`  
) can be omitted (which makes the statement look the same on all architectures).

The shared library must be located in the plugin directory (that is, the directory named by the

`plugin_dir`

system variable). The library must be in the plugin directory itself, not in a subdirectory. By default,  
`plugin_dir`  
is plugin directory under the directory named by the  
`pkglibdir`  
configuration variable, but it can be changed by setting the value of  
`plugin_dir`  
at server startup. For example, set its value in a  
`my.cnf`  
file:

```
[mysqld]
plugin_dir=/path/to/plugin/directory
```

If the value of `plugin_dir` is a relative path name, it is taken to be relative to the MySQL base directory (the value of the  
`basedir`  
system variable).

`INSTALL SONAME`  
adds one or more lines to the  
`mysql.plugin`  
table that describes the plugin. This table contains the plugin name and library file name.

`INSTALL SONAME`  
causes the server to read option (  
`my.cnf`  
) files just as during server startup. This enables the plugin to pick up any relevant options from those files. It is possible to add plugin options to  
an option file even before loading a plugin (if the loose prefix is used). It is also possible to uninstall a plugin, edit  
`my.cnf`  
, and install the plugin again. Restarting the plugin this way enables it to the new option values without a server restart.

`INSTALL SONAME`  
also loads and initializes the plugin code to make the plugin available for use. A plugin is initialized by executing its initialization function, which  
handles any setup that the plugin must perform before it can be used.

To use

`INSTALL SONAME`  
, you must have the [INSERT privilege](#) for the  
`mysql.plugin`  
table.

At server startup, the server loads and initializes any plugin that is listed in the  
`mysql.plugin`

table. This means that a plugin is installed with  
INSTALL SONAME  
only once, not every time the server starts. Plugin loading at startup does not occur if the server is started with the  
--skip-grant-tables  
option.

When the server shuts down, it executes the de-initialization function for each plugin that is loaded so that the plugin has a chance to perform any final cleanup.

If you need to load plugins for a single server startup when the  
--skip-grant-tables  
option is given (which tells the server not to read system tables), use the  
--plugin-load  
`mysql option`.

If you need to install only one plugin from a library, use the [INSTALL PLUGIN](#) statement.

## Examples

To load the XtraDB storage engine and all of its

information\_schema  
tables with one statement, use

```
INSTALL SONAME 'ha_xtradb';
```

This statement can be used instead of

INSTALL PLUGIN  
even when the library contains only one plugin:

```
INSTALL SONAME 'ha_sequence';
```

## 1.1.2.6.6 UNINSTALL SONAME

### Syntax

```
UNINSTALL SONAME [IF EXISTS] 'plugin_library'
```

### Contents

1. [Syntax](#)
2. [Description](#)
  - 1. [IF EXISTS](#)
3. [Examples](#)
4. [See Also](#)

### Description

This statement is a variant of [UNINSTALL PLUGIN](#) statement, that removes all [plugins](#) belonging to a specified `plugin_library`. See [UNINSTALL PLUGIN](#) for details.

`plugin_library` is the name of the shared library that contains the plugin code. The file name extension (for example, `libmyplugin.so` or `libmyplugin.dll`)

) can be omitted (which makes the statement look the same on all architectures).

To use

```
UNINSTALL SONAME  
, you must have the DELETE privilege for the  
mysql.plugin  
table.
```

MariaDB starting with 10.4.0

## IF EXISTS

If the

```
IF EXISTS  
clause is used, MariaDB will return a note instead of an error if the plugin library does not exist. See SHOW WARNINGS.
```

## Examples

To uninstall the XtraDB plugin and all of its

```
information_schema  
tables with one statement, use
```

```
UNINSTALL SONAME 'ha_xtradb';
```

From MariaDB 10.4.0 :

```
UNINSTALL SONAME IF EXISTS 'ha_example';  
Query OK, 0 rows affected (0.099 sec)  
  
UNINSTALL SONAME IF EXISTS 'ha_example';  
Query OK, 0 rows affected, 1 warning (0.000 sec)  
  
SHOW WARNINGS;  
+-----+-----+  
| Level | Code | Message |  
+-----+-----+  
| Note | 1305 | SONAME ha_example.so does not exist |  
+-----+-----+
```

- [mysql\\_plugin](#)
- [List of Plugins](#)

## 1.1.2.6.7 mysql\_plugin

MariaDB starting with 10.4.6

From MariaDB 10.4.6 ,

```
mariadb-plugin  
is a symlink to  
mysql_plugin
```

MariaDB starting with 10.5.2

From MariaDB 10.5.2 ,

```
mysql_plugin  
is the symlink, and  
mariadb-plugin  
the binary name.
```

## Contents

1. [Usage](#)
2. [Options](#)
3. [See Also](#)

`mysql_plugin`  
is a tool for enabling or disabling [plugins](#).

It is a commandline alternative to the [INSTALL PLUGIN](#) and [UNINSTALL PLUGIN](#) statements, and the  
`--plugin-load` option  
to [mysqld](#).

`mysql_plugin`  
must be run while the server is offline, and works by adding or removing rows from the [mysql.plugin](#) table.

## Usage

```
mysql_plugin [options] <plugin> ENABLE|DISABLE
```

`mysql_plugin`  
expects to find a configuration file that indicates how to configure the plugins. The configuration file is by default the same name as the plugin,  
with a  
.ini  
extension. For example:

```
mysql_plugin crazyplugins ENABLE
```

Here,

`mysql_plugin`  
will look for a file called  
crazyplugins.ini

```
crazyplugins
crazyplugin1
crazyplugin2
crazyplugin3
```

The first line should contain the name of the library object file, with no extension. The other lines list the names of the components. Each value should be  
on a separate line, and the

#  
character at the start of the line indicates a comment.

## Options

The following options can be specified on the command line, while some can be specified in the

[mysqld]  
group of any option file. For options specified in a  
[mysqld]  
group, only the  
`--basedir`  
,  
`--datadir`  
, and  
`--plugin-dir`  
options can be used - the rest are ignored.

Option	Description
<code>-b</code> , <code>--basedir=name</code>	The base directory for the server.

<pre>-d , --datadir=name</pre>	The data directory for the server.
<pre>-? , --help</pre>	Display help and exit.
<pre>-f , --my-print-defaults=name</pre>	Path to my_print_defaults executable. Example: /source/temp11/extra
<pre>-m , --mysqld=name</pre>	Path to mysqld executable. Example: /sbin/temp1/mysql/bin
<pre>-n , --no-defaults</pre>	Do not read values from configuration file.
<pre>-p , --plugin-dir=name</pre>	The plugin directory for the server.
<pre>-i , --plugin-ini=name</pre>	Read plugin information from configuration file specified instead of from <plugin-dir>/<plugin_name>.ini
<pre>-P , --print-defaults</pre>	Show default values from configuration file.
<pre>-v , --verbose</pre>	More verbose output; you can use this multiple times to get even more verbose output.
<pre>-V , --version</pre>	Output version information and exit.

## 1.1.2.7 SET Commands

### 1.1.2.7.1 SET

# Syntax

```
SET variable_assignment [, variable_assignment] ...
variable_assignment:
    user_var_name = expr
    | [GLOBAL | SESSION] system_var_name = expr
    | @@global. | @@session. | @@system_var_name = expr
```

## Contents

1. [Syntax](#)
2. [Description](#)
  1. [GLOBAL / SESSION](#)
  2. [DEFAULT](#)
3. [Examples](#)
4. [See Also](#)

One can also set a user variable in any expression with this syntax:

```
user_var_name := expr
```

## Description

The

```
SET
```

statement assigns values to different types of variables that affect the operation of the server or your client. Older versions of MySQL employed `SET OPTION`, but this syntax was deprecated in favor of `SET` without `OPTION`, and was removed in [MariaDB 10.0](#).

Changing a system variable by using the `SET` statement does not make the change permanently. To do so, the change must be made in a [configuration file](#).

For setting variables on a per-query basis (from [MariaDB 10.1.2](#)), see

[SET STATEMENT](#)

See

[SHOW VARIABLES](#)

for documentation on viewing server system variables.

See [Server System Variables](#) for a list of all the system variables.

## GLOBAL / SESSION

When setting a system variable, the scope can be specified as either GLOBAL or SESSION.

A global variable change affects all new sessions. It does not affect any currently open sessions, including the one that made the change.

A session variable change affects the current session only.

If the variable has a session value, not specifying either GLOBAL or SESSION will be the same as specifying SESSION. If the variable only has a global value, not specifying GLOBAL or SESSION will apply to the change to the global value.

## DEFAULT

Setting a global variable to DEFAULT will restore it to the server default, and setting a session variable to DEFAULT will restore it to the current global value.

## Examples

- [innodb\\_sync\\_spin\\_loops](#) is a global variable.
- [skip\\_parallel\\_replication](#) is a session variable.
- [max\\_error\\_count](#) is both global and session.

```

SELECT VARIABLE_NAME, SESSION_VALUE, GLOBAL_VALUE FROM
INFORMATION_SCHEMA.SYSTEM_VARIABLES WHERE
VARIABLE_NAME IN ('max_error_count', 'skip_parallel_replication', 'innodb_sync_spin_loops');
+-----+-----+-----+
| VARIABLE_NAME | SESSION_VALUE | GLOBAL_VALUE |
+-----+-----+-----+
| MAX_ERROR_COUNT | 64 | 64 |
| SKIP_PARALLEL_REPLICATION | OFF | NULL |
| INNODB_SYNC_SPIN_LOOPS | NULL | 30 |
+-----+-----+-----+

```

Setting the session values:

```

SET max_error_count=128;Query OK, 0 rows affected (0.000 sec)

SET skip_parallel_replication=ON;Query OK, 0 rows affected (0.000 sec)

SET innodb_sync_spin_loops=60;
ERROR 1229 (HY000): Variable 'innodb_sync_spin_loops' is a GLOBAL variable
and should be set with SET GLOBAL

```

```

SELECT VARIABLE_NAME, SESSION_VALUE, GLOBAL_VALUE FROM
INFORMATION_SCHEMA.SYSTEM_VARIABLES WHERE
VARIABLE_NAME IN ('max_error_count', 'skip_parallel_replication', 'innodb_sync_spin_loops');
+-----+-----+-----+
| VARIABLE_NAME | SESSION_VALUE | GLOBAL_VALUE |
+-----+-----+-----+
| MAX_ERROR_COUNT | 128 | 64 |
| SKIP_PARALLEL_REPLICATION | ON | NULL |
| INNODB_SYNC_SPIN_LOOPS | NULL | 30 |
+-----+-----+-----+

```

Setting the global values:

```

SET GLOBAL max_error_count=256;

SET GLOBAL skip_parallel_replication=ON;
ERROR 1228 (HY000): Variable 'skip_parallel_replication' is a SESSION variable
and can't be used with SET GLOBAL

SET GLOBAL innodb_sync_spin_loops=120;

SELECT VARIABLE_NAME, SESSION_VALUE, GLOBAL_VALUE FROM
INFORMATION_SCHEMA.SYSTEM_VARIABLES WHERE
VARIABLE_NAME IN ('max_error_count', 'skip_parallel_replication', 'innodb_sync_spin_loops');
+-----+-----+-----+
| VARIABLE_NAME | SESSION_VALUE | GLOBAL_VALUE |
+-----+-----+-----+
| MAX_ERROR_COUNT | 128 | 256 |
| SKIP_PARALLEL_REPLICATION | ON | NULL |
| INNODB_SYNC_SPIN_LOOPS | NULL | 120 |
+-----+-----+-----+

```

**SHOW VARIABLES** will by default return the session value unless the variable is global only.

```

SHOW VARIABLES LIKE 'max_error_count';
+-----+-----+
| Variable_name | Value |
+-----+-----+
| max_error_count | 128 |
+-----+-----+

SHOW VARIABLES LIKE 'skip_parallel_replication';
+-----+-----+
| Variable_name | Value |
+-----+-----+
| skip_parallel_replication | ON |
+-----+-----+

SHOW VARIABLES LIKE 'innodb_sync_spin_loops';
+-----+-----+
| Variable_name | Value |
+-----+-----+
| innodb_sync_spin_loops | 120 |
+-----+-----+

```

Using the inplace syntax:

```

SELECT (@a:=1);
+-----+
| (@a:=1) |
+-----+
|   1   |
+-----+

SELECT @a;
+-----+
| @a   |
+-----+
|   1   |
+-----+

```

## 1.1.2.7.2 SET CHARACTER SET

### Syntax

```

SET {CHARACTER SET | CHARSET}
{charset_name | DEFAULT}

```

### Description

Sets the `character_set_client` and `character_set_results` session system variables to the specified character set and `collation_connection` to the value of `collation_database`, which implicitly sets `character_set_connection` to the value of `character_set_database`.

This maps all strings sent between the current client and the server with the given mapping.

### Example

```

SHOW VARIABLES LIKE 'character_set\%';
+-----+-----+
| Variable_name      | Value   |
+-----+-----+
| character_set_client | utf8    |
| character_set_connection | utf8    |
| character_set_database | latin1  |
| character_set_filesystem | binary  |
| character_set_results | utf8    |
| character_set_server | latin1  |
| character_set_system | utf8    |
+-----+-----+

SHOW VARIABLES LIKE 'collation%';
+-----+-----+
| Variable_name      | Value   |
+-----+-----+
| collation_connection | utf8_general_ci |
| collation_database | latin1_swedish_ci |
| collation_server | latin1_swedish_ci |
+-----+-----+

SET CHARACTER SET utf8mb4;

SHOW VARIABLES LIKE 'character_set\%';
+-----+-----+
| Variable_name      | Value   |
+-----+-----+
| character_set_client | utf8mb4 |
| character_set_connection | latin1  |
| character_set_database | latin1  |
| character_set_filesystem | binary  |
| character_set_results | utf8mb4 |
| character_set_server | latin1  |
| character_set_system | utf8    |
+-----+-----+

SHOW VARIABLES LIKE 'collation%';
+-----+-----+
| Variable_name      | Value   |
+-----+-----+
| collation_connection | latin1_swedish_ci |
| collation_database | latin1_swedish_ci |
| collation_server | latin1_swedish_ci |
+-----+-----+

```

## See Also

- [SET NAMES](#)

### 1.1.2.7.3 SET GLOBAL SQL\_SLAVE\_SKIP\_COUNTER

#### Contents

1. [Syntax](#)
2. [Description](#)
3. [Example](#)
4. [Multiple Replication Domains](#)
5. [See Also](#)

## Syntax

```
SET GLOBAL sql_slave_skip_counter = N
```

## Description

This statement skips the next

*N*

events from the master. This is useful for recovering from [replication](#) stops caused by a statement.

If multi-source replication is used, this statement applies to the default connection. It could be necessary to change the value of the

```
default_master_connection
```

server system variable.

Note that, if the event is a [transaction](#), the whole transaction will be skipped. With non-transactional engines, an event is always a single statement.

This statement is valid only when the slave threads are not running. Otherwise, it produces an error.

The statement does not automatically restart the slave threads.

## Example

```
SHOW SLAVE STATUS \G  
...  
SET GLOBAL sql_slave_skip_counter = 1;  
START SLAVE;
```

Multi-source replication:

```
SET @@default_master_connection = 'master_01';  
SET GLOBAL SQL_SLAVE_SKIP_COUNTER = 1;  
START SLAVE;
```

## Multiple Replication Domains

`sql_slave_skip_counter`  
can't be used to skip transactions on a slave if [GTID replication](#) is in use and if

```
gtid_slave_pos
```

contains multiple

```
gtid_domain_id
```

values. In that case, you'll get an error like the following:

```
ERROR 1966 (HY000): When using parallel replication and GTID with multiple  
replication domains, @@sql_slave_skip_counter can not be used. Instead,  
setting @@gtid_slave_pos explicitly can be used to skip to after a given GTID  
position.
```

In order to skip transactions in cases like this, you will have to manually change

```
gtid_slave_pos
```

## See Also

- [Selectively Skipping Replication of Binlog Events](#)

## 1.1.2.7.4 SET NAMES

### Syntax

```
SET NAMES {'charset_name'  
[COLLATE 'collation_name'] | DEFAULT}
```

### Contents

1. [Syntax](#)
2. [Description](#)
3. [Examples](#)
4. [See Also](#)

# Description

Sets the `character_set_client`, `character_set_connection`, `character_set_results` and, implicitly, the `collation_connection` session system variables to the specified character set and collation.

This determines which `character set` the client will use to send statements to the server, and the server will use for sending results back to the client.

```
ucs2
,
utf16
, and
utf32
are not valid character sets for
SET NAMES
, as they cannot be used as client character sets.
```

The collation clause is optional. If not defined (or if

```
DEFAULT
is specified), the default collation for the character set will be used.
```

Quotes are optional for the character set or collation clauses.

## Examples

```

SELECT VARIABLE_NAME, SESSION_VALUE
  FROM INFORMATION_SCHEMA.SYSTEM_VARIABLES WHERE
VARIABLE_NAME LIKE 'character_set_c%' OR
VARIABLE_NAME LIKE 'character_set_re%' OR
VARIABLE_NAME LIKE 'collation_c%';
+-----+-----+
| VARIABLE_NAME | SESSION_VALUE |
+-----+-----+
| CHARACTER_SET_RESULTS | utf8 |
| CHARACTER_SET_CONNECTION | utf8 |
| CHARACTER_SET_CLIENT | utf8 |
| COLLATION_CONNECTION | utf8_general_ci |
+-----+-----+

SET NAMES big5;

SELECT VARIABLE_NAME, SESSION_VALUE
  FROM INFORMATION_SCHEMA.SYSTEM_VARIABLES WHERE
VARIABLE_NAME LIKE 'character_set_c%' OR
VARIABLE_NAME LIKE 'character_set_re%' OR
VARIABLE_NAME LIKE 'collation_c%';
+-----+-----+
| VARIABLE_NAME | SESSION_VALUE |
+-----+-----+
| CHARACTER_SET_RESULTS | big5 |
| CHARACTER_SET_CONNECTION | big5 |
| CHARACTER_SET_CLIENT | big5 |
| COLLATION_CONNECTION | big5_chinese_ci |
+-----+-----+

SET NAMES 'latin1' COLLATE 'latin1_bin';

SELECT VARIABLE_NAME, SESSION_VALUE
  FROM INFORMATION_SCHEMA.SYSTEM_VARIABLES WHERE
VARIABLE_NAME LIKE 'character_set_c%' OR
VARIABLE_NAME LIKE 'character_set_re%' OR
VARIABLE_NAME LIKE 'collation_c%';
+-----+-----+
| VARIABLE_NAME | SESSION_VALUE |
+-----+-----+
| CHARACTER_SET_RESULTS | latin1 |
| CHARACTER_SET_CONNECTION | latin1 |
| CHARACTER_SET_CLIENT | latin1 |
| COLLATION_CONNECTION | latin1_bin |
+-----+-----+

SET NAMES DEFAULT;

SELECT VARIABLE_NAME, SESSION_VALUE
  FROM INFORMATION_SCHEMA.SYSTEM_VARIABLES WHERE
VARIABLE_NAME LIKE 'character_set_c%' OR
VARIABLE_NAME LIKE 'character_set_re%' OR
VARIABLE_NAME LIKE 'collation_c%';
+-----+-----+
| VARIABLE_NAME | SESSION_VALUE |
+-----+-----+
| CHARACTER_SET_RESULTS | latin1 |
| CHARACTER_SET_CONNECTION | latin1 |
| CHARACTER_SET_CLIENT | latin1 |
| COLLATION_CONNECTION | latin1_swedish_ci |
+-----+-----+

```

## See Also

- [SET CHARACTER SET](#)
- [Character Sets and Collations](#)

## 1.1.2.7.5 SET PASSWORD

### Syntax

```
SET PASSWORD [FOR user] =
{
    PASSWORD('some password')
    | OLD_PASSWORD('some password')
    | 'encrypted password'
}
```

## Contents

1. [Syntax](#)
2. [Description](#)
3. [Authentication Plugin Support](#)
4. [Passwordless User Accounts](#)
5. [Example](#)
6. [See Also](#)

## Description

The

```
SET PASSWORD
```

statement assigns a password to an existing MariaDB user account.

If the password is specified using the

```
PASSWORD()
```

or

```
OLD_PASSWORD()
```

function, the literal text of the password should be given. If the password is specified without using either function, the password should be the already-encrypted password value as returned by

```
PASSWORD()
```

```
OLD_PASSWORD()
```

should only be used if your MariaDB/MySQL clients are very old (< 4.0.0).

With no

```
FOR
```

clause, this statement sets the password for the current user. Any client that has connected to the server using a non-anonymous account can change the password for that account.

With a

```
FOR
```

clause, this statement sets the password for a specific account on the current server host. Only clients that have the

```
UPDATE
```

privilege for the

```
mysql
```

database can do this. The user value should be given in

```
user_name@host_name
```

format, where

```
user_name
```

and

```
host_name
```

are exactly as they are listed in the User and Host columns of the

```
mysql.user
```

table entry.

The argument to

```
PASSWORD()
```

and the password given to MariaDB clients can be of arbitrary length.

# Authentication Plugin Support

MariaDB starting with [10.4](#)

In [MariaDB 10.4](#) and later,

```
SET PASSWORD  
(with or without  
PASSWORD()  
) works for accounts authenticated via any authentication plugin that supports passwords stored in the
```

`mysql.global_priv`

table.

The

`ed25519`

,

`mysql_native_password`

, and

`mysql_old_password`

authentication plugins store passwords in the

`mysql.global_priv`

table.

If you run

```
SET PASSWORD  
on an account that authenticates with one of these authentication plugins that stores passwords in the
```

`mysql.global_priv`

table, then the

`PASSWORD()`

function is evaluated by the specific authentication plugin used by the account. The authentication plugin hashes the password with a method that is compatible with that specific authentication plugin.

The

`unix_socket`

,

`named_pipe`

,

`gssapi`

, and

`pam`

authentication plugins do **not** store passwords in the

`mysql.global_priv`

table. These authentication plugins rely on other methods to authenticate the user.

If you attempt to run

```
SET PASSWORD  
on an account that authenticates with one of these authentication plugins that doesn't store a password in the
```

`mysql.global_priv`

table, then MariaDB Server will raise a warning like the following:

SET PASSWORD is ignored for users authenticating via unix\_socket plugin

See [Authentication from MariaDB 10.4](#) for an overview of authentication changes in [MariaDB 10.4](#).

#### MariaDB until 10.3

In [MariaDB 10.3](#) and before,

```
SET PASSWORD  
(with or without  
PASSWORD()  
) only works for accounts authenticated via
```

`mysql_native_password`

or

`mysql_old_password`

authentication plugins

## Passwordless User Accounts

User accounts do not always require passwords to login.

The

`unix_socket`

,

`named_pipe`

and

`gssapi`

authentication plugins do not require a password to authenticate the user.

The

`pam`

authentication plugin may or may not require a password to authenticate the user, depending on the specific configuration.

The

`mysql_native_password`

and

`mysql_old_password`

authentication plugins require passwords for authentication, but the password can be blank. In that case, no password is required.

If you provide a password while attempting to log into the server as an account that doesn't require a password, then MariaDB server will simply ignore the password.

#### MariaDB starting with 10.4

In [MariaDB 10.4](#) and later, a user account can be defined to use multiple authentication plugins in a specific order of preference. This specific scenario may be more noticeable in these versions, since an account could be associated with some authentication plugins that require a password, and some that do not.

## Example

For example, if you had an entry with User and Host column values of '

```
bob  
' and '  
.loc.gov
```

', you would write the statement like this:

```
SET PASSWORD FOR 'bob'@'%loc.gov' = PASSWORD('newpass');
```

If you want to delete a password for a user, you would do:

```
SET PASSWORD FOR 'bob'@localhost = PASSWORD("");
```

## See Also

- [Password Validation Plugins](#) - permits the setting of basic criteria for passwords
- [ALTER USER](#)

## 1.1.2.7.6 SET ROLE

### Syntax

```
SET ROLE { role | NONE }
```

#### Contents

1. [Syntax](#)
2. [Description](#)
3. [Example](#)

### Description

The

```
SET ROLE
```

statement enables a [role](#), along with all of its associated permissions, for the current session. To unset a role, use [NONE](#).

If a role that doesn't exist, or to which the user has not been assigned, is specified, an

```
ERROR 1959 (OP000): Invalid role specification
```

error occurs.

An automatic SET ROLE is implicitly performed when a user connects if that user has been assigned a default role. See [SET DEFAULT ROLE](#).

### Example

```
SELECT CURRENT_ROLE;
+-----+
| CURRENT_ROLE |
+-----+
| NULL         |
+-----+

SET ROLE staff;

SELECT CURRENT_ROLE;
+-----+
| CURRENT_ROLE |
+-----+
| staff        |
+-----+

SET ROLE NONE;

SELECT CURRENT_ROLE();
+-----+
| CURRENT_ROLE() |
+-----+
| NULL          |
+-----+
```

## 1.1.2.7.7 SET SQL\_LOG\_BIN

### Syntax

```
SET [SESSION] sql_log_bin = {0|1}
```

### Description

Sets the [sql\\_log\\_bin](#) system variable, which disables or enables [binary logging](#) for the current connection, if the client has the [SUPER](#) [privilege](#). The statement is refused with an error if the client does not have that privilege.

Before MariaDB 5.5 and before MySQL 5.6 one could also set  
sql\_log\_bin  
as a global variable. This has now been disabled as this was too dangerous as it could damage replication.

## 1.1.2.7.8 SET STATEMENT

### Contents

1. [Syntax](#)
2. [Description](#)
3. [Examples](#)
4. [Limitations](#)
5. [Source](#)

MariaDB starting with [10.1.2](#)

Per-query variables were introduced in [MariaDB 10.1.2](#)

SET STATEMENT

can be used to set the value of a system variable for the duration of the statement. It is also possible to set multiple variables.

### Syntax

```
SET STATEMENT var1=value1 [, var2=value2, ...]  
FOR <statement>
```

where

varN

is a system variable (list of allowed variables is provided below), and

valueN

is a constant literal.

### Description

```
SET STATEMENT var1=value1 FOR stmt
```

is roughly equivalent to

```
SET @save_value=@var1;  
SET SESSION var1=value1;  
stmt;  
SET SESSION var1=@save_value;
```

The server parses the whole statement before executing it, so any variables set in this fashion that affect the parser may not have the expected effect. Examples include the charset variables, sql\_mode=ansi\_quotes, etc.

### Examples

One can limit statement execution time

```
max_statement_time  
:  
SET STATEMENT max_statement_time=1000 FOR SELECT ... ;
```

One can switch on/off individual optimizations:

```
SET STATEMENT optimizer_switch='materialization=off' FOR SELECT ....;
```

It is possible to enable MRR/BKA for a query:

```
SET STATEMENT join_cache_level=6, optimizer_switch='mrr=on' FOR SELECT ...
```

Note that it makes no sense to try to set a session variable inside a

```
SET STATEMENT  
:  
#USELESS STATEMENT  
SET STATEMENT sort_buffer_size = 100000 for SET SESSION sort_buffer_size = 200000;
```

For the above, after setting sort\_buffer\_size to 200000 it will be reset to its original state (the state before the

```
SET STATEMENT  
started) after the statement execution.
```

## Limitations

There are a number of variables that cannot be set on per-query basis. These include:

- autocommit
- character\_set\_client
- character\_set\_connection
- character\_set\_filesystem
- collation\_connection
- default\_master\_connection
- debug\_sync
- interactive\_timeout
- gtid\_domain\_id
- last\_insert\_id
- log\_slow\_filter
- log\_slow\_rate\_limit
- log\_slow\_verbosity

- long\_query\_time
- min\_examined\_row\_limit
- profiling
- profiling\_history\_size
- query\_cache\_type
- rand\_seed1
- rand\_seed2
- skip\_replication
- slow\_query\_log
- sql\_log\_off
- tx\_isolation
- wait\_timeout

## Source

- The feature was originally implemented as a Google Summer of Code 2009 project by Joseph Lukas.
- Percona Server 5.6 included it as [Per-query variable statement](#)
- MariaDB ported the patch and fixed *many* bugs. The task in MariaDB Jira is [MDEV-5231](#) .

## 1.1.2.7.9 SET TRANSACTION

### Syntax

```
SET [GLOBAL | SESSION] TRANSACTION
    transaction_property [, transaction_property] ...

transaction_property:
    ISOLATION LEVEL level
    | READ WRITE
    | READ ONLY

level:
    REPEATABLE READ
    | READ COMMITTED
    | READ UNCOMMITTED
    | SERIALIZABLE
```

## Contents

1. [Syntax](#)
2. [Description](#)
  1. [Isolation Level](#)
  2. [Isolation Levels](#)
    1. [READ UNCOMMITTED](#)
    2. [READ COMMITTED](#)
    3. [REPEATABLE READ](#)
    4. [SERIALIZABLE](#)
  3. [Access Mode](#)
  3. [Examples](#)

## Description

This statement sets the transaction isolation level or the transaction access mode globally, for the current session, or for the next transaction:

- With the

GLOBAL keyword, the statement sets the default transaction level globally for all subsequent sessions. Existing sessions are unaffected.

- With the

SESSION keyword, the statement sets the default transaction level for all subsequent transactions performed within the current session.

- Without any

SESSION  
or  
GLOBAL keyword, the statement sets the isolation level for the next (not started) transaction performed within the current session.

A change to the global default isolation level requires the

SUPER

privilege. Any session is free to change its session isolation level (even in the middle of a transaction), or the isolation level for its next transaction.

## Isolation Level

To set the global default isolation level at server startup, use the

--transaction-isolation=level

option on the command line or in an option file. Values of level for this option use dashes rather than spaces, so the allowable values are READ-UNCOMMITTED

,  
READ-COMMITTED

,  
REPEATABLE-READ  
, OR  
SERIALIZABLE

. For example, to set the default isolation level to REPEATABLE READ, use these lines in the [mysqld] section of an option file:

```
[mysqld]
transaction-isolation = REPEATABLE-READ
```

To determine the global and session transaction isolation levels at runtime, check the value of the

tx\_isolation

system variable:

```
SELECT @@GLOBAL.tx_isolation, @@tx_isolation;
```

InnoDB supports each of the transaction isolation levels described here using different locking strategies. The default level is

REPEATABLE READ

. For additional information about InnoDB record-level locks and how it uses them to execute various types of statements, see [InnoDB Lock Modes](#), and <http://dev.mysql.com/doc/refman/en/innodb-locks-set.html>.

## Isolation Levels

The following sections describe how MariaDB supports the different transaction levels.

### READ UNCOMMITTED

SELECT

statements are performed in a non-locking fashion, but a possible earlier version of a row might be used. Thus, using this isolation level, such reads are not consistent. This is also called a "dirty read." Otherwise, this isolation level works like

READ COMMITTED

### READ COMMITTED

A somewhat Oracle-like isolation level with respect to consistent (non-locking) reads: Each consistent read, even within the same transaction, sets and reads its own fresh snapshot. See <http://dev.mysql.com/doc/refman/en/innodb-consistent-read.html>.

For locking reads (

SELECT

with

FOR UPDATE

or

LOCK IN SHARE MODE

), InnoDB locks only index records, not the gaps before them, and thus allows the free insertion of new records next to locked records. For

UPDATE

and

DELETE

statements, locking depends on whether the statement uses a unique index with a unique search condition (such as

WHERE id = 100

), or a range-type search condition (such as

WHERE id > 100

). For a unique index with a unique search condition, InnoDB locks only the index record found, not the gap before it. For range-type searches, InnoDB locks the index range scanned, using gap locks or next-key (gap plus index-record) locks to block insertions by other sessions into the gaps covered by the range. This is necessary because "phantom rows" must be blocked for MySQL replication and recovery to work.

**Note:** If the

READ COMMITTED

isolation level is used or the `innodb_locks_unsafe_for_binlog` system variable is enabled, there is no InnoDB gap locking except for `foreign-key` constraint checking and duplicate-key checking. Also, record locks for non-matching rows are released after MariaDB has evaluated the

WHERE

condition. If you use

READ COMMITTED

or enable `innodb_locks_unsafe_for_binlog`, you must use row-based binary logging.

### REPEATABLE READ

This is the default isolation level for InnoDB. For consistent reads, there is an important difference from the

READ COMMITTED

isolation level: All consistent reads within the same transaction read the snapshot established by the first read. This convention means that if you issue several plain (non-locking)

SELECT

statements within the same transaction, these

SELECT

statements are consistent also with respect to each other. See <http://dev.mysql.com/doc/refman/en/innodb-consistent-read.html>.

For locking reads (SELECT with FOR UPDATE or LOCK IN SHARE MODE), UPDATE, and DELETE statements, locking depends on whether the statement uses a unique index with a unique search condition, or a range-type search condition. For a unique index with a unique search condition, InnoDB locks only the index record found, not the gap before it. For other search conditions, InnoDB locks the index range scanned, using gap locks or next-key (gap plus index-record) locks to block insertions by other sessions into the gaps covered by the range.

This is the minimum isolation level for non-distributed [XA transactions](#).

### SERIALIZABLE

This level is like REPEATABLE READ, but InnoDB implicitly converts all plain SELECT statements to

SELECT ... LOCK IN SHARE MODE

if

autocommit

is disabled. If autocommit is enabled, the SELECT is its own transaction. It therefore is known to be read only and can be serialized if performed as a consistent (non-locking) read and need not block for other transactions. (This means that to force a plain SELECT to block if other transactions have modified the selected rows, you should disable autocommit.)

Distributed [XA transactions](#) should always use this isolation level.

## Access Mode

The access mode specifies whether the transaction is allowed to write data or not. By default, transactions are in

READ WRITE  
mode (see the [tx\\_read\\_only](#) system variable).

READ ONLY

mode allows the storage engine to apply optimizations that cannot be used for transactions which write data. The only exception to this rule is that read only transactions can perform DDL statements on temporary tables.

It is not permitted to specify both

READ WRITE  
and  
READ ONLY  
in the same statement.

READ WRITE  
and  
READ ONLY  
can also be specified in the

[START TRANSACTION](#)

statement, in which case the specified mode is only valid for one transaction.

## Examples

```
SET GLOBAL TRANSACTION ISOLATION LEVEL SERIALIZABLE;
```

Attempting to set the isolation level within an existing transaction without specifying

GLOBAL  
or  
SESSION

```
START TRANSACTION;
```

```
SET TRANSACTION ISOLATION LEVEL SERIALIZABLE;  
ERROR 1568 (25001): Transaction characteristics can't be changed while a transaction is in progress
```

## 1.1.2.7.10 SET Variable

### Syntax

```
SET var_name = expr [, var_name = expr] ...
```

#### Contents

1. [Syntax](#)
2. [Description](#)
3. [See Also](#)

### Description

The

SET  
statement in [stored programs](#) is an extended version of the general

[SET](#)

statement. Referenced variables may be ones declared inside a stored program, global system variables, or user-defined variables.

The

```
SET  
statement in stored programs is implemented as part of the pre-existing SET syntax. This allows an extended syntax of  
SET a=x,  
b=y, ...
```

where different variable types (locally declared variables, global and session server variables, user-defined variables) can be mixed. This also allows combinations of local variables and some options that make sense only for system variables; in that case, the options are recognized but ignored.

```
SET  
can be used with both local variables and user-defined variables .
```

When setting several variables using the columns returned by a query,

```
SELECT INTO
```

should be preferred.

To set many variables to the same value, the

```
LAST_VALUE( )
```

function can be used.

Below is an example of how a user-defined variable may be set:

```
SET @x = 1;
```

## See Also

- [SET](#)
- [SET STATEMENT](#)
- [DECLARE Variable](#)

## 1.1.2.8 SHOW

### 1.1.2.8.1 About SHOW

```
SHOW
```

has many forms that provide information about databases, tables, columns, or status information about the server. These include:

- [SHOW AUTHORS](#)
- [SHOW CHARACTER SET \[like\\_or\\_where\]](#)
- [SHOW COLLATION \[like\\_or\\_where\]](#)
- [SHOW \[FULL\] COLUMNS FROM tbl\\_name \[FROM db\\_name\] \[like\\_or\\_where\]](#)
- [SHOW CONTRIBUTORS](#)
- [SHOW CREATE DATABASE db\\_name](#)
- [SHOW CREATE EVENT event\\_name](#)
- [SHOW CREATE PACKAGE package\\_name](#)
- [SHOW CREATE PACKAGE BODY package\\_name](#)
- [SHOW CREATE PROCEDURE proc\\_name](#)
- [SHOW CREATE TABLE tbl\\_name](#)
- [SHOW CREATE TRIGGER trigger\\_name](#)
- [SHOW CREATE VIEW view\\_name](#)
- [SHOW DATABASES \[like\\_or\\_where\]](#)
- [SHOW ENGINE engine\\_name {STATUS | MUTEX}](#)
- [SHOW \[STORAGE\] ENGINES](#)
- [SHOW ERRORS \[LIMIT \[offset,\] row\\_count\]](#)
- [SHOW \[FULL\] EVENTS](#)
- [SHOW FUNCTION CODE func\\_name](#)
- [SHOW FUNCTION STATUS \[like\\_or\\_where\]](#)
- [SHOW GRANTS FOR user](#)
- [SHOW INDEX FROM tbl\\_name \[FROM db\\_name\]](#)
- [SHOW INNODB STATUS](#)
- [SHOW OPEN TABLES \[FROM db\\_name\] \[like\\_or\\_where\]](#)
- [SHOW PLUGINS](#)
- [SHOW PROCEDURE CODE proc\\_name](#)
- [SHOW PROCEDURE STATUS \[like\\_or\\_where\]](#)
- [SHOW PRIVILEGES](#)
- [SHOW \[FULL\] PROCESSLIST](#)

- SHOW PROFILE [types] [FOR QUERY n] [OFFSET n] [LIMIT n]
- SHOW PROFILES
- SHOW [GLOBAL | SESSION] STATUS [like\_or\_where]
- SHOW TABLE STATUS [FROM db\_name] [like\_or\_where]
- SHOW TABLES [FROM db\_name] [like\_or\_where]
- SHOW TRIGGERS [FROM db\_name] [like\_or\_where]
- SHOW [GLOBAL | SESSION] VARIABLES [like\_or\_where]
- SHOW WARNINGS [LIMIT [offset,] row\_count]

```
like_or_where:
  LIKE 'pattern'
  | WHERE expr
```

If the syntax for a given

```
SHOW
statement includes a
LIKE 'pattern'
part,
'pattern'
is a string that can contain the SQL "
%
" and "
-
" wildcard characters. The pattern is useful for restricting statement output to matching values.
```

Several

```
SHOW
statements also accept a
WHERE
clause that provides more flexibility in specifying which rows to display. See Extended Show.
```

## 1.1.2.8.2 Extended Show

### Contents

1. [Examples](#)

The following

```
SHOW
```

```
statements can be extended by using a
WHERE
clause and a
LIKE
clause to refine the results:
```

- [SHOW CHARACTER SET](#)
- [SHOW COLLATION](#)
- [SHOW COLUMNS](#)
- [SHOW DATABASES](#)
- [SHOW FUNCTION STATUS](#)
- [SHOW INDEX](#)
- [SHOW OPEN TABLES](#)
- [SHOW PACKAGE STATUS](#)
- [SHOW PACKAGE BODY STATUS](#)
- [SHOW INDEX](#)
- [SHOW PROCEDURE STATUS](#)
- [SHOW STATUS](#)
- [SHOW TABLE STATUS](#)
- [SHOW TABLES](#)
- [SHOW TRIGGERS](#)
- [SHOW VARIABLES](#)

As with a regular

```
SELECT
```

```
, the
WHERE
clause can be used for the specific columns returned, and the
```

clause with the regular wildcards.

## Examples

```
SHOW TABLES;
+-----+
| Tables_in_test |
+-----+
| animal_count   |
| animals        |
| are_the_mooses_loose |
| aria_test2     |
| t1             |
| view1          |
+-----+
```

Showing the tables beginning with a only.

```
SHOW TABLES WHERE Tables_in_test LIKE 'a%';
+-----+
| Tables_in_test |
+-----+
| animal_count   |
| animals        |
| are_the_mooses_loose |
| aria_test2     |
+-----+
```

Variables whose name starts with *aria* and with a value of greater than 8192:

```
SHOW VARIABLES WHERE Variable_name LIKE 'aria%' AND Value >8192;
+-----+
| Variable_name | Value |
+-----+
| aria_checkpoint_log_activity | 1048576 |
| aria_log_file_size | 1073741824 |
| aria_max_sort_file_size | 9223372036853727232 |
| aria_pagecache_buffer_size | 134217728 |
| aria_sort_buffer_size | 134217728 |
+-----+
```

Shortcut, just returning variables whose name begins with *aria* .

```
SHOW VARIABLES LIKE 'aria%';
+-----+
| Variable_name | Value |
+-----+
| aria_block_size | 8192 |
| aria_checkpoint_interval | 30 |
| aria_checkpoint_log_activity | 1048576 |
| aria_force_start_after_recovery_failures | 0 |
| aria_group_commit | none |
| aria_group_commit_interval | 0 |
| aria_log_file_size | 1073741824 |
| aria_log_purge_type | immediate |
| aria_max_sort_file_size | 9223372036853727232 |
| aria_page_checksum | ON |
| aria_pagecache_age_threshold | 300 |
| aria_pagecache_buffer_size | 134217728 |
| aria_pagecache_division_limit | 100 |
| aria_recover | NORMAL |
| aria_repair_threads | 1 |
| aria_sort_buffer_size | 134217728 |
| aria_stats_method | nulls_unequal |
| aria_sync_log_dir | NEWFILE |
| aria_used_for_temp_tables | ON |
+-----+
```

## 1.1.2.8.3 SHOW AUTHORS

# Syntax

```
SHOW AUTHORS
```

## Description

The

```
SHOW AUTHORS
```

statement displays information about the people who work on MariaDB. For each author, it displays Name, Location, and Comment values. All columns are encoded as latin1.

These include:

- First the active people in MariaDB are listed.
- Then the active people in MySQL.
- Last the people that have contributed to MariaDB/MySQL in the past.

The order is somewhat related to importance of the contribution given to the MariaDB project, but this is not 100% accurate. There is still room for improvement and debate...

## Example

```
SHOW AUTHORS;
```

Name	Location	Comment
Michael (Monty) Widenius	Tusby, Finland	Lead developer and main author
Sergei Golubchik	Kerpen, Germany	Architect, Full-text search, precision math, plugin f
Igor Babaev	Bellevue, USA	Optimizer, keycache, core work
Sergey Petrunia	St. Petersburg, Russia	Optimizer
Oleksandr Byelkin	Lugansk, Ukraine	Query Cache (4.0), Subqueries (4.1), Views (5.0)
Timour Katchaounov	Sofia , Bulgaria	Optimizer
Kristian Nielsen	Copenhagen, Denmark	Replication, Async client protocol, General buildbo
Alexander (Bar) Barkov	Izhevsk, Russia	Unicode and character sets
Alexey Botchkov (Holyfoot)	Izhevsk, Russia	GIS extensions, embedded server, precision math
Daniel Bartholomew	Raleigh, USA	MariaDB documentation
Colin Charles	Selangor, Malesia	MariaDB documentation, talks at a LOT of conferences
Sergey Vojtovich	Izhevsk, Russia	initial implementation of plugin architecture, mainta
Vladislav Vaintroub	Mannheim, Germany	MariaDB Java connector, new thread pool, Windows opti
Elena Stepanova	Sankt Petersburg, Russia	QA, test cases
Georg Richter	Heidelberg, Germany	New LGPL C connector, PHP connector
Jan Lindström	Ylämylly, Finland	Working on InnoDB
Lixun Peng	Hangzhou, China	Multi Source replication
Percona	CA, USA	XtraDB, microslow patches, extensions to slow log
...		

## See Also

- [SHOW CONTRIBUTORS](#) . This list all members and sponsors of the MariaDB Foundation and other sponsors.

### 1.1.2.8.4 SHOW BINARY LOGS

## Syntax

```
SHOW BINARY LOGS  
SHOW MASTER LOGS
```

## Description

Lists the [binary log](#) files on the server. This statement is used as part of the procedure described in

```
PURGE BINARY LOGS
```

, that shows how to determine which logs can be purged.

This statement requires the [SUPER](#) privilege, the [REPLICATION\\_CLIENT](#) privilege, or, from [MariaDB 10.5.2](#) , the [BINLOG MONITOR](#) privilege.

## Examples

```
SHOW BINARY LOGS;
+-----+-----+
| Log_name | File_size |
+-----+-----+
| mariadb-bin.000001 | 19039 |
| mariadb-bin.000002 | 717389 |
| mariadb-bin.000003 | 300 |
| mariadb-bin.000004 | 333 |
| mariadb-bin.000005 | 899 |
| mariadb-bin.000006 | 125 |
| mariadb-bin.000007 | 18907 |
| mariadb-bin.000008 | 19530 |
| mariadb-bin.000009 | 151 |
| mariadb-bin.000010 | 151 |
| mariadb-bin.000011 | 125 |
| mariadb-bin.000012 | 151 |
| mariadb-bin.000013 | 151 |
| mariadb-bin.000014 | 125 |
| mariadb-bin.000015 | 151 |
| mariadb-bin.000016 | 314 |
+-----+-----+
```

### 1.1.2.8.5 SHOW BINLOG EVENTS

#### Syntax

```
SHOW BINLOG EVENTS
[IN 'log_name'] [FROM pos] [LIMIT [offset,] row_count]
```

#### Description

Shows the events in the [binary log](#). If you do not specify '

log\_name  
' , the first binary log is displayed.

Requires the [BINLOG MONITOR](#) privilege (>= MariaDB 10.5.2) or the [REPLICATION SLAVE](#) privilege (<= MariaDB 10.5.1).

#### Example

```
SHOW BINLOG EVENTS IN 'mysql_sandbox10019-bin.000002';
+-----+-----+-----+-----+-----+
| Log_name | Pos | Event_type | Server_id | End_log_pos | Info
+-----+-----+-----+-----+-----+
| mysql_sandbox10019-bin.000002 | 4 | Format_desc | 1 | 248 | Server ver: 10.0.19-MariaDB-log, Binlog ve
| mysql_sandbox10019-bin.000002 | 248 | Gtid_list | 1 | 273 | []
| mysql_sandbox10019-bin.000002 | 273 | Binlog_checkpoint | 1 | 325 | mysql_sandbox10019-bin.000002
| mysql_sandbox10019-bin.000002 | 325 | Gtid | 1 | 363 | GTID 0-1-1
| mysql_sandbox10019-bin.000002 | 363 | Query | 1 | 446 | CREATE DATABASE blog
| mysql_sandbox10019-bin.000002 | 446 | Gtid | 1 | 484 | GTID 0-1-2
| mysql_sandbox10019-bin.000002 | 484 | Query | 1 | 571 | use `blog`; CREATE TABLE bb (id INT)
```

### 1.1.2.8.6 SHOW CHARACTER SET

#### Syntax

```
SHOW CHARACTER SET
[LIKE 'pattern' | WHERE expr]
```

## Contents

1. [Syntax](#)
2. [Description](#)
3. [Examples](#)
4. [See Also](#)

## Description

The

```
SHOW CHARACTER SET
statement shows all available character sets . The
LIKE
clause, if present on its own, indicates which character set names to match. The
WHERE
and
LIKE
clauses can be given to select rows using more general conditions, as discussed in Extended SHOW .
```

The same information can be queried from the [Information Schema CHARACTER\\_SETS](#) table.

See [Setting Character Sets and Collations](#) for details on specifying the character set at the server, database, table and column levels.

## Examples

```
SHOW CHARACTER SET LIKE 'latin%';
+-----+-----+-----+
| Charset | Description          | Default collation | Maxlen |
+-----+-----+-----+
| latin1  | cp1252 West European   | latin1_swedish_ci |      1 |
| latin2  | ISO 8859-2 Central European | latin2_general_ci |      1 |
| latin5  | ISO 8859-9 Turkish       | latin5_turkish_ci |      1 |
| latin7  | ISO 8859-13 Baltic       | latin7_general_ci |      1 |
+-----+-----+-----+
```

```
SHOW CHARACTER SET WHERE Maxlen LIKE '2';
+-----+-----+-----+
| Charset | Description          | Default collation | Maxlen |
+-----+-----+-----+
| big5   | Big5 Traditional Chinese | big5_chinese_ci   |      2 |
| sjis   | Shift-JIS Japanese     | sjis_japanese_ci |      2 |
| euckr  | EUC-KR Korean          | euckr_korean_ci  |      2 |
| gb2312 | GB2312 Simplified Chinese | gb2312_chinese_ci |      2 |
| gbk    | GBK Simplified Chinese | gbk_chinese_ci   |      2 |
| ucs2   | UCS-2 Unicode           | ucs2_general_ci  |      2 |
| cp932  | SJIS for Windows Japanese | cp932_japanese_ci |      2 |
+-----+-----+-----+
```

## 1.1.2.8.7 SHOW CLIENT\_STATISTICS

### Syntax

```
SHOW CLIENT_STATISTICS
```

## Description

The

```
SHOW CLIENT_STATISTICS
statement is part of the User Statistics feature. It was removed as a separate statement in MariaDB 10.1.1 , but effectively replaced by the generic SHOW information\_schema\_table statement. The information\_schema.CLIENT\_STATISTICS table holds statistics about client connections.
```

The [userstat](#) system variable must be set to 1 to activate this feature. See the [User Statistics](#) and [information\\_schema.CLIENT\\_STATISTICS](#) articles for

more information.

## Example

```
SHOW CLIENT_STATISTICS
*****
1. row ****
Client: localhost
Total_connections: 35
Concurrent_connections: 0
Connected_time: 708
    Busy_time: 2.555797999999985
    Cpu_time: 0.0412374000000002
Bytes_received: 3883
Bytes_sent: 21595
Binlog_bytes_written: 0
    Rows_read: 18
    Rows_sent: 115
Rows_deleted: 0
Rows_inserted: 0
Rows_updated: 0
Select_commands: 70
Update_commands: 0
Other_commands: 0
Commit_transactions: 1
Rollback_transactions: 0
Denied_connections: 0
Lost_connections: 0
Access_denied: 0
Empty_queries: 35
```

### 1.1.2.8.8 SHOW COLUMNS

### 1.1.2.8.9 SHOW CONTRIBUTORS

#### Syntax

```
SHOW CONTRIBUTORS
```

#### Description

The

```
SHOW CONTRIBUTORS
```

statement displays information about the companies and people who financially contribute to MariaDB. For each contributor, it displays Name  
,  
Location  
, and  
Comment  
values. All columns are encoded as latin1

It displays all [members and sponsors of the MariaDB Foundation](#) as well as other financial contributors.

## Example

Name	Location	Comment
Booking.com	<a href="https://www.booking.com">https://www.booking.com</a>	Founding member, Platinum Sponsor of the MariaDB Foundation
Alibaba Cloud	<a href="https://www.alibabacloud.com/">https://www.alibabacloud.com/</a>	Platinum Sponsor of the MariaDB Foundation
Tencent Cloud	<a href="https://cloud.tencent.com">https://cloud.tencent.com</a>	Platinum Sponsor of the MariaDB Foundation
Microsoft	<a href="https://microsoft.com/">https://microsoft.com/</a>	Platinum Sponsor of the MariaDB Foundation
MariaDB Corporation	<a href="https://mariadb.com">https://mariadb.com</a>	Founding member, Platinum Sponsor of the MariaDB Foundation
Visma	<a href="https://visma.com">https://visma.com</a>	Gold Sponsor of the MariaDB Foundation
DBS	<a href="https://dbs.com">https://dbs.com</a>	Gold Sponsor of the MariaDB Foundation
IBM	<a href="https://www.ibm.com">https://www.ibm.com</a>	Gold Sponsor of the MariaDB Foundation
Tencent Games	<a href="http://game.qq.com/">http://game.qq.com/</a>	Gold Sponsor of the MariaDB Foundation
Nexedi	<a href="https://www.nexedi.com">https://www.nexedi.com</a>	Silver Sponsor of the MariaDB Foundation
Acronis	<a href="https://www.acronis.com">https://www.acronis.com</a>	Silver Sponsor of the MariaDB Foundation
Verkkokauppa.com	<a href="https://www.verkkokauppa.com">https://www.verkkokauppa.com</a>	Bronze Sponsor of the MariaDB Foundation
Virtuozzo	<a href="https://virtuozzo.com">https://virtuozzo.com</a>	Bronze Sponsor of the MariaDB Foundation
Tencent Game DBA	<a href="http://tencentdba.com/about">http://tencentdba.com/about</a>	Bronze Sponsor of the MariaDB Foundation
Tencent TDSQL	<a href="http://tdsql.org">http://tdsql.org</a>	Bronze Sponsor of the MariaDB Foundation
Percona	<a href="https://www.percona.com/">https://www.percona.com/</a>	Bronze Sponsor of the MariaDB Foundation
Google	USA	Sponsoring encryption, parallel replication and GTID
Facebook	USA	Sponsoring non-blocking API, LIMIT ROWS EXAMINED etc
Ronald Bradford	Brisbane, Australia	EFF contribution for UC2006 Auction
Sheeri Kritzer	Boston, Mass. USA	EFF contribution for UC2006 Auction
Mark Shuttleworth	London, UK.	EFF contribution for UC2006 Auction

## 1.1.2.8.10 SHOW CREATE DATABASE

### Syntax

```
SHOW CREATE {DATABASE | SCHEMA} db_name
```

### Contents

1. [Syntax](#)
2. [Description](#)
3. [Examples](#)
4. [See Also](#)

### Description

Shows the [CREATE DATABASE](#) statement that creates the given database.

```
SHOW CREATE SCHEMA
is a synonym for
SHOW CREATE DATABASE
.
SHOW CREATE DATABASE
quotes database names according to the value of the sql\_quote\_show\_create server system variable.
```

### Examples

```
SHOW CREATE DATABASE test;
+-----+
| Database | Create Database |
+-----+
| test      | CREATE DATABASE `test` /*!40100 DEFAULT CHARACTER SET latin1 */ |
+-----+  
  
SHOW CREATE SCHEMA test;
+-----+
| Database | Create Database |
+-----+
| test      | CREATE DATABASE `test` /*!40100 DEFAULT CHARACTER SET latin1 */ |
+-----+
```

With

## sql\_quote\_show\_create

off:

```
SHOW CREATE DATABASE test;
+-----+-----+
| Database | Create Database
+-----+-----+
| test      | CREATE DATABASE test /*!40100 DEFAULT CHARACTER SET latin1 */ |
+-----+-----+
```

With a comment, from MariaDB 10.5 :

```
SHOW CREATE DATABASE p;
+-----+-----+
| Database | Create Database |
+-----+-----+
| p       | CREATE DATABASE `p` /*!40100 DEFAULT CHARACTER SET latin1 */ COMMENT 'presentations' |
+-----+-----+
```

#### See Also

- CREATE DATABASE
  - ALTER DATABASE
  - Character Sets and Collations

## 1.1.2.8.11 SHOW CREATE EVENT

## Syntax

```
SHOW CREATE EVENT event_name
```

## Description

This statement displays the

CREATE EVENT

statement needed to re-create a given `event` , as well as the

SOL MODE

that was used when the trigger has been created and the character set used by the connection. To find out which events are present, use

#### [SHOW EVENTS](#)

The output of this statement is unreliablely affected by the

sql quote show create

server system variable - see <http://bugs.mysql.com/bug.php?id=12719>

The

`information_schema.EVENTS`

table provides similar, but more complete, information.

## Examples

```
SHOW CREATE EVENT test.e_daily\G
*****
1. row ****
Event: e_daily
sql_mode:
time_zone: SYSTEM
Create Event: CREATE EVENT `e_daily`
    ON SCHEDULE EVERY 1 DAY
    STARTS CURRENT_TIMESTAMP + INTERVAL 6 HOUR
    ON COMPLETION NOT PRESERVE
    ENABLE
    COMMENT 'Saves total number of sessions then
              clears the table each day'
    DO BEGIN
        INSERT INTO site_activity.totals (time, total)
        SELECT CURRENT_TIMESTAMP, COUNT(*)
        FROM site_activity.sessions;
        DELETE FROM site_activity.sessions;
    END
character_set_client: latin1
collation_connection: latin1_swedish_ci
Database Collation: latin1_swedish_ci
```

## See also

- [Events Overview](#)
- 

[CREATE EVENT](#)

•

[ALTER EVENT](#)

•

[DROP EVENT](#)

## 1.1.2.8.12 SHOW CREATE FUNCTION

### Syntax

```
SHOW CREATE FUNCTION func_name
```

### Description

This statement is similar to

`SHOW CREATE PROCEDURE`

but for [stored functions](#).

The output of this statement is unreliable affected by the

`sql_quote_show_create`

## Example

```
MariaDB [test]> SHOW CREATE FUNCTION VatCents\G
***** 1. row *****
    Function: VatCents
    sql_mode:
  Create Function: CREATE DEFINER='root'@`localhost` FUNCTION `VatCents`(price DECIMAL(10,2)) RETURNS int(11)
DETERMINISTIC
BEGIN
DECLARE x INT;
SET x = price * 114;
RETURN x;
END
character_set_client: utf8
collation_connection: utf8_general_ci
Database Collation: latin1_swedish_ci
```

## See also:

- [Stored Functions](#)
- 

[CREATE FUNCTION](#)

## 1.1.2.8.13 SHOW CREATE PACKAGE

MariaDB starting with [10.3.5](#)

Oracle-style packages were introduced in [MariaDB 10.3.5](#).

## Syntax

```
SHOW CREATE PACKAGE [ db_name . ] package_name
```

### Contents

1. [Syntax](#)
2. [Description](#)
3. [Examples](#)
4. [See Also](#)

## Description

The

```
SHOW CREATE PACKAGE
```

statement can be used when [Oracle SQL\\_MODE](#) is set.

Shows the

```
CREATE
```

statement that creates the given package specification.

## Examples

```
SHOW CREATE PACKAGE employee_tools\G
*****
***** 1. row *****
  Package: employee_tools
  sql_mode: PIPES_AS_CONCAT,ANSI_QUOTES,IGNORE_SPACE,ORACLE,NO_KEY_OPTIONS,NO_TABLE_OPTIONS,NO_FIELD_OPTIONS,NO_AUTO_C
  Create Package: CREATE DEFINER="root"@"localhost" PACKAGE "employee_tools" AS
    FUNCTION getSalary(eid INT) RETURN DECIMAL(10,2);
    PROCEDURE raiseSalary(eid INT, amount DECIMAL(10,2));
    PROCEDURE raiseSalaryStd(eid INT);
    PROCEDURE hire(ename TEXT, esalary DECIMAL(10,2));
  END
  character_set_client: utf8
  collation_connection: utf8_general_ci
  Database Collation: latin1_swedish_ci
```

## See Also

- [CREATE PACKAGE](#)
- [DROP PACKAGE](#)
- [CREATE PACKAGE BODY](#)
- [SHOW CREATE PACKAGE BODY](#)
- [DROP PACKAGE BODY](#)
- [Oracle SQL\\_MODE](#)

## 1.1.2.8.14 SHOW CREATE PACKAGE BODY

MariaDB starting with [10.3.5](#)

Oracle-style packages were introduced in [MariaDB 10.3.5](#).

## Syntax

```
SHOW CREATE PACKAGE BODY [ db_name . ] package_name
```

### Contents

1. [Syntax](#)
2. [Description](#)
3. [Examples](#)
4. [See also](#)

## Description

The

```
SHOW CREATE PACKAGE BODY
```

statement can be used when [Oracle SQL\\_MODE](#) is set.

Shows the

```
CREATE
```

statement that creates the given package body (i.e. the implementation).

## Examples

```

SHOW CREATE PACKAGE BODY employee_tools\G
***** 1. row *****
  Package body: employee_tools
    sql_mode: PIPES_AS_CONCAT,ANSI_QUOTES,IGNORE_SPACE,ORACLE,NO_KEY_OPTIONS,NO_TABLE_OPTIONS,NO_FIELD_OPTIONS,NO_AUTO_C
Create Package Body: CREATE DEFINER="root"@"localhost" PACKAGE BODY "employee_tools" AS

stdRaiseAmount DECIMAL(10,2):=500;

PROCEDURE log (eid INT, ecmnt TEXT) AS
BEGIN
  INSERT INTO employee_log (id, cmnt) VALUES (eid, ecmnt);
END;

PROCEDURE hire(ename TEXT, esalary DECIMAL(10,2)) AS
  eid INT;
BEGIN
  INSERT INTO employee (name, salary) VALUES (ename, esalary);
  eid:= last_insert_id();
  log(eid, 'hire ' || ename);
END;

FUNCTION getSalary(eid INT) RETURN DECIMAL(10,2) AS
  nSalary DECIMAL(10,2);
BEGIN
  SELECT salary INTO nSalary FROM employee WHERE id=eid;
  log(eid, 'getSalary id=' || eid || ' salary=' || nSalary);
  RETURN nSalary;
END;

PROCEDURE raiseSalary(eid INT, amount DECIMAL(10,2)) AS
BEGIN
  UPDATE employee SET salary=salary+amount WHERE id=eid;
  log(eid, 'raiseSalary id=' || eid || ' amount=' || amount);
END;

PROCEDURE raiseSalaryStd(eid INT) AS
BEGIN
  raiseSalary(eid, stdRaiseAmount);
  log(eid, 'raiseSalaryStd id=' || eid);
END;

BEGIN
  log(0, 'Session ' || connection_id() || ' ' || current_user || ' started');
END
character_set_client: utf8
collation_connection: utf8_general_ci
  Database Collation: latin1_swedish_ci

```

## See also

- [CREATE PACKAGE](#)
- [SHOW CREATE PACKAGE](#)
- [DROP PACKAGE](#)
- [CREATE PACKAGE BODY](#)
- [DROP PACKAGE BODY](#)

## 1.1.2.8.15 SHOW CREATE PROCEDURE

### Syntax

```
SHOW CREATE PROCEDURE proc_name
```

### Contents

1. [Syntax](#)
2. [Description](#)
3. [Examples](#)
4. [See Also](#)

### Description

This statement is a MariaDB extension. It returns the exact string that can be used to re-create the named `stored procedure`, as well as the

`SQL_MODE`

that was used when the trigger has been created and the character set used by the connection.. A similar statement,

`SHOW CREATE FUNCTION`

, displays information about `stored functions`.

Both statements require that you are the owner of the routine or have the

`SELECT`

privilege on the

`mysql.proc`

table. When neither is true, the statements display

NULL  
for the  
Create Procedure  
or  
Create Function  
field.

#### Warning Users with

`SELECT`  
privileges on

`mysql.proc`

or  
`USAGE`  
privileges on  
`*.*`

can view the text of routines, even when they do not have privileges for the function or procedure itself.

The output of these statements is unreliablely affected by the

`sql_quote_show_create`

server system variable - see <http://bugs.mysql.com/bug.php?id=12719>

## Examples

Here's a comparison of the

`SHOW CREATE PROCEDURE`  
and

`SHOW CREATE FUNCTION`

statements.

```
SHOW CREATE PROCEDURE test.simpleproc\G
*****
***** 1. row *****
Procedure: simpleproc
sql_mode:
Create Procedure: CREATE PROCEDURE `simpleproc`(OUT param1 INT)
    BEGIN
        SELECT COUNT(*) INTO param1 FROM t;
    END
character_set_client: latin1
collation_connection: latin1_swedish_ci
Database Collation: latin1_swedish_ci

SHOW CREATE FUNCTION test.hello\G
*****
***** 1. row *****
Function: hello
sql_mode:
Create Function: CREATE FUNCTION `hello`(s CHAR(20))
    RETURNS CHAR(50)
    RETURN CONCAT('Hello, ',s,'!')
character_set_client: latin1
collation_connection: latin1_swedish_ci
Database Collation: latin1_swedish_ci
```

When the user issuing the statement does not have privileges on the routine, attempting to

`CALL`

the procedure raises Error 1370.

```
CALL test.prc1();
Error 1370 (42000): execute command denied to user 'test_user'@'localhost' for routine 'test'.'prc1'
```

If the user neither has privilege to the routine nor the

`SELECT`

privilege on

`mysql.proc`

table, it raises Error 1305, informing them that the procedure does not exist.

```
SHOW CREATE TABLES test.prc1\G
Error 1305 (42000): PROCEDURE prc1 does not exist
```

## See Also

- [Stored Procedure Overview](#)
- [CREATE PROCEDURE](#)

- [Information Schema ROUTINES Table](#)

## 1.1.2.8.16 SHOW CREATE SEQUENCE

MariaDB starting with [10.3.1](#)

Sequences were introduced in [MariaDB 10.3](#).

## Syntax

```
SHOW CREATE SEQUENCE sequence_name;
```

## Contents

1. Syntax
2. Description
3. Example
4. Notes
5. See Also

## Description

Shows the `CREATE SEQUENCE` statement that created the given sequence. The statement requires the

`SELECT`

privilege for the table.

## Example

```
CREATE SEQUENCE s1 START WITH 50;
SHOW CREATE SEQUENCE s1\G;
***** 1. row *****
Table: s1
Create Table: CREATE SEQUENCE `s1` start with 50 minvalue 1 maxvalue 9223372036854775806
increment by 1 cache 1000 nocycle ENGINE=InnoDB
```

## Notes

If you want to see the underlying table structure used for the

`SEQUENCE`

you can use `SHOW CREATE TABLE` on the

`SEQUENCE`

. You can also use

`SELECT`

to read the current recorded state of the

`SEQUENCE`

:

```
SHOW CREATE TABLE s1\G
***** 1. row *****
Table: s1
Create Table: CREATE TABLE `s1` (
`next_not_cached_value` bigint(21) NOT NULL,
`minimum_value` bigint(21) NOT NULL,
`maximum_value` bigint(21) NOT NULL,
`start_value` bigint(21) NOT NULL COMMENT 'start value when sequences is created
or value if RESTART is used',
`increment` bigint(21) NOT NULL COMMENT 'increment value',
`cache_size` bigint(21) unsigned NOT NULL,
`cycle_option` tinyint(1) unsigned NOT NULL COMMENT '0 if no cycles are allowed,
1 if the sequence should begin a new cycle when maximum_value is passed',
`cycle_count` bigint(21) NOT NULL COMMENT 'How many cycles have been done'
) ENGINE=InnoDB SEQUENCE=1

SELECT * FROM s1\G
***** 1. row *****
next_not_cached_value: 50
minimum_value: 1
maximum_value: 9223372036854775806
start_value: 50
increment: 1
cache_size: 1000
cycle_option: 0
cycle_count: 0
```

## See Also

- [CREATE SEQUENCE](#)
- [ALTER SEQUENCE](#)

## 1.1.2.8.17 SHOW CREATE TABLE

## 1.1.2.8.18 SHOW CREATE TRIGGER

### Syntax

```
SHOW CREATE TRIGGER trigger_name
```

### Contents

1. [Syntax](#)
2. [Description](#)
3. [Examples](#)
4. [See also](#)

### Description

This statement shows a

`CREATE TRIGGER`

statement that creates the given trigger, as well as the

`SQL_MODE`

that was used when the trigger has been created and the character set used by the connection.

The output of this statement is unreliablely affected by the

`sql_quote_show_create`

server system variable - see <http://bugs.mysql.com/bug.php?id=12719>

### Examples

```
SHOW CREATE TRIGGER example\G
***** 1. row *****
Trigger: example
sql_mode: ONLY_FULL_GROUP_BY,STRICT_TRANS_TABLES,STRICT_ALL_TABLES
,NO_ZERO_IN_DATE,NO_ZERO_DATE,ERROR_FOR_DIVISION_BY_ZERO,NO_AUTO_CREATE_USER,NO_
ENGINE_SUBSTITUTION
SQL Original Statement: CREATE DEFINER=`root`@`localhost` TRIGGER example BEFORE
INSERT ON t FOR EACH ROW
BEGIN
    SET NEW.c = NEW.c * 2;
END
character_set_client: cp850
collation_connection: cp850_general_ci
Database Collation: utf8_general_ci
Created: 2016-09-29 13:53:34.35
```

MariaDB starting with 10.2.3

The

Created

column was added in MySQL 5.7 and MariaDB 10.2.3 as part of introducing multiple trigger events per action.

### See also

- [Trigger Overview](#)
- 

`CREATE TRIGGER`

•

`DROP TRIGGER`

information\_schema.TRIGGERS Table

SHOW TRIGGERS

- Trigger Limitations

## 1.1.2.8.19 SHOW CREATE USER

## 1.1.2.8.20 SHOW CREATE VIEW

### Syntax

```
SHOW CREATE VIEW view_name
```

### Description

This statement shows a

CREATE VIEW

statement that creates the given [view](#) , as well as the character set used by the connection when the view was created. This statement also works with views.

```
SHOW CREATE VIEW
quotes table, column and stored function names according to the value of the
sql_quote_show_create
server system variable.
```

### Examples

```
SHOW CREATE VIEW example\G
***** 1. row *****
View: example
Create View: CREATE ALGORITHM=UNDEFINED DEFINER=`root`@`localhost` SQL
SECURITY DEFINER VIEW `example` AS (select `t`.`id` AS `id`,`t`.`s` AS `s` from
`t`)
character_set_client: cp850
collation_connection: cp850_general_ci
```

With

sql\_quote\_show\_create

off:

```
SHOW CREATE VIEW example\G
***** 1. row *****
View: example
Create View: CREATE ALGORITHM=UNDEFINED DEFINER=root@localhost SQL SECU
RITY DEFINER VIEW example AS (select t.id AS id,t.s AS s from t)
character_set_client: cp850
collation_connection: cp850_general_ci
```

## 1.1.2.8.21 SHOW DATABASES

# Syntax

```
SHOW {DATABASES | SCHEMAS}
      [LIKE 'pattern' | WHERE expr]
```

## Contents

1. [Syntax](#)
2. [Description](#)
3. [Examples](#)
4. [See Also](#)

## Description

`SHOW DATABASES`

lists the databases on the MariaDB server host.

`SHOW SCHEMAS`

is a synonym for

`SHOW DATABASES`

. The

`LIKE`

clause, if present on its own, indicates which database names to match. The

`WHERE`

and

`LIKE`

clauses can be given to select rows using more general conditions, as discussed in [Extended SHOW](#).

You see only those databases for which you have some kind of privilege, unless you have the global `SHOW DATABASES` privilege. You can also get this list using the `mysqlshow` command.

If the server was started with the

`--skip-show-database`

option, you cannot use this statement at all unless you have the `SHOW DATABASES` privilege.

The list of results returned by

`SHOW DATABASES`

is based on directories in the data directory, which is how MariaDB implements databases. It's possible that output includes directories that do not correspond to actual databases.

The [Information Schema SCHEMATA table](#) also contains database information.

## Examples

```
SHOW DATABASES;
+-----+
| Database |
+-----+
| information_schema |
| mysql |
| performance_schema |
| test |
+-----+
```

```
SHOW DATABASES LIKE 'm%';
+-----+
| Database (m%) |
+-----+
| mysql |
+-----+
```

## See Also

- [CREATE DATABASE](#)

- [Information Schema SCHEMATA Table](#)

## 1.1.2.8.22 SHOW ENGINE

### Contents

1. [Syntax](#)
2. [Description](#)
  1. [SHOW ENGINE INNODB STATUS](#)
  2. [SHOW ENGINE INNODB MUTEX](#)
  3. [SHOW ENGINE PERFORMANCE\\_SCHEMA STATUS](#)
  4. [SHOW ENGINE ROCKSDB STATUS](#)

### Syntax

```
SHOW ENGINE engine_name {STATUS | MUTEX}
```

### Description

SHOW ENGINE

displays operational information about a storage engine. The following statements currently are supported:

```
SHOW ENGINE INNODB STATUS  
SHOW ENGINE INNODB MUTEX  
SHOW ENGINE PERFORMANCE_SCHEMA STATUS  
SHOW ENGINE ROCKSDB STATUS
```

If the [Sphinx Storage Engine](#) is installed, the following is also supported:

```
SHOW ENGINE SPHINX STATUS
```

See

[SHOW ENGINE SPHINX STATUS](#)

Older (and now removed) synonyms were

```
SHOW INNODB STATUS  
for  
SHOW ENGINE INNODB STATUS  
and  
SHOW MUTEX STATUS  
for  
SHOW ENGINE INNODB MUTEX
```

### SHOW ENGINE INNODB STATUS

[SHOW ENGINE INNODB STATUS](#)

displays extensive information from the standard InnoDB Monitor about the state of the InnoDB storage engine. See

[SHOW ENGINE INNODB STATUS](#)

for more.

### SHOW ENGINE INNODB MUTEX

[SHOW ENGINE INNODB MUTEX](#)

displays InnoDB mutex statistics.

The statement displays the following output fields:

- **Type:** Always InnoDB.
- **Name:** The source file where the mutex is implemented, and the line number in the file where the mutex is created. The line number is dependent on the MariaDB version.
- **Status:** This field displays the following values if

```

UNIV_DEBUG
was defined at compilation time (for example, in include/univ.h in the InnoDB part of the source tree). Only the
os_waits
value is displayed if
UNIV_DEBUG
was not defined. Without
UNIV_DEBUG
, the information on which the output is based is insufficient to distinguish regular mutexes and mutexes that protect rw-locks (which allow
multiple readers or a single writer). Consequently, the output may appear to contain multiple rows for the same mutex.

- count indicates how many times the mutex was requested.
- spin_waits indicates how many times the spinlock had to run.
- spin_rounds indicates the number of spinlock rounds. (spin_rounds divided by spin_waits provides the average round count.)
- os_waits indicates the number of operating system waits. This occurs when the spinlock did not work (the mutex was not locked during the
spinlock and it was necessary to yield to the operating system and wait).
- os_yields indicates the number of times a the thread trying to lock a mutex gave up its timeslice and yielded to the operating system (on the
presumption that allowing other threads to run will free the mutex so that it can be locked).
- os_wait_times indicates the amount of time (in ms) spent in operating system waits, if the timed_mutexes system variable is 1 (ON). If
timed_mutexes is 0 (OFF), timing is disabled, so os_wait_times is 0. timed_mutexes is off by default.

```

Information from this statement can be used to diagnose system problems. For example, large values of spin\_waits and spin\_rounds may indicate scalability problems.

The

[information\\_schema](#)

[INNODB\\_MUTEXES](#)

table provides similar information.

## SHOW ENGINE PERFORMANCE\_SCHEMA STATUS

This statement shows how much memory is used for

[performance\\_schema](#)

tables and internal buffers.

The output contains the following fields:

- **Type:** Always  
[performance\\_schema](#)
- **Name:** The name of a table, the name of an internal buffer, or the  
[performance\\_schema](#)  
word, followed by a dot and an attribute. Internal buffers names are enclosed by parenthesis.  
[performance\\_schema](#)  
means that the attribute refers to the whole database (it is a total).
- **Status:** The value for the attribute.

The following attributes are shown, in this order, for all tables:

- **row\_size:** The memory used for an individual record. This value will never change.
- **row\_count:** The number of rows in the table or buffer. For some tables, this value depends on a server system variable.
- **memory:** For tables and  
[performance\\_schema](#)  
, this is the result of  
[row\\_size](#)  
\*  
[row\\_count](#)

For internal buffers, the attributes are:

- count
- size

## SHOW ENGINE ROCKSDB STATUS

See also [MyRocks Performance Troubleshooting](#)

## 1.1.2.8.23 SHOW ENGINE INNODB STATUS

```
SHOW ENGINE INNODB STATUS
```

is a specific form of the [SHOW ENGINE](#) statement that displays the [InnoDB Monitor](#) output, which is extensive InnoDB information which can be useful in diagnosing problems.

The following sections are displayed

- **Status:** Shows the timestamp, monitor name and the number of seconds, or the elapsed time between the current time and the time the InnoDB Monitor output was last displayed. The per-second averages are based upon this time.
- **BACKGROUND THREAD:** `srv_master_thread` lines show work performed by the main background thread.
- **SEMAPHORES:** Threads waiting for a semaphore and stats on how the number of times threads have needed a spin or a wait on a mutex or rw-lock semaphore. If this number of threads is large, there may be I/O or contention issues. Reducing the size of the [innodb\\_thread\\_concurrency](#) system variable may help if contention is related to thread scheduling.
  - Spin rounds per wait
    - shows the number of spinlock rounds per OS wait for a mutex.
- **LATEST FOREIGN KEY ERROR:** Only shown if there has been a foreign key constraint error, it displays the failed statement and information about the constraint and the related tables.
- **LATEST DETECTED DEADLOCK:** Only shown if there has been a deadlock, it displays the transactions involved in the deadlock and the statements being executed, held and required locked and the transaction rolled back to.
- **TRANSACTIONS:** The output of this section can help identify lock contention, as well as reasons for the deadlocks.
- **FILE I/O:** InnoDB thread information as well as pending I/O operations and I/O performance statistics.
- **INSERT BUFFER AND ADAPTIVE HASH INDEX:** InnoDB insert buffer (old name for the [change buffer](#)) and adaptive hash index status information, including the number of each type of operation performed, and adaptive hash index performance.
- **LOG:** InnoDB log information, including current log sequence number, how far the log has been flushed to disk, the position at which InnoDB last took a checkpoint, pending writes and write performance statistics.
- **BUFFER POOL AND MEMORY:** Information on buffer pool pages read and written, which allows you to see the number of data file I/O operations performed by your queries. See [InnoDB Buffer Pool](#) for more. Similar information is also available from the [INFORMATION\\_SCHEMA.INNODB\\_BUFFER\\_POOL\\_STATS](#) table.
- **ROW OPERATIONS:** Information about the main thread, including the number and performance rate for each type of row operation.

If the [innodb\\_status\\_output\\_locks](#) system variable is set to

```
1
```

, extended lock information will be displayed.

Example output:

```

=====

```

## 1.1.2.8.24 SHOW ENGINES

### Syntax

```
SHOW [STORAGE] ENGINES
```

# Description

`SHOW ENGINES`

displays status information about the server's storage engines. This is particularly useful for checking whether a storage engine is supported, or to see what the default engine is.

`SHOW TABLE TYPES`

is a deprecated synonym.

The

`information_schema.ENGINES`

table provides the same information.

Since storage engines are plugins, different information about them is also shown in the

`information_schema.PLUGINS`

table and by the

`SHOW PLUGINS`

statement.

Note that both MySQL's InnoDB and Percona's XtraDB replacement are labeled as

InnoDB

. However, if XtraDB is in use, it will be specified in the

COMMENT

field. See [XtraDB and InnoDB](#) . The same applies to [FederatedX](#) .

The output consists of the following columns:

- Engine  
indicates the engine's name.
- Support  
indicates whether the engine is installed, and whether it is the default engine for the current session.
- Comment  
is a brief description.
- Transactions  
,  
XA  
and  
Savepoints  
indicate whether `transactions` , `XA transactions` and `transaction savepoints` are supported by the engine.

## Examples

```

SHOW ENGINES\G
***** 1. row *****
  Engine: InnoDB
  Support: DEFAULT
  Comment: Supports transactions, row-level locking, and foreign keys
Transactions: YES
    XA: YES
  Savepoints: YES
***** 2. row *****
  Engine: CSV
  Support: YES
  Comment: CSV storage engine
Transactions: NO
    XA: NO
  Savepoints: NO
***** 3. row *****
  Engine: MyISAM
  Support: YES
  Comment: MyISAM storage engine
Transactions: NO
    XA: NO
  Savepoints: NO
***** 4. row *****
  Engine: BLACKHOLE
  Support: YES
  Comment: /dev/null storage engine (anything you write to it disappears)
Transactions: NO
    XA: NO
  Savepoints: NO
***** 5. row *****
  Engine: FEDERATED
  Support: YES
  Comment: FederatedX pluggable storage engine
Transactions: YES
    XA: NO
  Savepoints: YES
***** 6. row *****
  Engine: MRG_MyISAM
  Support: YES
  Comment: Collection of identical MyISAM tables
Transactions: NO
    XA: NO
  Savepoints: NO
***** 7. row *****
  Engine: ARCHIVE
  Support: YES
  Comment: Archive storage engine
Transactions: NO
    XA: NO
  Savepoints: NO
***** 8. row *****
  Engine: MEMORY
  Support: YES
  Comment: Hash based, stored in memory, useful for temporary tables
Transactions: NO
    XA: NO
  Savepoints: NO
***** 9. row *****
  Engine: PERFORMANCE_SCHEMA
  Support: YES
  Comment: Performance Schema
Transactions: NO
    XA: NO
  Savepoints: NO
***** 10. row *****
  Engine: Aria
  Support: YES
  Comment: Crash-safe tables with MyISAM heritage
Transactions: NO
    XA: NO
  Savepoints: NO
10 rows in set (0.00 sec)

```

## 1.1.2.8.25 SHOW ERRORS

# Syntax

```
SHOW ERRORS [LIMIT [offset,] row_count]
SHOW ERRORS [LIMIT row_count OFFSET offset]
SHOW COUNT(*) ERRORS
```

## Contents

1. [Syntax](#)
2. [Description](#)
3. [Examples](#)

## Description

This statement is similar to [SHOW WARNINGS](#), except that instead of displaying errors, warnings, and notes, it displays only errors.

The

```
LIMIT
clause has the same syntax as for the SELECT statement.
```

The

```
SHOW COUNT(*) ERRORS
statement displays the number of errors. You can also retrieve this number from the error\_count variable.
```

```
SHOW COUNT(*) ERRORS;
SELECT @@error_count;
```

The value of [error\\_count](#) might be greater than the number of messages displayed by [SHOW WARNINGS](#) if the [max\\_error\\_count](#) system variable is set so low that not all messages are stored.

For a list of MariaDB error codes, see [MariaDB Error Codes](#).

## Examples

```
SELECT f();
ERROR 1305 (42000): FUNCTION f does not exist
```

```
SHOW COUNT(*) ERRORS;
+-----+
| @@session.error_count |
+-----+
| 1 |
+-----+

SHOW ERRORS;
+-----+
| Level | Code | Message           |
+-----+
| Error | 1305 | FUNCTION f does not exist |
+-----+
```

## 1.1.2.8.26 SHOW EVENTS

### Syntax

```
SHOW EVENTS [{FROM | IN} schema_name]
[LIKE 'pattern' | WHERE expr]
```

## Description

Shows information about Event Manager [events](#) (created with

[CREATE EVENT](#)

). Requires the

[EVENT](#)

privilege. Without any arguments,  
SHOW EVENTS  
lists all of the events in the current schema:

```
SELECT CURRENT_USER(), SCHEMA();
+-----+-----+
| CURRENT_USER() | SCHEMA() |
+-----+-----+
| jon@ghidora   | myschema  |
+-----+-----+

SHOW EVENTS\G
***** 1. row *****
          Db: myschema
          Name: e_daily
      Definer: jon@ghidora
    Time zone: SYSTEM
        Type: RECURRING
   Execute at: NULL
Interval value: 10
 Interval field: SECOND
      Starts: 2006-02-09 10:41:23
        Ends: NULL
      Status: ENABLED
Originator: 0
character_set_client: latin1
collation_connection: latin1_swedish_ci
 Database Collation: latin1_swedish_ci
```

To see the event action, use

```
SHOW CREATE EVENT
```

instead, or look at the

```
information_schema.EVENTS
```

table.

To see events for a specific schema, use the

```
FROM
```

clause. For example, to see events for the test schema, use the following statement:

```
SHOW EVENTS FROM test;
```

The

```
LIKE
```

clause, if present, indicates which event names to match. The

```
WHERE
```

clause can be given to select rows using more general conditions, as discussed in [Extended Show](#).

## 1.1.2.8.27 SHOW FUNCTION STATUS

### Syntax

```
SHOW FUNCTION STATUS
[LIKE 'pattern' | WHERE expr]
```

### Description

This statement is similar to

```
SHOW PROCEDURE STATUS
```

but for [stored functions](#).

The LIKE clause, if present on its own, indicates which function names to match.

The

WHERE  
and  
LIKE  
clauses can be given to select rows using more general conditions, as discussed in [Extended SHOW](#) .

The

```
information_schema.ROUTINES
```

table contains more detailed information.

## Examples

Showing all stored functions:

```
SHOW FUNCTION STATUS\G
***** 1. row *****
    Db: test
    Name: VatCents
    Type: FUNCTION
    Definer: root@localhost
    Modified: 2013-06-01 12:40:31
    Created: 2013-06-01 12:40:31
    Security_type: DEFINER
    Comment:
character_set_client: utf8
collation_connection: utf8_general_ci
    Database Collation: latin1_swedish_ci
```

Stored functions whose name starts with 'V':

```
SHOW FUNCTION STATUS LIKE 'V%'\G
***** 1. row *****
    Db: test
    Name: VatCents
    Type: FUNCTION
    Definer: root@localhost
    Modified: 2013-06-01 12:40:31
    Created: 2013-06-01 12:40:31
    Security_type: DEFINER
    Comment:
character_set_client: utf8
collation_connection: utf8_general_ci
    Database Collation: latin1_swedish_ci
```

Stored functions with a security type of 'DEFINER':

```
SHOW FUNCTION STATUS WHERE Security_type LIKE 'DEFINER'\G
***** 1. row *****
    Db: test
    Name: VatCents
    Type: FUNCTION
    Definer: root@localhost
    Modified: 2013-06-01 12:40:31
    Created: 2013-06-01 12:40:31
    Security_type: DEFINER
    Comment:
character_set_client: utf8
collation_connection: utf8_general_ci
    Database Collation: latin1_swedish_ci
```

## 1.1.2.8.28 SHOW GRANTS

## 1.1.2.8.29 SHOW INDEX

## 1.1.2.8.30 SHOW INDEX\_STATISTICS

### Syntax

```
SHOW INDEX_STATISTICS
```

## Description

The

```
SHOW INDEX_STATISTICS
```

statement was introduced in MariaDB 5.2 as part of the [User Statistics](#) feature. It was removed as a separate statement in MariaDB 10.1.1 , but effectively replaced by the generic [SHOW information\\_schema\\_table](#) statement. The [information\\_schmea.INDEX\\_STATISTICS](#) table shows statistics on index usage and makes it possible to do such things as locating unused indexes and generating the commands to remove them.

The [userstat](#) system variable must be set to 1 to activate this feature. See the [User Statistics](#) and [information\\_schema.INDEX\\_STATISTICS](#) table for more information.

## Example

```
SHOW INDEX_STATISTICS;
+-----+-----+-----+
| Table_schema | Table_name      | Index_name | Rows_read |
+-----+-----+-----+
| test        | employees_example | PRIMARY    |      1     |
+-----+-----+-----+
```

### 1.1.2.8.32 SHOW LOCALES

```
SHOW LOCALES
```

was introduced as part of the [Information Schema plugin extension](#) .

```
SHOW LOCALES
```

is used to return

```
locales
```

information as part of the [Locales](#) plugin. While the

```
information_schema.LOCALES
```

table has 8 columns, the

```
SHOW LOCALES
```

statement will only display 4 of them:

## Example

```
SHOW LOCALES;
+-----+-----+-----+
| Id   | Name      | Description          | Error_Message_Language |
+-----+-----+-----+
| 0    | en_US     | English - United States | english                |
| 1    | en_GB     | English - United Kingdom | english                |
| 2    | ja_JP     | Japanese - Japan     | japanese               |
| 3    | sv_SE     | Swedish - Sweden     | swedish               |
...
```

### 1.1.2.8.33 SHOW BINLOG STATUS

### 1.1.2.8.34 SHOW OPEN TABLES

## Syntax

```
SHOW OPEN TABLES [FROM db_name]
[LIKE 'pattern' | WHERE expr]
```

## Description

SHOW OPEN TABLES  
lists the non-  
TEMPORARY  
tables that are currently open in the table cache. See <http://dev.mysql.com/doc/refman/5.1/en/table-cache.html>.

The  
FROM  
and  
LIKE  
clauses may be used.

The  
FROM  
clause, if present, restricts the tables shown to those present in the  
db\_name  
database.

The  
LIKE  
clause, if present on its own, indicates which table names to match. The  
WHERE  
and  
LIKE  
clauses can be given to select rows using more general conditions, as discussed in [Extended SHOW](#).

The following information is returned:

Column	Description
Database	Database name.
Name	Table name.
In_use	Number of table instances being used.
Name_locked	1 if the table is name-locked, e.g. if it is being dropped or renamed, otherwise 0

Before [MariaDB 5.5](#), each use of, for example, `LOCK TABLE ... WRITE` would increment  
`In_use`  
for that table. With the implementation of the metadata locking improvements in [MariaDB 5.5](#),  
`LOCK TABLE... WRITE`  
acquires a strong MDL lock, and concurrent connections will wait on this MDL lock, so any subsequent  
`LOCK TABLE... WRITE`  
will not increment  
`In_use`

## Example

```
SHOW OPEN TABLES;
+-----+-----+-----+
| Database | Table | In_use | Name_locked |
+-----+-----+-----+
...
| test    | xjson   |     0 |      0 |
| test    | jauthor |     0 |      0 |
| test    | locks   |     1 |      0 |
...
+-----+-----+-----+
```

### 1.1.2.8.35 SHOW PACKAGE BODY STATUS

MariaDB starting with [10.3.5](#)

Oracle-style packages were introduced in [MariaDB 10.3.5](#).

# Syntax

```
SHOW PACKAGE BODY STATUS  
[LIKE 'pattern' | WHERE expr]
```

## Contents

1. [Syntax](#)
2. [Description](#)
3. [Examples](#)
4. [See Also](#)

## Description

The

```
SHOW PACKAGE BODY STATUS
```

statement returns characteristics of stored package bodies (implementations), such as the database, name, type, creator, creation and modification dates, and character set information. A similar statement,

```
SHOW PACKAGE STATUS
```

, displays information about stored package specifications.

The

LIKE

clause, if present, indicates which package names to match. The

WHERE

and

LIKE

clauses can be given to select rows using more general conditions, as discussed in [Extended SHOW](#).

The [ROUTINES table](#) in the INFORMATION\_SCHEMA database contains more detailed information.

## Examples

```
SHOW PACKAGE BODY STATUS LIKE 'pkg1'\G  
*****  
1. row *****  
      Db: test  
      Name: pkg1  
      Type: PACKAGE BODY  
      Definer: root@localhost  
      Modified: 2018-02-27 14:44:14  
      Created: 2018-02-27 14:44:14  
      Security_type: DEFINER  
      Comment: This is my first package body  
character_set_client: utf8  
collation_connection: utf8_general_ci  
Database Collation: latin1_swedish_ci
```

## See Also

- [SHOW PACKAGE STATUS](#)
- [SHOW CREATE PACKAGE BODY](#)
- [CREATE PACKAGE BODY](#)
- [DROP PACKAGE BODY](#)
- [Oracle SQL\\_MODE](#)

## 1.1.2.8.36 SHOW PACKAGE STATUS

MariaDB starting with [10.3.5](#)

Oracle-style packages were introduced in [MariaDB 10.3.5](#).

## Syntax

```
SHOW PACKAGE STATUS  
[LIKE 'pattern' | WHERE expr]
```

## Contents

1. [Syntax](#)
2. [Description](#)
3. [Examples](#)
4. [See Also](#)

## Description

The

```
SHOW PACKAGE STATUS
```

statement returns characteristics of stored package specifications, such as the database, name, type, creator, creation and modification dates, and character set information. A similar statement,

```
SHOW PACKAGE BODY STATUS
```

, displays information about stored package bodies (i.e. implementations).

The

LIKE

clause, if present, indicates which package names to match. The

WHERE

and

LIKE

clauses can be given to select rows using more general conditions, as discussed in [Extended SHOW](#).

The [ROUTINES table](#) in the INFORMATION\_SCHEMA database contains more detailed information.

## Examples

```
SHOW PACKAGE STATUS LIKE 'pkg1'\G
*****
Db: test
Name: pkg1
Type: PACKAGE
Definer: root@localhost
Modified: 2018-02-27 14:38:15
Created: 2018-02-27 14:38:15
Security_type: DEFINER
Comment: This is my first package
character_set_client: utf8
collation_connection: utf8_general_ci
Database Collation: latin1_swedish_ci
```

## See Also

- [SHOW PACKAGE BODY](#)
- [SHOW CREATE PACKAGE](#)
- [CREATE PACKAGE](#)
- [DROP PACKAGE](#)
- [Oracle SQL\\_MODE](#)

### 1.1.2.8.37 SHOW PLUGINS

### 1.1.2.8.38 SHOW PLUGINS SONAME

### 1.1.2.8.39 SHOW PRIVILEGES

## Syntax

```
SHOW PRIVILEGES
```

## Description

SHOW PRIVILEGES

shows the list of [system privileges](#) that the MariaDB server supports. The exact list of privileges depends on the version of your server.

Note that before [MariaDB 10.3.23](#), [MariaDB 10.4.13](#) and [MariaDB 10.5.2](#), the [Delete history](#) privilege displays as

Delete versioning rows  
( [MDEV-20382](#) ).

## Example

From [MariaDB 10.5.9](#)

Privilege	Context	Comment
Alter	Tables	To alter the table
Alter routine	Functions,Procedures	To alter or drop stored functions/procedures
Create	Databases,Tables,Indexes	To create new databases and tables
Create routine	Databases	To use CREATE FUNCTION/PROCEDURE
Create temporary tables	Databases	To use CREATE TEMPORARY TABLE
Create view	Tables	To create new views
Create user	Server Admin	To create new users
Delete	Tables	To delete existing rows
Delete history	Tables	To delete versioning table historical rows
Drop	Databases,Tables	To drop databases, tables, and views
Event	Server Admin	To create, alter, drop and execute events
Execute	Functions,Procedures	To execute stored routines
File	File access on server	To read and write files on the server
Grant option	Databases,Tables,Functions,Procedures	To give to other users those privileges you possess
Index	Tables	To create or drop indexes
Insert	Tables	To insert data into tables
Lock tables	Databases	To use LOCK TABLES (together with SELECT privilege)
Process	Server Admin	To view the plain text of currently executing queries
Proxy	Server Admin	To make proxy user possible
References	Databases,Tables	To have references on tables
Reload	Server Admin	To reload or refresh tables, logs and privileges
Binlog admin	Server	To purge binary logs
Binlog monitor	Server	To use SHOW BINLOG STATUS and SHOW BINARY LOG
Binlog replay	Server	To use BINLOG (generated by mariadb-binlog)
Replication master admin	Server	To monitor connected slaves
Replication slave admin	Server	To start/stop slave and apply binlog events
Slave monitor	Server	To use SHOW SLAVE STATUS and SHOW RELAYLOG EVENTS
Replication slave	Server Admin	To read binary log events from the master
Select	Tables	To retrieve rows from table
Show databases	Server Admin	To see all databases with SHOW DATABASES
Show view	Tables	To see views with SHOW CREATE VIEW
Shutdown	Server Admin	To shut down the server
Super	Server Admin	To use KILL thread, SET GLOBAL, CHANGE MASTER, etc.
Trigger	Tables	To use triggers

GRANTS/PRIVILEGES  
for a user.

## 1.1.2.8.40 SHOW PROCEDURE CODE

### Syntax

```
SHOW PROCEDURE CODE proc_name
```

## Contents

1. [Syntax](#)
2. [Description](#)
3. [Examples](#)
4. [See Also](#)

## Description

This statement is a MariaDB extension that is available only for servers that have been built with debugging support. It displays a representation of the internal implementation of the named [stored procedure](#). A similar statement,

```
SHOW FUNCTION CODE
```

, displays information about [stored functions](#).

Both statements require that you be the owner of the routine or have

```
SELECT
```

access to the

```
mysql.proc
```

table.

If the named routine is available, each statement produces a result set. Each row in the result set corresponds to one "instruction" in the routine. The first column is Pos, which is an ordinal number beginning with 0. The second column is Instruction, which contains an SQL statement (usually changed from the original source), or a directive which has meaning only to the stored-routine handler.

## Examples

```
DELIMITER //  
  
CREATE PROCEDURE p1 ()  
BEGIN  
    DECLARE fanta INT DEFAULT 55;  
    DROP TABLE t2;  
    LOOP  
        INSERT INTO t3 VALUES (fanta);  
    END LOOP;  
END//  
Query OK, 0 rows affected (0.00 sec)  
  
SHOW PROCEDURE CODE p1//  
+-----+  
| Pos | Instruction          |  
+-----+  
| 0  | set fanta@0 55      |  
| 1  | stmt 9 "DROP TABLE t2"  
| 2  | stmt 5 "INSERT INTO t3 VALUES (fanta)" |  
| 3  | jump 2                |  
+-----+
```

## 1.1.2.8.41 SHOW PROCEDURE STATUS

### Syntax

```
SHOW PROCEDURE STATUS  
[LIKE 'pattern' | WHERE expr]
```

## Description

This statement is a MariaDB extension. It returns characteristics of a stored procedure, such as the database, name, type, creator, creation and modification dates, and character set information. A similar statement,

```
SHOW FUNCTION STATUS
```

, displays information about stored functions.

The

LIKE clause, if present, indicates which procedure or function names to match. The WHERE and LIKE clauses can be given to select rows using more general conditions, as discussed in [Extended SHOW](#).

The [ROUTINES table](#) in the INFORMATION\_SCHEMA database contains more detailed information.

## Examples

```
SHOW PROCEDURE STATUS LIKE 'p1'\G  
***** 1. row *****  
      Db: test  
      Name: p1  
      Type: PROCEDURE  
      Definer: root@localhost  
      Modified: 2010-08-23 13:23:03  
      Created: 2010-08-23 13:23:03  
      Security_type: DEFINER  
      Comment:  
character_set_client: latin1  
collation_connection: latin1_swedish_ci  
      Database Collation: latin1_swedish_ci
```

## 1.1.2.8.42 SHOW PROCESSLIST

### Syntax

```
SHOW [FULL] PROCESSLIST
```

## Description

```
SHOW PROCESSLIST
```

shows you which threads are running. You can also get this information from the [information\\_schema.PROCESSLIST](#) table or the [mysqladmin processlist](#) command. If you have the

```
PROCESS privilege
```

, you can see all threads. Otherwise, you can see only your own threads (that is, threads associated with the MariaDB account that you are using). If you do not use the

```
FULL
```

keyword, only the first 100 characters of each statement are shown in the Info field.

The columns shown in

SHOW PROCESSLIST

are:

Name	Description
ID	The client's process ID.
USER	The username associated with the process.
HOST	The host the client is connected to.
DB	The default database of the process (NULL if no default).
COMMAND	The command type. See <a href="#">Thread Command Values</a> .
TIME	The amount of time, in seconds, the process has been in its current state. For a replica SQL thread before MariaDB 10.1, this is the time in seconds between the last replicated event's timestamp and the replica machine's real time.
STATE	See <a href="#">Thread States</a> .
INFO	The statement being executed.
PROGRESS	The total progress of the process (0-100%) (see <a href="#">Progress Reporting</a> ).

See

TIME\_MS  
column in [information\\_schema.PROCESSLIST](#) for differences in the  
TIME  
column between MariaDB and MySQL.

The [information\\_schema.PROCESSLIST](#) table contains the following additional columns:

Name	Description
TIME_MS	The amount of time, in milliseconds, the process has been in its current state.
STAGE	The stage the process is currently in.
MAX_STAGE	The maximum number of stages.
PROGRESS	The progress of the process within the current stage (0-100%).

MEMORY_USED	The amount of memory used by the process.
EXAMINED_ROWS	The number of rows the process has examined.
QUERY_ID	Query ID.

Note that the

```
PROGRESS
field from the information schema, and the
PROGRESS
field from
SHOW PROCESSLIST
display different results.
SHOW PROCESSLIST
shows the total progress, while the information schema shows the progress for the current stage only.
```

Threads can be killed using their `thread_id` or their `query_id`, with the `KILL` statement.

Since queries on this table are locking, if the `performance_schema` is enabled, you may want to query the `THREADS` table instead.

## Examples

```
SHOW PROCESSLIST;
+-----+-----+-----+-----+-----+-----+
| Id | User      | Host     | db    | Command | Time       | Info          | Progress |
+-----+-----+-----+-----+-----+-----+
| 2 | event_scheduler | localhost | NULL | Daemon | 2693 | Waiting on empty queue | NULL | 0.000 |
| 4 | root        | localhost | NULL | Query   | 0 | Table lock | SHOW PROCESSLIST | 0.000 |
+-----+-----+-----+-----+-----+-----+
```

## See also

[CONNECTION\\_ID\(\)](#)

### 1.1.2.8.43 SHOW PROFILES

#### Syntax

```
SHOW PROFILES
```

#### Description

The

```
SHOW PROFILES
```

statement displays profiling information that indicates resource usage for statements executed during the course of the current session. It is used together with

```
SHOW PROFILE
```

### 1.1.2.8.44 SHOW QUERY\_RESPONSE\_TIME

It is possible to use

```
SHOW QUERY_RESPONSE_TIME
```

as an alternative for retrieving information from the `QUERY_RESPONSE_TIME` plugin.

This was introduced as part of the [Information Schema plugin extension](#).

### 1.1.2.8.45 SHOW RELAYLOG EVENTS

## 1.1.2.8.46 SHOW REPLICHOSTS

## 1.1.2.8.47 SHOW REPLICA STATUS

## 1.1.2.8.48 SHOW STATUS

### Syntax

```
SHOW [GLOBAL | SESSION] STATUS  
[LIKE 'pattern' | WHERE expr]
```

### Description

SHOW STATUS

provides server status information. This information also can be obtained using the

`mysqladmin extended-status`

command, or by querying the [Information Schema GLOBAL\\_STATUS and SESSION\\_STATUS tables](#). The

LIKE

clause, if present, indicates which variable names to match. The

WHERE

clause can be given to select rows using more general conditions.

With the

GLOBAL

modifier,

SHOW STATUS

displays the status values for all connections to MariaDB. With

SESSION

, it displays the status values for the current connection. If no modifier is present, the default is

SESSION

.

LOCAL

is a synonym for

SESSION

. If you see a lot of 0 values, the reason is probably that you have used

SHOW STATUS

with a new connection instead of

SHOW GLOBAL STATUS

.

Some status variables have only a global value. For these, you get the same value for both

GLOBAL

and

SESSION

.

See [Server Status Variables](#) for a full list, scope and description of the variables that can be viewed with

SHOW STATUS

.

The

LIKE

clause, if present on its own, indicates which variable name to match.

The

WHERE

and

LIKE

clauses can be given to select rows using more general conditions, as discussed in [Extended SHOW](#).

### Examples

Full output from [MariaDB 10.1.17](#):

## 1.1.2.8.49 SHOW TABLE STATUS

# Syntax

```
SHOW TABLE STATUS [{FROM | IN} db_name]
[LIKE 'pattern' | WHERE expr]
```

## Contents

1. [Syntax](#)
2. [Description](#)
3. [Example](#)

## Description

SHOW TABLE STATUS  
works like

[SHOW TABLES](#)

, but provides more extensive information about each non-  
TEMPORARY  
table.

The

LIKE  
clause, if present on its own, indicates which table names to match. The  
WHERE  
and  
LIKE  
clauses can be given to select rows using more general conditions, as discussed in [Extended SHOW](#).

The following information is returned:

Column	Description
Name	Table name.
Engine	Table <a href="#">storage engine</a> .
Version	Version number from the table's .frm file.
Row_format	Row format (see <a href="#">InnoDB</a> , <a href="#">Aria</a> and <a href="#">MyISAM</a> row formats).
Rows	Number of rows in the table. Some engines, such as <a href="#">XtraDB</a> and <a href="#">InnoDB</a> may store an estimate.
Avg_row_length	Average row length in the table.
Data_length	For <a href="#">InnoDB/XtraDB</a> , the index size, in pages, multiplied by the page size. For <a href="#">Aria</a> and <a href="#">MyISAM</a> , length of the data file, in bytes. For <a href="#">MEMORY</a> , the approximate allocated memory.
Max_data_length	Maximum length of the data file, ie the total number of bytes that could be stored in the table. Not used in <a href="#">XtraDB</a> and <a href="#">InnoDB</a> .
Index_length	Length of the index file.
Data_free	Bytes allocated but unused. For InnoDB tables in a shared tablespace, the free space of the shared tablespace with small safety margin. An estimate in the case of partitioned tables - see the <a href="#">PARTITIONS</a> table.
Auto_increment	Next <a href="#">AUTO_INCREMENT</a> value.
Create_time	Time the table was created.

Update_time	Time the table was last updated. On Windows, the timestamp is not updated on update, so MyISAM values will be inaccurate. In <a href="#">InnoDB</a> , if shared tablespaces are used, will be NULL , while buffering can also delay the update, so the value will differ from the actual time of the last UPDATE , INSERT or DELETE .
Check_time	Time the table was last checked. Not kept by all storage engines, in which case will be NULL .
Collation	<a href="#">Character set and collation</a> .
Checksum	Live checksum value, if any.
Create_options	Extra  <a href="#">CREATE TABLE</a>  options.
Comment	Table comment provided when MariaDB created the table.
Max_index_length	Maximum index length (supported by MyISAM and Aria tables). Added in <a href="#">MariaDB 10.3.5</a> .
Temporary	Placeholder to signal that a table is a temporary table. Currently always "N", except "Y" for generated information_schema tables and NULL for <a href="#">views</a> . Added in <a href="#">MariaDB 10.3.5</a> .

Similar information can be found in the

[information\\_schema.TABLES](#)

table as well as by using

[mysqlshow](#)

:

```
mysqlshow --status db_name
```

## Example

```
show table status\G
***** 1. row *****
  Name: bus_routes
  Engine: InnoDB
  Version: 10
Row_format: Dynamic
  Rows: 5
Avg_row_length: 3276
  Data_length: 16384
Max_data_length: 0
  Index_length: 0
  Data_free: 0
Auto_increment: NULL
  Create_time: 2017-05-24 11:17:46
  Update_time: NULL
  Check_time: NULL
  Collation: latin1_swedish_ci
  Checksum: NULL
Create_options:
  Comment:
```

## 1.1.2.8.50 SHOW TABLES

### Syntax

```
SHOW [FULL] TABLES [FROM db_name]
      [LIKE 'pattern' | WHERE expr]
```

## Contents

1. [Syntax](#)
2. [Description](#)
3. [Examples](#)
4. [See Also](#)

## Description

SHOW TABLES  
lists the non-  
TEMPORARY  
tables, [sequences](#) and [views](#) in a given database.

The

LIKE  
clause, if present on its own, indicates which table names to match. The  
WHERE  
and  
LIKE  
clauses can be given to select rows using more general conditions, as discussed in [Extended SHOW](#). For example, when searching for tables in  
the  
test  
database, the column name for use in the  
WHERE  
and  
LIKE  
clauses will be  
`Tables_in_test`

The

FULL  
modifier is supported such that  
SHOW FULL TABLES  
displays a second output column. Values for the second column.  
Table\_type  
, are  
BASE TABLE  
for a table,  
VIEW  
for a [view](#) and  
SEQUENCE  
for a [sequence](#).

You can also get this information using:

```
mysqlshow db_name
```

See [mysqlshow](#) for more details.

If you have no privileges for a base table or view, it does not show up in the output from

```
SHOW TABLES
or
mysqlshow
db_name
```

The

```
information_schema.TABLES
```

table, as well as the

```
SHOW TABLE STATUS
```

statement, provide extended information about tables.

## Examples

```
SHOW TABLES;
+-----+
| Tables_in_test |
+-----+
| animal_count   |
| animals        |
| are_the_mooses_loose |
| aria_test2     |
| t1             |
| view1          |
+-----+
```

Showing the tables beginning with a only.

```
SHOW TABLES WHERE Tables_in_test LIKE 'a%';
+-----+
| Tables_in_test |
+-----+
| animal_count   |
| animals        |
| are_the_mooses_loose |
| aria_test2     |
+-----+
```

Showing tables and table types:

```
SHOW FULL TABLES;
+-----+-----+
| Tables_in_test | Table_type |
+-----+-----+
| s1           | SEQUENCE   |
| student       | BASE TABLE |
| v1           | VIEW        |
+-----+-----+
```

## See Also

- [SHOW TABLE STATUS](#)
- The [information\\_schema.TABLES](#) table

## 1.1.2.8.51 SHOW TABLE\_STATISTICS

### Syntax

```
SHOW TABLE_STATISTICS
```

### Description

The

```
SHOW TABLE_STATISTICS
```

statement is part of the [User Statistics](#) feature. It was removed as a separate statement in [MariaDB 10.1.1](#), but effectively replaced by the generic [SHOW information\\_schema\\_table](#) statement. The [information\\_schema.TABLE\\_STATISTICS](#) table shows statistics on table usage

The [userstat](#) system variable must be set to 1 to activate this feature. See the [User Statistics](#) and [information\\_schema.TABLE\\_STATISTICS](#) articles for more information.

### Example

```

SHOW TABLE_STATISTICS[G]
*****
***** 1. row *****
  Table_schema: mysql
    Table_name: proxies_priv
      Rows_read: 2
      Rows_changed: 0
Rows_changed_x_indexes: 0
***** 2. row *****
  Table_schema: test
    Table_name: employees_example
      Rows_read: 7
      Rows_changed: 0
Rows_changed_x_indexes: 0
***** 3. row *****
  Table_schema: mysql
    Table_name: user
      Rows_read: 16
      Rows_changed: 0
Rows_changed_x_indexes: 0
***** 4. row *****
  Table_schema: mysql
    Table_name: db
      Rows_read: 2
      Rows_changed: 0
Rows_changed_x_indexes: 0

```

## 1.1.2.8.52 SHOW TRIGGERS

### Syntax

```

SHOW TRIGGERS [FROM db_name]
  [LIKE 'pattern' | WHERE expr]

```

### Contents

- 1. [Syntax](#)
- 2. [Description](#)
- 3. [Examples](#)
- 4. [See also](#)

### Description

`SHOW TRIGGERS`  
lists the triggers currently defined for tables in a database (the default database unless a `FROM` clause is given). This statement requires the

#### TRIGGER

privilege (prior to MySQL 5.1.22, it required the `SUPER` privilege).

The

`LIKE` clause, if present on its own, indicates which table names to match and causes the statement to display triggers for those tables. The `WHERE` and `LIKE` clauses can be given to select rows using more general conditions, as discussed in [Extended SHOW](#).

Similar information is stored in the

#### `information_schema.TRIGGERS`

table.

MariaDB starting with 10.2.3

If there are multiple triggers for the same action, then the triggers are shown in action order.

## Examples

For the trigger defined at [Trigger Overview](#) :

```
SHOW triggers Like 'animals' \G
***** 1. row *****
    Trigger: the_mooses_are_loose
      Event: INSERT
      Table: animals
    Statement: BEGIN
IF NEW.name = 'Moose' THEN
  UPDATE animal_count SET animal_count.animals = animal_count.animals+100;
ELSE
  UPDATE animal_count SET animal_count.animals = animal_count.animals+1;
END IF;
END
      Timing: AFTER
      Created: 2016-09-29 13:53:34.35
      sql_mode:
        Definer: root@localhost
character_set_client: utf8
collation_connection: utf8_general_ci
  Database Collation: latin1_swedish_ci
```

Listing all triggers associated with a certain table:

```
SHOW TRIGGERS FROM test WHERE `Table` = 'user' \G
***** 1. row *****
    Trigger: user_ai
      Event: INSERT
      Table: user
    Statement: BEGIN END
      Timing: AFTER
      Created: 2016-09-29 13:53:34.35
      sql_mode:
        Definer: root@%
character_set_client: utf8
collation_connection: utf8_general_ci
  Database Collation: latin1_swedish_ci
```

```
SHOW triggers WHERE Event Like 'Insert' \G
***** 1. row *****
    Trigger: the_mooses_are_loose
      Event: INSERT
      Table: animals
    Statement: BEGIN
IF NEW.name = 'Moose' THEN
  UPDATE animal_count SET animal_count.animals = animal_count.animals+100;
ELSE
  UPDATE animal_count SET animal_count.animals = animal_count.animals+1;
END IF;
END
      Timing: AFTER
      Created: 2016-09-29 13:53:34.35
      sql_mode:
        Definer: root@localhost
character_set_client: utf8
collation_connection: utf8_general_ci
  Database Collation: latin1_swedish_ci
```

- character\_set\_client  
is the session value of the  
[character\\_set\\_client](#)  
system variable when the trigger was created.
- collation\_connection  
is the session value of the

`collation_connection`

system variable when the trigger was created.

- Database Collation

is the collation of the database with which the trigger is associated.

These columns were added in MariaDB/MySQL 5.1.21.

Old triggers created before MySQL 5.7 and [MariaDB 10.2.3](#) has NULL in the  
Created  
column.

## 1.1.2.8.53 SHOW USER\_STATISTICS

### Syntax

```
SHOW USER_STATISTICS
```

### Description

The

```
SHOW USER_STATISTICS
```

statement is part of the [User Statistics](#) feature. It was removed as a separate statement in [MariaDB 10.1.1](#), but effectively replaced by the generic `SHOW information_schema_table` statement. The `information_schema.USER_STATISTICS` table holds statistics about user activity. You can use this table to find out such things as which user is causing the most load and which users are being abusive. You can also use this table to measure how close to capacity the server may be.

The `userstat` system variable must be set to 1 to activate this feature. See the [User Statistics](#) and `information_schema.USER_STATISTICS` table for more information.

### Example

```

SHOW USER_STATISTICS [G]
*****
***** 1. row *****
    User: root
    Total_connections: 1
    Concurrent_connections: 0
    Connected_time: 3297
        Busy_time: 0.1411340000000006
        Cpu_time: 0.01763700000000003
    Bytes_received: 969
        Bytes_sent: 22355
    Binlog_bytes_written: 0
        Rows_read: 10
        Rows_sent: 67
        Rows_deleted: 0
        Rows_inserted: 0
        Rows_updated: 0
    Select_commands: 7
    Update_commands: 0
    Other_commands: 0
    Commit_transactions: 1
    Rollback_transactions: 0
    Denied_connections: 0
    Lost_connections: 0
    Access_denied: 0
    Empty_queries: 7

```

## 1.1.2.8.54 SHOW VARIABLES

### Syntax

```

SHOW [GLOBAL | SESSION] VARIABLES
[LIKE 'pattern' | WHERE expr]

```

### Contents

1. [Syntax](#)
2. [Description](#)
3. [Examples](#)

### Description

`SHOW VARIABLES`  
shows the values of MariaDB [system variables](#). This information also can be obtained using the

`mysqladmin`

variables command. The  
`LIKE`  
clause, if present, indicates which variable names to match. The  
`WHERE`  
clause can be given to select rows using more general conditions.

With the

`GLOBAL`  
modifier,  
`SHOW VARIABLES`  
displays the values that are used for new connections to MariaDB. With  
`SESSION`  
, it displays the values that are in effect for the current connection. If no modifier is present, the default is  
`SESSION`  
  
`LOCAL`  
is a synonym for  
`SESSION`  
. With a  
`LIKE`  
clause, the statement displays only rows for those variables with names that match the pattern. To obtain the row for a specific variable, use a  
`LIKE`  
clause as shown:

```
SHOW VARIABLES LIKE 'maria_group_commit';
SHOW SESSION VARIABLES LIKE 'maria_group_commit';
```

To get a list of variables whose name match a pattern, use the "

%  
" wildcard character in a  
LIKE  
clause:

```
SHOW VARIABLES LIKE '%maria%';
SHOW GLOBAL VARIABLES LIKE '%maria%';
```

Wildcard characters can be used in any position within the pattern to be matched. Strictly speaking, because "

" is a wildcard that matches any single character, you should escape it as "  
\\_"  
" to match it literally. In practice, this is rarely necessary.

The

WHERE  
and  
LIKE

clauses can be given to select rows using more general conditions, as discussed in [Extended SHOW](#).

See

[SET](#)

for information on setting server system variables.

See [Server System Variables](#) for a list of all the variables that can be set.

You can also see the server variables by querying the [Information Schema GLOBAL\\_VARIABLES](#) and [SESSION\\_VARIABLES](#) tables.

## Examples

```
SHOW VARIABLES LIKE 'aria%';
+-----+-----+
| Variable_name          | Value   |
+-----+-----+
| aria_block_size         | 8192    |
| aria_checkpoint_interval | 30      |
| aria_checkpoint_log_activity | 1048576 |
| aria_force_start_after_recovery_failures | 0       |
| aria_group_commit        | none    |
| aria_group_commit_interval | 0       |
| aria_log_file_size       | 1073741824 |
| aria_log_purge_type      | immediate |
| aria_max_sort_file_size  | 9223372036853727232 |
| aria_page_checksum        | ON      |
| aria_pagecache_age_threshold | 300    |
| aria_pagecache_buffer_size | 134217728 |
| aria_pagecache_division_limit | 100    |
| aria_recover             | NORMAL  |
| aria_repair_threads       | 1       |
| aria_sort_buffer_size     | 134217728 |
| aria_stats_method         | nulls_unequal |
| aria_sync_log_dir         | NEWFILE |
| aria_used_for_temp_tables | ON      |
+-----+-----+
```

```

SELECT VARIABLE_NAME, SESSION_VALUE, GLOBAL_VALUE FROM
INFORMATION_SCHEMA.SYSTEM_VARIABLES WHERE
VARIABLE_NAME LIKE 'max_error_count' OR
VARIABLE_NAME LIKE 'innodb_sync_spin_loops';
+-----+-----+-----+
| VARIABLE_NAME | SESSION_VALUE | GLOBAL_VALUE |
+-----+-----+-----+
| MAX_ERROR_COUNT | 64 | 64 |
| INNODB_SYNC_SPIN_LOOPS | NULL | 30 |
+-----+-----+-----+

SET GLOBAL max_error_count=128;

SELECT VARIABLE_NAME, SESSION_VALUE, GLOBAL_VALUE FROM
INFORMATION_SCHEMA.SYSTEM_VARIABLES WHERE
VARIABLE_NAME LIKE 'max_error_count' OR
VARIABLE_NAME LIKE 'innodb_sync_spin_loops';
+-----+-----+-----+
| VARIABLE_NAME | SESSION_VALUE | GLOBAL_VALUE |
+-----+-----+-----+
| MAX_ERROR_COUNT | 64 | 128 |
| INNODB_SYNC_SPIN_LOOPS | NULL | 30 |
+-----+-----+-----+

SET GLOBAL max_error_count=128;

SHOW VARIABLES LIKE 'max_error_count';
+-----+-----+
| Variable_name | Value |
+-----+-----+
| max_error_count | 64 |
+-----+-----+

SHOW GLOBAL VARIABLES LIKE 'max_error_count';
+-----+-----+
| Variable_name | Value |
+-----+-----+
| max_error_count | 128 |
+-----+-----+

```

Because the following variable only has a global scope, the global value is returned even when specifying SESSION (in this case by default):

```

SHOW VARIABLES LIKE 'innodb_sync_spin_loops';
+-----+-----+
| Variable_name | Value |
+-----+-----+
| innodb_sync_spin_loops | 30 |
+-----+-----+

```

## 1.1.2.8.55 SHOW WARNINGS

### Syntax

```

SHOW WARNINGS [LIMIT [offset,] row_count]
SHOW ERRORS [LIMIT row_count OFFSET offset]
SHOW COUNT(*) WARNINGS

```

### Contents

1. [Syntax](#)
2. [Description](#)
3. [Examples](#)
  1. [Stack Trace](#)
4. [See Also](#)

### Description

`SHOW WARNINGS`

shows the error, warning, and note messages that resulted from the last statement that generated messages in the current session. It shows nothing if the last statement used a table and generated no messages. (That is, a statement that uses a table but generates no messages clears the

message list.) Statements that do not use tables and do not generate messages have no effect on the message list.

A note is different to a warning in that it only appears if the

#### `sql_notes`

variable is set to 1 (the default), and is not converted to an error if

#### `strict mode`

is enabled.

A related statement,

#### `SHOW ERRORS`

, shows only the errors.

The

`SHOW COUNT(*) WARNINGS`

statement displays the total number of errors, warnings, and notes. You can also retrieve this number from the `warning_count` variable:

```
SHOW COUNT(*) WARNINGS;  
SELECT @@warning_count;
```

The value of

#### `warning_count`

might be greater than the number of messages displayed by

`SHOW WARNINGS`

if the

#### `max_error_count`

system variable is set so low that not all messages are stored.

The

`LIMIT`

clause has the same syntax as for the

#### `SELECT statement`

.

.

`SHOW WARNINGS`  
can be used after

#### `EXPLAIN EXTENDED`

to see how a query is internally rewritten by MariaDB.

If the

#### `sql_notes`

server variable is set to 1, Notes are included in the output of

`SHOW WARNINGS`

; if it is set to 0, this statement will not show (or count) Notes.

The results of

`SHOW WARNINGS`

and

`SHOW COUNT(*) WARNINGS`

are directly sent to the client. If you need to access those information in a stored program, you can use the

#### `GET DIAGNOSTICS`

statement instead.

For a list of MariaDB error codes, see [MariaDB Error Codes](#).

The

```
mysql
```

client also has a number of options related to warnings. The  
\W  
command will show warnings after every statement, while  
\w  
will disable this. Starting the client with the  
--show-warnings  
option will show warnings after every statement.

MariaDB 10.3.1 implements a stored routine error stack trace.

```
SHOW WARNINGS
```

can also be used to show more information. See the example below.

## Examples

```
SELECT 1/0;
+-----+
| 1/0 |
+-----+
| NULL |
+-----+

SHOW COUNT(*) WARNINGS;
+-----+
| @@session.warning_count |
+-----+
| 1 |
+-----+

SHOW WARNINGS;
+-----+-----+
| Level | Code | Message      |
+-----+-----+
| Warning | 1365 | Division by 0 |
+-----+-----+
```

## Stack Trace

From MariaDB 10.3.1 , displaying a stack trace:

```
DELIMITER $$  
CREATE OR REPLACE PROCEDURE p1()  
BEGIN  
    DECLARE c CURSOR FOR SELECT * FROM not_existing;  
    OPEN c;  
    CLOSE c;  
END;  
$$  
CREATE OR REPLACE PROCEDURE p2()  
BEGIN  
    CALL p1;  
END;  
$$  
DELIMITER ;  
CALL p2;  
ERROR 1146 (42S02): Table 'test.not_existing' doesn't exist

SHOW WARNINGS;
+-----+-----+
| Level | Code | Message      |
+-----+-----+
| Error | 1146 | Table 'test.not_existing' doesn't exist |
| Note  | 4091 | At line 6 in test.p1          |
| Note  | 4091 | At line 4 in test.p2          |
+-----+-----+
```

SHOW WARNINGS  
displays a stack trace, showing where the error actually happened:

- Line 4 in test.p1 is the OPEN command which actually raised the error

- Line 3 in test.p2 is the CALL statement, calling p1 from p2.

## See Also

- [SHOW ERRORS](#)

## 1.1.2.8.56 SHOW WSREP\_MEMBERSHIP

SHOW WSREP\_MEMBERSHIP  
is part of the

[WSREP\\_INFO](#)

plugin.

## Syntax

```
SHOW WSREP_MEMBERSHIP
```

## Description

The

SHOW WSREP\_MEMBERSHIP  
statement returns [Galera](#) node cluster membership information. It returns the same information as found in the  
[information\\_schema.WSREP\\_MEMBERSHIP](#)  
table. Only users with the  
[SUPER](#)  
privilege can access this information.

## Examples

```
SHOW WSREP_MEMBERSHIP;
+-----+-----+-----+
| Index | Uuid                | Name      | Address      |
+-----+-----+-----+
|   0   | 19058073-8940-11e4-8570-16af7bf8fcfd | my_node1  | 10.0.2.15:16001 |
|   1   | 19f2b00-8942-11e4-9cb8-b39e8ee0b5dd | my_node3  | 10.0.2.15:16003 |
|   2   | d85e62db-8941-11e4-b1ef-4bc9980e476d | my_node2  | 10.0.2.15:16002 |
+-----+-----+-----+
```

## 1.1.2.8.57 SHOW WSREP\_STATUS

SHOW WSREP\_STATUS  
is part of the

[WSREP\\_INFO](#)

plugin.

## Syntax

```
SHOW WSREP_STATUS
```

## Description

The

SHOW WSREP\_STATUS  
statement returns [Galera](#) node and cluster status information. It returns the same information as found in the

## [information\\_schema.WSREP\\_STATUS](#)

table. Only users with the

[SUPER](#)

privilege can access this information.

## Examples

```
SHOW WSREP_STATUS;
+-----+-----+-----+
| Node_Index | Node_Status | Cluster_Status | Cluster_Size |
+-----+-----+-----+
|      0 | Synced     | Primary       |      3 |
+-----+-----+-----+
```

## 1.1.2.9 System Tables

### 1.1.2.9.1 Information Schema

#### 1.1.2.9.1.1 Information Schema Tables

##### 1.1.2.9.1.1.1 Information Schema InnoDB Tables

###### 1.1.2.9.1.1.1.1 Information Schema

###### **INNODB\_BUFFER\_PAGE** Table

The [Information Schema](#)

[INNODB\\_BUFFER\\_PAGE](#)

table contains information about pages in the [buffer pool](#).

The

[PROCESS](#)

[privilege](#) is required to view the table.

It has the following columns:

Column	Description
POOL_ID	Buffer Pool identifier. From <a href="#">MariaDB 10.5.1</a> returns a value of 0, since multiple InnoDB buffer pool instances has been removed.
BLOCK_ID	Buffer Pool Block identifier.
SPACE	Tablespace identifier. Matches the SPACE value in the <a href="#">INNODB_SYS_TABLES</a> table.
PAGE_NUMBER	Buffer pool page number.

PAGE_TYPE	Page type; one of allocated (newly-allocated page), index (B-tree node), undo_log (undo log page), inode (index node), ibuf_free_list (insert buffer free list), ibuf_bitmap (insert buffer bitmap), system (system page), trx_system (transaction system data), file_space_header (file space header), extent_descriptor (extent descriptor page), blob (uncompressed blob page), compressed_blob (first compressed blob page), compressed_blob2 (subsequent compressed blob page) or unknown .
FLUSH_TYPE	Flush type.
FIX_COUNT	Count of the threads using this block in the buffer pool. When it is zero, the block can be evicted from the buffer pool.
IS_HASHED	Whether or not a hash index has been built on this page.
NEWEST_MODIFICATION	Most recent modification's Log Sequence Number.
OLDEST_MODIFICATION	Oldest modification's Log Sequence Number.
ACCESS_TIME	Abstract number representing the time the page was first accessed.
TABLE_NAME	Table that the page belongs to.
INDEX_NAME	Index that the page belongs to, either a clustered index or a secondary index.
NUMBER_RECORDS	Number of records the page contains.

DATA_SIZE	Size in bytes of all the records contained in the page.
COMPRESSED_SIZE	Compressed size in bytes of the page, or NULL for pages that aren't compressed.
PAGE_STATE	Page state; one of FILE_PAGE (page from a file) or MEMORY (page from an in-memory object) for valid data, or one of NULL , READY_FOR_USE , NOT_USED , REMOVE_HASH
IO_FIX	Whether there is I/O pending for the page; one of IO_NONE (no pending I/O), IO_READ (read pending), IO_WRITE (write pending).
IS_OLD	Whether the page is old or not.
FREE_PAGE_CLOCK	Freed_page_clock counter, which tracks the number of blocks removed from the end of the least recently used (LRU) list, at the time the block was last placed at the head of the list.

The related [INFORMATION\\_SCHEMA.INNODB\\_BUFFER\\_PAGE\\_LRU](#) table contains the same information, but with an LRU (least recently used) position rather than block id.

## Examples

```
DESC information_schema.innodb_buffer_page;
+-----+-----+-----+-----+-----+
| Field | Type | Null | Key | Default | Extra |
+-----+-----+-----+-----+-----+
| POOL_ID | bigint(21) unsigned | NO | | 0 | |
| BLOCK_ID | bigint(21) unsigned | NO | | 0 | |
| SPACE | bigint(21) unsigned | NO | | 0 | |
| PAGE_NUMBER | bigint(21) unsigned | NO | | 0 | |
| PAGE_TYPE | varchar(64) | YES | | NULL | |
| FLUSH_TYPE | bigint(21) unsigned | NO | | 0 | |
| FIX_COUNT | bigint(21) unsigned | NO | | 0 | |
| IS_HASHED | varchar(3) | YES | | NULL | |
| NEWEST_MODIFICATION | bigint(21) unsigned | NO | | 0 | |
| OLDEST_MODIFICATION | bigint(21) unsigned | NO | | 0 | |
| ACCESS_TIME | bigint(21) unsigned | NO | | 0 | |
| TABLE_NAME | varchar(1024) | YES | | NULL | |
| INDEX_NAME | varchar(1024) | YES | | NULL | |
| NUMBER_RECORDS | bigint(21) unsigned | NO | | 0 | |
| DATA_SIZE | bigint(21) unsigned | NO | | 0 | |
| COMPRESSED_SIZE | bigint(21) unsigned | NO | | 0 | |
| PAGE_STATE | varchar(64) | YES | | NULL | |
| IO_FIX | varchar(64) | YES | | NULL | |
| IS_OLD | varchar(3) | YES | | NULL | |
| FREE_PAGE_CLOCK | bigint(21) unsigned | NO | | 0 | |
+-----+-----+-----+-----+-----+
```

```

SELECT * FROM INFORMATION_SCHEMA.INNODB_BUFFER_PAGE\G
...
***** 6. row *****

  IS_OLD: NO
FREE_PAGE_CLOCK: 0
...

```

## 1.1.2.9.1.1.1.2 Information Schema INNODB\_BUFFER\_PAGE\_LRU Table

The [Information Schema](#)

`INNODB_BUFFER_PAGE_LRU`

table contains information about pages in the [buffer pool](#) and how they are ordered for eviction purposes.

The

`PROCESS`

[privilege](#) is required to view the table.

It has the following columns:

Column	Description
<code>POOL_ID</code>	Buffer Pool identifier. From <a href="#">MariaDB 10.5.1</a> returns a value of 0, since multiple InnoDB buffer pool instances has been removed.
<code>LRU_POSITION</code>	LRU (Least recently-used), for determining eviction order from the buffer pool.
<code>SPACE</code>	Tablespace identifier. Matches the <code>SPACE</code> value on the <a href="#">INNODB_SYS_TABLES</a> table.
<code>PAGE_NUMBER</code>	Buffer pool page number.

PAGE_TYPE	Page type; one of allocated (newly-allocated page), index (B-tree node), undo_log (undo log page), inode (index node), ibuf_free_list (insert buffer free list), ibuf_bitmap (insert buffer bitmap), system (system page), trx_system (transaction system data), file_space_header (file space header), extent_descriptor (extent descriptor page), blob (uncompressed blob page), compressed_blob (first compressed blob page), compressed_blob2 (subsequent compressed blob page) or unknown .
FLUSH_TYPE	Flush type.
FIX_COUNT	Count of the threads using this block in the buffer pool. When it is zero, the block can be evicted from the buffer pool.
IS_HASHED	Whether or not a hash index has been built on this page.
NEWEST_MODIFICATION	Most recent modification's Log Sequence Number.
OLDEST_MODIFICATION	Oldest modification's Log Sequence Number.
ACCESS_TIME	Abstract number representing the time the page was first accessed.
TABLE_NAME	Table that the page belongs to.
INDEX_NAME	Index that the page belongs to, either a clustered index or a secondary index.
NUMBER_RECORDS	Number of records the page contains.
DATA_SIZE	Size in bytes of all the records contained in the page.

COMPRESSED_SIZE	Compressed size in bytes of the page, or NULL for pages that aren't compressed.
PAGE_STATE	Page state; one of FILE_PAGE (page from a file) or MEMORY (page from an in-memory object) for valid data, or one of NULL , READY_FOR_USE , NOT_USED , REMOVE_HASH .
IO_FIX	Whether there is I/O pending for the page; one of IO_NONE (no pending I/O), IO_READ (read pending), IO_WRITE (write pending).
IS_OLD	Whether the page is old or not.
FREE_PAGE_CLOCK	Freed_page_clock counter, which tracks the number of blocks removed from the end of the LRU list, at the time the block was last placed at the head of the list.

The related [INFORMATION\\_SCHEMA.INNODB\\_BUFFER\\_PAGE](#) table contains the same information, but with a block id rather than LRU position.

## Example

```
DESC information_schema.innodb_buffer_page_lru;
+-----+-----+-----+-----+-----+
| Field | Type | Null | Key | Default | Extra |
+-----+-----+-----+-----+-----+
| POOL_ID | bigint(21) unsigned | NO | | 0 | |
| LRU_POSITION | bigint(21) unsigned | NO | | 0 | |
| SPACE | bigint(21) unsigned | NO | | 0 | |
| PAGE_NUMBER | bigint(21) unsigned | NO | | 0 | |
| PAGE_TYPE | varchar(64) | YES | | NULL | |
| FLUSH_TYPE | bigint(21) unsigned | NO | | 0 | |
| FIX_COUNT | bigint(21) unsigned | NO | | 0 | |
| IS_HASHED | varchar(3) | YES | | NULL | |
| NEWEST_MODIFICATION | bigint(21) unsigned | NO | | 0 | |
| OLDEST_MODIFICATION | bigint(21) unsigned | NO | | 0 | |
| ACCESS_TIME | bigint(21) unsigned | NO | | 0 | |
| TABLE_NAME | varchar(1024) | YES | | NULL | |
| INDEX_NAME | varchar(1024) | YES | | NULL | |
| NUMBER_RECORDS | bigint(21) unsigned | NO | | 0 | |
| DATA_SIZE | bigint(21) unsigned | NO | | 0 | |
| COMPRESSED_SIZE | bigint(21) unsigned | NO | | 0 | |
| COMPRESSED | varchar(3) | YES | | NULL | |
| IO_FIX | varchar(64) | YES | | NULL | |
| IS_OLD | varchar(3) | YES | | NULL | |
| FREE_PAGE_CLOCK | bigint(21) unsigned | NO | | 0 | |
+-----+-----+-----+-----+-----+
```

```

SELECT * FROM INFORMATION_SCHEMA.INNODB_BUFFER_PAGE_LRU\G
...
***** 6. row *****
    POOL_ID: 0
    LRU_POSITION: 5
    SPACE: 0
    PAGE_NUMBER: 11
    PAGE_TYPE: INDEX
    FLUSH_TYPE: 1
    FIX_COUNT: 0
    IS_HASHED: NO
    NEWEST_MODIFICATION: 2046835
    OLDEST_MODIFICATION: 0
    ACCESS_TIME: 2585566280
    TABLE_NAME: `SYS_INDEXES`
    INDEX_NAME: CLUST_IND
    NUMBER_RECORDS: 57
    DATA_SIZE: 4016
    COMPRESSED_SIZE: 0
    COMPRESSED: NO
    IO_FIX: IO_NONE
    IS_OLD: NO
    FREE_PAGE_CLOCK: 0
...

```

## 1.1.2.9.1.1.3 Information Schema INNODB\_BUFFER\_POOL\_PAGES Table

The [Information Schema](#)

`INNODB_BUFFER_POOL_PAGES` table is a Percona enhancement, and is only available for XtraDB, not InnoDB (see [XtraDB](#) and [InnoDB](#) ). It contains a record for each page in the [buffer pool](#) .

It has the following columns:

Column	Description
PAGE_TYPE	Type of page; one of index , undo_log , inode , ibuf_free_list , allocated, bitmap , sys , trx_sys , fsp_hdr , xdes , blob , zblob , zblob2 and unknown .
SPACE_ID	Tablespace ID.
PAGE_NO	Page offset within tablespace.

LRU_POSITION	Page position in the LRU (least-recently-used) list.
FIX_COUNT	Page reference count, incremented each time the page is accessed. 0 if the page is not currently being accessed.
FLUSH_TYPE	Flush type of the most recent flush. 0 (LRU), 2 (flush_list)

## 1.1.2.9.1.1.1.4 Information Schema INNODB\_BUFFER\_POOL\_PAGES\_BLOB Table

The [Information Schema](#)

`INNODB_BUFFER_POOL_PAGES_BLOB` table is a Percona enhancement, and is only available for XtraDB, not InnoDB (see [XtraDB](#) and [InnoDB](#) ). It contains information about `buffer pool` blob pages.

It has the following columns:

Column	Description
SPACE_ID	Tablespace ID.
PAGE_NO	Page offset within tablespace.
COMPRESSED	1 if the blob contains compressed data, 0 if not.
PART_LEN	Page data length.
NEXT_PAGE_NO	Next page number.
LRU_POSITION	Page position in the LRU (least-recently-used) list.
FIX_COUNT	Page reference count, incremented each time the page is accessed. 0 if the page is not currently being accessed.
FLUSH_TYPE	Flush type of the most recent flush. 0 (LRU), 2 (flush_list)

## 1.1.2.9.1.1.1.5 Information Schema INNODB\_BUFFER\_POOL\_PAGES\_INDEX Table

The [Information Schema](#)

`INNODB_BUFFER_POOL_PAGES` table is a Percona enhancement, and is only available for XtraDB, not InnoDB (see [XtraDB](#) and [InnoDB](#) ). It contains information about `buffer pool` index pages.

It has the following columns:

Column	Description
--------	-------------

INDEX_ID	Index name
SPACE_ID	Tablespace ID
PAGE_NO	Page offset within tablespace.
N_RECS	Number of user records on the page.
DATA_SIZE	Total data size in bytes of records in the page.
HASHED	1 if the block is in the adaptive hash index, 0 if not.
ACCESS_TIME	Page's last access time.
MODIFIED	1 if the page has been modified since being loaded, 0 if not.
DIRTY	1 if the page has been modified since it was last flushed, 0 if not
OLD	1 if the page in the in the <i>old</i> blocks of the LRU (least-recently-used) list, 0 if not.
LRU_POSITION	Position in the LRU (least-recently-used) list.
FIX_COUNT	Page reference count, incremented each time the page is accessed. 0 if the page is not currently being accessed.
FLUSH_TYPE	Flush type of the most recent flush. 0 (LRU), 2 (flush_list)

## 1.1.2.9.1.1.1.6 Information Schema INNODB\_BUFFER\_POOL\_STATS Table

The [Information Schema](#)

INNODB\_BUFFER\_POOL\_STATS

table contains information about pages in the [buffer pool](#), similar to what is returned with the

`SHOW ENGINE INNODB STATUS`

statement.

The

## PROCESS

[privilege](#) is required to view the table.

It has the following columns:

Column	Description
POOL_ID	Buffer Pool identifier. From <a href="#">MariaDB 10.5.1</a> returns a value of 0, since multiple InnoDB buffer pool instances has been removed.
POOL_SIZE	Size in pages of the buffer pool.
FREE_BUFFERS	Number of free pages in the buffer pool.
DATABASE_PAGES	Total number of pages in the buffer pool.
OLD_DATABASE_PAGES	Number of pages in the <i>old</i> sublist.
MODIFIED_DATABASE_PAGES	Number of dirty pages.
PENDING_DECOMPRESS	Number of pages pending decompression.
PENDING_READS	Pending buffer pool level reads.
PENDING_FLUSH_LRU	Number of pages in the LRU pending flush.
PENDING_FLUSH_LIST	Number of pages in the flush list pending flush.
PAGES_MADE_YOUNG	Pages moved from the <i>old</i> sublist to the <i>new</i> sublist.
PAGES_NOT_MADE_YOUNG	Pages that have remained in the <i>old</i> sublist without moving to the <i>new</i> sublist.
PAGES_MADE_YOUNG_RATE	Hits that cause blocks to move to the top of the <i>new</i> sublist.
PAGES_MADE_NOT_YOUNG_RATE	Hits that do not cause blocks to move to the top of the <i>new</i> sublist due to the <a href="#">innodb_old_blocks</a> delay not being met.
NUMBER_PAGES_READ	Number of pages read.
NUMBER_PAGES_CREATED	Number of pages created.
NUMBER_PAGES_WRITTEN	Number of pages written.

PAGES_READ_RATE	Number of pages read since the last printout divided by the time elapsed, giving pages read per second.
PAGES_CREATE_RATE	Number of pages created since the last printout divided by the time elapsed, giving pages created per second.
PAGES_WRITTEN_RATE	Number of pages written since the last printout divided by the time elapsed, giving pages written per second.
NUMBER_PAGES_GET	Number of logical read requests.
HIT_RATE	Buffer pool hit rate.
YOUNG_MAKE_PER_THOUSAND_GETS	For every 1000 gets, the number of pages made young.
NOT_YOUNG_MAKE_PER_THOUSAND_GETS	For every 1000 gets, the number of pages not made young.
NUMBER_PAGES_READ_AHEAD	Number of pages read ahead.
NUMBER_READ_AHEAD_EVICTED	Number of pages read ahead by the read-ahead thread that were later evicted without being accessed by any queries.
READ_AHEAD_RATE	Pages read ahead since the last printout divided by the time elapsed, giving read-ahead rate per second.
READ_AHEAD_EVICTED_RATE	Read-ahead pages not accessed since the last printout divided by time elapsed, giving the number of read-ahead pages evicted without access per second.
LRU_IO_TOTAL	Total least-recently used I/O.
LRU_IO_CURRENT	Least-recently used I/O for the current interval.
UNCOMPRESS_TOTAL	Total number of pages decompressed.
UNCOMPRESS_CURRENT	Number of pages decompressed in the current interval

## Examples

Field	Type	Null	Key	Default	Extra
POOL_ID	bigint(21) unsigned	NO		0	
POOL_SIZE	bigint(21) unsigned	NO		0	
FREE_BUFFERS	bigint(21) unsigned	NO		0	
DATABASE_PAGES	bigint(21) unsigned	NO		0	
OLD_DATABASE_PAGES	bigint(21) unsigned	NO		0	
MODIFIED_DATABASE_PAGES	bigint(21) unsigned	NO		0	
PENDING_DECOMPRESS	bigint(21) unsigned	NO		0	
PENDING_READS	bigint(21) unsigned	NO		0	
PENDING_FLUSH_LRU	bigint(21) unsigned	NO		0	
PENDING_FLUSH_LIST	bigint(21) unsigned	NO		0	
PAGES_MADE_YOUNG	bigint(21) unsigned	NO		0	
PAGES_NOT_MADE_YOUNG	bigint(21) unsigned	NO		0	
PAGES_MADE_YOUNG_RATE	double	NO		0	
PAGES_MADE_NOT_YOUNG_RATE	double	NO		0	
NUMBER_PAGES_READ	bigint(21) unsigned	NO		0	
NUMBER_PAGES_CREATED	bigint(21) unsigned	NO		0	
NUMBER_PAGES_WRITTEN	bigint(21) unsigned	NO		0	
PAGES_READ_RATE	double	NO		0	
PAGES_CREATE_RATE	double	NO		0	
PAGES_WRITTEN_RATE	double	NO		0	
NUMBER_PAGES_GET	bigint(21) unsigned	NO		0	
HIT_RATE	bigint(21) unsigned	NO		0	
YOUNG_MAKE_PER_THOUSAND_GETS	bigint(21) unsigned	NO		0	
NOT_YOUNG_MAKE_PER_THOUSAND_GETS	bigint(21) unsigned	NO		0	
NUMBER_PAGES_READ_AHEAD	bigint(21) unsigned	NO		0	
NUMBER_READ_AHEAD_EVICTED	bigint(21) unsigned	NO		0	
READ_AHEAD_RATE	double	NO		0	
READ_AHEAD_EVICTED_RATE	double	NO		0	
LRU_IO_TOTAL	bigint(21) unsigned	NO		0	
LRU_IO_CURRENT	bigint(21) unsigned	NO		0	
UNCOMPRESS_TOTAL	bigint(21) unsigned	NO		0	
UNCOMPRESS_CURRENT	bigint(21) unsigned	NO		0	

## 1.1.2.9.1.1.1.7 Information Schema INNODB\_CHANGED\_PAGES Table

The [Information Schema](#)

### INNODB\_CHANGED\_PAGES

Table contains data about modified pages from the bitmap file. It is updated at checkpoints by the log tracking thread parsing the log, so does not contain real-time data.

The number of records is limited by the value of the [innodb\\_max\\_changed\\_pages](#) system variable.

The

#### PROCESS

[privilege](#) is required to view the table.

It has the following columns:

Column	Description
SPACE_ID	Modified page space id
PAGE_ID	Modified page id
START_LSN	Interval start after which page was changed (equal to checkpoint LSN)
END_LSN	Interval end before which page was changed (equal to checkpoint LSN)

## 1.1.2.9.1.1.1.8 Information Schema INNODB\_CMP and

# INNODB\_CMP\_RESET Tables

The

INNODB\_CMP

and

INNODB\_CMP\_RESET

tables contain status information on compression operations related to [compressed XtraDB/InnoDB tables](#).

The

PROCESS

privilege is required to query this table.

These tables contain the following columns:

Column Name	Description
PAGE_SIZE	Compressed page size, in bytes. This value is unique in the table; other values are totals which refer to pages of this size.
COMPRESS_OPS	How many times a page of the size PAGE_SIZE has been compressed. This happens when a new page is created because the compression log runs out of space. This value includes both successful operations and <i>compression failures</i> .
COMPRESS_OPS_OK	How many times a page of the size PAGE_SIZE has been successfully compressed. This value should be as close as possible to COMPRESS_OPS . If it is notably lower, either avoid compressing some tables, or increase the KEY_BLOCK_SIZE for some compressed tables.
COMPRESS_TIME	Time (in seconds) spent to compress pages of the size PAGE_SIZE . This value includes time spent in <i>compression failures</i> .
UNCOMPRESS_OPS	How many times a page of the size PAGE_SIZE has been uncompressed. This happens when an uncompressed version of a page is created in the buffer pool, or when a <i>compression failure</i> occurs.
UNCOMPRESS_TIME	Time (in seconds) spent to uncompress pages of the size PAGE_SIZE .

These tables can be used to measure the effectiveness of XtraDB/InnoDB table compression. When you have to decide a value for

KEY\_BLOCK\_SIZE

, you can create more than one version of the table (one for each candidate value) and run a realistic workload on them. Then, these tables can be used to see how the operations performed with different page sizes.

INNODB\_CMP

and

INNODB\_CMP\_RESET

have the same columns and always contain the same values, but when

INNODB\_CMP\_RESET

is queried, both the tables are cleared.

INNODB\_CMP\_RESET

can be used, for example, if a script periodically logs the performances of compression in the last period of time.

INNODB\_CMP

can be used to see the cumulated statistics.

## Examples

```

SELECT * FROM information_schema.INNODB_CMP\G
*****
1. row ****
page_size: 1024
compress_ops: 0
compress_ops_ok: 0
compress_time: 0
uncompress_ops: 0
uncompress_time: 0
...

```

## See Also

Other tables that can be used to monitor XtraDB/InnoDB compressed tables:

- [INNODB\\_CMP\\_PER\\_INDEX](#) and [INNODB\\_CMP\\_PER\\_INDEX\\_RESET](#)
- [INNODB\\_CMPPMEM](#) and [INNODB\\_CMPPMEM\\_RESET](#)

## 1.1.2.9.1.1.1.9 Information Schema INNODB\_CMPPMEM and INNODB\_CMPPMEM\_RESET Tables

The

[INNODB\\_CMPPMEM](#)

and

[INNODB\\_CMPPMEM\\_RESET](#)

tables contain status information on compressed pages in the [buffer pool](#) (see InnoDB [COMPRESSED](#) format).

The [PROCESS](#) privilege is required to query this table.

These tables contain the following columns:

Column Name	Description
PAGE_SIZE	Compressed page size, in bytes. This value is unique in the table; other values are totals which refer to pages of this size.
BUFFER_POOL_INSTANCE	Buffer Pool identifier. From <a href="#">MariaDB 10.5.1</a> returns a value of 0, since multiple InnoDB buffer pool instances has been removed.
PAGES_USED	Number of pages of the size PAGE_SIZE which are currently in the buffer pool.
PAGES_FREE	Number of pages of the size PAGE_SIZE which are currently free, and thus are available for allocation. This value represents the buffer pool's fragmentation. A totally unfragmented buffer pool has at most 1 free page.
RELOCATION_OPS	How many times a page of the size PAGE_SIZE has been relocated. This happens when data exceeds a page (because a row must be copied into a new page) and when two pages are merged (because their data shrunk and can now be contained in one page).
RELOCATION_TIME	Time (in seconds) spent in relocation operations for pages of the size PAGE_SIZE . This column is reset when the <a href="#">INNODB_CMPPMEM_RESET</a> table is queried.

These tables can be used to measure the effectiveness of InnoDB table compression. When you have to decide a value for

[KEY\\_BLOCK\\_SIZE](#)

, you can create more than one version of the table (one for each candidate value) and run a realistic workload on them. Then, these tables can be used to see how the operations performed with different page sizes.

[INNODB\\_CMPPMEM](#)

and

[INNODB\\_CMPPMEM\\_RESET](#)

have the same columns and always contain the same values, but when

[INNODB\\_CMPPMEM\\_RESET](#)

is queried, the  
**RELOCATION\_TIME**  
column from both the tables are cleared.  
**INNODB\_CMPMEM\_RESET**  
can be used, for example, if a script periodically logs the performances of compression in the last period of time.  
**INNODB\_CMPMEM**  
can be used to see the cumulated statistics.

## Example

```
SELECT * FROM information_schema.INNODB_CMPMEM\G
*****
1. row *****
    page_size: 1024
buffer_pool_instance: 0
    pages_used: 0
    pages_free: 0
relocation_ops: 0
relocation_time: 0
```

## See Also

Other tables that can be used to monitor InnoDB compressed tables:

- [INNODB\\_CMP](#) and [INNODB\\_CMP\\_RESET](#)
- [INNODB\\_CMP\\_PER\\_INDEX](#) and [INNODB\\_CMP\\_PER\\_INDEX\\_RESET](#)

### 1.1.2.9.1.1.10 Information Schema **INNODB\_CMP\_PER\_INDEX** and **INNODB\_CMP\_PER\_INDEX\_RESET** Tables

The

[INNODB\\_CMP\\_PER\\_INDEX](#)

and

[INNODB\\_CMP\\_PER\\_INDEX\\_RESET](#)

tables contain status information on compression operations related to [compressed XtraDB/InnoDB tables](#), grouped by individual indexes.

These tables are only populated if the [innodb\\_cmp\\_per\\_index\\_enabled](#) system variable is set to

ON

The [PROCESS](#) privilege is required to query this table.

These tables contains the following columns:

Column Name	Description
<b>DATABASE_NAME</b>	Database containing the index.
<b>TABLE_NAME</b>	Table containing the index.
<b>INDEX_NAME</b>	Other values are totals which refer to this index's compression.
<b>COMPRESS_OPS</b>	How many times a page of <b>INDEX_NAME</b> has been compressed. This happens when a new page is created because the compression log runs out of space. This value includes both successful operations and <i>compression failures</i> .
<b>COMPRESS_OPS_OK</b>	How many times a page of <b>INDEX_NAME</b> has been successfully compressed. This value should be as close as possible to <b>COMPRESS_OPS</b> . If it is notably lower, either avoid compressing some tables, or increase the <b>KEY_BLOCK_SIZE</b> for some compressed tables.

COMPRESS_TIME	Time (in seconds) spent to compress pages of the size PAGE_SIZE . This value includes time spent in <i>compression failures</i> .
UNCOMPRESS_OPS	How many times a page of INDEX_NAME has been uncompressed. This happens when an uncompressed version of a page is created in the buffer pool, or when a <i>compression failure</i> occurs.
UNCOMPRESS_TIME	Time (in seconds) spent to uncompress pages of INDEX_NAME .

These tables can be used to measure the effectiveness of XtraDB/InnoDB compression, per table or per index. The values in these tables show which tables perform better with index compression, and which tables cause too many *compression failures* or perform too many compression/uncompression operations. When compression performs badly for a table, this might mean that you should change its

KEY\_BLOCK\_SIZE  
, or that the table should not be compressed.

INNODB\_CMP\_PER\_INDEX  
and  
INNODB\_CMP\_PER\_INDEX\_RESET  
have the same columns and always contain the same values, but when  
INNODB\_CMP\_PER\_INDEX\_RESET  
is queried, both the tables are cleared.  
INNODB\_CMP\_PER\_INDEX\_RESET  
can be used, for example, if a script periodically logs the performances of compression in the last period of time.  
INNODB\_CMP\_PER\_INDEX  
can be used to see the cumulated statistics.

## See Also

Other tables that can be used to monitor XtraDB/InnoDB compressed tables:

- [INNODB\\_CMP](#) and [INNODB\\_CMP\\_RESET](#)
- [INNODB\\_CMPPMEM](#) and [INNODB\\_CMPPMEM\\_RESET](#)

## 1.1.2.9.1.1.11 Information Schema INNODB\_FT\_BEING\_DELETED Table

The [Information Schema](#)

INNODB\_FT\_BEING\_DELETED  
table is only used while document ID's in the related [INNODB\\_FT\\_DELETED](#) are being removed from an InnoDB [fulltext index](#) while an [OPTIMIZE TABLE](#) is underway. At all other times the table will be empty.

The

SUPER  
[privilege](#) is required to view the table, and it also requires the [innodb\\_ft\\_aux\\_table](#) system variable to be set.

It has the following column:

Column	Description
DOC_ID	Document ID of the row being deleted. Either an underlying ID value, or a sequence value generated by InnoDB if no usable option exists.

## 1.1.2.9.1.1.12 Information Schema INNODB\_FT\_CONFIG Table

The [Information Schema](#)

INNODB\_FT\_CONFIG  
table contains InnoDB [fulltext index](#) metadata.

The

SUPER  
[privilege](#) is required to view the table, and it also requires the [innodb\\_ft\\_aux\\_table](#) system variable to be set.

It has the following columns:

Column	Description
KEY	Metadata item name.
VALUE	Associated value.

## Example

```
SELECT * FROM INNODB_FT_CONFIG;
+-----+-----+
| KEY      | VALUE |
+-----+-----+
| optimize_checkpoint_limit | 180   |
| synced_doc_id           | 6     |
| last_optimized_word     |       |
| deleted_doc_count       | 0     |
| total_word_count        |       |
| optimize_start_time     |       |
| optimize_end_time       |       |
| stopword_table_name     |       |
| use_stopword            | 1     |
| table_state              | 0     |
+-----+-----+
```

## 1.1.2.9.1.1.1.13 Information Schema INNODB\_FT\_DEFAULT\_STOPWORD Table

The [Information Schema](#)

INNODB\_FT\_DEFAULT\_STOPWORD  
table contains a list of default [stopwords](#) used when creating an InnoDB [fulltext index](#).

The

PROCESS  
[privilege](#) is required to view the table.

It has the following column:

Column	Description
VALUE	Default  stopword  for an InnoDB <a href="#">fulltext index</a> . Setting either the <a href="#">innodb_ft_server_stopword_table</a> or the <a href="#">innodb_ft_user_stopword_table</a> system variable will override this.

## Example

```
SELECT * FROM information_schema.INNODB_FT_DEFAULT_STOPWORD\G
***** 1. row *****
value: a
***** 2. row *****
value: about
***** 3. row *****
value: an
***** 4. row *****
value: are
...
***** 36. row *****
value: www
```

## 1.1.2.9.1.1.1.14 Information Schema INNODB\_FT\_DELETED Table

## The Information Schema

### INNODB\_FT\_DELETED

table contains rows that have been deleted from an InnoDB fulltext index . This information is then used to filter results on subsequent searches, removing the need to expensively reorganise the index each time a row is deleted.

The fulltext index is then only reorganized when an [OPTIMIZE TABLE](#) statement is underway. The related [INNODB\\_FT\\_BEING\\_DELETED](#) table contains rows being deleted while an

```
OPTIMIZE TABLE  
is in the process of running.
```

The

SUPER

[privilege](#) is required to view the table, and it also requires the [innodb\\_ft\\_aux\\_table](#) system variable to be set.

It has the following column:

Column	Description
DOC_ID	Document ID of the deleted row deleted. Either an underlying ID value, or a sequence value generated by InnoDB if no usable option exists.

## Example

```
SELECT * FROM INFORMATION_SCHEMA.INNODB_FT_DELETED;  
+-----+  
| DOC_ID |  
+-----+  
|      2 |  
+-----+  
  
DELETE FROM test.ft_innodb LIMIT 1;  
  
SELECT * FROM INFORMATION_SCHEMA.INNODB_FT_DELETED;  
+-----+  
| DOC_ID |  
+-----+  
|      2 |  
|      3 |  
+-----+
```

## 1.1.2.9.1.1.1.15 Information Schema INNODB\_FT\_INDEX\_CACHE Table

### The Information Schema

#### INNODB\_FT\_INDEX\_CACHE

table contains information about rows that have recently been inserted into an InnoDB fulltext index . To avoid re-organizing the fulltext index each time a change is made, which would be very expensive, new changes are stored separately and only integrated when an [OPTIMIZE TABLE](#) is run.

The

SUPER

[privilege](#) is required to view the table, and it also requires the [innodb\\_ft\\_aux\\_table](#) system variable to be set.

It has the following columns:

Column	Description
WORD	Word from the text of a newly added row. Words can appear multiple times in the table, once per DOC_ID and POSITION combination.
FIRST_DOC_ID	First document ID where this word appears in the index.
LAST_DOC_ID	Last document ID where this word appears in the index.

DOC_COUNT	Number of rows containing this word in the index.
DOC_ID	Document ID of the newly added row, either an appropriate ID column or an internal InnoDB value.
POSITION	Position of this word instance within the DOC_ID , as an offset added to the previous POSITION instance.

Note that for

```
OPTIMIZE TABLE
to process InnoDB fulltext index data, the innodb_optimize_fulltext_only system variable needs to be set to
1
. When this is done, and an
OPTIMIZE TABLE
statement run, the
INNODB_FT_INDEX_CACHE
table will be emptied, and the INNODB_FT_INDEX_TABLE table will be updated.
```

## Examples

```
SELECT * FROM INNODB_FT_INDEX_CACHE;
+-----+-----+-----+-----+-----+
| WORD      | FIRST_DOC_ID | LAST_DOC_ID | DOC_COUNT | DOC_ID | POSITION |
+-----+-----+-----+-----+-----+
| and       |        4 |        4 |        1 |    4 |      0 |
| arrived   |        4 |        4 |        1 |    4 |     20 |
| ate       |        1 |        1 |        1 |    1 |      4 |
| everybody |        1 |        1 |        1 |    1 |      8 |
| goldilocks |        4 |        4 |        1 |    4 |      9 |
| hungry    |        3 |        3 |        1 |    3 |      8 |
| then      |        4 |        4 |        1 |    4 |      4 |
| wicked   |        2 |        2 |        1 |    2 |      4 |
| witch    |        2 |        2 |        1 |    2 |     11 |
+-----+-----+-----+-----+-----+
9 rows in set (0.00 sec)
```

```
INSERT INTO test.ft_innodb VALUES(3,'And she ate a pear');
```

```
SELECT * FROM INNODB_FT_INDEX_CACHE;
+-----+-----+-----+-----+-----+
| WORD      | FIRST_DOC_ID | LAST_DOC_ID | DOC_COUNT | DOC_ID | POSITION |
+-----+-----+-----+-----+-----+
| and       |        4 |        5 |        2 |    4 |      0 |
| and       |        4 |        5 |        2 |    5 |      0 |
| arrived   |        4 |        4 |        1 |    4 |     20 |
| ate       |        1 |        5 |        2 |    1 |      4 |
| ate       |        1 |        5 |        2 |    5 |      8 |
| everybody |        1 |        1 |        1 |    1 |      8 |
| goldilocks |        4 |        4 |        1 |    4 |      9 |
| hungry    |        3 |        3 |        1 |    3 |      8 |
| pear      |        5 |        5 |        1 |    5 |     14 |
| she       |        5 |        5 |        1 |    5 |      4 |
| then      |        4 |        4 |        1 |    4 |      4 |
| wicked   |        2 |        2 |        1 |    2 |      4 |
| witch    |        2 |        2 |        1 |    2 |     11 |

Empty set (0.00 sec)

```

## 1.1.2.9.1.1.1.16 Information Schema INNODB\_FT\_INDEX\_TABLE Table

The [Information Schema](#)

`INNODB_FT_INDEX_TABLE`

table contains information about InnoDB [fulltext indexes](#). To avoid re-organizing the fulltext index each time a change is made, which would be very expensive, new changes are stored separately and only integrated when an `OPTIMIZE TABLE` is run. See the [INNODB\\_FT\\_INDEX\\_CACHE](#) table.

The

`SUPER`

`privilege` is required to view the table, and it also requires the `innodb_ft_aux_table` system variable to be set.

It has the following columns:

Column	Description
--------	-------------

WORD	Word from the text of a column with a fulltext index. Words can appear multiple times in the table, once per DOC_ID and POSITION combination.
FIRST_DOC_ID	First document ID where this word appears in the index.
LAST_DOC_ID	Last document ID where this word appears in the index.
DOC_COUNT	Number of rows containing this word in the index.
DOC_ID	Document ID of the newly added row, either an appropriate ID column or an internal InnoDB value.
POSITION	Position of this word instance within the DOC_ID , as an offset added to the previous POSITION instance.

Note that for

```
OPTIMIZE TABLE
to process InnoDB fulltext index data, the innodb\_optimize\_fulltext\_only system variable needs to be set to
1
. When this is done, and an
OPTIMIZE TABLE
statement run, the INNODB\_FT\_INDEX\_CACHE table will be emptied, and the
INNODB_FT_INDEX_TABLE
table will be updated.
```

## Examples

```
SELECT * FROM INNODB_FT_INDEX_TABLE;
Empty set (0.00 sec)

SET GLOBAL innodb_optimize_fulltext_only =1;

OPTIMIZE TABLE test.ft_innodb;
+-----+-----+-----+-----+
| Table | Op      | Msg_type | Msg_text |
+-----+-----+-----+-----+
| test.ft_innodb | optimize | status   | OK       |
+-----+-----+-----+-----+

SELECT * FROM INNODB_FT_INDEX_TABLE;
+-----+-----+-----+-----+-----+-----+
| WORD    | FIRST_DOC_ID | LAST_DOC_ID | DOC_COUNT | DOC_ID | POSITION |
+-----+-----+-----+-----+-----+-----+
| and     |        4 |        5 |        2 |        4 |        0 |
| and     |        4 |        5 |        2 |        5 |        0 |
| arrived |        4 |        4 |        1 |        4 |      20 |
| ate     |        1 |        5 |        2 |        1 |        4 |
| ate     |        1 |        5 |        2 |        5 |        8 |
| everybody |        1 |        1 |        1 |        1 |        8 |
| goldilocks |        4 |        4 |        1 |        4 |        9 |
| hungry  |        3 |        3 |        1 |        3 |        8 |
| pear    |        5 |        5 |        1 |        5 |      14 |
| she    |        5 |        5 |        1 |        5 |        4 |

| wicked |        2 |        2 |        1 |        2 |        4 |
| witch  |        2 |        2 |        1 |        2 |      11 |
+-----+-----+-----+-----+-----+
```

## 1.1.2.9.1.1.1.17 Information Schema

# INNODB\_LOCK\_WAITS Table

The [Information Schema](#)

INNODB\_LOCK\_WAITS  
table contains information about blocked InnoDB transactions. The  
PROCESS  
[privilege](#) is required to view the table.

It contains the following columns:

Column	Description
REQUESTING_TRX_ID	Requesting transaction ID from the <a href="#">INNODB_TRX</a> table.
REQUESTED_LOCK_ID	Lock ID from the <a href="#">INNODB_LOCKS</a> table for the waiting transaction.
BLOCKING_TRX_ID	Blocking transaction ID from the <a href="#">INNODB_TRX</a> table.
BLOCKING_LOCK_ID	Lock ID from the <a href="#">INNODB_LOCKS</a> table of a lock held by a transaction that is blocking another transaction.

The table is often used in conjunction with the [INNODB\\_LOCKS](#) and [INNODB\\_TRX](#) tables to diagnose problematic locks and transactions.

## 1.1.2.9.1.1.1.18 Information Schema INNODB\_LOCKS Table

The [Information Schema](#)

INNODB\_LOCKS  
table stores information about locks that InnoDB transactions have requested but not yet acquired, or that are blocking another transaction.

It has the following columns:

Column	Description
LOCK_ID	Lock ID number - the format is not fixed, so do not rely upon the number for information.
LOCK_TRX_ID	Lock's transaction ID. Matches the <a href="#">INNODB_TRX.TRX_ID</a> column.
LOCK_MODE	<a href="#">Lock mode</a> . One of S (shared), X (exclusive), IS (intention shared), IX (intention exclusive row lock), S_GAP (shared gap lock), X_GAP (exclusive gap lock), IS_GAP (intention shared gap lock), IX_GAP (intention exclusive gap lock) or AUTO_INC ( <a href="#">auto-increment table level lock</a> ).
LOCK_TYPE	Whether the lock is RECORD (row level) or TABLE level.

LOCK_TABLE	Name of the locked table, or table containing locked rows.
LOCK_INDEX	Index name if a RECORD  , or NULL if not.
LOCK_SPACE	Tablespace ID if a RECORD  , or NULL if not.
LOCK_PAGE	Locked record page number if a RECORD  , or NULL if not.
LOCK_REC	Locked record heap number if a RECORD  , or NULL if not.
LOCK_DATA	Locked record primary key as an SQL string if a RECORD  , or NULL if not. If no primary key exists, the internal InnoDB row_id number is instead used. To avoid unnecessary IO,  also NULL if the locked record page is not in the <a href="#">buffer pool</a>

The table is often used in conjunction with the [INNODB\\_LOCK\\_WAIT](#)s and [INNODB\\_TRX](#) tables to diagnose problematic locks and transactions

## Example

```
-- session 1
START TRANSACTION;
UPDATE t SET id = 15 WHERE id = 10;

-- session 2
DELETE FROM t WHERE id = 10;

-- session 1
USE information_schema;
SELECT 1.* , t.* 
  FROM information_schema.INNODB_LOCKS l 
  JOIN information_schema.INNODB_TRX t 
    ON l.lock trx_id = t.trx_id 
   WHERE trx_state = 'LOCK WAIT' \G
*****
1. row ****
lock_id: 840:40:3:2
lock_trx_id: 840
lock_mode: X
lock_type: RECORD
lock_table: `test`.`t`
lock_index: PRIMARY
lock_space: 40
lock_page: 3
lock_rec: 2
lock_data: 10
trx_id: 840
trx_state: LOCK WAIT
trx_started: 2019-12-23 18:43:46
trx_requested_lock_id: 840:40:3:2
trx_wait_started: 2019-12-23 18:43:46
trx_weight: 2
trx_mysql_thread_id: 46
trx_query: DELETE FROM t WHERE id = 10
trx_operation_state: starting index read
trx_tables_in_use: 1
trx_tables_locked: 1
trx_lock_structs: 2
trx_lock_memory_bytes: 1136
trx_rows_locked: 1
trx_rows_modified: 0
trx_concurrency_tickets: 0
trx_isolation_level: REPEATABLE READ
trx_unique_checks: 1
trx_foreign_key_checks: 1
trx_last_foreign_key_error: NULL
trx_is_read_only: 0
trx_autocommit_non_locking: 0
```

## 1.1.2.9.1.1.1.19 Information Schema INNODB\_METRICS Table

### Contents

1. [Enabling and Disabling Counters](#)
2. [Resetting Counters](#)
3. [Simplifying from MariaDB 10.6](#)
4. [Examples](#)

The [Information Schema](#)

`INNODB_METRICS`

table contains a list of useful InnoDB performance metrics. Each row in the table represents an instrumented counter that can be stopped, started and reset, and which can be grouped together by module.

The

`PROCESS`

`privilege` is required to view the table.

It has the following columns:

Column	Description
--------	-------------

NAME	Unique counter name.
SUBSYSTEM	InnoDB subsystem. See below for the matching module to use to enable/disable monitoring this subsystem with the <a href="#">innodb_monitor_enable</a> and <a href="#">innodb_monitor_disable</a> system variables.
COUNT	Count since being enabled.
MAX_COUNT	Maximum value since being enabled.
MIN_COUNT	Minimum value since being enabled.
AVG_COUNT	Average value since being enabled.
COUNT_RESET	Count since last being reset.
MAX_COUNT_RESET	Maximum value since last being reset.
MIN_COUNT_RESET	Minimum value since last being reset.
AVG_COUNT_RESET	Average value since last being reset.
TIME_ENABLED	Time last enabled.
TIME_DISABLED	Time last disabled
TIME_ELAPSED	Time since enabled
TIME_RESET	Time last reset.
STATUS	Whether the counter is currently enabled to disabled.

TYPE	Item type; one of counter ,, value ,, status_counter ,, set_owner ,, set_member .
COMMENT	Counter description.

## Enabling and Disabling Counters

Most of the counters are disabled by default. To enable them, use the `innodb_monitor_enable` system variable. You can either enable a variable by its name, for example:

```
SET GLOBAL innodb_monitor_enable = icp_match;
```

or enable a number of counters grouped by module. The

SUBSYSTEM

field indicates which counters are grouped together, but the following module names need to be used:

Module Name	Subsystem Field
module_metadata	metadata
module_lock	lock
module_buffer	buffer
module_buf_page	buffer_page_io
module_os	os
module_trx	transaction
module_purge	purge
module_compress	compression
module_file	file_system
module_index	index

module_adaptive_hash	adaptive_hash_index From <a href="#">MariaDB 10.6.2</a> , if <code>innodb_adaptive_hash_index</code> is disabled (the default), <code>adaptive_hash_index</code> will not be updated.
module_ibuf_system	change_buffer
module_srv	server
module_ddl	ddl
module_dml	dml
module_log	recovery
module_icp	icp

There are four counters in the

icp  
subsystem:

```
SELECT NAME, SUBSYSTEM FROM INNODB_METRICS WHERE SUBSYSTEM='icp';
+-----+-----+
| NAME      | SUBSYSTEM |
+-----+-----+
| icp_attempts    | icp      |
| icp_no_match    | icp      |
| icp_out_of_range | icp      |
| icp_match      | icp      |
+-----+-----+
```

To enable them all, use the associated module name from the table above,

`module_icp`

```
SET GLOBAL innodb_monitor_enable = module_icp;
```

The

`%`

wildcard, used to represent any number of characters, can also be used when naming counters, for example:

```
SET GLOBAL innodb_monitor_enable = 'buffer%'
```

To disable counters, use the `innodb_monitor_disable` system variable, using the same naming rules as described above for enabling.

Counter status is not persistent, and will be reset when the server restarts. It is possible to use the options on the command line, or the

`innodb_monitor_enable`

option only in a configuration file.

## Resetting Counters

Counters can also be reset. Resetting sets all the

`*_COUNT_RESET`

values to zero, while leaving the

`*_COUNT`

values, which perform counts since the counter was enabled, untouched. Resetting is performed with the `innodb_monitor_reset` (for individual counters) and `innodb_monitor_reset_all` (for all counters) system variables.

## Simplifying from MariaDB 10.6

MariaDB starting with 10.6

From MariaDB 10.6 , the interface was simplified by removing the following:

- buffer\_LRU\_batches\_flush
- buffer\_LRU\_batch\_flush\_pages
- buffer\_LRU\_batches\_evict
- buffer\_LRU\_batch\_evict\_pages

and by making the following reflect the status variables:

- buffer\_LRU\_batch\_flush\_total\_pages: innodb\_buffer\_pool\_pages\_LRU\_flushed
- buffer\_LRU\_batch\_evict\_total\_pages: innodb\_buffer\_pool\_pages\_LRU\_freed

The intention is to eventually remove the interface entirely (see [MDEV-15706](#) ).

## Examples

Until MariaDB 10.5 :

name	subsystem	type	comment
metadata_table_handles_opened	metadata	counter	Number of table handles opened
metadata_table_handles_closed	metadata	counter	Number of table handles closed
metadata_table_reference_count	metadata	counter	Table reference counter
lock_deadlocks	lock	counter	Number of deadlocks
lock_timeouts	lock	counter	Number of lock timeouts
lock_rec_lock_waits	lock	counter	Number of times enqueued into record lock
lock_table_lock_waits	lock	counter	Number of times enqueued into table lock w
lock_rec_lock_requests	lock	counter	Number of record locks requested
lock_rec_lock_created	lock	counter	Number of record locks created
lock_rec_lock_removed	lock	counter	Number of record locks removed from the lo
lock_rec_locks	lock	counter	Current number of record locks on tables
lock_table_lock_created	lock	counter	Number of table locks created
lock_table_lock_removed	lock	counter	Number of table locks removed from the loc
lock_table_locks	lock	counter	Current number of table locks on tables
lock_row_lock_current_waits	lock	status_counter	Number of row locks currently being waited
lock_row_lock_time	lock	status_counter	Time spent in acquiring row locks, in mill
lock_row_lock_time_max	lock	value	The maximum time to acquire a row lock, in
lock_row_lock_waits	lock	status_counter	Number of times a row lock had to be waite
lock_row_lock_time_avg	lock	value	The average time to acquire a row lock, in
buffer_pool_size	server	value	Server buffer pool size (all buffer pools)
buffer_pool_reads	buffer	status_counter	Number of reads directly from disk (innodb
buffer_pool_read_requests	buffer	status_counter	Number of logical read requests (innodb_bu
buffer_pool_write_requests	buffer	status_counter	Number of write requests (innodb_buffer_po
buffer_pool_wait_free	buffer	status_counter	Number of times waited for free buffer (in
buffer_pool_read_ahead	buffer	status_counter	Number of pages read as read ahead (innodb
buffer_pool_read_ahead_evicted	buffer	status_counter	Read-ahead pages evicted without being acc
buffer_pool_pages_total	buffer	value	Total buffer pool size in pages (innodb_bu
buffer_pool_pages_misc	buffer	value	Buffer pages for misc use such as row lock
buffer_pool_pages_data	buffer	value	Buffer pages containing data (innodb_buffe
buffer_pool_bytes_data	buffer	value	Buffer bytes containing data (innodb_buffe
buffer_pool_pages_dirty	buffer	value	Buffer pages currently dirty (innodb_buffe
buffer_pool_bytes_dirty	buffer	value	Buffer bytes currently dirty (innodb_buffe
buffer_pool_pages_free	buffer	value	Buffer pages currently free (innodb_buffer
buffer_pages_created	buffer	status_counter	Number of pages created (innodb_pages_crea
buffer_pages_written	buffer	status_counter	Number of pages written (innodb_pages_writ
buffer_index_pages_written	buffer	status_counter	Number of index pages written (innodb_inde
buffer_non_index_pages_written	buffer	status_counter	Number of non index pages written (innodb_
buffer_pages_read	buffer	status_counter	Number of pages read (innodb_pages_read)
buffer_index_sec_rec_cluster_reads	buffer	status_counter	Number of secondary record reads triggered
buffer_index_sec_rec_cluster_reads_ignored	buffer	status_counter	Number of secondary record reads avoided t
buffer_data_reads	buffer	status_counter	Amount of data read in bytes (innodb_data_
buffer_data_written	buffer	status_counter	Amount of data written in bytes (innodb_da
buffer_flush_batch_scanned	buffer	set_owner	Total pages scanned as part of flush batch
buffer_flush_batch_num_scan	buffer	set_member	Number of times buffer flush list flush is
buffer_flush_batch_scanned_per_call	buffer	set_member	Pages scanned per flush batch scan
buffer_flush_batch_total_pages	buffer	set_owner	Total pages flushed as part of flush batch
buffer_flush_batches	buffer	set_member	Number of flush batches
buffer_flush_batch_pages	buffer	set_member	Pages queued as a flush batch
buffer_flush_neighbor_total_pages	buffer	set_owner	Total neighbors flushed as part of neighbo
buffer_flush_neighbor	buffer	set_member	Number of times neighbors flushing is invo
buffer_flush_neighbor_pages	buffer	set_member	Pages queued as a neighbor batch
buffer_flush_n_to_flush_requested	buffer	counter	Number of pages requested for flushing.
buffer_flush_n_to_flush_by_age	buffer	counter	Number of pages target by LSN Age for flus

buffer_flush_adaptive_avg_time	buffer	counter	Avg time (ms) spent for adaptive flushing
buffer_flush_adaptive_avg_pass	buffer	counter	Number of adaptive flushes passed during t
buffer_LRU_get_free_loops	buffer	counter	Total loops in LRU get free.
buffer_LRU_get_free_waits	buffer	counter	Total sleep waits in LRU get free.
buffer_flush_avg_page_rate	buffer	counter	Average number of pages at which flushing
buffer_flush_lsn_avg_rate	buffer	counter	Average redo generation rate
buffer_flush_pct_for_dirty	buffer	counter	Percent of IO capacity used to avoid max d
buffer_flush_pct_for_lsn	buffer	counter	Percent of IO capacity used to avoid reusa
buffer_flush_sync_waits	buffer	counter	Number of times a wait happens due to sync
buffer_flush_adaptive_total_pages	buffer	set_owner	Total pages flushed as part of adaptive fl
buffer_flush_adaptive	buffer	set_member	Number of adaptive batches
buffer_flush_adaptive_pages	buffer	set_member	Pages queued as an adaptive batch
buffer_flush_sync_total_pages	buffer	set_owner	Total pages flushed as part of sync batch
buffer_flush_sync	buffer	set_member	Number of sync batches
buffer_flush_sync_pages	buffer	set_member	Pages queued as a sync batch
buffer_flush_background_total_pages	buffer	set_owner	Total pages flushed as part of background
buffer_flush_background	buffer	set_member	Number of background batches
buffer_flush_background_pages	buffer	set_member	Pages queued as a background batch
buffer_LRU_batch_scanned	buffer	set_owner	Total pages scanned as part of LRU batch
buffer_LRU_batch_num_scan	buffer	set_member	Number of times LRU batch is called
buffer_LRU_batch_scanned_per_call	buffer	set_member	Pages scanned per LRU batch call
buffer_LRU_batch_flush_total_pages	buffer	set_owner	Total pages flushed as part of LRU batches
buffer_LRU_batches_flush	buffer	set_member	Number of LRU batches
buffer_LRU_batch_flush_pages	buffer	set_member	Pages queued as an LRU batch
buffer_LRU_batch_evict_total_pages	buffer	set_owner	Total pages evicted as part of LRU batches
buffer_LRU_batches_evict	buffer	set_member	Number of LRU batches
buffer_LRU_batch_evict_pages	buffer	set_member	Pages queued as an LRU batch
buffer_LRU_single_flush_failure_count	Buffer	counter	Number of times attempt to flush a single
buffer_LRU_get_free_search	Buffer	counter	Number of searches performed for a clean p
buffer_LRU_search_scanned	buffer	set_owner	Total pages scanned as part of LRU search
buffer_LRU_search_num_scan	buffer	set_member	Number of times LRU search is performed
buffer_LRU_search_scanned_per_call	buffer	set_member	Page scanned per single LRU search
buffer_LRU_unzip_search_scanned	buffer	set_owner	Total pages scanned as part of LRU unzip s
buffer_LRU_unzip_search_num_scan	buffer	set_member	Number of times LRU unzip search is perfor
buffer_LRU_unzip_search_scanned_per_call	buffer	set_member	Page scanned per single LRU unzip search
buffer_page_read_index_leaf	buffer_page_io	counter	Number of Index Leaf Pages read
buffer_page_read_index_non_leaf	buffer_page_io	counter	Number of Index Non-leaf Pages read
buffer_page_read_index_ibuf_leaf	buffer_page_io	counter	Number of Insert Buffer Index Leaf Pages r
buffer_page_read_index_ibuf_non_leaf	buffer_page_io	counter	Number of Insert Buffer Index Non-Leaf Pag
buffer_page_read_undo_log	buffer_page_io	counter	Number of Undo Log Pages read
buffer_page_read_index_inode	buffer_page_io	counter	Number of Index Inode Pages read
buffer_page_read_ibuf_free_list	buffer_page_io	counter	Number of Insert Buffer Free List Pages re
buffer_page_read_ibuf_bitmap	buffer_page_io	counter	Number of Insert Buffer Bitmap Pages read
buffer_page_read_system_page	buffer_page_io	counter	Number of System Pages read
buffer_page_read_trx_system	buffer_page_io	counter	Number of Transaction System Pages read
buffer_page_read_fsp_hdr	buffer_page_io	counter	Number of File Space Header Pages read
buffer_page_read_xdes	buffer_page_io	counter	Number of Extent Descriptor Pages read
buffer_page_read_blob	buffer_page_io	counter	Number of Uncompressed BLOB Pages read
buffer_page_read_zblob	buffer_page_io	counter	Number of First Compressed BLOB Pages read
buffer_page_read_zblob2	buffer_page_io	counter	Number of Subsequent Compressed BLOB Pages
buffer_page_read_other	buffer_page_io	counter	Number of other/unknown (old version of In
buffer_page_written_index_leaf	buffer_page_io	counter	Number of Index Leaf Pages written
buffer_page_written_index_non_leaf	buffer_page_io	counter	Number of Index Non-leaf Pages written
buffer_page_written_index_ibuf_leaf	buffer_page_io	counter	Number of Insert Buffer Index Leaf Pages w
buffer_page_written_index_ibuf_non_leaf	buffer_page_io	counter	Number of Insert Buffer Index Non-Leaf Pag
buffer_page_written_undo_log	buffer_page_io	counter	Number of Undo Log Pages written
buffer_page_written_index_inode	buffer_page_io	counter	Number of Index Inode Pages written
buffer_page_written_ibuf_free_list	buffer_page_io	counter	Number of Insert Buffer Free List Pages wr
buffer_page_written_ibuf_bitmap	buffer_page_io	counter	Number of Insert Buffer Bitmap Pages writt
buffer_page_written_system_page	buffer_page_io	counter	Number of System Pages written
buffer_page_written_trx_system	buffer_page_io	counter	Number of Transaction System Pages written
buffer_page_written_fsp_hdr	buffer_page_io	counter	Number of File Space Header Pages written
buffer_page_written_xdes	buffer_page_io	counter	Number of Extent Descriptor Pages written
buffer_page_written_blob	buffer_page_io	counter	Number of Uncompressed BLOB Pages written
buffer_page_written_zblob	buffer_page_io	counter	Number of First Compressed BLOB Pages writ
buffer_page_written_zblob2	buffer_page_io	counter	Number of Subsequent Compressed BLOB Pages
buffer_page_written_other	buffer_page_io	counter	Number of other/unknown (old version InnoDB)
os_data_reads	os	status_counter	Number of reads initiated (innodb_data_rea
os_data_writes	os	status_counter	Number of writes initiated (innodb_data_wr
os_data_fsyncs	os	status_counter	Number of fsync() calls (innodb_data_fsync
os_pending_reads	os	counter	Number of reads pending
os_pending_writes	os	counter	Number of writes pending
os_log_bytes_written	os	status_counter	Bytes of log written (innodb_os_log_writte
os_log_fsyncs	os	status_counter	Number of fsync log writes (innodb_os_log_
os_log_pending_fsyncs	os	status_counter	Number of pending fsync write (innodb_os_l
os_log_pending_writes	os	status_counter	Number of pending log file writes (innodb_
trx_rw_commits	transaction	counter	Number of read-write transactions committ
trx_ro_commits	transaction	counter	Number of read-only transactions committed

trx_nl_ro_commits	transaction	counter	Number of non-locking auto-commit read-onl
trx_commits_insert_update	transaction	counter	Number of transactions committed with inse
trx_rollbacks	transaction	counter	Number of transactions rolled back
trx_rollbacks_savepoint	transaction	counter	Number of transactions rolled back to save
trx_active_transactions	transaction	counter	Number of active transactions
trx_rseg_history_len	transaction	value	Length of the TRX_RSEG_HISTORY list
trx_undo_slots_used	transaction	counter	Number of undo slots used
trx_undo_slots_cached	transaction	counter	Number of undo slots cached
trx_rseg_current_size	transaction	value	Current rollback segment size in pages
purge_del_mark_records	purge	counter	Number of delete-marked rows purged
purge_upd_exist_or_extern_records	purge	counter	Number of purges on updates of existing re
purge_invoked	purge	counter	Number of times purge was invoked
purge_undo_log_pages	purge	counter	Number of undo log pages handled by the pu
purge_dml_delay_usec	purge	value	Microseconds DML to be delayed due to purg
purge_stop_count	purge	value	Number of times purge was stopped
purge_resume_count	purge	value	Number of times purge was resumed
log_checkpoints	recovery	counter	Number of checkpoints
log_lsn_last_flush	recovery	value	LSN of Last flush
log_lsn_last_checkpoint	recovery	value	LSN at last checkpoint
log_lsn_current	recovery	value	Current LSN value
log_lsn_checkpoint_age	recovery	value	Current LSN value minus LSN at last checkp
log_lsn_buf_pool_oldest	recovery	value	The oldest modified block LSN in the buffe
log_max_modified_age_async	recovery	value	Maximum LSN difference; when exceeded, sta
log_pending_log_flushes	recovery	value	Pending log flushes
log_pending_checkpoint_writes	recovery	value	Pending checkpoints
log_num_log_io	recovery	value	Number of log I/Os
log_waits	recovery	status_counter	Number of log waits due to small log buffe
log_write_requests	recovery	status_counter	Number of log write requests (innodb_log_w
log_writes	recovery	status_counter	Number of log writes (innodb_log_writes)
log_padded	recovery	status_counter	Bytes of log padded for log write ahead
compress_pages_compressed	compression	counter	Number of pages compressed
compress_pages_decompressed	compression	counter	Number of pages decompressed
compression_pad_increments	compression	counter	Number of times padding is incremented to
compression_pad_decrements	compression	counter	Number of times padding is decremented due
compress_saved	compression	counter	Number of bytes saved by page compression
compress_pages_page_compressed	compression	counter	Number of pages compressed by page compres
compress_page_compressed_trim_op	compression	counter	Number of TRIM operation performed by page
compress_pages_page_decompressed	compression	counter	Number of pages decompressed by page compr
compress_pages_page_compression_error	compression	counter	Number of page compression errors
compress_pages_encrypted	compression	counter	Number of pages encrypted
compress_pages_decrypted	compression	counter	Number of pages decrypted
index_page_splits	index	counter	Number of index page splits
index_page_merge_attempts	index	counter	Number of index page merge attempts
index_page_merge_successful	index	counter	Number of successful index page merges
index_page_reorg_attempts	index	counter	Number of index page reorganization attemp
index_page_reorg_successful	index	counter	Number of successful index page reorganiza
index_page_discards	index	counter	Number of index pages discarded
adaptive_hash_searches	adaptive_hash_index	status_counter	Number of successful searches using Adapti
adaptive_hash_searches_btree	adaptive_hash_index	status_counter	Number of searches using B-tree on an inde
adaptive_hash_pages_added	adaptive_hash_index	counter	Number of index pages on which the Adaptiv
adaptive_hash_pages_removed	adaptive_hash_index	counter	Number of index pages whose corresponding
adaptive_hash_rows_added	adaptive_hash_index	counter	Number of Adaptive Hash Index rows added
adaptive_hash_rows_removed	adaptive_hash_index	counter	Number of Adaptive Hash Index rows removed
adaptive_hash_rows_deleted_no_hash_entry	adaptive_hash_index	counter	Number of rows deleted that did not have c
adaptive_hash_rows_updated	adaptive_hash_index	counter	Number of Adaptive Hash Index rows updated
file_num_open_files	file_system	value	Number of files currently open (innodb_num
ibuf_merges_insert	change_buffer	status_counter	Number of inserted records merged by chang
ibuf_merges_delete_mark	change_buffer	status_counter	Number of deleted records merged by change
ibuf_merges_delete	change_buffer	status_counter	Number of purge records merged by change b
ibuf_merges_discard_insert	change_buffer	status_counter	Number of insert merged operations discard
ibuf_merges_discard_delete_mark	change_buffer	status_counter	Number of deleted merged operations discar
ibuf_merges_discard_delete	change_buffer	status_counter	Number of purge merged operations discard
ibuf_merges	change_buffer	status_counter	Number of change buffer merges
ibuf_size	change_buffer	status_counter	Change buffer size in pages
innodb_master_thread_sleeps	server	counter	Number of times (seconds) master thread sl
innodb_activity_count	server	status_counter	Current server activity count
innodb_master_active_loops	server	counter	Number of times master thread performs its
innodb_master_idle_loops	server	counter	Number of times master thread performs its
innodb_background_drop_table_usec	server	counter	Time (in microseconds) spent to process dr
innodb_log_flush_usec	server	counter	Time (in microseconds) spent to flush log
innodb_dict_lru_usec	server	counter	Time (in microseconds) spent to process DI
innodb_dict_lru_count_active	server	counter	Number of tables evicted from DICT LRU lis
innodb_dict_lru_count_idle	server	counter	Number of tables evicted from DICT LRU lis
innodb dblwr_writes	server	status_counter	Number of doublewrite operations that have
innodb dblwr_pages_written	server	status_counter	Number of pages that have been written for
innodb_page_size	server	value	InnoDB page size in bytes (innodb_page_siz
innodb_rwlock_s_spin_waits	server	status_counter	Number of rwlock spin waits due to shared
innodb_rwlock_x_spin_waits	server	status_counter	Number of rwlock spin waits due to exclusive

innodb_rwlock_x_spin_waits	server	status_counter	Number of rwlock spin waits due to exclusive
innodb_rwlock_sx_spin_waits	server	status_counter	Number of rwlock spin waits due to sx latch
innodb_rwlock_s_spin_rounds	server	status_counter	Number of rwlock spin loop rounds due to s
innodb_rwlock_x_spin_rounds	server	status_counter	Number of rwlock spin loop rounds due to e
innodb_rwlock_sx_spin_rounds	server	status_counter	Number of rwlock spin loop rounds due to s
innodb_rwlock_s_os_waits	server	status_counter	Number of OS waits due to shared latch req
innodb_rwlock_x_os_waits	server	status_counter	Number of OS waits due to exclusive latch
innodb_rwlock_sx_os_waits	server	status_counter	Number of OS waits due to sx latch request
dml_reads	dml	status_counter	Number of rows read
dml_inserts	dml	status_counter	Number of rows inserted
dml_deletes	dml	status_counter	Number of rows deleted
dml_updates	dml	status_counter	Number of rows updated
dml_system_reads	dml	status_counter	Number of system rows read
dml_system_inserts	dml	status_counter	Number of system rows inserted
dml_system Deletes	dml	status_counter	Number of system rows deleted
dml_system_updates	dml	status_counter	Number of system rows updated
ddl_background_drop_indexes	ddl	counter	Number of indexes waiting to be dropped af
ddl_background_drop_tables	ddl	counter	Number of tables in background drop table
ddl_online_create_index	ddl	counter	Number of indexes being created online
ddl_pending_alter_table	ddl	counter	Number of ALTER TABLE, CREATE INDEX, DROP
ddl_sort_file_alter_table	ddl	counter	Number of sort files created during alter
ddl_log_file_alter_table	ddl	counter	Number of log files created during alter t
icp_attempts	icp	counter	Number of attempts for index push-down con
icp_no_match	icp	counter	Index push-down condition does not match
icp_out_of_range	icp	counter	Index push-down condition out of range
icp_match	icp	counter	Index push-down condition matches

234 rows in set (0.001 sec)

From MariaDB 10.6

name	subsystem	type	comment
metadata_table_handles_opened	metadata	counter	Number of table handles opened
lock_deadlocks	lock	value	Number of deadlocks
lock_timeouts	lock	value	Number of lock timeouts
lock_rec_lock_waits	lock	counter	Number of times enqueued into record lock
lock_table_lock_waits	lock	counter	Number of times enqueued into table lock w

buffer_pool_bytes_dirty	buffer	value	Buffer bytes currently dirty (innodb_buffe
buffer_pool_pages_free	buffer	value	Buffer pages currently free (innodb_buffer
buffer_pages_created	buffer	status_counter	Number of pages created (innodb_pages_crea
buffer_pages_written	buffer	status_counter	Number of pages written (innodb_pages_writ
buffer_index_pages_written	buffer	status_counter	Number of index pages written (innodb_inde
buffer_non_index_pages_written	buffer	status_counter	Number of non index pages written (innodb_
buffer_pages_read	buffer	status_counter	Number of pages read (innodb_pages_read)
buffer_index_sec_rec_cluster_reads	buffer	status_counter	Number of secondary record reads triggered
buffer_index_sec_rec_cluster_reads_avoided	buffer	status_counter	Number of secondary record reads avoided t
buffer_data_reads	buffer	status_counter	Amount of data read in bytes (innodb_da
buffer_data_written	buffer	status_counter	Amount of data written in bytes (innodb_da
buffer_flush_batch_scanned	buffer	set_owner	Total pages scanned as part of flush batch
buffer_flush_batch_num_scan	buffer	set_member	Number of times buffer flush list flush is

buffer_flush_batch_scanned_per_call	buffer	set_member	Pages scanned per flush batch scan
buffer_flush_batch_total_pages	buffer	set_owner	Total pages flushed as part of flush batch
buffer_flush_batches	buffer	set_member	Number of flush batches
buffer_flush_batch_pages	buffer	set_member	Pages queued as a flush batch
buffer_flush_neighbor_total_pages	buffer	set_owner	Total neighbors flushed as part of neighbor
buffer_flush_neighbor	buffer	set_member	Number of times neighbors flushing is involved
buffer_flush_neighbor_pages	buffer	set_member	Pages queued as a neighbor batch
buffer_flush_n_to_flush_requested	buffer	counter	Number of pages requested for flushing.
buffer_flush_n_to_flush_by_age	buffer	counter	Number of pages target by LSN Age for flush
buffer_flush_adaptive_avg_time	buffer	counter	Avg time (ms) spent for adaptive flushing
buffer_flush_adaptive_avg_pass	buffer	counter	Number of adaptive flushes passed during time
buffer_LRU_get_free_loops	buffer	counter	Total loops in LRU get free.
buffer_LRU_get_free_waits	buffer	counter	Total sleep waits in LRU get free.
buffer_flush_avg_page_rate	buffer	counter	Average number of pages at which flushing
buffer_flush_lsn_avg_rate	buffer	counter	Average redo generation rate
buffer_flush_pct_for_dirty	buffer	counter	Percent of IO capacity used to avoid max dirty
buffer_flush_pct_for_lsn	buffer	counter	Percent of IO capacity used to avoid reuse
buffer_flush_sync_waits	buffer	counter	Number of times a wait happens due to sync
buffer_flush_adaptive_total_pages	buffer	set_owner	Total pages flushed as part of adaptive flush
buffer_flush_adaptive	buffer	set_member	Number of adaptive batches
buffer_flush_adaptive_pages	buffer	set_member	Pages queued as an adaptive batch
buffer_flush_sync_total_pages	buffer	set_owner	Total pages flushed as part of sync batches
buffer_flush_sync	buffer	set_member	Number of sync batches
buffer_flush_sync_pages	buffer	set_member	Pages queued as a sync batch
buffer_flush_background_total_pages	buffer	set_owner	Total pages flushed as part of background
buffer_flush_background	buffer	set_member	Number of background batches
buffer_flush_background_pages	buffer	set_member	Pages queued as a background batch
buffer_LRU_batch_scanned	buffer	set_owner	Total pages scanned as part of LRU batch
buffer_LRU_batch_num_scan	buffer	set_member	Number of times LRU batch is called
buffer_LRU_batch_scanned_per_call	buffer	set_member	Pages scanned per LRU batch call
buffer_LRU_batch_flush_total_pages	buffer	status_counter	Total pages flushed as part of LRU batches
buffer_LRU_batch_evict_total_pages	buffer	status_counter	Total pages evicted as part of LRU batches
buffer_LRU_single_flush_failure_count	Buffer	counter	Number of times attempt to flush a single page
buffer_LRU_get_free_search	Buffer	counter	Number of searches performed for a clean page
buffer_LRU_search_scanned	buffer	set_owner	Total pages scanned as part of LRU search
buffer_LRU_search_num_scan	buffer	set_member	Number of times LRU search is performed
buffer_LRU_search_scanned_per_call	buffer	set_member	Page scanned per single LRU search
buffer_LRU_unzip_search_scanned	buffer	set_owner	Total pages scanned as part of LRU unzip search
buffer_LRU_unzip_search_num_scan	buffer	set_member	Number of times LRU unzip search is performed
buffer_LRU_unzip_search_scanned_per_call	buffer	set_member	Page scanned per single LRU unzip search
buffer_page_read_index_leaf	buffer_page_io	counter	Number of Index Leaf Pages read
buffer_page_read_index_non_leaf	buffer_page_io	counter	Number of Index Non-leaf Pages read
buffer_page_read_index_ibuf_leaf	buffer_page_io	counter	Number of Insert Buffer Index Leaf Pages read
buffer_page_read_index_ibuf_non_leaf	buffer_page_io	counter	Number of Insert Buffer Index Non-Leaf Pages read
buffer_page_read_undo_log	buffer_page_io	counter	Number of Undo Log Pages read
buffer_page_read_index_inode	buffer_page_io	counter	Number of Index Inode Pages read
buffer_page_read_ibuf_free_list	buffer_page_io	counter	Number of Insert Buffer Free List Pages read
buffer_page_read_ibuf_bitmap	buffer_page_io	counter	Number of Insert Buffer Bitmap Pages read
buffer_page_read_system_page	buffer_page_io	counter	Number of System Pages read
buffer_page_read_trx_system	buffer_page_io	counter	Number of Transaction System Pages read
buffer_page_read_fsp_hdr	buffer_page_io	counter	Number of File Space Header Pages read
buffer_page_read_xdes	buffer_page_io	counter	Number of Extent Descriptor Pages read
buffer_page_read_blob	buffer_page_io	counter	Number of Uncompressed BLOB Pages read
buffer_page_read_zblob	buffer_page_io	counter	Number of First Compressed BLOB Pages read
buffer_page_read_zblob2	buffer_page_io	counter	Number of Subsequent Compressed BLOB Pages read
buffer_page_read_other	buffer_page_io	counter	Number of other/unknown (old version of InnoDB)
buffer_page_written_index_leaf	buffer_page_io	counter	Number of Index Leaf Pages written
buffer_page_written_index_non_leaf	buffer_page_io	counter	Number of Index Non-leaf Pages written
buffer_page_written_index_ibuf_leaf	buffer_page_io	counter	Number of Insert Buffer Index Leaf Pages written
buffer_page_written_index_ibuf_non_leaf	buffer_page_io	counter	Number of Insert Buffer Index Non-Leaf Pages written
buffer_page_written_undo_log	buffer_page_io	counter	Number of Undo Log Pages written
buffer_page_written_index_inode	buffer_page_io	counter	Number of Index Inode Pages written
buffer_page_written_ibuf_free_list	buffer_page_io	counter	Number of Insert Buffer Free List Pages written
buffer_page_written_ibuf_bitmap	buffer_page_io	counter	Number of Insert Buffer Bitmap Pages written
buffer_page_written_system_page	buffer_page_io	counter	Number of System Pages written
buffer_page_written_trx_system	buffer_page_io	counter	Number of Transaction System Pages written
buffer_page_written_fsp_hdr	buffer_page_io	counter	Number of File Space Header Pages written
buffer_page_written_xdes	buffer_page_io	counter	Number of Extent Descriptor Pages written
buffer_page_written_blob	buffer_page_io	counter	Number of Uncompressed BLOB Pages written
buffer_page_written_zblob	buffer_page_io	counter	Number of First Compressed BLOB Pages written
buffer_page_written_zblob2	buffer_page_io	counter	Number of Subsequent Compressed BLOB Pages written
buffer_page_written_other	buffer_page_io	counter	Number of other/unknown (old version InnoDB)
os_data_reads	os	status_counter	Number of reads initiated (innodb_data_reads)
os_data_writes	os	status_counter	Number of writes initiated (innodb_data_writes)
os_data_fsyncs	os	status_counter	Number of fsync() calls (innodb_data_fsyncs)
os_pending_reads	os	counter	Number of reads pending
os_pending_writes	os	counter	Number of writes pending
os_log_bytes_written	os	status_counter	Bytes of log written (innodb_log_written)

innodb_log_bytes_written	os	status_counter	Bytes of log written (innodb_os_log_written)
os_log_fsyncs	os	status_counter	Number of fsync log writes (innodb_os_log_fsyncs)
os_log_pending_fsyncs	os	status_counter	Number of pending fsync write (innodb_os_log_pending_fsyncs)
os_log_pending_writes	os	status_counter	Number of pending log file writes (innodb_os_log_pending_writes)
trx_rw_commits	transaction	counter	Number of read-write transactions committed
trx_ro_commits	transaction	counter	Number of read-only transactions committed
trx_nl_ro_commits	transaction	counter	Number of non-locking auto-commit read-only transactions committed
trx_commits_insert_update	transaction	counter	Number of transactions committed with insert or update
trx_rollbacks	transaction	counter	Number of transactions rolled back
trx_rollbacks_savepoint	transaction	counter	Number of transactions rolled back to save point
trx_rseg_history_len	transaction	value	Length of the TRX_RSEG_HISTORY list
trx_undo_slots_used	transaction	counter	Number of undo slots used
trx_undo_slots_cached	transaction	counter	Number of undo slots cached
trx_rseg_current_size	transaction	value	Current rollback segment size in pages
purge_del_mark_records	purge	counter	Number of delete-marked rows purged
purge_upd_exist_or_extern_records	purge	counter	Number of purges on updates of existing records
purge_invoked	purge	counter	Number of times purge was invoked
purge_undo_log_pages	purge	counter	Number of undo log pages handled by the purge operation
purge_dml_delay_usec	purge	value	Microseconds DML to be delayed due to purge
purge_stop_count	purge	value	Number of times purge was stopped
purge_resume_count	purge	value	Number of times purge was resumed
log_checkpoints	recovery	counter	Number of checkpoints
log_lsn_last_flush	recovery	value	LSN of Last flush
log_lsn_last_checkpoint	recovery	value	LSN at last checkpoint
log_lsn_current	recovery	value	Current LSN value
log_lsn_checkpoint_age	recovery	value	Current LSN value minus LSN at last checkpoint
log_lsn_buf_pool_oldest	recovery	value	The oldest modified block LSN in the buffer pool
log_max_modified_age_async	recovery	value	Maximum LSN difference; when exceeded, start a log flush
log_pending_log_flushes	recovery	value	Pending log flushes
log_pending_checkpoint_writes	recovery	value	Pending checkpoints
log_num_log_io	recovery	value	Number of log I/Os
log_waits	recovery	status_counter	Number of log waits due to small log buffer pool
log_write_requests	recovery	status_counter	Number of log write requests (innodb_log_write_requests)
log_writes	recovery	status_counter	Number of log writes (innodb_log_writes)
log_padded	recovery	status_counter	Bytes of log padded for log write ahead
compress_pages_compressed	compression	counter	Number of pages compressed
compress_pages_decompressed	compression	counter	Number of pages decompressed
compression_pad_increments	compression	counter	Number of times padding is incremented due to page compression
compression_pad_decrements	compression	counter	Number of times padding is decremented due to page compression
compress_saved	compression	counter	Number of bytes saved by page compression
compress_pages_page_compressed	compression	counter	Number of pages compressed by page compression
compress_page_compressed_trim_op	compression	counter	Number of TRIM operation performed by page compression
compress_pages_page_decompressed	compression	counter	Number of pages decompressed by page compression
compress_pages_page_compression_error	compression	counter	Number of page compression errors
compress_pages_encrypted	compression	counter	Number of pages encrypted
compress_pages_decrypted	compression	counter	Number of pages decrypted
index_page_splits	index	counter	Number of index page splits
index_page_merge_attempts	index	counter	Number of index page merge attempts
index_page_merge_successful	index	counter	Number of successful index page merges
index_page_reorg_attempts	index	counter	Number of index page reorganization attempts
index_page_reorg_successful	index	counter	Number of successful index page reorganization attempts
index_page_discards	index	counter	Number of index pages discarded
adaptive_hash_searches	adaptive_hash_index	status_counter	Number of successful searches using Adaptive Hash Index
adaptive_hash_searches_btree	adaptive_hash_index	status_counter	Number of searches using B-tree on an index
adaptive_hash_pages_added	adaptive_hash_index	counter	Number of index pages on which the Adaptive Hash Index was added
adaptive_hash_pages_removed	adaptive_hash_index	counter	Number of index pages whose corresponding Adaptive Hash Index was removed
adaptive_hash_rows_added	adaptive_hash_index	counter	Number of Adaptive Hash Index rows added
adaptive_hash_rows_removed	adaptive_hash_index	counter	Number of Adaptive Hash Index rows removed
adaptive_hash_rows_deleted_no_hash_entry	adaptive_hash_index	counter	Number of rows deleted that did not have a corresponding hash entry
adaptive_hash_rows_updated	adaptive_hash_index	counter	Number of Adaptive Hash Index rows updated
file_num_open_files	file_system	value	Number of files currently open (innodb_num_open_files)
ibuf_merges_insert	change_buffer	status_counter	Number of inserted records merged by change buffer
ibuf_merges_delete_mark	change_buffer	status_counter	Number of deleted records merged by change buffer
ibuf_merges_delete	change_buffer	status_counter	Number of purge records merged by change buffer
ibuf_merges_discard_insert	change_buffer	status_counter	Number of insert merged operations discard
ibuf_merges_discard_delete_mark	change_buffer	status_counter	Number of deleted merged operations discard
ibuf_merges_discard_delete	change_buffer	status_counter	Number of purge merged operations discard
ibuf_merges	change_buffer	status_counter	Number of change buffer merges
ibuf_size	change_buffer	status_counter	Change buffer size in pages
innodb_master_thread_sleeps	server	counter	Number of times (seconds) master thread slept
innodb_activity_count	server	status_counter	Current server activity count
innodb_master_active_loops	server	counter	Number of times master thread performs its active loops
innodb_master_idle_loops	server	counter	Number of times master thread performs its idle loops
innodb_log_flush_usec	server	counter	Time (in microseconds) spent to flush log
innodb_dict_lru_usec	server	counter	Time (in microseconds) spent to process DICT LRU
innodb_dict_lru_count_active	server	counter	Number of tables evicted from DICT LRU list
innodb_dict_lru_count_idle	server	counter	Number of tables evicted from DICT LRU list
innodb dblwr_writes	server	status_counter	Number of doublewrite operations that have been written

```

| innodb dblwr_pages_written | server | status_counter | Number of pages that have been written for
| innodb_page_size           | server | value          | InnoDB page size in bytes (innodb_page_size)
| dml_reads                  | dml   | status_counter | Number of rows read
| dml_inserts                | dml   | status_counter | Number of rows inserted
| dml_deletes                | dml   | status_counter | Number of rows deleted
| dml_updates                | dml   | status_counter | Number of rows updated
| dml_system_reads           | dml   | status_counter | Number of system rows read
| dml_system_inserts          | dml   | status_counter | Number of system rows inserted
| dml_system_deletes          | dml   | status_counter | Number of system rows deleted
| dml_system_updates          | dml   | status_counter | Number of system rows updated
| ddl_background_drop_indexes | ddl   | counter        | Number of indexes waiting to be dropped af
| ddl_online_create_index    | ddl   | counter        | Number of indexes being created online
| ddl_pending_alter_table    | ddl   | counter        | Number of ALTER TABLE, CREATE INDEX, DROP
| ddl_sort_file_alter_table  | ddl   | counter        | Number of sort files created during alter
| ddl_log_file_alter_table   | ddl   | counter        | Number of log files created during alter t
| icp_attempts               | icp   | counter        | Number of attempts for index push-down con
| icp_no_match               | icp   | counter        | Index push-down condition does not match
| icp_out_of_range           | icp   | counter        | Index push-down condition out of range
| icp_match                  | icp   | counter        | Index push-down condition matches

216 rows in set (0.000 sec)

```

## 1.1.2.9.1.1.1.20 Information Schema INNODB\_MUTEXES Table

The

### INNODB\_MUTEXES

table monitors mutex and rw locks waits. It has the following columns:

Column	Description
NAME	Name of the lock, as it appears in the source code.
CREATE_FILE	File name of the mutex implementation.
CREATE_LINE	Line number of the mutex implementation.
OS_WAITS	How many times the mutex occurred.

The

CREATE\_FILE

and

CREATE\_LINE

columns depend on the InnoDB/XtraDB version.

Note that since [MariaDB 10.2.2](#), the table has only been providing information about `rw_lock_t`, not any mutexes. From [MariaDB 10.2.2](#) until [MariaDB 10.2.32](#), [MariaDB 10.3.23](#), [MariaDB 10.4.13](#) and [MariaDB 10.5.1](#), the

NAME

column was not populated ([MDEV-21636](#)).

The [SHOW ENGINE INNODB STATUS](#) statement provides similar information.

## Examples

```

SELECT * FROM INNODB_MUTEXES;
+-----+-----+-----+-----+
| NAME           | CREATE_FILE      | CREATE_LINE | OS_WAITS |
+-----+-----+-----+-----+
| &dict_sys->mutex      | dict0dict.cc    |      989 |      2 |
| &buf_pool->flush_state_mutex | buf0buf.cc     |     1388 |      1 |
| &log_sys->checkpoint_lock | log0log.cc      |     1014 |      2 |
| &block->lock          | combined buf0buf.cc |    1120 |      1 |
+-----+-----+-----+-----+

```

## 1.1.2.9.1.1.1.21 Information Schema INNODB\_SYS\_COLUMNS Table

The [Information Schema](#)

INNODB\_SYS\_COLUMNS  
table contains information about InnoDB fields.

The

PROCESS  
privilege is required to view the table.

It has the following columns:

Column	Description
TABLE_ID	Table identifier, matching the value from <a href="#">INNODB_SYS_TABLES.TABLE_ID</a> .
NAME	Column name.
POS	Ordinal position of the column in the table, starting from 0. This value is adjusted when columns are added or removed.
MTYPE	Numeric column type identifier, (see the table below for an explanation of its values).
PRTYPE	Binary value of the InnoDB precise type, representing the data type, character set code and nullability.
LEN	Column length. For multi-byte character sets, represents the length in bytes.

The column

[MTYPE](#)  
uses a numeric column type identifier, which has the following values:

Column Type Identifier	Description
1	VARCHAR
2	CHAR
3	FIXBINARY
4	BINARY
5	BLOB

6	INT
7	SYS_CHILD
8	SYS
9	FLOAT
10	DOUBLE
11	DECIMAL
12	VARMYSQL
13	MYSQL

## Example

```

SELECT * FROM information_schema.INNODB_SYS_COLUMNS LIMIT 3\G
*****
1. row ****
TABLE_ID: 11
  NAME: ID
  POS: 0
  MTYPE: 1
  PRTYPE: 524292
  LEN: 0
*****
2. row ****
TABLE_ID: 11
  NAME: FOR_NAME
  POS: 0
  MTYPE: 1
  PRTYPE: 524292
  LEN: 0
*****
3. row ****
TABLE_ID: 11
  NAME: REF_NAME
  POS: 0
  MTYPE: 1
  PRTYPE: 524292
  LEN: 0
3 rows in set (0.00 sec)

```

## 1.1.2.9.1.1.1.22 Information Schema INNODB\_SYS\_DATAFILES Table

MariaDB until 10.5

The

**INNODB\_SYS\_DATAFILES**  
table was added in [MariaDB 10.0.4](#) , and removed in [MariaDB 10.6.0](#) .

The [Information Schema](#)

**INNODB\_SYS\_DATAFILES**  
table contains information about InnoDB datafile paths. It was intended to provide metadata for tablespaces inside InnoDB tables, which was never implemented in MariaDB and was removed in [MariaDB 10.6](#) . The [PROCESS privilege](#) is required to view the table.

It contains the following columns:

Column	Description
SPACE	Numeric tablespace. Matches the <a href="#">INNODB_SYS_TABLES.SPACE</a> value.
PATH	Tablespace datafile path.

## Example

```
SELECT * FROM INNODB_SYS_DATAFILES;
+-----+-----+
| SPACE | PATH           |
+-----+-----+
|   19  | ./test/t2.ibd  |
|   20  | ./test/t3.ibd  |
...
|   68  | ./test/animals.ibd |
|   69  | ./test/animal_count.ibd |
|   70  | ./test/t.ibd    |
+-----+-----+
```

## 1.1.2.9.1.1.1.23 Information Schema INNODB\_SYS\_FIELDS Table

The [Information Schema](#)

**INNODB\_SYS\_FIELDS**  
table contains information about fields that are part of an InnoDB index.

The

[PROCESS privilege](#) is required to view the table.

It has the following columns:

Column	Description
INDEX_ID	Index identifier, matching the value from <a href="#">INNODB_SYS_INDEXES.INDEX_ID</a> .
NAME	Field name, matching the value from <a href="#">INNODB_SYS_COLUMNS.NAME</a> .
POS	Ordinal position of the field within the index, starting from 0 . This is adjusted as columns are removed.

## Example

```

SELECT * FROM information_schema.INNODB_SYS_FIELDS LIMIT 3\G
***** 1. row *****
INDEX_ID: 11
  NAME: ID
  POS: 0
***** 2. row *****
INDEX_ID: 12
  NAME: FOR_NAME
  POS: 0
***** 3. row *****
INDEX_ID: 13
  NAME: REF_NAME
  POS: 0
3 rows in set (0.00 sec)

```

## 1.1.2.9.1.1.1.24 Information Schema INNODB\_SYS\_FOREIGN Table

The [Information Schema](#)

`INNODB_SYS_FOREIGN`  
table contains information about InnoDB [foreign keys](#).

The

`PROCESS`  
`privilege` is required to view the table.

It has the following columns:

Column	Description
ID	Database name and foreign key name.
FOR_NAME	Database and table name of the foreign key child.
REF_NAME	Database and table name of the foreign key parent.
N_COLS	Number of foreign key index columns.
TYPE	Bit flag providing information about the foreign key.

The

`TYPE`  
column provides a bit flag with information about the foreign key. This information is  
OR  
'ed together to read:

Bit Flag	Description
1	ON DELETE CASCADE
2	ON UPDATE SET NULL
4	ON UPDATE CASCADE
8	ON UPDATE SET NULL

16	ON DELETE NO ACTION
32	ON UPDATE NO ACTION

## Example

```
SELECT * FROM INNODB_SYS_FOREIGN\G
***** 1. row *****
ID: mysql/innodb_index_stats_ibfk_1
FOR_NAME: mysql/innodb_index_stats
REF_NAME: mysql/innodb_table_stats
N_COLS: 2
TYPE: 0
...
...
```

## 1.1.2.9.1.1.1.25 Information Schema INNODB\_SYS\_FOREIGN\_COLS Table

The [Information Schema](#)

`INNODB_SYS_FOREIGN_COLS`  
table contains information about InnoDB [foreign key](#) columns.

The

`PROCESS`  
[privilege](#) is required to view the table.

It has the following columns:

Column	Description
ID	Foreign key index associated with this column, matching the <code>INNODB_SYS_FOREIGN.ID</code> field.
FOR_COL_NAME	Child column name.
REF_COL_NAME	Parent column name.
POS	Ordinal position of the column in the table, starting from 0.

## 1.1.2.9.1.1.1.26 Information Schema INNODB\_SYS\_INDEXES Table

The [Information Schema](#)

`INNODB_SYS_INDEXES`  
table contains information about InnoDB indexes.

The

`PROCESS`  
[privilege](#) is required to view the table.

It has the following columns:

Field	Type	Null	Key	Default	Description
INDEX_ID	bigint(21) unsigned	NO		0	A unique index identifier.

NAME	varchar(64)	NO			<p>Index name, lowercase for all user-created indexes, or uppercase for implicitly-created indexes;</p> <pre> PRIMARY (primary key), GEN_CLUST_INDEX (index representing primary key where there isn't one), ID_IND , FOR_IND (validating foreign key constraint) , REF_IND .</pre>
TABLE_ID	bigint(21) unsigned	NO		0	Table identifier, matching the value from <a href="#">INNODB_SYS_TABLES.TABLE_ID</a> .
TYPE	int(11)	NO		0	<p>Numeric type identifier; one of</p> <ul style="list-style-type: none"> <li>0 (secondary index),</li> <li>1 (clustered index),</li> <li>2 (unique index),</li> <li>3 (primary index),</li> <li>32 ( <a href="#">full-text index</a> ).</li> </ul>
N_FIELDS	int(11)	NO		0	Number of columns in the index. GEN_CLUST_INDEX's have a value of 0 as the index is not based on an actual column in the table.
PAGE_NO	int(11)	NO		0	<p>Index B-tree's root page number.</p> <ul style="list-style-type: none"> <li>-1 (unused) for full-text indexes, as they are laid out over several auxiliary tables.</li> </ul>
SPACE	int(11)	NO		0	<p>Tablespace identifier where the index resides.</p> <ul style="list-style-type: none"> <li>0 represents the InnoDB system tablespace, while any other value represents a table created in file-per-table mode (see the <a href="#">innodb_file_per_table</a> system variable).</li> </ul> <p>Remains unchanged after a <a href="#">TRUNCATE TABLE</a> statement, and not necessarily unique.</p>
MERGE_THRESHOLD	int(11)	NO		0	

## Example

```

SELECT * FROM information_schema.INNODB_SYS_INDEXES LIMIT 3\G
***** 1. row *****
INDEX_ID: 11
  NAME: ID_IND
TABLE_ID: 11
  TYPE: 3
N_FIELDS: 1
PAGE_NO: 302
  SPACE: 0
MERGE_THRESHOLD: 50
***** 2. row *****
INDEX_ID: 12
  NAME: FOR_IND
TABLE_ID: 11
  TYPE: 0
N_FIELDS: 1
PAGE_NO: 303
  SPACE: 0
MERGE_THRESHOLD: 50
***** 3. row *****
INDEX_ID: 13
  NAME: REF_IND
TABLE_ID: 11
  TYPE: 3
N_FIELDS: 1
PAGE_NO: 304
  SPACE: 0
MERGE_THRESHOLD: 50
3 rows in set (0.00 sec)

```

## 1.1.2.9.1.1.1.27 Information Schema INNODB\_SYS\_SEMAPHORE\_WAITS Table

The [Information Schema](#) INNODB\_SYS\_SEMAPHORE\_WAITS table is meant to contain information about current semaphore waits. At present it is not correctly populated. See [MDEV-21330](#).

The [PROCESS privilege](#) is required to view the table.

It contains the following columns:

Column	Description
THREAD_ID	Thread id waiting for semaphore
OBJECT_NAME	Semaphore name
FILE	File name where semaphore was requested
LINE	Line number on above file
WAIT_TIME	Wait time
WAIT_OBJECT	
WAIT_TYPE	Object type (mutex, rw-lock)
HOLDER_THREAD_ID	Holder thread id
HOLDER_FILE	File name where semaphore was acquired
HOLDER_LINE	Line number for above
CREATED_FILE	Creation file name
CREATED_LINE	Line number for above
WRITER_THREAD	Last write request thread id
RESERVATION_MODE	Reservation mode (shared, exclusive)
READERS	Number of readers if only shared mode
WAITERS_FLAG	Flags
LOCK_WORD	Lock word (for developers)
LAST_READER_FILE	Removed
LAST_READER_LINE	Removed

LAST_WRITER_FILE	Last writer file name
LAST_WRITER_LINE	Above line number
OS_WAIT_COUNT	Wait count

## 1.1.2.9.1.1.1.28 Information Schema INNODB\_SYS\_TABLES Table

The [Information Schema](#)

INNODB\_SYS\_TABLES

table contains information about InnoDB tables.

The

PROCESS

[privilege](#) is required to view the table.

It has the following columns:

Field	Type	Null	Key	Default	Description
TABLE_ID	bigint(21) unsigned	NO		0	Unique InnoDB table identifier.
NAME	varchar(655)	NO			Database and table name, or the uppercase InnoDB system table name.
FLAG	int(11)	NO		0	See <a href="#">Flag</a> below
N_COLS	int(11) unsigned (>= <a href="#">MariaDB 10.5</a> ) int(11) (<= <a href="#">MariaDB 10.4</a> )	NO		0	Number of columns in the table.
SPACE	int(11) unsigned (>= <a href="#">MariaDB 10.5</a> ) int(11) (<= <a href="#">MariaDB 10.4</a> )	NO		0	Tablespace identifier where the index resides.  0 represents the InnoDB system tablespace, while any other value represents a table created in file-per-table mode (see the <a href="#">innodb_file_per_table</a> system variable). Remains unchanged after a <a href="#">TRUNCATE TABLE</a> statement.
FILE_FORMAT	varchar(10)	YES		NULL	<a href="#">InnoDB file format</a> (Antelope or Barracuda). Removed in <a href="#">MariaDB 10.3</a> .
ROW_FORMAT	enum('Redundant', 'Compact', 'Compressed', 'Dynamic') (>= <a href="#">MariaDB 10.5</a> ) varchar(12) (<= <a href="#">MariaDB 10.4</a> )	YES		NULL	<a href="#">InnoDB storage format</a> (Compact, Redundant, Dynamic, or Compressed).
ZIP_PAGE_SIZE	int(11) unsigned	NO		0	For Compressed tables, the zipped page size.
SPACE_TYPE	enum('Single','System') (>= <a href="#">MariaDB 10.5</a> ) varchar(10) (<= <a href="#">MariaDB 10.4</a> )	YES		NULL	

### Flag

The flag field returns the dict\_table\_t::flags that correspond to the data dictionary record.

Bit	Description
0	Set if ROW_FORMAT is not REDUNDANT.
1 to 4	0 , except for ROW_FORMAT=COMPRESSED, where they will determine the KEY_BLOCK_SIZE (the compressed page size).
5	Set for ROW_FORMAT=DYNAMIC or ROW_FORMAT=COMPRESSED.

	6	Set if the DATA DIRECTORY attribute was present when the table was originally created.
	7	Set if the page_compressed attribute is present.
	8 to 11	Determine the page_compression_level.
	12 13	Normally 00 , but 11 for "no-rollback tables" ( <a href="#">MariaDB 10.3 CREATE SEQUENCE</a> ). In <a href="#">MariaDB 10.1</a> , these bits could be 01 or 10 for ATOMIC_WRITES=ON or ATOMIC_WRITES=OFF.

Note that the table flags returned here are not the same as tablespace flags (FSP\_SPACE\_FLAGS).

## Example

```
SELECT * FROM information_schema.INNODB_SYS_TABLES LIMIT 2\G
*****
1. row ****
TABLE_ID: 14
  NAME: SYS_DATAFILES
  FLAG: 0
  N_COLS: 5
  SPACE: 0
FILE_FORMAT: Antelope
ROW_FORMAT: Redundant
ZIP_PAGE_SIZE: 0
SPACE_TYPE: System
*****
2. row ****
TABLE_ID: 11
  NAME: SYS_FOREIGN
  FLAG: 0
  N_COLS: 7
  SPACE: 0
FILE_FORMAT: Antelope
ROW_FORMAT: Redundant
ZIP_PAGE_SIZE: 0
SPACE_TYPE: System
2 rows in set (0.00 sec)
```

## See Also

- [InnoDB Data Dictionary Troubleshooting](#)

## 1.1.2.9.1.1.1.29 Information Schema INNODB\_SYS\_TABLESPACES Table

The [Information Schema](#)

INNODB\_SYS\_TABLESPACES

table contains information about InnoDB tablespaces. Until [MariaDB 10.5](#) it was based on the internal

SYS\_TABLESPACES

table. This internal table was removed in [MariaDB 10.6.0](#), so this Information Schema table has been repurposed to directly reflect the filesystem (fil\_system.space\_list).

The

PROCESS

privilege is required to view the table.

It has the following columns:

Column	Description
SPACE	Unique InnoDB tablespace identifier.
NAME	Database and table name separated by a backslash, or the uppercase InnoDB system table name.
FLAG	<pre> 1 if a DATA DIRECTORY option has been specified in  CREATE TABLE  , otherwise 0 . </pre>
FILE_FORMAT	InnoDB file format .
ROW_FORMAT	InnoDB storage format used for this tablespace. If the Antelope file format is used, this value is always Compact or Redundant .
PAGE_SIZE	Page size in bytes for this tablespace. Until MariaDB 10.5.0 , this was the value of the innodb_page_size variable. From MariaDB 10.6.0 , contains the physical page size of a page (previously ZIP_PAGE_SIZE ).
ZIP_PAGE_SIZE	Zip page size for this tablespace. Removed in MariaDB 10.6.0 .
SPACE_TYPE	Tablespace type. Can be General for general tablespaces or Single for file-per-table tablespaces. Introduced MariaDB 10.2.1 . Removed MariaDB 10.5.0 .
FS_BLOCK_SIZE	File system block size. Introduced MariaDB 10.2.1 .
FILE_SIZE	Maximum size of the file, uncompressed. Introduced MariaDB 10.2.1 .
ALLOCATED_SIZE	Actual size of the file as per space allocated on disk. Introduced MariaDB 10.2.1 .
FILENAME	Tablespace datafile path, previously part of the INNODB_SYS_DATAFILES table . Added in MariaDB 10.6.0 .

## Examples

MariaDB 10.4 :

```
DESC information_schema.innodb_sys_tablespaces;
+-----+-----+-----+-----+-----+
| Field | Type | Null | Key | Default | Extra |
+-----+-----+-----+-----+-----+
| SPACE | int(11) unsigned | NO | 0 | NULL | |
| NAME | varchar(655) | NO | 0 | NULL | |
| FLAG | int(11) unsigned | NO | 0 | NULL | |
| FILE_FORMAT | varchar(10) | YES | NULL | NULL | |
| ROW_FORMAT | varchar(22) | YES | NULL | NULL | |
| PAGE_SIZE | int(11) unsigned | NO | 0 | NULL | |
| ZIP_PAGE_SIZE | int(11) unsigned | NO | 0 | NULL | |
| SPACE_TYPE | varchar(10) | YES | NULL | NULL | |
| FS_BLOCK_SIZE | int(11) unsigned | NO | 0 | NULL | |
| FILE_SIZE | bigint(21) unsigned | NO | 0 | NULL | |
| ALLOCATED_SIZE | bigint(21) unsigned | NO | 0 | NULL | |
+-----+-----+-----+-----+-----+
```

From MariaDB 10.4 :

```
SELECT * FROM information_schema.INNODB_SYS_TABLESPACES LIMIT 2\G
*****
1. row *****
    SPACE: 2
        NAME: mysql/innodb_table_stats
        FLAG: 33
    FILE_FORMAT: Barracuda
    ROW_FORMAT: Dynamic
    PAGE_SIZE: 16384
    ZIP_PAGE_SIZE: 0
    SPACE_TYPE: Single
    FS_BLOCK_SIZE: 4096
        FILE_SIZE: 98304
    ALLOCATED_SIZE: 98304
*****
2. row *****
    SPACE: 3
        NAME: mysql/innodb_index_stats
        FLAG: 33
    FILE_FORMAT: Barracuda
    ROW_FORMAT: Dynamic
    PAGE_SIZE: 16384
    ZIP_PAGE_SIZE: 0
    SPACE_TYPE: Single
    FS_BLOCK_SIZE: 4096
        FILE_SIZE: 98304
    ALLOCATED_SIZE: 98304
```

## 1.1.2.9.1.1.30 Information Schema INNODB\_SYS\_TABLESTATS Table

The [Information Schema](#)

### INNODB\_SYS\_TABLESTATS

table contains InnoDB status information. It can be used for developing new performance-related extensions, or high-level performance monitoring.

The

### PROCESS

[privilege](#) is required to view the table.

Note that the MySQL InnoDB and Percona XtraDB versions of the tables differ (see [XtraDB and InnoDB](#) ).

It contains the following columns:

Column	Description
TABLE_ID	Table ID, matching the <a href="#">INNODB_SYS_TABLES.TABLE_ID</a> value.
SCHEMA	Database name (XtraDB only).
NAME	Table name, matching the <a href="#">INNODB_SYS_TABLES.NAME</a> value.

STATS_INITIALIZED	Initialized if statistics have already been collected, otherwise Uninitialized
NUM_ROWS	Estimated number of rows currently in the table. Updated after each statement modifying the data, but uncommitted transactions mean it may not be accurate.
CLUST_INDEX_SIZE	Number of pages on disk storing the clustered index, holding InnoDB table data in primary key order, or NULL if not statistics yet collected.
OTHER_INDEX_SIZE	Number of pages on disk storing secondary indexes for the table, or NULL if not statistics yet collected.
MODIFIED_COUNTER	Number of rows modified by statements modifying data.
AUTOINC	<a href="#">Auto_increment</a> value.
REF_COUNT	Countdown to zero, when table metadata can be removed from the table cache. (InnoDB only)
MYSQL_HANDLES_OPENED	(XtraDB only).

## 1.1.2.9.1.1.1.31 Information Schema INNODB\_SYS\_VIRTUAL Table

MariaDB starting with [10.2](#)

The

`INNODB_SYS_VIRTUAL`  
table was added in [MariaDB 10.2](#).

The [Information Schema](#)

`INNODB_SYS_VIRTUAL`  
table contains information about base columns of [virtual columns](#). The  
`PROCESS`  
`privilege` is required to view the table.

It contains the following columns:

Field	Type	Null	Key	Default	Description
TABLE_ID	bigint(21) unsigned	NO		0	
POS	int(11) unsigned	NO		0	
BASE_POS	int(11) unsigned	NO		0	

## 1.1.2.9.1.1.1.32 Information Schema INNODB\_TABLESPACES\_ENCRYPTION Table

The [Information Schema](#)

`INNODB_TABLESPACES_ENCRYPTION`  
table contains metadata about [encrypted InnoDB tablespaces](#). When you [enable encryption for an InnoDB tablespace](#), an entry for the  
tablespace is added to this table. If you later [disable encryption for the InnoDB tablespace](#), then the row still remains in this table, but the  
`ENCRYPTION_SCHEME`  
and

CURRENT\_KEY\_VERSION  
columns will be set to  
0

Viewing this table requires the [PROCESS](#) privilege, although a bug in versions before MariaDB 10.1.46 , 10.2.33 , 10.3.24 , 10.4.14 and 10.5.5 mean the [SUPER](#) privilege was required ( [MDEV-23003](#) ).

It has the following columns:

Column	Description	Added
SPACE	InnoDB tablespace ID.	
NAME	Path to the InnoDB tablespace file, without the extension.	
ENCRYPTION_SCHEME	Key derivation algorithm. Only 1 is currently used to represent an algorithm. If this value is 0 , then the tablespace is unencrypted.	
KEYSERVER_REQUESTS	Number of times InnoDB has had to request a key from the <a href="#">encryption key management plugin</a> . The three most recent keys are cached internally.	
MIN_KEY_VERSION	Minimum key version used to encrypt a page in the tablespace. Different pages may be encrypted with different key versions.	
CURRENT_KEY_VERSION	Key version that will be used to encrypt pages. If this value is 0 , then the tablespace is unencrypted.	
KEY_ROTATION_PAGE_NUMBER	Page that a <a href="#">background encryption thread</a> is currently rotating. If key rotation is not enabled, then the value will be NULL	
KEY_ROTATION_MAX_PAGE_NUMBER	When a <a href="#">background encryption thread</a> starts rotating a tablespace, the field contains its current size. If key rotation is not enabled, then the value will be NULL	
CURRENT_KEY_ID	Key ID for the encryption key currently in use.	MariaDB 10.1.13
ROTATING_OR_FLUSHING	Current key rotation status. If this value is 1 , then the <a href="#">background encryption threads</a> are working on the tablespace. See <a href="#">MDEV-11738</a>	MariaDB 10.2.5 , MariaDB 10.1.23

When the [InnoDB system tablespace](#) is encrypted, it is represented in this table with the special name:

innodb\_system

## Example

```

SELECT * FROM information_schema.INNODB_TABLESPACES_ENCRYPTION
WHERE NAME LIKE 'db_encrypt%';
+-----+-----+-----+-----+-----+
| SPACE | NAME | ENCRYPTION_SCHEME | KEYSERVER_REQUESTS | MIN_KEY_VERSION | CURRENT_KEY |
+-----+-----+-----+-----+-----+
| 18 | db_encrypt/t_encrypted_existing_key | 1 | 1 | 1 | |
| 19 | db_encrypt/t_not_encrypted_existing_key | 1 | 0 | 1 |
| 20 | db_encrypt/t_not_encrypted_non_existing_key | 1 | 0 | 4294967295 | 429 |
| 21 | db_encrypt/t_default_encryption_existing_key | 1 | 1 | 1 |
| 22 | db_encrypt/t_encrypted_default_key | 1 | 1 | 1 |
| 23 | db_encrypt/t_not_encrypted_default_key | 1 | 0 | 1 |
| 24 | db_encrypt/t_defaults | 1 | 1 | 1 |
+-----+-----+-----+-----+-----+
7 rows in set (0.00 sec)

```

- [Encryption Key Management](#)

## 1.1.2.9.1.1.1.33 Information Schema INNODB\_TABLESPACES\_SCRUBBING Table

MariaDB 10.1.3 - 10.5.1

InnoDB and XtraDB data scrubbing was introduced in [MariaDB 10.1.3](#). The table was removed in [MariaDB 10.5.2](#) - see [MDEV-15528](#).

The [Information Schema](#)

INNODB\_TABLESPACES\_SCRUBBING  
table contains [data scrubbing](#) information.

The

PROCESS  
[privilege](#) is required to view the table.

It has the following columns:

Column	Description
SPACE	InnoDB table space id number.
NAME	Path to the table space file, without the extension.
COMPRESSED	The compressed page size, or zero if uncompressed.
LAST_SCRUB_COMPLETED	Date and time when the last scrub was completed, or NULL if never been performed.
CURRENT_SCRUB_STARTED	Date and time when the current scrub started, or NULL if never been performed.
CURRENT_SCRUB_ACTIVE_THREADS	Number of threads currently scrubbing the tablespace.
CURRENT_SCRUB_PAGE_NUMBER	Page that the scrubbing thread is currently scrubbing, or NULL if not enabled.
CURRENT_SCRUB_MAX_PAGE_NUMBER	When a scrubbing starts rotating a table space, the field contains its current size. NULL if not enabled.

## Example

```
SELECT * FROM information_schema.INNODB_TABLESPACES_SCRUBBING LIMIT 1\G
***** 1. row *****
    SPACE: 1
        NAME: mysql/innodb_table_stats
    COMPRESSED: 0
    LAST_SCRUB_COMPLETED: NULL
    CURRENT_SCRUB_STARTED: NULL
    CURRENT_SCRUB_PAGE_NUMBER: NULL
CURRENT_SCRUB_MAX_PAGE_NUMBER: 0
    ROTATING_OR_FLUSHING: 0
1 rows in set (0.00 sec)
```

## 1.1.2.9.1.1.1.34 Information Schema INNODB\_TRX Table

The [Information Schema](#)

INNODB\_TRX

table stores information about all currently executing InnoDB transactions.

It has the following columns:

Column	Description
TRX_ID	Unique transaction ID number.
TRX_STATE	Transaction execution state; one of RUNNING , LOCK_WAIT , ROLLING BACK or COMMITTING .
TRX_STARTED	Time that the transaction started.
TRX_REQUESTED_LOCK_ID	If TRX_STATE is LOCK_WAIT , the  INNODB_LOCKS.LOCK_ID  value of the lock being waited on. NULL if any other state.
TRX_WAIT_STARTED	If TRX_STATE is LOCK_WAIT , the time the transaction started waiting for the lock, otherwise NULL .
TRX_WEIGHT	Transaction weight, based on the number of locked rows and the number of altered rows. To resolve deadlocks, lower weighted transactions are rolled back first. Transactions that have affected non-transactional tables are always treated as having a heavier weight.
TRX_MYSQL_THREAD_ID	Thread ID from the  PROCESSTLIST  table (note that the locking and transaction information schema tables use a different snapshot from the processlist, so records may appear in one but not the other).

TRX_QUERY	SQL that the transaction is currently running.
TRX_OPERATION_STATE	Transaction's current state, or NULL
TRX_TABLES_IN_USE	Number of InnoDB tables currently being used for processing the current SQL statement.
TRX_TABLES_LOCKED	Number of InnoDB tables that have row locks held by the current SQL statement.
TRX_LOCK_STRUCTS	Number of locks reserved by the transaction.
TRX_LOCK_MEMORY_BYTES	Total size in bytes of the memory used to hold the lock structures for the current transaction in memory.
TRX_ROWS_LOCKED	Number of rows the current transaction has locked. An approximation, and may include rows not visible to the current transaction that are delete-marked but physically present.
TRX_ROWS_MODIFIED	Number of rows added or changed in the current transaction.
TRX_CONCURRENCY_TICKETS	Indicates how much work the current transaction can do before being swapped out, see the <a href="#">innodb_concurrency_tickets</a> system variable.
TRX_ISOLATION_LEVEL	<a href="#">Isolation level</a> of the current transaction.
TRX_UNIQUE_CHECKS	Whether unique checks are on or off for the current transaction. Bulk data are a case where unique checks would be off.
TRX_FOREIGN_KEY_CHECKS	Whether foreign key checks are on or off for the current transaction. Bulk data are a case where foreign keys checks would be off.
TRX_LAST_FOREIGN_KEY_ERROR	Error message for the most recent foreign key error, or NULL if none.
TRX_ADAPTIVE_HASH_LATCHED	Whether the adaptive hash index is locked by the current transaction or not. One transaction at a time can change the adaptive hash index.
TRX_ADAPTIVE_HASH_TIMEOUT	Whether the adaptive hash index search latch should be relinquished immediately or reserved across all MariaDB calls. 0 if there is no contention on the adaptive hash index, in which case the latch is reserved until completion, otherwise counts down to zero and the latch is released after each row lookup.

TRX_IS_READ_ONLY	<pre> 1 if a read-only transaction, otherwise 0 . </pre>
TRX_AUTOCOMMIT_NON_LOCKING	<pre> 1 if the transaction only contains this one statement, that is, a  SELECT  statement not using FOR UPDATE or LOCK IN SHARED MODE , and with autocommit on. If this and TRX_IS_READ_ONLY are both 1, the transaction can be optimized by the storage engine to reduce some overheads </pre>

The table is often used in conjunction with the [INNODB\\_LOCKS](#) and [INNODB\\_LOCK\\_WAITS](#) tables to diagnose problematic locks and transactions.

[XA transactions](#) are not stored in this table. To see them,

`XA RECOVER`  
can be used.

## Example

```
-- session 1
START TRANSACTION;
UPDATE t SET id = 15 WHERE id = 10;

-- session 2
DELETE FROM t WHERE id = 10;

-- session 1
USE information_schema;
SELECT 1.* , t.* 
  FROM information_schema.INNODB_LOCKS l 
  JOIN information_schema.INNODB_TRX t 
    ON l.lock trx_id = t.trx_id 
   WHERE trx_state = 'LOCK WAIT' \G
*****
1. row ****
lock_id: 840:40:3:2
lock_trx_id: 840
lock_mode: X
lock_type: RECORD
lock_table: `test`.`t`
lock_index: PRIMARY
lock_space: 40
lock_page: 3
lock_rec: 2
lock_data: 10
trx_id: 840
trx_state: LOCK WAIT
trx_started: 2019-12-23 18:43:46
trx_requested_lock_id: 840:40:3:2
trx_wait_started: 2019-12-23 18:43:46
trx_weight: 2
trx_mysql_thread_id: 46
trx_query: DELETE FROM t WHERE id = 10
trx_operation_state: starting index read
trx_tables_in_use: 1
trx_tables_locked: 1
trx_lock_structs: 2
trx_lock_memory_bytes: 1136
trx_rows_locked: 1
trx_rows_modified: 0
trx_concurrency_tickets: 0
trx_isolation_level: REPEATABLE READ
trx_unique_checks: 1
trx_foreign_key_checks: 1
trx_last_foreign_key_error: NULL
trx_is_read_only: 0
trx_autocommit_non_locking: 0
```

## 1.1.2.9.1.1.35 Information Schema TEMP\_TABLES\_INFO Table

MariaDB 10.2.2 - 10.2.3

The

`TEMP_TABLES_INFO`

table was introduced in MariaDB 10.2.2 and was removed in MariaDB 10.2.4 . See [MDEV-12459](#) progress on an alternative.

The [Information Schema](#)

`TEMP_TABLES_INFO`

table contains information about active InnoDB temporary tables. All user and system-created temporary tables are reported when querying this table, with the exception of optimized internal temporary tables. The data is stored in memory.

Previously, InnoDB temp table metadata was rather stored in InnoDB system tables.

It has the following columns:

Column	Description
TABLE_ID	Table ID.

NAME	Table name.
N_COLS	Number of columns in the temporary table, including three hidden columns that InnoDB creates ( DB_ROW_ID , DB_TRX_ID , and DB_ROLL_PTR ).
SPACE	Numerical identifier for the tablespace identifier holding the temporary table. Compressed temporary tables are stored by default in separate per-table tablespaces in the temporary file directory. For non-compressed tables, the shared temporary table is named ibtmp1 , found in the data directory. Always a non-zero value, and regenerated on server restart.
PER_TABLE_TABLESPACE	If TRUE , the temporary table resides in a separate per-table tablespace. If FALSE , it resides in the shared temporary tablespace.
IS_COMPRESSED	TRUE if the table is compressed.

The `PROCESS` privilege is required to view the table.

## Examples

```
CREATE TEMPORARY TABLE t (i INT) ENGINE=INNODB;

SELECT * FROM INFORMATION_SCHEMA.INNODB_TEMP_TABLE_INFO;
+-----+-----+-----+-----+
| TABLE_ID | NAME      | N_COLS | SPACE | PER_TABLE_TABLESPACE | IS_COMPRESSED |
+-----+-----+-----+-----+
|     39 | #sql1c93_3_1 |      4 |    64 | FALSE             | FALSE          |
+-----+-----+-----+-----+
```

Adding a compressed table:

```
SET GLOBAL innodb_file_format="Barracuda";

CREATE TEMPORARY TABLE t2 (i INT) ROW_FORMAT=COMPRESSED ENGINE=INNODB;

SELECT * FROM INFORMATION_SCHEMA.INNODB_TEMP_TABLE_INFO;
+-----+-----+-----+-----+
| TABLE_ID | NAME      | N_COLS | SPACE | PER_TABLE_TABLESPACE | IS_COMPRESSED |
+-----+-----+-----+-----+
|     40 | #sql1c93_3_3 |      4 |    65 | TRUE              | TRUE           |
|     39 | #sql1c93_3_1 |      4 |    64 | FALSE             | FALSE          |
+-----+-----+-----+-----+
```

### 1.1.2.9.1.1.2 Information Schema MyRocks Tables

#### 1.1.2.9.1.1.2.1 Information Schema ROCKSDB\_CFSTATS Table

The [Information Schema](#)

`ROCKSDB_CFSTATS` table is included as part of the [MyRocks](#) storage engine.

The

`PROCESS` privilege is required to view the table.

It contains the following columns:

Column	Description
CF_NAME	
STAT_TYPE	
VALUE	

## 1.1.2.9.1.1.2.2 Information Schema ROCKSDB\_CF\_OPTIONS Table

The [Information Schema](#)

ROCKSDB\_CF\_OPTIONS table is included as part of the [MyRocks](#) storage engine, and contains information about MyRocks [column families](#).

The

[PROCESS](#)  
[privilege](#) is required to view the table.

It contains the following columns:

Column	Description
CF_NAME	<a href="#">Column family</a> name.
OPTION_TYPE	
VALUE	

## 1.1.2.9.1.1.2.3 Information Schema ROCKSDB\_COMPACTION\_STATS Table

The [Information Schema](#)

ROCKSDB\_COMPACTION\_STATS table is included as part of the [MyRocks](#) storage engine.

The

[PROCESS](#)  
[privilege](#) is required to view the table.

It contains the following columns:

Column	Description
CF_NAME	
LEVEL	
TYPE	
VALUE	

## 1.1.2.9.1.1.2.4 Information Schema ROCKSDB\_DBSTATS Table

The [Information Schema](#)

ROCKSDB\_DBSTATS  
table is included as part of the [MyRocks](#) storage engine.

The

PROCESS  
privilege is required to view the table.

It contains the following columns:

Column	Description
STAT_TYPE	
VALUE	

## 1.1.2.9.1.1.2.5 Information Schema ROCKSDB\_DDL Table

The [Information Schema](#)

ROCKSDB\_DDL  
table is included as part of the [MyRocks](#) storage engine.

The

PROCESS  
privilege is required to view the table.

It contains the following columns:

Column	Description
TABLE_SCHEMA	
TABLE_NAME	
PARTITION_NAME	
INDEX_NAME	
COLUMN_FAMILY	
INDEX_NUMBER	
INDEX_TYPE	
KV_FORMAT_VERSION	
TTL_DURATION	
INDEX_FLAGS	

CF	
AUTO_INCREMENT	

## 1.1.2.9.1.1.2.6 Information Schema ROCKSDB\_DEADLOCK Table

The [Information Schema](#)

ROCKSDB\_DEADLOCK  
table is included as part of the [MyRocks](#) storage engine.

The

PROCESS  
[privilege](#) is required to view the table.

It contains the following columns:

Column	Description
DEADLOCK_ID	
TIMESTAMP	
TRANSACTION_ID	
CF_NAME	
WAITING_KEY	
LOCK_TYPE	
INDEX_NAME	
TABLE_NAME	
ROLLED_BACK	

## 1.1.2.9.1.1.2.7 Information Schema ROCKSDB\_GLOBAL\_INFO Table

The [Information Schema](#)

ROCKSDB\_GLOBAL\_INFO  
table is included as part of the [MyRocks](#) storage engine.

The

PROCESS  
[privilege](#) is required to view the table.

It contains the following columns:

Column	Description
--------	-------------

TYPE	
NAME	
VALUE	

## 1.1.2.9.1.1.2.8 Information Schema ROCKSDB\_INDEX\_FILE\_MAP Table

The [Information Schema](#)

ROCKSDB\_INDEX\_FILE\_MAP  
table is included as part of the [MyRocks](#) storage engine.

The

PROCESS  
[privilege](#) is required to view the table.

It contains the following columns:

Column	Description
COLUMN_FAMILY	
INDEX_NUMBER	
SST_NAME	
NUM_ROWS	
DATA_SIZE	
ENTRY_DELETES	
ENTRY_SINGLEDELETES	
ENTRY_MERGES	
ENTRY_OTHERS	
DISTINCT_KEYS_PREFIX	

## 1.1.2.9.1.1.2.9 Information Schema ROCKSDB\_LOCKS Table

The [Information Schema](#)

ROCKSDB\_LOCKS  
table is included as part of the [MyRocks](#) storage engine.

The

PROCESS

[privilege](#) is required to view the table.

It contains the following columns:

Column	Description
COLUMN_FAMILY_ID	
TRANSACTION_ID	
KEY	
MODE	

## 1.1.2.9.1.1.2.10 Information Schema ROCKSDB\_PERF\_CONTEXT Table

The [Information Schema](#)

ROCKSDB\_PERF\_CONTEXT

table is included as part of the [MyRocks](#) storage engine and includes per-table/partition counters .

The

PROCESS

[privilege](#) is required to view the table.

It contains the following columns:

Column	Description
TABLE_SCHEMA	
TABLE_NAME	
PARTITION_NAME	
STAT_TYPE	
VALUE	

Note: for multi-table queries, all counter increments are "billed" to the first table in the query: <https://github.com/facebook/mysql-5.6/issues/1018>

## 1.1.2.9.1.1.2.11 Information Schema ROCKSDB\_PERF\_CONTEXT\_GLOBAL Table

The [Information Schema](#)

ROCKSDB\_PERF\_CONTEXT\_GLOBAL

table is included as part of the [MyRocks](#) storage engine and includes global counter information.

The

PROCESS

[privilege](#) is required to view the table.

It contains the following columns:

Column	Description
--------	-------------

STAT_TYPE	
VALUE	

## 1.1.2.9.1.1.2.12 Information Schema ROCKSDB\_SST\_PROPS Table

The [Information Schema](#)

ROCKSDB\_SST\_PROPS  
table is included as part of the [MyRocks](#) storage engine.

The

PROCESS  
privilege is required to view the table.

It contains the following columns:

Column	Description
SST_NAME	
COLUMN_FAMILY	
DATA_BLOCKS	
ENTRIES	
RAW_KEY_SIZE	
RAW_VALUE_SIZE	
DATA_BLOCK_SIZE	
INDEX_BLOCK_SIZE	
INDEX_PARTITIONS	
TOP_LEVEL_INDEX_SIZE	
FILTER_BLOCK_SIZE	
COMPRESSION_ALGO	
CREATION_TIME	

## 1.1.2.9.1.1.2.13 Information Schema ROCKSDB\_TRX

# Table

The [Information Schema](#)

ROCKSDB\_TRX  
table is included as part of the [MyRocks](#) storage engine.

The

PROCESS  
[privilege](#) is required to view the table.

It contains the following columns:

Column	Description
TRANSACTION_ID	
STATE	
NAME	
WRITE_COUNT	
LOCK_COUNT	
TIMEOUT_SEC	
WAITING_KEY	
WAITING_COLUMN_FAMILY_ID	
IS_REPLICATION	
SKIP_TRX_API	
READ_ONLY	
HAS_DEADLOCK_DETECTION	
NUM_ONGOING_BULKLOAD	
THREAD_ID	
QUERY	

## 1.1.2.9.1.1.3 ColumnStore Information Schema Tables

1. COLUMNSTORE\_TABLES
2. COLUMNSTORE\_COLUMNS
3. COLUMNSTORE\_EXTENTS
4. COLUMNSTORE\_FILES
5. Stored Procedures
  1. total\_usage()
  2. table\_usage()
  3. compression\_ratio()

MariaDB ColumnStore has four Information Schema tables that expose information about the table and column storage. These tables were added in version 1.0.5 of ColumnStore and were heavily modified for 1.0.6.

## COLUMNSTORE\_TABLES

The first table is the INFORMATION\_SCHEMA.COLUMNSTORE\_TABLES. This contains information about the tables inside ColumnStore. The table layout is as follows:

Column	Description
TABLE_SCHEMA	The database schema for the table
TABLE_NAME	The table name
OBJECT_ID	The ColumnStore object ID for the table
CREATION_DATE	The date the table was created
COLUMN_COUNT	The number of columns in the table
AUTOINCREMENT	The start autoincrement value for the table set during CREATE TABLE

**Note:** Tables created with ColumnStore 1.0.4 or lower will have the year field of the creation data set incorrectly by 1900 years.

## COLUMNSTORE\_COLUMNS

The INFORMATION\_SCHEMA.COLUMNSTORE\_COLUMNS table contains information about every single column inside ColumnStore. The table layout is as follows:

Column	Description
TABLE_SCHEMA	The database schema for the table
TABLE_NAME	The table name for the column
COLUMN_NAME	The column name
OBJECT_ID	The object ID for the column
DICTIONARY_OBJECT_ID	The dictionary object ID for the column (NULL if there is no dictionary object)
LIST_OBJECT_ID	Placeholder for future information
TREE_OBJECT_ID	Placeholder for future information
DATA_TYPE	The data type for the column
COLUMN_LENGTH	The data length for the column
COLUMN_POSITION	The position of the column in the table, starting at 0
COLUMN_DEFAULT	The default value for the column
IS_NULLABLE	Whether or not the column can be set to NULL
NUMERIC_PRECISION	The numeric precision for the column
NUMERIC_SCALE	The numeric scale for the column
IS_AUTOINCREMENT	Set to 1 if the column is an autoincrement column
COMPRESSION_TYPE	The type of compression (either "None" or "Snappy")

## COLUMNSTORE\_EXTENTS

This table displays the extent map in a user consumable form. An extent is a collection of details about a section of data related to a columnstore column. A majority of columns in ColumnStore will have multiple extents and the columns table above can be joined to this one to filter results by table or column. The table layout is as follows:

Column	Description
OBJECT_ID	The object ID for the extent
OBJECT_TYPE	Whether this is a "Column" or "Dictionary" extent
LOGICAL_BLOCK_START	ColumnStore's internal start LBID for this extent
LOGICAL_BLOCK_END	ColumnStore's internal end LBID for this extent
MIN_VALUE	This minimum value stored in this extent
MAX_VALUE	The maximum value stored in this extent
WIDTH	The data width for the extent
DBROOT	The DBRoot number for the extent
PARTITION_ID	The partition ID for the extent
SEGMENT_ID	The segment ID for the extent
BLOCK_OFFSET	The block offset for the data file, each data file can contain multiple extents for a column
MAX_BLOCKS	The maximum number of blocks for the extent
HIGH_WATER_MARK	The last block committed to the extent (starting at 0)
STATE	The state of the extent (see below)
STATUS	The availability status for the column which is either "Available", "Unavailable" or "Out of service"
DATA_SIZE	The uncompressed data size for the extent calculated as $(HWM + 1) * BLOCK\_SIZE$

#### Notes:

1. The state is "Valid" for a normal state, "Invalid" if a cpimport has completed but the table has not yet been accessed (min/max values will be invalid) or "Updating" if there is a DML statement writing to the column
2. In ColumnStore the block size is 8192 bytes
3. By default ColumnStore will write create an extent file of  $256 * 1024 * WIDTH$  bytes for the first partition, if this is too small then for uncompressed data it will create a file of the maximum size for the extent ( $MAX\_BLOCKS * BLOCK\_SIZE$ ). Snappy always compression adds a header block.
4. Object IDs of less than 3000 are for internal tables and will not appear in any of the information schema tables
5. Prior to 1.0.12 / 1.1.2 DATA\_SIZE was incorrectly calculated
6. HWM is set to zero for the lower segments when there are multiple segments in an extent file, these can be observed when BLOCK\_OFFSET > 0
7. When HWM is 0 the DATA\_SIZE will show 0 instead of 8192 to avoid confusion when there is multiple segments in an extent file

## COLUMNSTORE\_FILES

The columnstore\_files table provides information about each file associated with extensions. Each extension can reuse a file at different block offsets so this is not a 1:1 relationship to the columnstore\_extents table.

Column	Description
OBJECT_ID	The object ID for the extent
SEGMENT_ID	The segment ID for the extent
PARTITION_ID	The partition ID for the extent
FILENAME	The full path and filename for the extent file, multiple extents for the same column can point to this file with different BLOCK_OFFSETS
FILE_SIZE	The disk file size for the extent
COMPRESSED_DATA_SIZE	The amount of the compressed file used, NULL if this is an uncompressed file

## Stored Procedures

A few stored procedures were added in 1.0.6 to provide summaries based on the information schema tables. These can be accessed from the COLUMNSTORE\_INFO schema.

### total\_usage()

The total\_usage() procedure gives a total disk usage summary for all the columns in ColumnStore with the exception of the columns used for internal maintenance. It is executed using the following query:

```
> call columnstore_info.total_usage();
```

## table\_usage()

The table\_usage() procedure gives a the total data disk usage, dictionary disk usage and grand total disk usage per-table. It can be called in several ways, the first gives a total for each table:

```
> call columnstore_info.table_usage(NULL, NULL);
```

Or for a specific table, my\_table in my\_schema in this example:

```
> call columnstore_info.table_usage('my_schema', 'my_table');
```

You can also request all tables for a specified schema:

```
> call columnstore_info.table_usage('my_schema', NULL);
```

**Note:** The quotes around the table name are required, an error will occur without them.

## compression\_ratio()

The compression\_ratio() procedure calculates the average compression ratio across all the compressed extents in ColumnStore. It is called using:

```
> call columnstore_info.compression_ratio();
```

**Note:** The compression ratio is incorrectly calculated before versions 1.0.12 / 1.1.2

## 1.1.2.9.1.1.4 Information Schema ALL\_PLUGINS Table Description

The [Information Schema](#)

ALL\_PLUGINS

table contains information about [server plugins](#), whether installed or not.

It contains the following columns:

Column	Description
PLUGIN_NAME	Name of the plugin.
PLUGIN_VERSION	Version from the plugin's general type descriptor.
PLUGIN_STATUS	Plugin status, one of ACTIVE , INACTIVE , DISABLED , DELETED or NOT INSTALLED .

PLUGIN_TYPE	Plugin type: STORAGE ENGINE , INFORMATION_SCHEMA , AUTHENTICATION , REPLICATION , DAEMON or AUDIT .
PLUGIN_TYPE_VERSION	Version from the plugin's type-specific descriptor.
PLUGIN_LIBRARY	Plugin's shared object file name, located in the directory specified by the  <code>plugin_dir</code>  system variable, and used by the  <code>INSTALL PLUGIN</code>  and  <code>UNINSTALL PLUGIN</code>  statements. NULL if the plugin is compiled in and cannot be uninstalled.
PLUGIN_LIBRARY_VERSION	Version from the plugin's API interface.
PLUGIN_AUTHOR	Author of the plugin.
PLUGIN_DESCRIPTION	Description.
PLUGIN_LICENSE	Plugin's licence.
LOAD_OPTION	How the plugin was loaded; one of OFF , ON , FORCE or FORCE_PLUS_PERMANENT . See <a href="#">Installing Plugins</a> .
PLUGIN_MATURITY	Plugin's maturity level; one of Unknown , Experimental , Alpha , Beta , 'Gamma , and Stable .

PLUGIN_AUTH_VERSION	Plugin's version as determined by the plugin author. An example would be '0.99 beta 1'.
---------------------	---

It provides a superset of the information shown by the

`SHOW PLUGINS SONAME`

statement, as well as the

`information_schema.PLUGINS`

table. For specific information about storage engines (a particular type of plugin), see the [Information Schema ENGINES table](#) and the

`SHOW ENGINES`

statement.

The table is not a standard Information Schema table, and is a MariaDB extension.

## Example

```

SELECT * FROM information_schema.all_plugins\G
***** 1. row *****
  PLUGIN_NAME: binlog
  PLUGIN_VERSION: 1.0
  PLUGIN_STATUS: ACTIVE
  PLUGIN_TYPE: STORAGE ENGINE

```

## 1.1.2.9.1.1.5 Information Schema APPLICABLE\_ROLES Table

The [Information Schema](#)

APPLICABLE\_ROLES

table shows the [role authorizations](#) that the current user may use.

It contains the following columns:

Column	Description	Added
GRANTEE	Account that the role was granted to.	
ROLE_NAME	Name of the role.	
IS_GRANTABLE	Whether the role can be granted or not.	
IS_DEFAULT	Whether the role is the user's default role or not	MariaDB 10.1.3

The current role is in the [ENABLED\\_ROLES](#) Information Schema table.

## Example

```
SELECT * FROM information_schema.APPLICABLE_ROLES;
+-----+-----+-----+
| GRANTEE      | ROLE_NAME    | IS_GRANTABLE | IS_DEFAULT |
+-----+-----+-----+
| root@localhost | journalist   | YES          | NO         |
| root@localhost | staff        | YES          | NO         |
| root@localhost | dd           | YES          | NO         |
| root@localhost | dog          | YES          | NO         |
+-----+-----+-----+
```

## 1.1.2.9.1.1.6 Information Schema CHARACTER\_SETS Table

The [Information Schema](#)

CHARACTER\_SETS

table contains a list of supported [character sets](#), their default collations and maximum lengths.

It contains the following columns:

Column	Description
CHARACTER_SET_NAME	Name of the character set.
DEFAULT_COLLATE_NAME	Default collation used.
DESCRIPTION	Character set description.
MAXLEN	Maximum length.

The [SHOW CHARACTER SET](#) statement returns the same results (although in a different order), and both can be refined in the same way. For example, the following two statements return the same results:

```
SHOW CHARACTER SET WHERE Maxlen LIKE '2';
```

and

```
SELECT * FROM information_schema.CHARACTER_SETS
WHERE MAXLEN LIKE '2';
```

See [Setting Character Sets and Collations](#) for details on specifying the character set at the server, database, table and column levels, and [Supported Character Sets and Collations](#) for a full list of supported characters sets and collations.

## Example

```
SELECT CHARACTER_SET_NAME FROM information_schema.CHARACTER_SETS
WHERE DEFAULT_COLLATE_NAME LIKE '%chinese%';
+-----+
| CHARACTER_SET_NAME |
+-----+
| big5                |
| gb2312              |
| gbk                 |
+-----+
```

## 1.1.2.9.1.1.7 Information Schema CHECK\_CONSTRAINTS Table

MariaDB starting with [10.2.22](#)

The Information Schema CHECK\_CONSTRAINTS Table was introduced in [MariaDB 10.3.10](#) and [MariaDB 10.2.22](#).

The [Information Schema](#)

CHECK\_CONSTRAINTS  
table stores metadata about the [constraints](#) defined for tables in all databases.

It contains the following columns:

Column	Description
CONSTRAINT_CATALOG	Always contains the string 'def'.
CONSTRAINT_SCHEMA	Database name.
TABLE_NAME	Table name.
CONSTRAINT_NAME	Constraint name.

MariaDB starting with [10.5.10](#)

LEVEL	Type of the constraint ('Column' or 'Table').
-------	---

CHECK_CLAUSE	Constraint clause.
--------------	--------------------

## Example

A table with a numeric table check constraint and with a default check constraint name:

```
CREATE TABLE t ( a int, CHECK (a>10));
```

To see check constraint call

```
check_constraints  
table from information schema .
```

```
SELECT * from INFORMATION_SCHEMA.CHECK_CONSTRAINTS\G
```

```
***** 1. row *****  
CONSTRAINT_CATALOG: def  
CONSTRAINT_SCHEMA: test  
CONSTRAINT_NAME: CONSTRAINT_1  
TABLE_NAME: t  
CHECK_CLAUSE: `a` > 10
```

A new table check constraint called

```
a_upper  
:
```

```
ALTER TABLE t ADD CONSTRAINT a_upper CHECK (a<100);
```

```
SELECT * from INFORMATION_SCHEMA.CHECK_CONSTRAINTS\G
```

```
***** 1. row *****  
CONSTRAINT_CATALOG: def  
CONSTRAINT_SCHEMA: test  
CONSTRAINT_NAME: CONSTRAINT_1  
TABLE_NAME: t  
CHECK_CLAUSE: `a` > 10  
***** 2. row *****  
CONSTRAINT_CATALOG: def  
CONSTRAINT_SCHEMA: test  
CONSTRAINT_NAME: a_upper  
TABLE_NAME: t  
CHECK_CLAUSE: `a` < 100
```

A new table

```
tt
```

with a field check constraint called

```
b
```

, as well as a table check constraint called

```
b_upper  
:
```

```
CREATE TABLE tt(b int CHECK(b>0),CONSTRAINT b_upper CHECK(b<50));
```

```
SELECT * from INFORMATION_SCHEMA.CHECK_CONSTRAINTS;
```

CONSTRAINT_CATALOG	CONSTRAINT_SCHEMA	CONSTRAINT_NAME	TABLE_NAME	CHECK_CLAUSE
def	test	b	tt	`b` > 0
def	test	b_upper	tt	`b` < 50
def	test	CONSTRAINT_1	t	`a` > 10
def	test	a_upper	t	`a` < 100

Note: The name of the field constraint is the same as the field name.

After dropping the default table constraint called

```
CONSTRAINT_1  
:
```

```

ALTER TABLE t DROP CONSTRAINT CONSTRAINT_1;

SELECT * FROM INFORMATION_SCHEMA.CHECK_CONSTRAINTS;
+-----+-----+-----+-----+-----+
| CONSTRAINT_CATALOG | CONSTRAINT_SCHEMA | CONSTRAINT_NAME | TABLE_NAME | CHECK_CLAUSE |
+-----+-----+-----+-----+
| def                | test            | b                 | tt          | `b` > 0      |
| def                | test            | b_upper           | tt          | `b` < 50     |
| def                | test            | a_upper           | t           | `a` < 100    |
+-----+-----+-----+-----+

```

Trying to insert invalid arguments into table

t  
and  
tt  
generates an error.

```

INSERT INTO t VALUES (10),(20),(100);
ERROR 4025 (23000): CONSTRAINT `a_upper` failed for `test`.`t`

INSERT INTO tt VALUES (10),(-10),(100);
ERROR 4025 (23000): CONSTRAINT `b` failed for `test`.`tt`

INSERT INTO tt VALUES (10),(20),(100);
ERROR 4025 (23000): CONSTRAINT `b_upper` failed for `test`.`tt`

```

From MariaDB 10.5.10 :

```

create table majra(check(x>0), x int, y int check(y < 0), z int,
                    constraint z check(z>0), constraint xyz check(x<10 and y<10 and z<10));
Query OK, 0 rows affected (0.036 sec)

show create table majra;
+-----+-----+
| Table | Create Table
+-----+-----+
| majra | CREATE TABLE `majra` (
  `x` int(11) DEFAULT NULL,
  `y` int(11) DEFAULT NULL CHECK (`y` < 0),
  `z` int(11) DEFAULT NULL,
  CONSTRAINT `CONSTRAINT_1` CHECK (`x` > 0),
  CONSTRAINT `z` CHECK (`z` > 0),
  CONSTRAINT `xyz` CHECK (`x` < 10 and `y` < 10 and `z` < 10)
) ENGINE=InnoDB DEFAULT CHARSET=latin1 |
+-----+-----+
1 row in set (0.000 sec)

select * from information_schema.check_constraints where table_name='majra';
+-----+-----+-----+-----+-----+-----+
| CONSTRAINT_CATALOG | CONSTRAINT_SCHEMA | TABLE_NAME | CONSTRAINT_NAME | LEVEL | CHECK_CLAUSE |
+-----+-----+-----+-----+-----+
| def                | test            | majra     | y             | Column | `y` < 0      |
| def                | test            | majra     | CONSTRAINT_1  | Table  | `x` > 0      |
| def                | test            | majra     | z             | Table  | `z` > 0      |
| def                | test            | majra     | xyz           | Table  | `x` < 10 and `y` < 10 and `z` < 10 |
+-----+-----+-----+-----+-----+
4 rows in set (0.001 sec)

```

## 1.1.2.9.1.1.8 Information Schema CLIENT\_STATISTICS Table

The [Information Schema](#)

`CLIENT_STATISTICS`

table holds statistics about client connections. This is part of the [User Statistics](#) feature, which is not enabled by default.

It contains the following columns:

Field	Type	Notes
-------	------	-------

CLIENT	VARCHAR(64)	The IP address or hostname the connection originated from.
TOTAL_CONNECTIONS	INT(21)	The number of connections created for this client.
CONCURRENT_CONNECTIONS	INT(21)	The number of concurrent connections for this client.
CONNECTED_TIME	INT(21)	The cumulative number of seconds elapsed while there were connections from this client.
BUSY_TIME	DOUBLE	The cumulative number of seconds there was activity on connections from this client.
CPU_TIME	DOUBLE	The cumulative CPU time elapsed while servicing this client's connections. Note that this number may be wrong on SMP system if there was a CPU migration for the thread during the execution of the query.
BYTES_RECEIVED	INT(21)	The number of bytes received from this client's connections.
BYTES_SENT	INT(21)	The number of bytes sent to this client's connections.
BINLOG_BYTES_WRITTEN	INT(21)	The number of bytes written to the <a href="#">binary log</a> from this client's connections.
ROWS_READ	INT(21)	The number of rows read by this client's connections.
ROWS_SENT	INT(21)	The number of rows sent by this client's connections.
ROWS_DELETED	INT(21)	The number of rows deleted by this client's connections.
ROWS_INSERTED	INT(21)	The number of rows inserted by this client's connections.
ROWS_UPDATED	INT(21)	The number of rows updated by this client's connections.
SELECT_COMMANDS	INT(21)	The number of  SELECT  commands executed from this client's connections.

UPDATE_COMMANDS	INT(21)	The number of  <b>UPDATE</b>  commands executed from this client's connections.
OTHER_COMMANDS	INT(21)	The number of other commands executed from this client's connections.
COMMIT_TRANSACTIONS	INT(21)	The number of  <b>COMMIT</b>  commands issued by this client's connections.
ROLLBACK_TRANSACTIONS	INT(21)	The number of  <b>ROLLBACK</b>  commands issued by this client's connections.
DENIED_CONNECTIONS	INT(21)	The number of connections denied to this client.
LOST_CONNECTIONS	INT(21)	The number of this client's connections that were terminated uncleanly.
ACCESS_DENIED	INT(21)	The number of times this client's connections issued commands that were denied.
EMPTY_QUERIES	INT(21)	The number of times this client's connections sent queries that returned no results to the server.
TOTAL_SSL_CONNECTIONS	INT(21)	The number of <b>TLS connections</b> created for this client. (>= <a href="#">MariaDB 10.1.1</a> )
MAX_STATEMENT_TIME_EXCEEDED	INT(21)	The number of times a statement was aborted, because it was executed longer than its  <b>MAX_STATEMENT_TIME</b>  threshold. (>= <a href="#">MariaDB 10.1.1</a> )

## Example

```

SELECT * FROM information_schema.CLIENT_STATISTICS\G
***** 1. row *****
    CLIENT: localhost
    TOTAL_CONNECTIONS: 3
    CONCURRENT_CONNECTIONS: 0
    CONNECTED_TIME: 4883
        BUSY_TIME: 0.009722
        CPU_TIME: 0.0102131
    BYTES RECEIVED: 841
        BYTES SENT: 13897
    BINLOG_BYTES_WRITTEN: 0
        ROWS_READ: 0
        ROWS_SENT: 214
        ROWS_DELETED: 0
        ROWS_INSERTED: 207
        ROWS_UPDATED: 0
    SELECT_COMMANDS: 10
    UPDATE_COMMANDS: 0
    OTHER_COMMANDS: 13
    COMMIT_TRANSACTIONS: 0
    ROLLBACK_TRANSACTIONS: 0
    DENIED_CONNECTIONS: 0
    LOST_CONNECTIONS: 0
    ACCESS_DENIED: 0
    EMPTY_QUERIES: 1

```

## 1.1.2.9.1.1.9 Information Schema COLLATION\_CHARACTER\_SET\_APPLICABILITY Table

The [Information Schema](#)

`COLLATION_CHARACTER_SET_APPLICABILITY`  
table shows which [character sets](#) are associated with which collations.

It contains the following columns:

Column	Description
<code>COLLATION_NAME</code>	Collation name.
<code>CHARACTER_SET_NAME</code>	Name of the associated character set.

`COLLATION_CHARACTER_SET_APPLICABILITY`  
is essentially a subset of the

[COLLATIONS](#)

table.

```
SELECT COLLATION_NAME,CHARACTER_SET_NAME FROM information_schema.COLLATIONS;
```

and

```
SELECT * FROM information_schema.COLLATION_CHARACTER_SET_APPLICABILITY;
```

will return identical results.

See [Setting Character Sets and Collations](#) for details on specifying the character set at the server, database, table and column levels.

## Example

```

SELECT * FROM information_schema.COLLATION_CHARACTER_SET_APPLICABILITY
WHERE CHARACTER_SET_NAME='utf32';
+-----+-----+
| COLLATION_NAME | CHARACTER_SET_NAME |
+-----+-----+
| utf32_general_ci | utf32 |
| utf32_bin | utf32 |
| utf32_unicode_ci | utf32 |
| utf32_icelandic_ci | utf32 |
| utf32_latvian_ci | utf32 |
| utf32_romanian_ci | utf32 |
| utf32_slovenian_ci | utf32 |
| utf32_polish_ci | utf32 |
| utf32_estonian_ci | utf32 |
| utf32_spanish_ci | utf32 |
| utf32_swedish_ci | utf32 |
| utf32_turkish_ci | utf32 |
| utf32_czech_ci | utf32 |
| utf32_danish_ci | utf32 |
| utf32_lithuanian_ci | utf32 |
| utf32_slovak_ci | utf32 |
| utf32_spanish2_ci | utf32 |
| utf32_roman_ci | utf32 |
| utf32_persian_ci | utf32 |
| utf32_esperanto_ci | utf32 |
| utf32_hungarian_ci | utf32 |
| utf32_sinhala_ci | utf32 |
| utf32_german2_ci | utf32 |
| utf32_croatian_ci | utf32 |
+-----+-----+

```

## 1.1.2.9.1.1.10 Information Schema COLLATIONS Table

### Contents

1. [NO PAD collations](#)
2. [Example](#)
3. [See Also](#)

The [Information Schema](#)

`COLLATIONS`

table contains a list of supported [collations](#).

It contains the following columns:

Column	Description
<code>COLLATION_NAME</code>	Name of the collation.
<code>CHARACTER_SET_NAME</code>	Associated character set.
<code>ID</code>	Collation id.
<code>IS_DEFAULT</code>	Whether the collation is the character set's default.
<code>IS_COMPILED</code>	Whether the collation is compiled into the server.
<code>SORTLEN</code>	Sort length, used for determining the memory used to sort strings in this collation.

The [SHOW COLLATION](#) statement returns the same results and both can be reduced in a similar way.

For example, in MariaDB Server 10.6, the following two statements return the same results:

```
SHOW COLLATION WHERE Charset LIKE 'utf8mb3';
```

and

```
SELECT * FROM information_schema.COLLATIONS
WHERE CHARACTER_SET_NAME LIKE 'utf8mb3';
```

In MariaDB Server 10.5 and before,

utf8  
should be specified instead of  
utf8mb3

## NO PAD collations

MariaDB starting with 10.2

NO PAD  
collations regard trailing spaces as normal characters. You can get a list of all  
NO PAD  
collations as follows:

```
SELECT collation_name FROM information_schema.COLLATIONS
WHERE collation_name LIKE "%noplod%";
```

collation_name
big5_chinese_noplod_ci
big5_noplod_bin
...

## Example

```
SELECT * FROM information_schema.COLLATIONS;
```

COLLATION_NAME	CHARACTER_SET_NAME	ID	IS_DEFAULT	IS_COMPILED	SORTLEN
big5_chinese_ci	big5	1	Yes	Yes	1
big5_bin	big5	84		Yes	1
big5_chinese_noplod_ci	big5	1025		Yes	1
big5_noplod_bin	big5	1108		Yes	1
dec8_swedish_ci	dec8	3	Yes	Yes	1
dec8_bin	dec8	69		Yes	1
dec8_swedish_noplod_ci	dec8	1027		Yes	1
dec8_noplod_bin	dec8	1093		Yes	1
cp850_general_ci	cp850	4	Yes	Yes	1
cp850_bin	cp850	80		Yes	1
...					

## See Also

- [Supported Character Sets and Collations](#) - full list of supported characters sets and collations.

## 1.1.2.9.1.1.11 Information Schema COLUMN\_PRIVILEGES Table

The [Information Schema](#)

COLUMN\_PRIVILEGES  
table contains column privilege information derived from the

[mysql.columns\\_priv](#)

grant table.

It has the following columns:

Column	Description
--------	-------------

GRANTEE	In the format user_name@host_name . . .
TABLE_CATALOG	Always def . . .
TABLE_SCHEMA	Database name.
TABLE_NAME	Table name.
COLUMN_NAME	Column name.
PRIVILEGE_TYPE	One of SELECT , INSERT , UPDATE OR REFERENCES . . .
IS_GRANTABLE	Whether the user has the <b>GRANT OPTION</b> for this privilege.

Similar information can be accessed with the

`SHOW FULL COLUMNS`

and

`SHOW GRANTS`

statements. See the

`GRANT`

article for more about privileges.

This information is also stored in the

`columns_priv`

table, in the

`mysql`

system database.

For a description of the privileges that are shown in this table, see [column privileges](#).

## Example

In the following example, no column-level privilege has been explicitly assigned:

```
SELECT * FROM information_schema.COLUMN_PRIVILEGES;
Empty set
```

## 1.1.2.9.1.1.12 Information Schema COLUMNS Table

The [Information Schema](#)

`COLUMNS`

table provides information about columns in each table on the server.

It contains the following columns:

Column	Description	Introduced
TABLE_CATALOG	Always contains the string 'def'.	
TABLE_SCHEMA	Database name.	
TABLE_NAME	Table name.	
COLUMN_NAME	Column name.	
ORDINAL_POSITION	Column position in the table. Can be used for ordering.	
COLUMN_DEFAULT	<p>Default value for the column. From <a href="#">MariaDB 10.2.7</a>, literals are quoted to distinguish them from expressions.</p> <p>NULL means that the column has no default. In <a href="#">MariaDB 10.2.6</a> and earlier, no quotes were used for any type of default and</p> <p>NULL can either mean that there is no default, or that the default column value is</p> <p>NULL .</p>	
IS_NULLABLE	Whether the column can contain NULL s.	
DATA_TYPE	The column's <a href="#">data type</a> .	
CHARACTER_MAXIMUM_LENGTH	Maximum length.	
CHARACTER_OCTET_LENGTH	Same as the CHARACTER_MAXIMUM_LENGTH except for multi-byte <a href="#">character sets</a> .	
NUMERIC_PRECISION	For numeric types, the precision (number of significant digits) for the column. NULL if not a numeric field.	
NUMERIC_SCALE	For numeric types, the scale (significant digits to the right of the decimal point). NULL if not a numeric field.	
DATETIME_PRECISION	Fractional-seconds precision, or NULL if not a <a href="#">time data type</a> .	
CHARACTER_SET_NAME	<a href="#">Character set</a> if a non-binary <a href="#">string data type</a> , otherwise NULL.	
COLLATION_NAME	<a href="#">Collation</a> if a non-binary <a href="#">string data type</a> , otherwise NULL.	
COLUMN_TYPE	Column definition, a MySQL and MariaDB extension.	

COLUMN_KEY	Index type. PRI for primary key, UNI for unique index, MUL for multiple index. A MySQL and MariaDB extension.	
EXTRA	Additional information about a column, for example whether the column is an <a href="#">invisible column</a> , or, from <a href="#">MariaDB 10.3.6</a> , WITHOUT SYSTEM VERSIONING if the table is not a <a href="#">system-versioned table</a> . A MySQL and MariaDB extension.	
PRIVILEGES	Which privileges you have for the column. A MySQL and MariaDB extension.	
COLUMN_COMMENT	Column comments.	
IS_GENERATED	Indicates whether the column value is <a href="#">generated (virtual, or computed)</a> . Can be ALWAYS or NEVER	MariaDB 10.2.5
GENERATION_EXPRESSION	The expression used for computing the column value in a <a href="#">generated (virtual, or computed)</a> column.	MariaDB 10.2.5

It provides information similar to, but more complete, than

`SHOW COLUMNS`

and

`mysqlshow`

## Examples

```
SELECT * FROM information_schema.COLUMNS\G
...
***** 9. row *****
TABLE_CATALOG: def
TABLE_SCHEMA: test
TABLE_NAME: t2
COLUMN_NAME: j
ORDINAL_POSITION: 1
COLUMN_DEFAULT: NULL
COLUMN_NULLABLE: YES
DATA_TYPE: longtext
CHARACTER_MAXIMUM_LENGTH: 4294967295
CHARACTER_OCTET_LENGTH: 4294967295
NUMERIC_PRECISION: NULL
NUMERIC_SCALE: NULL
DATETIME_PRECISION: NULL
CHARACTER_SET_NAME: utf8mb4
COLLATION_NAME: utf8mb4_bin
COLUMN_TYPE: longtext
COLUMN_KEY:
EXTRA:
PRIVILEGES: select,insert,update,references
COLUMN_COMMENT:
IS_GENERATED: NEVER
GENERATION_EXPRESSION: NULL
...
```

```

CREATE TABLE t (
    s1 VARCHAR(20) DEFAULT 'ABC',
    s2 VARCHAR(20) DEFAULT (concat('A','B')),
    s3 VARCHAR(20) DEFAULT ("concat('A','B')"),
    s4 VARCHAR(20),
    s5 VARCHAR(20) DEFAULT NULL,
    s6 VARCHAR(20) NOT NULL,
    s7 VARCHAR(20) DEFAULT 'NULL' NULL,
    s8 VARCHAR(20) DEFAULT 'NULL' NOT NULL
);

SELECT
    table_name,
    column_name,
    ordinal_position,
    column_default,
    column_default IS NULL
FROM information_schema.COLUMNS
WHERE table_schema=DATABASE()
AND TABLE_NAME='t';

```

From MariaDB 10.2.7 :

table_name	column_name	ordinal_position	column_default	column_default IS NULL
t	s1	1	'ABC'	0
t	s2	2	concat('A','B')	0
t	s3	3	"concat('A','B')"	0
t	s4	4	NULL	0
t	s5	5	NULL	0
t	s6	6	NULL	1
t	s7	7	'NULL'	0
t	s8	8	'NULL'	0

In the results above, the two single quotes in

concat(''A'', ''B'')

indicate an escaped single quote - see [string-literals](#). Note that while [mysql-command-line-client](#) appears to show the same default value for columns

s5  
and  
s6

, the first is a 4-character string "NULL", while the second is the SQL NULL value.

MariaDB 10.2.6 and before:

table_name	column_name	ordinal_position	column_default	column_default IS NULL
t	s1	1	ABC	0
t	s2	2	concat('A','B')	0
t	s3	3	concat('A','B')	0
t	s4	4	NULL	1
t	s5	5	NULL	1
t	s6	6	NULL	1
t	s7	7	NULL	0
t	s8	8	NULL	0

## 1.1.2.9.1.1.13 Information Schema DISKS Table

MariaDB 10.1.32

The

DISKS

table was introduced in [MariaDB 10.1.32](#) , [MariaDB 10.2.14](#) , and [MariaDB 10.3.6](#) as part of the

DISKS

plugin.

## Contents

1. [Description](#)
2. [Example](#)
3. [See Also](#)

## Description

The

DISKS

table is created when the [DISKS](#) plugin is enabled, and shows metadata about disks on the system.

Before [MariaDB 10.4.7](#) , [MariaDB 10.3.17](#) , [MariaDB 10.2.26](#) and [MariaDB 10.1.41](#) , this plugin did **not** check [user privileges](#) . When it is enabled, **any** user can query the

`INFORMATION_SCHEMA.DISKS`

table and see all the information it provides.

Since [MariaDB 10.4.7](#) , [MariaDB 10.3.17](#) , [MariaDB 10.2.26](#) and [MariaDB 10.1.41](#) , it requires the [FILE privilege](#) .

The plugin only works on Linux.

The table contains the following columns:

Column	Description
DISK	Name of the disk itself.
PATH	Mount point of the disk.
TOTAL	Total space in KiB.
USED	Used amount of space in KiB.
AVAILABLE	Amount of space in KiB available to non-root users.

Note that as the amount of space available to root (OS user) may be more than what is available to non-root users, 'available' + 'used' may be less than 'total'.

All paths to which a particular disk has been mounted are reported. The rationale is that someone might want to take different action e.g. depending on which disk is relevant for a particular path. This leads to the same disk being reported multiple times.

## Example

```
SELECT * FROM information_schema.DISKS;
```

```
+-----+-----+-----+-----+
| Disk   | Path  | Total   | Used    | Available |
+-----+-----+-----+-----+
| /dev/vda1 | /   | 26203116 | 2178424 | 24024692 |
| /dev/vda1 | /boot | 26203116 | 2178424 | 24024692 |
| /dev/vda1 | /etc  | 26203116 | 2178424 | 24024692 |
+-----+-----+-----+-----+
```

## See Also

- [Disks Plugin](#) for details on installing, options
- [Plugin Overview](#) for details on managing plugins.

## 1.1.2.9.1.1.14 Information Schema ENABLED\_ROLES Table

The [Information Schema](#)

`ENABLED_ROLES`

table shows the enabled [roles](#) for the current session.

It contains the following column:

Column	Description
ROLE_NAME	The enabled role name, or NULL .

This table lists all roles that are currently enabled, one role per row — the current role, roles granted to the current role, roles granted to these roles and so on. If no role is set, the row contains a

NULL  
value.

The roles that the current user can enable are listed in the [APPLICABLE\\_ROLES](#) Information Schema table.

See also [CURRENT\\_ROLE\(\)](#).

## Examples

```
SELECT * FROM information_schema.ENABLED_ROLES;
+-----+
| ROLE_NAME |
+-----+
| NULL      |
+-----+
SET ROLE staff;

SELECT * FROM information_schema.ENABLED_ROLES;
+-----+
| ROLE_NAME |
+-----+
| staff     |
+-----+
```

## 1.1.2.9.1.1.15 Information Schema ENGINES Table

The [Information Schema](#)

ENGINES  
table displays status information about the server's [storage engines](#).

It contains the following columns:

Column	Description
ENGINE	Name of the storage engine.
SUPPORT	Whether the engine is the default, or is supported or not.
COMMENT	Storage engine comments.
TRANSACTIONS	Whether or not the engine supports <a href="#">transactions</a> .
XA	Whether or not the engine supports <a href="#">XA transactions</a> .
SAVEPOINTS	Whether or not <a href="#">savepoints</a> are supported.

It provides identical information to the

[SHOW ENGINES](#)

statement. Since storage engines are plugins, different information about them is also shown in the

```
information_schema.PLUGINS
```

table and by the

```
SHOW PLUGINS
```

statement.

The table is not a standard Information Schema table, and is a MySQL and MariaDB extension.

Note that both MySQL's InnoDB and Percona's XtraDB replacement are labeled as

```
InnoDB
```

. However, if XtraDB is in use, it will be specified in the

```
COMMENT
```

field. See [XtraDB and InnoDB](#) . The same applies to [FederatedX](#) .

## Example

```

SELECT * FROM information_schema.ENGINES\G;
***** 1. row *****
ENGINE: InnoDB
SUPPORT: DEFAULT
COMMENT: Supports transactions, row-level locking, and foreign keys
TRANSACTIONS: YES
XA: YES
SAVEPOINTS: YES
***** 2. row *****
ENGINE: CSV
SUPPORT: YES
COMMENT: CSV storage engine
TRANSACTIONS: NO
XA: NO
SAVEPOINTS: NO
***** 3. row *****
ENGINE: MyISAM
SUPPORT: YES
COMMENT: MyISAM storage engine
TRANSACTIONS: NO
XA: NO
SAVEPOINTS: NO
***** 4. row *****
ENGINE: BLACKHOLE
SUPPORT: YES
COMMENT: /dev/null storage engine (anything you write to it disappears)
TRANSACTIONS: NO
XA: NO
SAVEPOINTS: NO
***** 5. row *****
ENGINE: FEDERATED
SUPPORT: YES
COMMENT: FederatedX pluggable storage engine
TRANSACTIONS: YES
XA: NO
SAVEPOINTS: YES
***** 6. row *****
ENGINE: MRG_MyISAM
SUPPORT: YES
COMMENT: Collection of identical MyISAM tables
TRANSACTIONS: NO
XA: NO
SAVEPOINTS: NO
***** 7. row *****
ENGINE: ARCHIVE
SUPPORT: YES
COMMENT: Archive storage engine
TRANSACTIONS: NO
XA: NO
SAVEPOINTS: NO
***** 8. row *****
ENGINE: MEMORY
SUPPORT: YES
COMMENT: Hash based, stored in memory, useful for temporary tables
TRANSACTIONS: NO
XA: NO
SAVEPOINTS: NO
***** 9. row *****
ENGINE: PERFORMANCE_SCHEMA
SUPPORT: YES
COMMENT: Performance Schema
TRANSACTIONS: NO
XA: NO
SAVEPOINTS: NO
***** 10. row *****
ENGINE: Aria
SUPPORT: YES
COMMENT: Crash-safe tables with MyISAM heritage
TRANSACTIONS: NO
XA: NO
SAVEPOINTS: NO
10 rows in set (0.00 sec)

```

Check if a given storage engine is available:

```
SELECT SUPPORT FROM information_schema.ENGINES WHERE ENGINE LIKE 'tokudb';
Empty set
```

Check which storage engine supports XA transactions:

```
SELECT ENGINE FROM information_schema.ENGINES WHERE XA = 'YES';
+-----+
| ENGINE |
+-----+
| InnoDB |
+-----+
```

## 1.1.2.9.1.1.16 Information Schema EVENTS Table

The [Information Schema](#)

EVENTS

table stores information about [Events](#) on the server.

It contains the following columns:

Column	Description
EVENT_CATALOG	Always def
EVENT_SCHEMA	Database where the event was defined.
EVENT_NAME	Event name.
DEFINER	Event definer.
TIME_ZONE	Time zone used for the event's scheduling and execution, by default SYSTEM
EVENT_BODY	SQL
EVENT_DEFINITION	The SQL defining the event.
EVENT_TYPE	Either ONE TIME or RECURRING
EXECUTE_AT	DATETIME when the event is set to execute, or NULL if recurring.
INTERVAL_VALUE	Numeric interval between event executions for a recurring event, or NULL if not recurring.
INTERVAL_FIELD	Interval unit (e.g., HOUR )

SQL_MODE	The  <code>SQL_MODE</code>  at the time the event was created.
STARTS	Start  <code>DATETIME</code>  for a recurring event, NULL if not defined or not recurring.
ENDS	End  <code>DATETIME</code>  for a recurring event, NULL if not defined or not recurring.
STATUS	One of  ENABLED , DISABLED or / SLAVESIDE_DISABLED  .
ON_COMPLETION	The  ON COMPLETION clause, either PRESERVE or NOT PRESERVE  .
CREATED	When the event was created.
LAST_ALTERED	When the event was last changed.
LAST_EXECUTED	When the event was last run.
EVENT_COMMENT	The comment provided in the  <code>CREATE EVENT</code>  statement, or an empty string if none.
ORIGINATOR	MariaDB server ID on which the event was created.
CHARACTER_SET_CLIENT	 <code>character_set_client</code>  system variable session value at the time the event was created.
COLLATION_CONNECTION	 <code>collation_connection</code> system variable session value at the time the event was created.
DATABASE_COLLATION	Database <code>collation</code> with which the event is linked.

The

```
SHOW EVENTS
```

and

```
SHOW CREATE EVENT
```

statements provide similar information.

## 1.1.2.9.1.1.17 Information Schema FEEDBACK Table

The [Information Schema](#)

FEEDBACK

table is created when the [Feedback Plugin](#) is enabled, and contains the complete contents submitted by the plugin.

It contains two columns:

Column	Description
VARIABLE_NAME	Name of the item of information being collected.
VARIABLE_VALUE	Contents of the item of information being collected.

It is possible to disable automatic collection, by setting the

```
feedback_url
```

variable to an empty string, and to submit the contents manually, as follows:

```
$ mysql -e 'SELECT * FROM information_schema.FEEDBACK' > report.txt
```

Then you can send it by opening

[https://mariadb.org/feedback\\_plugin/post](https://mariadb.org/feedback_plugin/post)

in your browser, and uploading your generated

report.txt

. Or you can do it from the command line with (for example):

```
$ curl -F data=@report.txt https://mariadb.org/feedback_plugin/post
```

Manual uploading allows you to be absolutely sure that we receive only the data shown in the

information\_schema.FEEDBACK

table and that no private or sensitive information is being sent.

## Example

```

SELECT * FROM information_schema.FEEDBACK\G
...
***** 906. row *****
VARIABLE_NAME: Uname_sysname
VARIABLE_VALUE: Linux
***** 907. row *****
VARIABLE_NAME: Uname_release
VARIABLE_VALUE: 3.13.0-53-generic
***** 908. row *****
VARIABLE_NAME: Uname_version
VARIABLE_VALUE: #89-Ubuntu SMP Wed May 20 10:34:39 UTC 2015
***** 909. row *****
VARIABLE_NAME: Uname_machine
VARIABLE_VALUE: x86_64
***** 910. row *****
VARIABLE_NAME: Uname_distribution
VARIABLE_VALUE: lsb: Ubuntu 14.04.2 LTS
***** 911. row *****
VARIABLE_NAME: Collation used latin1_german1_ci
VARIABLE_VALUE: 1
***** 912. row *****
VARIABLE_NAME: Collation used latin1_swedish_ci
VARIABLE_VALUE: 18
***** 913. row *****
VARIABLE_NAME: Collation used utf8_general_ci
VARIABLE_VALUE: 567
***** 914. row *****
VARIABLE_NAME: Collation used latin1_bin
VARIABLE_VALUE: 1
***** 915. row *****
VARIABLE_NAME: Collation used binary
VARIABLE_VALUE: 16
***** 916. row *****
VARIABLE_NAME: Collation used utf8_bin
VARIABLE_VALUE: 4044

```

## 1.1.2.9.1.1.18 Information Schema FILES Table

The

**FILES**

tables is unused in MariaDB. See [MDEV-11426](#).

## 1.1.2.9.1.1.19 Information Schema GEOMETRY\_COLUMNS Table

### Description

The [Information Schema](#)

**GEOMETRY\_COLUMNS**

table provides support for Spatial Reference systems for GIS data.

It contains the following columns:

Column	Type	Null	Description
F_TABLE_CATALOG	VARCHAR(512)	NO	Together with F_TABLE_SCHEMA and F_TABLE_NAME , the fully qualified name of the featured table containing the geometry column.
F_TABLE_SCHEMA	VARCHAR(64)	NO	Together with F_TABLE_CATALOG and F_TABLE_NAME , the fully qualified name of the featured table containing the geometry column.

F_TABLE_NAME	VARCHAR(64)	NO	Together with F_TABLE_CATALOG and F_TABLE_SCHEMA , the fully qualified name of the featured table containing the geometry column.
F_GEOMETRY_COLUMN	VARCHAR(64)	NO	Name of the column in the featured table that is the geometry column.
G_TABLE_CATALOG	VARCHAR(512)	NO	
G_TABLE_SCHEMA	VARCHAR(64)	NO	Database name of the table implementing the geometry column.
G_TABLE_NAME	VARCHAR(64)	NO	Table name that is implementing the geometry column.
G_GEOMETRY_COLUMN	VARCHAR(64)	NO	
STORAGE_TYPE	TINYINT(2)	NO	Binary geometry implementation. Always 1 in MariaDB.
GEOMETRY_TYPE	INT(7)	NO	Integer reflecting the type of geometry stored in this column (see table below).
COORD_DIMENSION	TINYINT(2)	NO	Number of dimensions in the spatial reference system. Always 2 in MariaDB.
MAX_PPR	TINYINT(2)	NO	Always 0 in MariaDB.
SRID	SMALLINT(5)	NO	ID of the Spatial Reference System used for the coordinate geometry in this table. It is a foreign key reference to the  <a href="#">SPATIAL_REF_SYS table</a>

## Storage\_type

The integers in the  
storage\_type  
field match the geometry types as follows:

Integer	Type
0	GEOMETRY
1	POINT

3	LINestring
5	POLYGON
7	MULTIPOINT
9	MULTILINESTRING
11	MULTIPOLYGON

## Example

```
CREATE TABLE g1(g GEOMETRY(9,4) REF_SYSTEM_ID=101);

SELECT * FROM information_schema.GEOMETRY_COLUMNS\G
***** 1. row *****
F_TABLE_CATALOG: def
F_TABLE_SCHEMA: test
F_TABLE_NAME: g1
F_GEOMETRY_COLUMN:
  G_TABLE_CATALOG: def
  G_TABLE_SCHEMA: test
  G_TABLE_NAME: g1
G_GEOMETRY_COLUMN: g
  STORAGE_TYPE: 1
  GEOMETRY_TYPE: 0
COORD_DIMENSION: 2
  MAX_PPR: 0
  SRID: 101
```

## See also

- The

[SPATIAL\\_REF\\_SYS](#)

table.

## 1.1.2.9.1.1.20 Information Schema GLOBAL\_STATUS and SESSION\_STATUS Tables

The [Information Schema](#)

GLOBAL\_STATUS

and

SESSION\_STATUS

tables store a record of all [status variables](#) and their global and session values respectively. This is the same information as displayed by the

[SHOW STATUS](#)

commands

`SHOW GLOBAL STATUS`

and

`SHOW SESSION STATUS`

They contain the following columns:

Column	Description
--------	-------------

VARIABLE_NAME	Status variable name.
VARIABLE_VALUE	Global or session value.

## Example

```
SELECT * FROM information_schema.GLOBAL_STATUS;
+-----+-----+
| VARIABLE_NAME          | VARIABLE_VALUE   |
+-----+-----+
...
| BINLOG_SNAPSHOT_FILE  | mariadb-bin.000208 |
| BINLOG_SNAPSHOT_POSITION | 369               |
...
| THREADS_CONNECTED      | 1                 |
| THREADS_CREATED        | 1                 |
| THREADS_RUNNING         | 1                 |
| UPTIME                  | 57358             |
| UPTIME_SINCE_FLUSH_STATUS | 57358             |
+-----+-----+
```

## 1.1.2.9.1.1.21 Information Schema GLOBAL\_VARIABLES and SESSION\_VARIABLES Tables

The [Information Schema](#)

GLOBAL\_VARIABLES

and

SESSION\_VARIABLES

tables stores a record of all [system variables](#) and their global and session values respectively. This is the same information as displayed by the

[SHOW VARIABLES](#)

commands

`SHOW GLOBAL VARIABLES`

and

`SHOW SESSION VARIABLES`

It contains the following columns:

Column	Description
VARIABLE_NAME	System variable name.
VARIABLE_VALUE	Global or session value.

## Example

```

SELECT * FROM information_schema.GLOBAL_VARIABLES ORDER BY VARIABLE_NAME\G
***** 1. row *****
VARIABLE_NAME: ARIA_BLOCK_SIZE
VARIABLE_VALUE: 8192
***** 2. row *****
VARIABLE_NAME: ARIA_CHECKPOINT_LOG_ACTIVITY
VARIABLE_VALUE: 1048576
***** 3. row *****
VARIABLE_NAME: ARIA_CHECKPOINT_INTERVAL
VARIABLE_VALUE: 30
...
***** 455. row *****
VARIABLE_NAME: VERSION_COMPILE_MACHINE
VARIABLE_VALUE: x86_64
***** 456. row *****
VARIABLE_NAME: VERSION_COMPILE_OS
VARIABLE_VALUE: debian-linux-gnu
***** 457. row *****
VARIABLE_NAME: WAIT_TIMEOUT
VARIABLE_VALUE: 600

```

## 1.1.2.9.1.1.22 Information Schema INDEX\_STATISTICS Table

The [Information Schema](#)

### INDEX\_STATISTICS

table shows statistics on index usage and makes it possible to do such things as locating unused indexes and generating the commands to remove them.

This is part of the [User Statistics](#) feature, which is not enabled by default.

It contains the following columns:

Field	Type	Notes
TABLE_SCHEMA	VARCHAR(192)	The schema (database) name.
TABLE_NAME	VARCHAR(192)	The table name.
INDEX_NAME	VARCHAR(192)	The index name (as visible in <a href="#">SHOW CREATE TABLE</a> ).
ROWS_READ	INT(21)	The number of rows read from this index.

## Example

```

SELECT * FROM information_schema.INDEX_STATISTICS
WHERE TABLE_NAME = "author";
+-----+-----+-----+-----+
| TABLE_SCHEMA | TABLE_NAME | INDEX_NAME | ROWS_READ |
+-----+-----+-----+-----+
| books       | author     | by_name    |      15   |
+-----+-----+-----+-----+

```

## 1.1.2.9.1.1.23 Information Schema KEY\_CACHES Table

The [Information Schema](#)

### KEY\_CACHES

table shows statistics about the [segmented key cache](#) ,.

It contains the following columns:

Column Name	Description
-------------	-------------

KEY_CACHE_NAME	The name of the key cache
SEGMENTS	total number of segments (set to NULL for regular key caches)
SEGMENT_NUMBER	segment number (set to NULL for any regular key caches and for rows containing aggregation statistics for segmented key caches)
FULL_SIZE	memory for cache buffers/auxiliary structures
BLOCK_SIZE	size of the blocks
USED_BLOCKS	number of currently used blocks
UNUSED_BLOCKS	number of currently unused blocks
DIRTY_BLOCKS	number of currently dirty blocks
READ_REQUESTS	number of read requests
READS	number of actual reads from files into buffers
WRITE_REQUESTS	number of write requests
WRITES	number of actual writes from buffers into files

## Example

```

SELECT * FROM information_schema.KEY_CACHES \G
*****
1. row ****
KEY_CACHE_NAME: default
SEGMENTS: NULL
SEGMENT_NUMBER: NULL
  FULL_SIZE: 134217728
  BLOCK_SIZE: 1024
  USED_BLOCKS: 36
  UNUSED_BLOCKS: 107146
  DIRTY_BLOCKS: 0
  READ_REQUESTS: 40305
  READS: 21
  WRITE_REQUESTS: 19239
  WRITES: 358

```

## 1.1.2.9.1.1.24 Information Schema KEY\_COLUMN\_USAGE Table

The [Information Schema](#)

KEY\_COLUMN\_USAGE  
table shows which key columns have constraints.

It contains the following columns:

Column	Description
CONSTRAINT_CATALOG	Always def
CONSTRAINT_SCHEMA	Database name of the constraint.
CONSTRAINT_NAME	Name of the constraint ( PRIMARY for the primary key).
TABLE_CATALOG	Always #def
TABLE_SCHEMA	Database name of the column constraint.
TABLE_NAME	Table name of the column constraint.
COLUMN_NAME	Column name of the constraint.
ORDINAL_POSITION	Position of the column within the constraint.
POSITION_IN_UNIQUE_CONSTRAINT	For foreign keys , the position in the unique constraint.
REFERENCED_TABLE_SCHEMA	For foreign keys, the referenced database name.
REFERENCED_TABLE_NAME	For foreign keys, the referenced table name.
REFERENCED_COLUMN_NAME	For foreign keys, the referenced column name.

## Example

```
SELECT * FROM information_schema.KEY_COLUMN_USAGE LIMIT 1 \G
*****
1. row ****
CONSTRAINT_CATALOG: def
CONSTRAINT_SCHEMA: my_website
CONSTRAINT_NAME: PRIMARY
TABLE_CATALOG: def
TABLE_SCHEMA: users
COLUMN_NAME: user_id
ORDINAL_POSITION: 1
POSITION_IN_UNIQUE_CONSTRAINT: NULL
REFERENCED_TABLE_SCHEMA: NULL
REFERENCED_TABLE_NAME: NULL
REFERENCED_COLUMN_NAME: NULL
```

## See Also

- [Finding Tables Without Primary Keys](#)

## 1.1.2.9.1.1.25 Information Schema KEYWORDS Table

The

KEYWORDS

table was added in [MariaDB 10.6.3](#).

## Description

The [Information Schema](#)

KEYWORDS

table contains the list of MariaDB keywords.

It contains a single column:

Column	Description
WORD	Keyword

The table is not a standard Information Schema table, and is a MariaDB extension.

## Example

```
SELECT * FROM INFORMATION_SCHEMA.KEYWORDS;
```

```
+-----+  
| WORD |  
+-----+  
| && |  
| <= |  
| <> |  
| != |  
| >= |  
| << |  
| >> |  
| <=> |  
| ACCESSIBLE |

## 1.1.2.9.1.1.26 Information Schema LOCALES Table

### Description

The [Information Schema](#)

#### LOCALES

table contains a list of all compiled-in locales. It is only available if the [LOCALES plugin](#) has been installed.

It contains the following columns:

Column	Description
ID	Row ID.
NAME	Locale name, for example en_GB
DESCRIPTION	Locale description, for example English - United Kingdom
MAX_MONTH_NAME_LENGTH	Numeric length of the longest month in the locale
MAX_DAY_NAME_LENGTH	Numeric length of the longest day name in the locale.
DECIMAL_POINT	Decimal point character (some locales use a comma).
THOUSAND_SEP	Thousand's character separator,
ERROR_MESSAGE_LANGUAGE	Error message language.

The table is not a standard Information Schema table, and is a MariaDB extension.

The

[SHOW LOCALES](#)

statement returns a subset of the information.

## Example

SELECT * FROM information_schema.LOCALES;						
ID	NAME	DESCRIPTION	MAX_MONTH_NAME_LENGTH	MAX_DAY_NAME_LENGTH	DECIMAL_POINT	THOUSAND_SEP
0	en_US	English - United States	9	9	.	,
1	en_GB	English - United Kingdom	9	9	.	,
2	ja_JP	Japanese - Japan	3	3	.	,
3	sv_SE	Swedish - Sweden	9	7	,	
4	de_DE	German - Germany	9	10	,	.
5	fr_FR	French - France	9	8	,	
6	ar_AE	Arabic - United Arab Emirates	6	8	.	,
7	ar_BH	Arabic - Bahrain	6	8	.	,
8	ar_JO	Arabic - Jordan	12	8	.	,
...						
106	no_NO	Norwegian - Norway	9	7	,	.
107	sv_FI	Swedish - Finland	9	7	,	
108	zh_HK	Chinese - Hong Kong SAR	3	3	.	,
109	el_GR	Greek - Greece	11	9	,	.

## 1.1.2.9.1.1.27 Information Schema METADATA\_LOCK\_INFO Table

The [Information Schema](#)

[METADATA\\_LOCK\\_INFO](#)

table is created by the [metadata\\_lock\\_info](#) plugin. It shows active [metadata locks](#) and user locks (the locks acquired with [GET\\_LOCK](#) ).

It has the following columns:

Column	Description
THREAD_ID	
LOCK_MODE	One of MDL_INTENTION_EXCLUSIVE , MDL_SHARED , MDL_SHARED_HIGH_PRIO , MDL_SHARED_READ , MDL_SHARED_READ_ONLY , MDL_SHARED_WRITE , MDL_SHARED_NO_WRITE , MDL_SHARED_NO_READ_WRITE , MDL_SHARED_UPGRADABLE or MDL_EXCLUSIVE .

LOCK_DURATION	One of MDL_STATEMENT ,MDL_TRANSACTION or MDL_EXPLICIT
LOCK_TYPE	One of Global read lock ,Schema metadata lock ,Table metadata lock ,Stored function metadata lock ,Stored procedure metadata lock ,Trigger metadata lock ,Event metadata lock ,Commit lock or User lock
TABLE_SCHEMA	
TABLE_NAME	

## "LOCK\_MODE" Descriptions

The

LOCK\_MODE

column can have the following values:

Value	Description
MDL_INTENTION_EXCLUSIVE	An intention exclusive metadata lock (IX). Used only for scoped locks. Owner of this type of lock can acquire upgradable exclusive locks on individual objects. Compatible with other IX locks, but is incompatible with scoped S and X locks. IX lock is taken in SCHEMA namespace when we intend to modify object metadata. Object may refer table, stored procedure, trigger, view/etc.
MDL_SHARED	A shared metadata lock (S). To be used in cases when we are interested in object metadata only and there is no intention to access object data (e.g. for stored routines or during preparing prepared statements). We also mis-use this type of lock for open HANDLERs, since lock acquired by this statement has to be compatible with lock acquired by LOCK TABLES ... WRITE statement, i.e. SNRW (We can't get by acquiring S lock at HANDLER ... OPEN time and upgrading it to SR lock for HANDLER ... READ as it doesn't solve problem with need to abort DML statements which wait on table level lock while having open HANDLER in the same connection). To avoid deadlock which may occur when SNRW lock is being upgraded to X lock for table on which there is an active S lock which is owned by thread which waits in its turn for table-level lock owned by thread performing upgrade we have to use <code>thr_abort_locks_for_thread()</code> facility in such situation. This problem does not arise for locks on stored routines as we don't use SNRW locks for them. It also does not arise when S locks are used during PREPARE calls as table-level locks are not acquired in this case. This lock is taken for global read lock, when caching a stored procedure in memory for the duration of the transaction and for tables used by prepared statements.
MDL_SHARED_HIGH_PRIO	A high priority shared metadata lock. Used for cases when there is no intention to access object data (i.e. data in the table). "High priority" means that, unlike other shared locks, it is granted ignoring pending requests for exclusive locks. Intended for use in cases when we only need to access metadata and not data, e.g. when filling an INFORMATION_SCHEMA table. Since SH lock is compatible with SNRW lock, the connection that holds SH lock lock should not try to acquire any kind of table-level or row-level lock, as this can lead to a deadlock. Moreover, after acquiring SH lock, the connection should not wait for any other resource, as it might cause starvation for X locks and a potential deadlock during upgrade of SNW or SNRW to X lock (e.g. if the upgrading connection holds the resource that is being waited for).
MDL_SHARED_READ	A shared metadata lock (SR) for cases when there is an intention to read data from table. A connection holding this kind of lock can read table metadata and read table data (after acquiring appropriate table and row-level locks). This means that one can only acquire TL_READ, TL_READ_NO_INSERT, and similar table-level locks on table if one holds SR MDL lock on it. To be used for tables in SELECTs, subqueries, and LOCK TABLE ... READ statements.

MDL_SHARED_WRITE	A shared metadata lock (SW) for cases when there is an intention to modify (and not just read) data in the table. A connection holding SW lock can read table metadata and modify or read table data (after acquiring appropriate table and row-level locks). To be used for tables to be modified by INSERT, UPDATE, DELETE statements, but not LOCK TABLE ... WRITE or DDL. Also taken by SELECT ... FOR UPDATE.
MDL_SHARED_UPGRADABLE	An upgradable shared metadata lock for cases when there is an intention to modify (and not just read) data in the table. Can be upgraded to MDL_SHARED_NO_WRITE and MDL_EXCLUSIVE. A connection holding SU lock can read table metadata and modify or read table data (after acquiring appropriate table and row-level locks). To be used for the first phase of ALTER TABLE.
MDL_SHARED_READ_ONLY	A shared metadata lock for cases when we need to read data from table and block all concurrent modifications to it (for both data and metadata). Used by LOCK TABLES READ statement.
MDL_SHARED_NO_WRITE	An upgradable shared metadata lock which blocks all attempts to update table data, allowing reads. A connection holding this kind of lock can read table metadata and read table data. Can be upgraded to X metadata lock. Note, that since this type of lock is not compatible with SNRW or SW lock types, acquiring appropriate engine-level locks for reading (TL_READ* for MyISAM, shared row locks in InnoDB) should be contention-free. To be used for the first phase of ALTER TABLE, when copying data between tables, to allow concurrent SELECTs from the table, but not UPDATEs.
MDL_SHARED_NO_READ_WRITE	An upgradable shared metadata lock which allows other connections to access table metadata, but not data. It blocks all attempts to read or update table data, while allowing INFORMATION_SCHEMA and SHOW queries. A connection holding this kind of lock can read table metadata modify and read table data. Can be upgraded to X metadata lock. To be used for LOCK TABLES WRITE statement. Not compatible with any other lock type except S and SH.
MDL_EXCLUSIVE	An exclusive metadata lock (X). A connection holding this lock can modify both table's metadata and data. No other type of metadata lock can be granted while this lock is held. To be used for CREATE/DROP/RENAME TABLE statements and for execution of certain phases of other DDL statements.

## Examples

User lock:

```
SELECT GET_LOCK('abc',1000);
+-----+
| GET_LOCK('abc',1000) |
+-----+
|           1 |
+-----+

SELECT * FROM information_schema.METADATA_LOCK_INFO;
+-----+-----+-----+-----+-----+
| THREAD_ID | LOCK_MODE          | LOCK_DURATION | LOCK_TYPE | TABLE_SCHEMA | TABLE_NAME |
+-----+-----+-----+-----+-----+
|       61 | MDL_SHARED_NO_READ_WRITE | MDL_EXPLICIT   | User lock  | abc          |          |
+-----+-----+-----+-----+-----+
```

Table metadata lock:

```
START TRANSACTION;

INSERT INTO t VALUES (1,2);

SELECT * FROM information_schema.METADATA_LOCK_INFO \G
***** 1. row *****
THREAD_ID: 4
LOCK_MODE: MDL_SHARED_WRITE
LOCK_DURATION: MDL_TRANSACTION
LOCK_TYPE: Table metadata lock
TABLE_SCHEMA: test
TABLE_NAME: t
```

```
SELECT * FROM information_schema.METADATA_LOCK_INFO;
+-----+-----+-----+-----+-----+
| THREAD_ID | LOCK_MODE | LOCK_DURATION | LOCK_TYPE | TABLE_SCHEMA | TABLE_NAME |
+-----+-----+-----+-----+-----+
| 31 | MDL_INTENTION_EXCLUSIVE | MDL_EXPLICIT | Global read lock |  | |
| 31 | MDL_INTENTION_EXCLUSIVE | MDL_EXPLICIT | Commit lock |  |
| 31 | MDL_INTENTION_EXCLUSIVE | MDL_EXPLICIT | Schema metadata lock | dbname |
| 31 | MDL_SHARED_NO_READ_WRITE | MDL_EXPLICIT | Table metadata lock | dbname | exotics |
+-----+-----+-----+-----+-----+
```

## See also

- [metadata locks](#)

## 1.1.2.9.1.1.28 Information Schema MROONGA\_STATS Table

The [Information Schema](#)

MROONGA\_STATS

table only exists if the [Mroonga](#) storage engine is installed, and contains information about its activities.

Column	Description
VERSION	Mroonga version.
rows_written	Number of rows written into Mroonga tables.
rows_read	Number of rows read from all Mroonga tables.

This table always contains 1 row.

## 1.1.2.9.1.1.29 Information Schema OPTIMIZER\_TRACE Table

MariaDB starting with [10.4.3](#)

Optimizer Trace was introduced in [MariaDB 10.4.3](#).

## Description

The [Information Schema](#)

OPTIMIZER\_TRACE

table contains [Optimizer Trace](#) information.

It contains the following columns:

Column	Description
QUERY	Displays the query that was asked to be traced.
TRACE	A JSON document displaying the stats we collected when the query was run.
MISSING_BYTES_BEYOND_MAX_MEM_SIZE	For huge trace, where the trace is truncated due to the optimizer_trace_max_mem_size limit being reached, displays the bytes that are missing in the trace
INSUFFICIENT_PRIVILEGES	Set to 1 if the user running the trace does not have the privileges to see the trace.

Structure:

```

SHOW CREATE TABLE INFORMATION_SCHEMA.OPTIMIZER_TRACE \G
*****
1. row *****

Table: OPTIMIZER_TRACE
Create Table: CREATE TEMPORARY TABLE `OPTIMIZER_TRACE` (
  `QUERY` longtext NOT NULL DEFAULT '',
  `TRACE` longtext NOT NULL DEFAULT '',
  `MISSING_BYTES_BEYOND_MAX_MEM_SIZE` int(20) NOT NULL DEFAULT 0,
  `INSUFFICIENT_PRIVILEGES` tinyint(1) NOT NULL DEFAULT 0
) ENGINE=Aria DEFAULT CHARSET=utf8 PAGE_CHECKSUM=0

```

## 1.1.2.9.1.1.30 Information Schema PARAMETERS Table

The [Information Schema](#)

PARAMETERS

table stores information about [stored procedures](#) and [stored functions](#) parameters.

It contains the following columns:

Column	Description
SPECIFIC_CATALOG	Always def . . .
SPECIFIC_SCHEMA	Database name containing the stored routine parameter.
SPECIFIC_NAME	Stored routine name.
ORDINAL_POSITION	Ordinal position of the parameter, starting at 1 . . . 0 for a function RETURNS clause.
PARAMETER_MODE	One of IN , OUT , INOUT or NULL for RETURNS.
PARAMETER_NAME	Name of the parameter, or NULL for RETURNS.
DATA_TYPE	The column's <a href="#">data type</a> .
CHARACTER_MAXIMUM_LENGTH	Maximum length.
CHARACTER_OCTET_LENGTH	Same as the CHARACTER_MAXIMUM_LENGTH except for multi-byte <a href="#">character sets</a> .
NUMERIC_PRECISION	For numeric types, the precision (number of significant digits) for the column. NULL if not a numeric field.
NUMERIC_SCALE	For numeric types, the scale (significant digits to the right of the decimal point). NULL if not a numeric field.
DATETIME_PRECISION	Fractional-seconds precision, or NULL if not a <a href="#">time data type</a> .

CHARACTER_SET_NAME	Character set if a non-binary string data type , otherwise NULL
COLLATION_NAME	Collation if a non-binary string data type , otherwise NULL
DTD_IDENTIFIER	Description of the data type.
ROUTINE_TYPE	PROCEDURE or FUNCTION

Information from this table is similar to that found in the

`param_list`  
column in the `mysql.proc` table, and the output of the

`SHOW CREATE PROCEDURE`

and

`SHOW CREATE FUNCTION`

statements.

To obtain information about the routine itself, you can query the [Information Schema ROUTINES table](#).

## Example

```
SELECT * FROM information_schema.PARAMETERS
LIMIT 1 \G
*****
1. row *****
SPECIFIC_CATALOG: def
SPECIFIC_SCHEMA: accounts
SPECIFIC_NAME: user_counts
ORDINAL_POSITION: 1
PARAMETER_MODE: IN
PARAMETER_NAME: user_order
DATA_TYPE: varchar
CHARACTER_MAXIMUM_LENGTH: 255
CHARACTER_OCTET_LENGTH: 765
NUMERIC_PRECISION: NULL
NUMERIC_SCALE: NULL
DATETIME_PRECISION: NULL
CHARACTER_SET_NAME: utf8
COLLATION_NAME: utf8_general_ci
DTD_IDENTIFIER: varchar(255)
ROUTINE_TYPE: PROCEDURE
```

## 1.1.2.9.1.1.31 Information Schema PARTITIONS Table

The [Information Schema](#)

`PARTITIONS`

contains information about table partitions, with each record corresponding to a single partition or subpartition of a partitioned table. Each non-partitioned table also has a record in the

`PARTITIONS`

table, but most of the values are

`NULL`

It contains the following columns:

Column	Description
TABLE_CATALOG	Always def

TABLE_SCHEMA	Database name.
TABLE_NAME	Table name containing the partition.
PARTITION_NAME	Partition name.
SUBPARTITION_NAME	Subpartition name, or NULL if not a subpartition.
PARTITION_ORDINAL_POSITION	Order of the partition starting from 1.
SUBPARTITION_ORDINAL_POSITION	Order of the subpartition starting from 1.
PARTITION_METHOD	The partitioning type; one of RANGE ,, LIST ,, HASH ,, LINEAR HASH ,, KEY or LINEAR KEY ..
SUBPARTITION_METHOD	Subpartition type; one of HASH ,, LINEAR HASH ,, KEY or LINEAR KEY ,, NULL if not a subpartition.
PARTITION_EXPRESSION	Expression used to create the partition by the  <code>CREATE TABLE</code>  or  <code>ALTER TABLE</code>  statement.
SUBPARTITION_EXPRESSION	Expression used to create the subpartition by the  <code>CREATE TABLE</code>  or  <code>ALTER TABLE</code>  statement, or NULL if not a subpartition.

PARTITION_DESCRIPTION	For a RANGE partition, contains either MAXINTEGER or an integer, as set in the VALUES LESS THAN clause. For a LIST partition, contains a comma-separated list of integers, as set in the VALUES IN . NULL if another type of partition.
TABLE_ROWS	Number of rows in the table (may be an estimate for some storage engines).
AVG_ROW_LENGTH	Average row length, that is DATA_LENGTH divided by TABLE_ROWS
DATA_LENGTH	Total number of bytes stored in all rows of the partition.
MAX_DATA_LENGTH	Maximum bytes that could be stored in the partition.
INDEX_LENGTH	Size in bytes of the partition index file.
DATA_FREE	Unused bytes allocated to the partition.
CREATE_TIME	Time the partition was created
UPDATE_TIME	Time the partition was last modified.
CHECK_TIME	Time the partition was last checked, or NULL for storage engines that don't record this information.
CHECKSUM	Checksum value, or NULL if none.
PARTITION_COMMENT	Partition comment, truncated to 80 characters, or an empty string if no comment.
NODEGROUP	Node group, only used for MySQL Cluster, defaults to 0 .
TABLESPACE_NAME	Always default .

## 1.1.2.9.1.1.32 Information Schema PLUGINS Table

The [Information Schema](#)

PLUGINS

table contains information about [server plugins](#).

It contains the following columns:

Column	Description
--------	-------------

PLUGIN_NAME	Name of the plugin.
PLUGIN_VERSION	Version from the plugin's general type descriptor.
PLUGIN_STATUS	Plugin status, one of ACTIVE , INACTIVE , DISABLED or DELETED .
PLUGIN_TYPE	Plugin type; STORAGE ENGINE , INFORMATION_SCHEMA , AUTHENTICATION , REPLICATION , DAEMON or AUDIT .
PLUGIN_TYPE_VERSION	Version from the plugin's type-specific descriptor.
PLUGIN_LIBRARY	Plugin's shared object file name, located in the directory specified by the <code>plugin_dir</code> system variable, and used by the <code>INSTALL PLUGIN</code> and <code>UNINSTALL PLUGIN</code> statements. NULL if the plugin is compiled in and cannot be uninstalled.
PLUGIN_LIBRARY_VERSION	Version from the plugin's API interface.
PLUGIN_AUTHOR	Author of the plugin.
PLUGIN_DESCRIPTION	Description.
PLUGIN_LICENSE	Plugin's licence.
LOAD_OPTION	How the plugin was loaded; one of OFF , ON , FORCE or FORCE_PLUS_PERMANENT . See <a href="#">Installing Plugins</a> .

PLUGIN_MATURITY	Plugin's maturity level; one of Unknown ,
	Experimental ,
	Alpha ,
	Beta ,
	'Gamma , and Stable

PLUGIN_AUTH_VERSION	Plugin's version as determined by the plugin author. An example would be '0.99 beta 1'.
---------------------	---

It provides a superset of the information shown by the [SHOW PLUGINS](#) statement. For specific information about storage engines (a particular type of plugins), see the [information\\_schema.ENGINES](#) table and the [SHOW ENGINES](#) statement.

This table provides a subset of the Information Schema [information\\_schema.ALL\\_PLUGINS](#) table, which contains all available plugins, installed or not.

The table is not a standard Information Schema table, and is a MariaDB extension.

## Examples

The easiest way to get basic information on plugins is with [SHOW PLUGINS](#) :

```
SHOW PLUGINS;
```

Name	Status	Type	Library	License
binlog	ACTIVE	STORAGE ENGINE	NULL	GPL
mysql_native_password	ACTIVE	AUTHENTICATION	NULL	GPL
mysql_old_password	ACTIVE	AUTHENTICATION	NULL	GPL
MRG_MyISAM	ACTIVE	STORAGE ENGINE	NULL	GPL
MyISAM	ACTIVE	STORAGE ENGINE	NULL	GPL
CSV	ACTIVE	STORAGE ENGINE	NULL	GPL
MEMORY	ACTIVE	STORAGE ENGINE	NULL	GPL
FEDERATED	ACTIVE	STORAGE ENGINE	NULL	GPL
PERFORMANCE_SCHEMA	ACTIVE	STORAGE ENGINE	NULL	GPL
Aria	ACTIVE	STORAGE ENGINE	NULL	GPL
InnoDB	ACTIVE	STORAGE ENGINE	NULL	GPL
INNODB_TRX	ACTIVE	INFORMATION SCHEMA	NULL	GPL
INNODB_LOCKS	ACTIVE	INFORMATION SCHEMA	NULL	GPL
INNODB_LOCK_WAITS	ACTIVE	INFORMATION SCHEMA	NULL	GPL
INNODB_CMP	ACTIVE	INFORMATION SCHEMA	NULL	GPL
INNODB_CMP_RESET	ACTIVE	INFORMATION SCHEMA	NULL	GPL
INNODB_CMPMEM	ACTIVE	INFORMATION SCHEMA	NULL	GPL
INNODB_CMPMEM_RESET	ACTIVE	INFORMATION SCHEMA	NULL	GPL
INNODB_BUFFER_PAGE	ACTIVE	INFORMATION SCHEMA	NULL	GPL
INNODB_BUFFER_PAGE_LRU	ACTIVE	INFORMATION SCHEMA	NULL	GPL
INNODB_BUFFER_POOL_STATS	ACTIVE	INFORMATION SCHEMA	NULL	GPL
INNODB_METRICS	ACTIVE	INFORMATION SCHEMA	NULL	GPL
INNODB_FT_DEFAULT_STOPWORD	ACTIVE	INFORMATION SCHEMA	NULL	GPL
INNODB_FT_INSERTED	ACTIVE	INFORMATION SCHEMA	NULL	GPL
INNODB_FT_DELETED	ACTIVE	INFORMATION SCHEMA	NULL	GPL
INNODB_FT_BEING_DELETED	ACTIVE	INFORMATION SCHEMA	NULL	GPL
INNODB_FT_CONFIG	ACTIVE	INFORMATION SCHEMA	NULL	GPL
INNODB_FT_INDEX_CACHE	ACTIVE	INFORMATION SCHEMA	NULL	GPL
INNODB_FT_INDEX_TABLE	ACTIVE	INFORMATION SCHEMA	NULL	GPL
INNODB_SYS_TABLES	ACTIVE	INFORMATION SCHEMA	NULL	GPL
INNODB_SYS_TABLESTATS	ACTIVE	INFORMATION SCHEMA	NULL	GPL
INNODB_SYS_INDEXES	ACTIVE	INFORMATION SCHEMA	NULL	GPL
INNODB_SYS_COLUMNS	ACTIVE	INFORMATION SCHEMA	NULL	GPL
INNODB_SYS_FIELDS	ACTIVE	INFORMATION SCHEMA	NULL	GPL
INNODB_SYS_FOREIGN	ACTIVE	INFORMATION SCHEMA	NULL	GPL
INNODB_SYS_FOREIGN_COLS	ACTIVE	INFORMATION SCHEMA	NULL	GPL
SPHINX	ACTIVE	STORAGE ENGINE	NULL	GPL
ARCHIVE	ACTIVE	STORAGE ENGINE	NULL	GPL
BLACKHOLE	ACTIVE	STORAGE ENGINE	NULL	GPL
FEEDBACK	DISABLED	INFORMATION SCHEMA	NULL	GPL
partition	ACTIVE	STORAGE ENGINE	NULL	GPL
pam	ACTIVE	AUTHENTICATION	auth_pam.so	GPL

```
SELECT LOAD_OPTION
FROM INFORMATION_SCHEMA.PLUGINS
WHERE PLUGIN_NAME LIKE 'tokudb';
Empty set
```

The equivalent `SELECT` query would be:

```
SELECT PLUGIN_NAME, PLUGIN_STATUS,
PLUGIN_TYPE, PLUGIN_LIBRARY, PLUGIN_LICENSE
FROM INFORMATION_SCHEMA.PLUGINS;
```

Other `SELECT` queries can be used to see additional information. For example:

```

SELECT PLUGIN_NAME, PLUGIN_DESCRIPTION,
PLUGIN_MATURITY, PLUGIN_AUTH_VERSION
FROM INFORMATION_SCHEMA.PLUGINS
WHERE PLUGIN_TYPE='STORAGE ENGINE'
ORDER BY PLUGIN_MATURITY [G]

***** 1. row *****
PLUGIN_NAME: FEDERATED
PLUGIN_DESCRIPTION: FederatedX pluggable storage engine
    PLUGIN_MATURITY: Beta
PLUGIN_AUTH_VERSION: 2.1
***** 2. row *****
PLUGIN_NAME: Aria
PLUGIN_DESCRIPTION: Crash-safe tables with MyISAM heritage
    PLUGIN_MATURITY: Gamma
PLUGIN_AUTH_VERSION: 1.5
***** 3. row *****
PLUGIN_NAME: PERFORMANCE_SCHEMA
PLUGIN_DESCRIPTION: Performance Schema
    PLUGIN_MATURITY: Gamma
PLUGIN_AUTH_VERSION: 0.1
***** 4. row *****
PLUGIN_NAME: binlog
PLUGIN_DESCRIPTION: This is a pseudo storage engine to represent the binlog in a transaction
    PLUGIN_MATURITY: Stable
PLUGIN_AUTH_VERSION: 1.0
***** 5. row *****
PLUGIN_NAME: MEMORY
PLUGIN_DESCRIPTION: Hash based, stored in memory, useful for temporary tables
    PLUGIN_MATURITY: Stable
PLUGIN_AUTH_VERSION: 1.0
***** 6. row *****
PLUGIN_NAME: MyISAM
PLUGIN_DESCRIPTION: MyISAM storage engine
    PLUGIN_MATURITY: Stable
PLUGIN_AUTH_VERSION: 1.0
***** 7. row *****
PLUGIN_NAME: MRG_MyISAM
PLUGIN_DESCRIPTION: Collection of identical MyISAM tables
    PLUGIN_MATURITY: Stable
PLUGIN_AUTH_VERSION: 1.0
***** 8. row *****
PLUGIN_NAME: CSV
PLUGIN_DESCRIPTION: CSV storage engine
    PLUGIN_MATURITY: Stable
PLUGIN_AUTH_VERSION: 1.0
***** 9. row *****
PLUGIN_NAME: InnoDB
PLUGIN_DESCRIPTION: Supports transactions, row-level locking, and foreign keys
    PLUGIN_MATURITY: Stable
PLUGIN_AUTH_VERSION: 1.2.5
***** 10. row *****
PLUGIN_NAME: BLACKHOLE
PLUGIN_DESCRIPTION: /dev/null storage engine (anything you write to it disappears)
    PLUGIN_MATURITY: Stable
PLUGIN_AUTH_VERSION: 1.0
***** 11. row *****
PLUGIN_NAME: ARCHIVE
PLUGIN_DESCRIPTION: Archive storage engine
    PLUGIN_MATURITY: Stable
PLUGIN_AUTH_VERSION: 1.0
***** 12. row *****
PLUGIN_NAME: partition
PLUGIN_DESCRIPTION: Partition Storage Engine Helper
    PLUGIN_MATURITY: Stable
PLUGIN_AUTH_VERSION: 1.0

```

Check if a given plugin is available:

```

SELECT LOAD_OPTION
FROM INFORMATION_SCHEMA.PLUGINS
WHERE PLUGIN_NAME LIKE 'tokudb';
Empty set

```

Show authentication plugins:

```

SELECT PLUGIN_NAME, LOAD_OPTION
FROM INFORMATION_SCHEMA.PLUGINS
WHERE PLUGIN_TYPE LIKE 'authentication' NG

***** 1. row *****
PLUGIN_NAME: mysql_native_password
LOAD_OPTION: FORCE
***** 2. row *****
PLUGIN_NAME: mysql_old_password
LOAD_OPTION: FORCE

```

## 1.1.2.9.1.1.33 Information Schema PROCESSLIST Table

### Contents

1. [Example](#)
2. [See Also](#)

The [Information Schema](#)

PROCESSLIST  
table contains information about running threads.

Similar information can also be returned with the

`SHOW [FULL] PROCESSLIST`

statement, or the

`mysqladmin processlist`

command.

It contains the following columns:

Column	Description
ID	Connection identifier.
USER	MariaDB User.
HOST	Connecting host.
DB	Default database, or NULL if none.
COMMAND	Type of command running, corresponding to the <code>Com_</code> <code>status variables</code> . See <a href="#">Thread Command Values</a> .
TIME	Seconds that the thread has spent on the current COMMAND so far.
STATE	Current state of the thread. See <a href="#">Thread States</a> .

INFO	Statement the thread is executing, or NULL if none.
TIME_MS	Time in milliseconds with microsecond precision that the thread has spent on the current COMMAND so far ( <a href="#">see more</a> ).
STAGE	The stage the process is currently in.
MAX_STAGE	The maximum number of stages.
PROGRESS	The progress of the process within the current stage (0-100%).
MEMORY_USED	Memory in bytes used by the thread.
EXAMINED_ROWS	Rows examined by the thread. Only updated by UPDATE, DELETE, and similar statements. For SELECT and other statements, the value remains zero.
QUERY_ID	Query ID.
INFO_BINARY	Binary data information
TID	Thread ID ( <a href="#">MDEV-6756</a> )

Note that as a difference to MySQL, in MariaDB the

`TIME`  
column (and also the  
`TIME_MS`  
column) are not affected by any setting of

`@TIMESTAMP`

. This means that it can be reliably used also for threads that change  
`@TIMESTAMP`  
(such as the `replication` SQL thread). See also [MySQL Bug #22047](#) .

As a consequence of this, the

`TIME`  
column of  
`SHOW FULL PROCESSLIST`  
and  
`INFORMATION_SCHEMA.PROCESSLIST`  
can not be used to determine if a slave is lagging behind. For this, use instead the  
`Seconds_Behind_Master`  
column in the output of [SHOW SLAVE STATUS](#) .

Note that the

`PROGRESS`  
field from the information schema, and the  
`PROGRESS`  
field from  
`SHOW PROCESSLIST`  
display different results.  
`SHOW PROCESSLIST`  
shows the total progress, while the information schema shows the progress for the current stage only.. To retrieve a similar "total" Progress value from

```
information_schema.PROCESSLIST
```

```
as the one from
```

```
SHOW PROCESSLIST
```

```
, use
```

```
SELECT CASE WHEN Max_Stage < 2 THEN Progress ELSE (Stage-1)/Max_Stage*100+Progress/Max_Stage END  
AS Progress FROM INFORMATION_SCHEMA.PROCESSLIST;
```

## Example

```
SELECT * FROM INFORMATION_SCHEMA.PROCESSLIST\G  
***** 1. row *****  
    ID: 9  
  USER: msandbox  
  HOST: localhost  
    DB: NULL  
COMMAND: Query  
   TIME: 0  
  STATE: Filling schema table  
  INFO: SELECT * FROM INFORMATION_SCHEMA.PROCESSLIST  
TIME_MS: 0.351  
 STAGE: 0  
MAX_STAGE: 0  
 PROGRESS: 0.000  
MEMORY_USED: 85392  
EXAMINED_ROWS: 0  
 QUERY_ID: 15  
INFO_BINARY: SELECT * FROM INFORMATION_SCHEMA.PROCESSLIST  
      TID: 11838  
***** 2. row *****  
    ID: 5  
  USER: system user  
  HOST:  
    DB: NULL  
COMMAND: Daemon  
   TIME: 0  
  STATE: InnoDB shutdown handler  
  INFO: NULL  
TIME_MS: 0.000  
 STAGE: 0  
MAX_STAGE: 0  
 PROGRESS: 0.000  
MEMORY_USED: 24160  
EXAMINED_ROWS: 0  
 QUERY_ID: 0  
INFO_BINARY: NULL  
      TID: 3856  
...  
...
```

## See Also

- [TIME\\_MS column in Information Schema SHOW PROCESSLIST](#)

## 1.1.2.9.1.1.34 Information Schema PROFILING Table

The [Information Schema](#)

PROFILING

table contains information about statement resource usage. Profiling information is only recorded if the

[profiling](#)

session variable is set to 1.

It contains the following columns:

Column Name	Description
QUERY_ID	Query_ID.

SEQ	Sequence number showing the display order for rows with the same QUERY_ID
STATE	Profiling state.
DURATION	Time in seconds that the statement has been in the current state.
CPU_USER	User CPU usage in seconds.
CPU_SYSTEM	System CPU usage in seconds.
CONTEXT_VOLUNTARY	Number of voluntary context switches.
CONTEXT_INVOLUNTARY	Number of involuntary context switches.
BLOCK_OPS_IN	Number of block input operations.
BLOCK_OPS_OUT	Number of block output operations.
MESSAGES_SENT	Number of communications sent.
MESSAGES RECEIVED	Number of communications received.
PAGE_FAULTS_MAJOR	Number of major page faults.
PAGE_FAULTS_MINOR	Number of minor page faults.
SWAPS	Number of swaps.
SOURCE_FUNCTION	Function in the source code executed by the profiled state.
SOURCE_FILE	File in the source code executed by the profiled state.
SOURCE_LINE	Line in the source code executed by the profiled state.

It contains similar information to the

[SHOW PROFILE](#)

and

[SHOW PROFILES](#)

statements.

## 1.1.2.9.1.1.35 Information Schema QUERY\_CACHE\_INFO Table

### Description

The table is not a standard Information Schema table, and is a MariaDB extension.

The

QUERY\_CACHE\_INFO

table is created by the [QUERY\\_CACHE\\_INFO](#) plugin, and allows you to see the contents of the [query cache](#). It creates a table in the [information\\_schema](#) database that shows all queries that are in the cache. You must have the [PROCESS](#) privilege (see [GRANT](#)) to use this table.

It contains the following columns:

Column	Description
STATEMENT_SCHEMA	Database used when query was included
STATEMENT_TEXT	Query text
RESULT_BLOCKS_COUNT	Number of result blocks
RESULT_BLOCKS_SIZE	Size in bytes of result blocks
RESULT_BLOCKS_SIZE_USED	Size in bytes of used blocks
LIMIT	Added <a href="#">MariaDB 10.1.8</a> .
MAX_SORT_LENGTH	Added <a href="#">MariaDB 10.1.8</a> .
GROUP_CONCAT_MAX_LENGTH	Added <a href="#">MariaDB 10.1.8</a> .
CHARACTER_SET_CLIENT	Added <a href="#">MariaDB 10.1.8</a> .
CHARACTER_SET_RESULT	Added <a href="#">MariaDB 10.1.8</a> .
COLLATION	Added <a href="#">MariaDB 10.1.8</a> .
TIMEZONE	Added <a href="#">MariaDB 10.1.8</a> .
DEFAULT_WEEK_FORMAT	Added <a href="#">MariaDB 10.1.8</a> .
DIV_PRECISION_INCREMENT	Added <a href="#">MariaDB 10.1.8</a> .

SQL_MODE	Added <a href="#">MariaDB 10.1.8</a> .
LC_TIME_NAMES	Added <a href="#">MariaDB 10.1.8</a> .
CLIENT_LONG_FLAG	Added <a href="#">MariaDB 10.1.8</a> .
CLIENT_PROTOCOL_41	Added <a href="#">MariaDB 10.1.8</a> .
PROTOCOL_TYPE	Added <a href="#">MariaDB 10.1.8</a> .
MORE_RESULTS_EXISTS	Added <a href="#">MariaDB 10.1.8</a> .
IN_TRANS	Added <a href="#">MariaDB 10.1.8</a> .
AUTOCOMMIT	Added <a href="#">MariaDB 10.1.8</a> .
PACKET_NUMBER	Added <a href="#">MariaDB 10.1.8</a> .
HITS	Incremented each time the query cache is hit. Added <a href="#">MariaDB 10.3.2</a> .

For example:

```
SELECT * FROM information_schema.QUERY_CACHE_INFO;
+-----+-----+-----+-----+-----+
| STATEMENT_SCHEMA | STATEMENT_TEXT | RESULT_BLOCKS_COUNT | RESULT_BLOCKS_SIZE | RESULT_BLOCKS_SIZE_USED |
+-----+-----+-----+-----+-----+
...
| test           | SELECT * FROM a |          1 |        512 |         143 |
| test           | select * FROM a |          1 |        512 |         143 |
...
+-----+-----+-----+-----+
```

## 1.1.2.9.1.1.36 Information Schema QUERY\_RESPONSE\_TIME Table

### Description

The [Information Schema](#)

`QUERY_RESPONSE_TIME`

table contains information about queries that take a long time to execute . It is only available if the `QUERY_RESPONSE_TIME` plugin has been installed.

It contains the following columns:

Column	Description
TIME	Time interval
COUNT	Count of queries falling into the time interval

TOTAL	Total execution time of all queries for this interval
-------	---

See [QUERY\\_RESPONSE\\_TIME](#) plugin for a full description.

The table is not a standard Information Schema table, and is a MariaDB extension.

```
SHOW QUERY_RESPONSE_TIME
is available from MariaDB 10.1.1 as an alternative for retrieving the data.
```

## Example

```
SELECT * FROM information_schema.QUERY_RESPONSE_TIME;
+-----+-----+-----+
| TIME | COUNT | TOTAL |
+-----+-----+-----+
| 0.000001 | 0 | 0.000000 |
| 0.000010 | 17 | 0.000094 |
| 0.000100 | 4301 | 0.236555 |
| 0.001000 | 1499 | 0.824450 |
| 0.010000 | 14851 | 81.680502 |
| 0.100000 | 8066 | 443.635693 |
| 1.000000 | 0 | 0.000000 |
| 10.000000 | 0 | 0.000000 |
| 100.000000 | 1 | 55.937094 |
| 1000.000000 | 0 | 0.000000 |
| 10000.000000 | 0 | 0.000000 |
| 100000.000000 | 0 | 0.000000 |
| 1000000.000000 | 0 | 0.000000 |
| TOO LONG | 0 | TOO LONG |
+-----+-----+-----+
```

## 1.1.2.9.1.1.37 Information Schema REFERENTIAL\_CONSTRAINTS Table

The [Information Schema](#)

`REFERENTIAL_CONSTRAINTS`  
table contains information about [foreign keys](#). The single columns are listed in the

[KEY\\_COLUMN\\_USAGE](#)

table.

It has the following columns:

Column	Description
CONSTRAINT_CATALOG	Always def .
CONSTRAINT_SCHEMA	Database name, together with CONSTRAINT_NAME identifies the foreign key.
CONSTRAINT_NAME	Foreign key name, together with CONSTRAINT_SCHEMA identifies the foreign key.
UNIQUE_CONSTRAINT_CATALOG	Always def .
UNIQUE_CONSTRAINT_SCHEMA	Database name, together with UNIQUE_CONSTRAINT_NAME and REFERENCED_TABLE_NAME identifies the referenced key.

UNIQUE_CONSTRAINT_NAME	Referenced key name, together with UNIQUE_CONSTRAINT_SCHEMA and REFERENCED_TABLE_NAME identifies the referenced key.
MATCH_OPTION	Always NONE
UPDATE_RULE	The Update Rule; one of CASCADED , SET NULL , SET DEFAULT , RESTRICT , NO ACTION
DELETE_RULE	The Delete Rule; one of CASCADED , SET NULL , SET DEFAULT , RESTRICT , NO ACTION
TABLE_NAME	Table name from the TABLE_CONSTRAINTS table.
REFERENCED_TABLE_NAME	Referenced key table name, together with UNIQUE_CONSTRAINT_SCHEMA and UNIQUE_CONSTRAINT_NAME identifies the referenced key.

## 1.1.2.9.1.1.38 Information Schema ROUTINES Table

The [Information Schema](#)

[ROUTINES](#)  
table stores information about [stored procedures](#) and [stored functions](#).

It contains the following columns:

Column	Description
SPECIFIC_NAME	
ROUTINE_CATALOG	Always def
ROUTINE_SCHEMA	Database name associated with the routine.
ROUTINE_NAME	Name of the routine.
ROUTINE_TYPE	Whether the routine is a PROCEDURE or a FUNCTION

DATA_TYPE	The return value's <a href="#">data type</a> (for stored functions).
CHARACTER_MAXIMUM_LENGTH	Maximum length.
CHARACTER_OCTET_LENGTH	Same as the CHARACTER_MAXIMUM_LENGTH except for multi-byte <a href="#">character sets</a> .
NUMERIC_PRECISION	For numeric types, the precision (number of significant digits) for the column. NULL if not a numeric field.
NUMERIC_SCALE	For numeric types, the scale (significant digits to the right of the decimal point). NULL if not a numeric field.
DATETIME_PRECISION	Fractional-seconds precision, or NULL if not a <a href="#">time data type</a> .
CHARACTER_SET_NAME	<a href="#">Character set</a> if a non-binary <a href="#">string data type</a> , otherwise NULL
COLLATION_NAME	<a href="#">Collation</a> if a non-binary <a href="#">string data type</a> , otherwise NULL.
DATA_TYPE	The column's <a href="#">data type</a> .
ROUTINE_BODY	Always SQL
ROUTINE_DEFINITION	Definition of the routine.
EXTERNAL_NAME	Always NULL
EXTERNAL_LANGUAGE	Always SQL
PARAMETER_STYLE	Always SQL
IS_DETERMINISTIC	Whether the routine is deterministic (can produce only one result for a given list of parameters) or not.
SQL_DATA_ACCESS	One of READS SQL DATA ,MODIFIES SQL DATA ,CONTAINS SQL , OR NO SQL
SQL_PATH	Always NULL

SECURITY_TYPE	INVOKER or DEFINER . Indicates which user's privileges apply to this routine.
CREATED	Date and time the routine was created.
LAST_ALTERED	Date and time the routine was last changed.
SQL_MODE	The  <a href="#">SQL_MODE</a>  at the time the routine was created.
ROUTINE_COMMENT	Comment associated with the routine.
DEFINER	If the  SECURITY_TYPE is DEFINER , this value indicates which user defined this routine.
CHARACTER_SET_CLIENT	The <a href="#">character set</a> used by the client that created the routine.
COLLATION_CONNECTION	The <a href="#">collation</a> (and character set) used by the connection that created the routine.
DATABASE_COLLATION	The default <a href="#">collation</a> (and character set) for the database, at the time the routine was created.

It provides information similar to, but more complete, than the

[SHOW PROCEDURE STATUS](#)

and

[SHOW FUNCTION STATUS](#)

statements.

For information about the parameters accepted by the routine, you can query the

[information\\_schema.PARAMETERS](#)

table.

## See also

- [Stored Function Overview](#)
- [Stored Procedure Overview](#)

## 1.1.2.9.1.1.39 Information Schema SCHEMA\_PRIVILEGES Table

The [Information Schema](#)

[SCHEMA\\_PRIVILEGES](#)

table contains information about [database privileges](#).

It contains the following columns:

Column	Description
--------	-------------

GRANTEE	Account granted the privilege in the format user_name@host_name
TABLE_CATALOG	Always def
TABLE_SCHEMA	Database name.
PRIVILEGE_TYPE	The granted privilege.
IS_GRANTABLE	Whether the privilege can be granted.

The same information in a different format can be found in the

[mysql.db](#)

table.

## 1.1.2.9.1.1.40 Information Schema SCHEMATA Table

The [Information Schema](#)

SCHEMATA

table stores information about databases on the server.

It contains the following columns:

Column	Description
CATALOG_NAME	Always def
SCHEMA_NAME	Database name.
DEFAULT_CHARACTER_SET_NAME	Default <a href="#">character set</a> for the database.
DEFAULT_COLLATION_NAME	Default <a href="#">collation</a> .
SQL_PATH	Always NULL
SCHEMA_COMMENT	Database comment. From <a href="#">MariaDB 10.5.0</a> .

## Example

```

SELECT * FROM INFORMATION_SCHEMA.SCHEMATA\G
*****
1. row *****
  CATALOG_NAME: def
    SCHEMA_NAME: information_schema
DEFAULT_CHARACTER_SET_NAME: utf8
  DEFAULT_COLLATION_NAME: utf8_general_ci
    SQL_PATH: NULL
*****
2. row *****
  CATALOG_NAME: def
    SCHEMA_NAME: mysql
DEFAULT_CHARACTER_SET_NAME: latin1
  DEFAULT_COLLATION_NAME: latin1_swedish_ci
    SQL_PATH: NULL
*****
3. row *****
  CATALOG_NAME: def
    SCHEMA_NAME: performance_schema
DEFAULT_CHARACTER_SET_NAME: utf8
  DEFAULT_COLLATION_NAME: utf8_general_ci
    SQL_PATH: NULL
*****
4. row *****
  CATALOG_NAME: def
    SCHEMA_NAME: test
DEFAULT_CHARACTER_SET_NAME: latin1
  DEFAULT_COLLATION_NAME: latin1_swedish_ci
    SQL_PATH: NULL
...

```

From MariaDB 10.5.0 :

```

SELECT * FROM INFORMATION_SCHEMA.SCHEMATA\G
...
*****
2. row *****
  CATALOG_NAME: def
    SCHEMA_NAME: presentations
DEFAULT_CHARACTER_SET_NAME: latin1
  DEFAULT_COLLATION_NAME: latin1_swedish_ci
    SQL_PATH: NULL
    SCHEMA_COMMENT: Presentations for conferences
...

```

## See Also

## 1.1.2.9.1.1.41 Information Schema SPATIAL\_REF\_SYS Table

MariaDB starting with [10.1.2](#)

The

SPATIAL\_REF\_SYS  
table was introduced in [MariaDB 10.1.2](#)

## Description

The [Information Schema](#)

SPATIAL\_REF\_SYS  
table stores information on each spatial reference system used in the database.

It contains the following columns:

Column	Type	Null	Description
--------	------	------	-------------

SRID	smallint(5)	NO	An integer value that uniquely identifies each Spatial Reference System within a database.
AUTH_NAME	varchar(512)	NO	The name of the standard or standards body that is being cited for this reference system.
AUTH_SRID	smallint(5)	NO	The numeric ID of the coordinate system in the above authority's catalog.
SRTEXT	varchar(2048)	NO	The <a href="#">Well-known Text Representation</a> of the Spatial Reference System.

Note: See [MDEV-7540](#).

## See also

- [information\\_schema.GEOMETRY\\_COLUMNS](#) table.

## 1.1.2.9.1.1.42 Information Schema SPIDER\_ALLOC\_MEM Table

The [Information Schema](#)

`SPIDER_ALLOC_MEM`

table is installed along with the [Spider](#) storage engine. It shows information about Spider's memory usage.

It contains the following columns:

Column	Description
ID	
FUNC_NAME	
FILE_NAME	
LINE_NO	
TOTAL_ALLOC_MEM	
CURRENT_ALLOC_MEM	
ALLOC_MEM_COUNT	
FREE_MEM_COUNT	

## 1.1.2.9.1.1.43 Information Schema

## SPIDER\_WRAPPER\_PROTOCOLS Table

MariaDB starting with [10.5.4](#)

The [Information Schema](#)

SPIDER\_WRAPPER\_PROTOCOLS  
table is installed along with the [Spider](#) storage engine from [MariaDB 10.5.4](#).

It contains the following columns:

Column	Type	Description
WRAPPER_NAME	varchar(64)	
WRAPPER_VERSION	varchar(20)	
WRAPPER_DESCRIPTION	longtext	
WRAPPER_MATURITY	varchar(12)	

## 1.1.2.9.1.1.44 Information Schema SQL\_FUNCTIONS Table

MariaDB starting with [10.6.3](#)

The

[SQL\\_FUNCTIONS](#)  
table was added in [MariaDB 10.6.3](#).

### Description

The [Information Schema](#)

[SQL\\_FUNCTIONS](#)  
table contains the list of [MariaDB functions](#).

It contains a single column:

Column	Description
FUNCTION	Function name

The table is not a standard Information Schema table, and is a MariaDB extension.

### Example

```
SELECT * FROM INFORMATION_SCHEMA.SQL_FUNCTIONS;
+-----+
| FUNCTION |
+-----+
| ADDDATE |
| ADD_MONTHS |
| BIT_AND |
| BIT_OR |
| BIT_XOR |
| CAST |
| COUNT |
| CUME_DIST |
| CURDATE |
| CURTIME |
| DATE_ADD |
```

```
| DATE_SUB  
| DATE_FORMAT  
| DECODE  
| DENSE_RANK  
| EXTRACT  
| FIRST_VALUE  
| GROUP_CONCAT  
| JSON_ARRAYAGG  
| JSON_OBJECTAGG  
| LAG  
| LEAD  
| MAX  
| MEDIAN  
| MID  
| MIN  
| NOW  
| NTH_VALUE

## See Also

- [Reserved Words](#)

## 1.1.2.9.1.1.45 Information Schema STATISTICS Table

The [Information Schema](#)

STATISTICS

table provides information about table indexes.

It contains the following columns:

Column	Description
TABLE_CATALOG	Always def
TABLE_SCHEMA	Database name.
TABLE_NAME	Table name.
NON_UNIQUE	1 if the index can have duplicates, 0 if not.
INDEX_SCHEMA	Database name.
INDEX_NAME	Index name. The primary key is always named PRIMARY
SEQ_IN_INDEX	The column sequence number, starting at 1.
COLUMN_NAME	Column name.
COLLATION	A for sorted in ascending order, or NULL for unsorted.
CARDINALITY	Estimate of the number of unique values stored in the index based on statistics stored as integers. Higher cardinalities usually mean a greater chance of the index being used in a join. Updated by the <a href="#">ANALYZE TABLE</a> statement or <a href="#">myisamchk -a</a> .
SUB_PART	NULL if the whole column is indexed, or the number of indexed characters if partly indexed.
PACKED	NULL if not packed, otherwise how the index is packed.
NULLABLE	YES if the column may contain NULLs, empty string if not.

INDEX_TYPE	Index type, one of BTREE , RTREE , HASH or FULLTEXT . See <a href="#">Storage Engine Index Types</a> .
COMMENT	Index comments from the <code>CREATE INDEX</code> statement.
IGNORED	Whether or not an index will be ignored by the optimizer. See <a href="#">Ignored Indexes</a> . From <a href="#">MariaDB 10.6.0</a> .

The

`SHOW INDEX`

statement produces similar output.

## Example

```
SELECT * FROM INFORMATION_SCHEMA.STATISTICS\G
...
***** 85. row *****
TABLE_CATALOG: def
TABLE_SCHEMA: test
TABLE_NAME: table1
NON_UNIQUE: 1
INDEX_SCHEMA: test
INDEX_NAME: col2
SEQ_IN_INDEX: 1
COLUMN_NAME: col2
COLLATION: A
CARDINALITY: 6
SUB_PART: NULL
PACKED: NULL
NULLABLE:
INDEX_TYPE: BTREE
COMMENT:
INDEX_COMMENT:
...
```

## 1.1.2.9.1.1.46 Information Schema SYSTEM\_VARIABLES Table

MariaDB starting with [10.1.1](#)

The

`information_schema.SYSTEM_VARIABLES`  
table was introduced in [MariaDB 10.1.1](#)

The [Information Schema](#)

`SYSTEM_VARIABLES`  
table shows current values and various metadata of all [system variables](#).

It contains the following columns:

Column	Description
VARIABLE_NAME	System variable name.

SESSION_VALUE	Session value of the variable or NULL if the variable only has a global scope.
GLOBAL_VALUE	Global value of the variable or NULL if the variable only has a session scope.
GLOBAL_VALUE_ORIGIN	How the global value was set — a compile-time default, auto-configured by the server, configuration file (or a command line), with the SQL statement.
DEFAULT_VALUE	Compile-time default value of the variable.
VARIABLE_SCOPE	Global, session, or session-only.
VARIABLE_TYPE	Data type of the variable value.
VARIABLE_COMMENT	Help text, usually shown in <pre>mysqld --help --verbose</pre> .
NUMERIC_MIN_VALUE	For numeric variables — minimal allowed value.
NUMERIC_MAX_VALUE	For numeric variables — maximal allowed value.
NUMERIC_BLOCK_SIZE	For numeric variables — a valid value must be a multiple of the "block size".
ENUM_VALUE_LIST	For <pre>ENUM , SET , and FLAGSET</pre> variables — the list of recognized values.
READ_ONLY	Whether a variable can be set with the SQL statement. Note that many "read only" variables can still be set on the command line.
COMMAND_LINE_ARGUMENT	Whether an argument is required when setting the variable on the command line. <pre>NULL when a variable can not be set on the command line.</pre>
GLOBAL_VALUE_PATH	Which config file the variable got its value from. <pre>NULL if not set in any config file. Added in MariaDB 10.5.0 .</pre>

## Example

```

SELECT * FROM information_schema.SYSTEM_VARIABLES
WHERE VARIABLE_NAME='JOIN_BUFFER_SIZE'\G
***** 1. row *****
VARIABLE_NAME: JOIN_BUFFER_SIZE
SESSION_VALUE: 131072
GLOBAL_VALUE: 131072
GLOBAL_VALUE_ORIGIN: COMPILE-TIME
DEFAULT_VALUE: 131072
VARIABLE_SCOPE: SESSION
VARIABLE_TYPE: BIGINT UNSIGNED
VARIABLE_COMMENT: The size of the buffer that is used for joins
NUMERIC_MIN_VALUE: 128
NUMERIC_MAX_VALUE: 18446744073709551615
NUMERIC_BLOCK_SIZE: 128
ENUM_VALUE_LIST: NULL
READ_ONLY: NO
COMMAND_LINE_ARGUMENT: REQUIRED

```

## 1.1.2.9.1.1.47 Information Schema TABLE\_CONSTRAINTS Table

The [Information Schema](#)

TABLE\_CONSTRAINTS

table contains information about tables that have [constraints](#).

It has the following columns:

Column	Description
CONSTRAINT_CATALOG	Always def
CONSTRAINT_SCHEMA	Database name containing the constraint.
CONSTRAINT_NAME	Constraint name.
TABLE_SCHEMA	Database name.
TABLE_NAME	Table name.
CONSTRAINT_TYPE	Type of constraint; one of UNIQUE , PRIMARY KEY , FOREIGN KEY or CHECK

The [REFERENTIAL\\_CONSTRAINTS](#) table has more information about foreign keys.

## 1.1.2.9.1.1.48 Information Schema TABLE\_PRIVILEGES Table

The [Information Schema](#)

TABLE\_PRIVILEGES

table contains table privilege information derived from the

[mysql.tables\\_priv](#)

grant table.

It has the following columns:

Column	Description
GRANTEE	In the format user_name@host_name
TABLE_CATALOG	Always def
TABLE_SCHEMA	Database name.
TABLE_NAME	Table name.
PRIVILEGE_TYPE	One of SELECT ,, INSERT ,, UPDATE ,, REFERENCES ,, ALTER ,, INDEX ,, DROP or CREATE VIEW
IS_GRANTABLE	Whether the user has the  <a href="#">GRANT OPTION</a>  for this privilege.

Similar information can be accessed with the

[SHOW GRANTS](#)

statement. See the

[GRANT](#)

article for more about privileges.

For a description of the privileges that are shown in this table, see [table privileges](#).

## 1.1.2.9.1.1.49 Information Schema TABLE\_STATISTICS Table

The [Information Schema](#)

`TABLE_STATISTICS`

table shows statistics on table usage.

This is part of the [User Statistics](#) feature, which is not enabled by default.

It contains the following columns:

Field	Type	Notes
TABLE_SCHEMA	varchar(192)	The schema (database) name.

TABLE_NAME	varchar(192)	The table name.
ROWS_READ	int(21)	The number of rows read from the table.
ROWS_CHANGED	int(21)	The number of rows changed in the table.
ROWS_CHANGED_X_INDEXES	int(21)	The number of rows changed in the table, multiplied by the number of indexes changed.

## Example

```
SELECT * FROM INFORMATION_SCHEMA.TABLE_STATISTICS WHERE TABLE_NAME='user';
+-----+-----+-----+-----+
| TABLE_SCHEMA | TABLE_NAME | ROWS_READ | ROWS_CHANGED | ROWS_CHANGED_X_INDEXES |
+-----+-----+-----+-----+
| mysql        | user       |      5 |          2 |                  2 |
+-----+-----+-----+-----+
```

## 1.1.2.9.1.1.50 Information Schema TABLES Table

### Contents

1. [Examples](#)
  1. [View Tables in Order of Size](#)
  2. [See Also](#)

The [Information Schema](#) table shows information about the various non-

TEMPORARY  
tables (except tables from the  
Information Schema  
database) and [views](#) on the server.

It contains the following columns:

Column	Description
TABLE_CATALOG	Always def .
TABLE_SCHEMA	Database name.
TABLE_NAME	Table name.
TABLE_TYPE	One of BASE TABLE for a regular table, VIEW for a <a href="#">view</a> , SYSTEM VIEW for <a href="#">Information Schema</a> tables, SYSTEM VERSIONED for <a href="#">system-versioned tables</a> or SEQUENCE for <a href="#">sequences</a> .

ENGINE	<a href="#">Storage Engine</a> .
VERSION	Version number from the table's .frm file
ROW_FORMAT	Row format (see <a href="#">InnoDB</a> , <a href="#">Aria</a> and <a href="#">MyISAM</a> row formats).
TABLE_ROWS	Number of rows in the table. Some engines, such as <a href="#">XtraDB</a> and <a href="#">InnoDB</a> may store an estimate.
AVG_ROW_LENGTH	Average row length in the table.
DATA_LENGTH	For <a href="#">InnoDB/XtraDB</a> , the index size, in pages, multiplied by the page size. For <a href="#">Aria</a> and <a href="#">MyISAM</a> , length of the data file, in bytes. For <a href="#">MEMORY</a> , the approximate allocated memory.
MAX_DATA_LENGTH	Maximum length of the data file, ie the total number of bytes that could be stored in the table. Not used in <a href="#">XtraDB</a> and <a href="#">InnoDB</a> .
INDEX_LENGTH	Length of the index file.
DATA_FREE	Bytes allocated but unused. For <a href="#">InnoDB</a> tables in a shared tablespace, the free space of the shared tablespace with small safety margin. An estimate in the case of partitioned tables - see the <a href="#">PARTITIONS</a> table.
AUTO_INCREMENT	Next <a href="#">AUTO_INCREMENT</a> value.
CREATE_TIME	Time the table was created.
UPDATE_TIME	Time the table was last updated. On Windows, the timestamp is not updated on update, so MyISAM values will be inaccurate. In <a href="#">InnoDB</a> , if shared tablespaces are used, will be NULL, while buffering can also delay the update, so the value will differ from the actual time of the last <a href="#">UPDATE</a> , <a href="#">INSERT</a> or <a href="#">DELETE</a>
CHECK_TIME	Time the table was last checked. Not kept by all storage engines, in which case will be NULL
TABLE_COLLATION	<a href="#">Character set and collation</a> .

CHECKSUM	Live checksum value, if any.
CREATE_OPTIONS	Extra CREATE TABLE options.
TABLE_COMMENT	Table comment provided when MariaDB created the table.
MAX_INDEX_LENGTH	Maximum index length (supported by MyISAM and Aria tables). Added in <a href="#">MariaDB 10.3.5</a> .
TEMPORARY	Placeholder to signal that a table is a temporary table. Currently always "N", except "Y" for generated information_schema tables and NULL for <a href="#">views</a> . Added in <a href="#">MariaDB 10.3.5</a> .

Although the table is standard in the Information Schema, all but

```
TABLE_CATALOG
,
TABLE_SCHEMA
,
TABLE_NAME
,
TABLE_TYPE
,
ENGINE
and
VERSION
are MySQL and MariaDB extensions.
```

[SHOW TABLES](#) lists all tables in a database.

## Examples

From [MariaDB 10.3.5](#):

```

SELECT * FROM information_schema.tables WHERE table_schema='test'\G
***** 1. row *****
TABLE_CATALOG: def
TABLE_SCHEMA: test
TABLE_NAME: xx5
TABLE_TYPE: BASE TABLE
ENGINE: InnoDB
VERSION: 10
ROW_FORMAT: Dynamic
TABLE_ROWS: 0
AVG_ROW_LENGTH: 0
DATA_LENGTH: 16384
MAX_DATA_LENGTH: 0
INDEX_LENGTH: 0
DATA_FREE: 0
AUTO_INCREMENT: NULL
CREATE_TIME: 2020-11-18 15:57:10
UPDATE_TIME: NULL
CHECK_TIME: NULL
TABLE_COLLATION: latin1_swedish_ci
CHECKSUM: NULL
CREATE_OPTIONS:
TABLE_COMMENT:
MAX_INDEX_LENGTH: 0
TEMPORARY: N
***** 2. row *****
TABLE_CATALOG: def
TABLE_SCHEMA: test
TABLE_NAME: xx4
TABLE_TYPE: BASE TABLE
ENGINE: MyISAM
VERSION: 10
ROW_FORMAT: Fixed
TABLE_ROWS: 0
AVG_ROW_LENGTH: 0
DATA_LENGTH: 0
MAX_DATA_LENGTH: 1970324836974591
INDEX_LENGTH: 1024
DATA_FREE: 0
AUTO_INCREMENT: NULL
CREATE_TIME: 2020-11-18 15:56:57
UPDATE_TIME: 2020-11-18 15:56:57
CHECK_TIME: NULL
TABLE_COLLATION: latin1_swedish_ci
CHECKSUM: NULL
CREATE_OPTIONS:
TABLE_COMMENT:
MAX_INDEX_LENGTH: 17179868160
TEMPORARY: N
...

```

Example with temporary = 'y', from [MariaDB 10.3.5](#) :

```

SELECT * FROM information_schema.tables WHERE temporary='y'\G
*****
1. row ****
TABLE_CATALOG: def
TABLE_SCHEMA: information_schema
TABLE_NAME: INNODB_FT_DELETED
TABLE_TYPE: SYSTEM VIEW
ENGINE: MEMORY
VERSION: 11
ROW_FORMAT: Fixed
TABLE_ROWS: NULL
AVG_ROW_LENGTH: 9
DATA_LENGTH: 0
MAX_DATA_LENGTH: 9437184
INDEX_LENGTH: 0
DATA_FREE: 0
AUTO_INCREMENT: NULL
CREATE_TIME: 2020-11-17 21:54:02
UPDATE_TIME: NULL
CHECK_TIME: NULL
TABLE_COLLATION: utf8_general_ci
CHECKSUM: NULL
CREATE_OPTIONS: max_rows=1864135
TABLE_COMMENT:
MAX_INDEX_LENGTH: 0
TEMPORARY: Y
...

```

## View Tables in Order of Size

Returns a list of all tables in the database, ordered by size:

```

SELECT table_schema AS `DB`, table_name AS `Table`,
ROUND(((data_length + index_length) / 1024 / 1024), 2) `Size (MB)`
FROM information_schema.TABLES
ORDER BY (data_length + index_length) DESC;

```

DB	Table	Size (MB)
wordpress	wp_simple_history_contexts	7.05
wordpress	wp_posts	6.59
wordpress	wp_simple_history	3.05
wordpress	wp_comments	2.73
wordpress	wp_commentmeta	2.47
wordpress	wp_simple_login_log	2.03
...		

## See Also

- [mysqlshow](#)
- [SHOW TABLE STATUS](#)
- [Finding Tables Without Primary Keys](#)

## 1.1.2.9.1.1.51 Information Schema TABLESPACES Table

The [Information Schema](#)

```

TABLESPACES
table contains information about active tablespaces..

```

The table is a MariaDB and MySQL extension, and does not include information about InnoDB tablespaces.

Column	Description
TABLESPACE_NAME	
ENGINE	

TABLESPACE_TYPE	
LOGFILE_GROUP_NAME	
EXTENT_SIZE	
AUTOEXTEND_SIZE	
MAXIMUM_SIZE	
NODEGROUP_ID	
TABLESPACE_COMMENT	

## 1.1.2.9.1.1.52 Information Schema THREAD\_POOL\_GROUPS Table

MariaDB starting with 10.5

The [Information Schema](#)

THREAD\_POOL\_GROUPS  
table was introduced in [MariaDB 10.5.0](#).

The table provides information about [thread pool](#) groups, and contains the following columns:

Column	Description
GROUP_ID	
CONNECTIONS	
THREADS	
ACTIVE_THREADS	
STANDBY_THREADS	
QUEUE_LENGTH	
HAS_LISTENER	
IS_STALLED	

Setting [thread\\_pool\\_dedicated\\_listener](#) will give each group its own dedicated listener, and the listener thread will not pick up work items. As a result, the actual queue size in the table will be more exact, since IO requests are immediately dequeued from poll, without delay.

## 1.1.2.9.1.1.53 Information Schema THREAD\_POOL\_STATS Table

MariaDB starting with [10.5](#)

The [Information Schema](#)

THREAD\_POOL\_STATS

table was introduced in [MariaDB 10.5.0](#).

The table provides performance counter information for the [thread pool](#), and contains the following columns:

Column	Description
GROUP_ID	
THREAD_CREATATIONS	
THREAD_CREATATIONS_DUE_TO_STALL	
WAKES	
WAKES_DUE_TO_STALL	
THROTTLES	
STALLS	
POLLS_BY_LISTENER	
POLLS_BY_WORKER	
DEQUEUES_BY_LISTENER	
DEQUEUES_BY_WORKER	

## 1.1.2.9.1.1.54 Information Schema THREAD\_POOL\_WAITS Table

MariaDB starting with [10.5](#)

The [Information Schema](#)

THREAD\_POOL\_WAITS

table was introduced in [MariaDB 10.5.0](#).

The table provides wait counters for the [thread pool](#), and contains the following columns:

Column	Description
REASON	

COUNT	
-------	--

## 1.1.2.9.1.1.55 Information Schema TRIGGERS Table

### Contents

1. See also

The [Information Schema](#)

TRIGGERS  
table contains information about [triggers](#).

It has the following columns:

Column	Description
TRIGGER_CATALOG	Always def
TRIGGER_SCHEMA	Database name in which the trigger occurs.
TRIGGER_NAME	Name of the trigger.
EVENT_MANIPULATION	The event that activates the trigger. One of INSERT , UPDATE or 'DELETE'
EVENT_OBJECT_CATALOG	Always def
EVENT_OBJECT_SCHEMA	Database name on which the trigger acts.
EVENT_OBJECT_TABLE	Table name on which the trigger acts.
ACTION_ORDER	Indicates the order that the action will be performed in (of the list of a table's triggers with identical EVENT_MANIPULATION and ACTION_TIMING values). Before MariaDB 10.2.3 introduced the <a href="#">FOLLOWS</a> and <a href="#">PRECEDES clauses</a> , always 0
ACTION_CONDITION	NULL
ACTION_STATEMENT	Trigger body, UTF-8 encoded.
ACTION_ORIENTATION	Always ROW
ACTION_TIMING	Whether the trigger acts BEFORE or AFTER the event that triggers it.

ACTION_REFERENCE_OLD_TABLE	Always NULL
ACTION_REFERENCE_NEW_TABLE	Always NULL
ACTION_REFERENCE_OLD_ROW	Always OLD
ACTION_REFERENCE_NEW_ROW	Always NEW
CREATED	Always NULL
SQL_MODE	The <code>SQL_MODE</code> when the trigger was created, and which it uses for execution.
DEFINER	The account that created the trigger, in the form <code>user_name@host_name</code>
CHARACTER_SET_CLIENT	The client <code>character set</code> when the trigger was created, from the session value of the <code>character_set_client</code> system variable.
COLLATION_CONNECTION	The client <code>collation</code> when the trigger was created, from the session value of the <code>collation_connection</code> system variable.
DATABASE_COLLATION	<code>Collation</code> of the associated database.

Queries to the

`TRIGGERS`  
table will return information only for databases and tables for which you have the  
`TRIGGER` privilege. Similar information is returned by the

`SHOW TRIGGERS`

statement.

## See also

- [Trigger Overview](#)
- 

[CREATE TRIGGER](#)

•

[DROP TRIGGER](#)

•

[SHOW TRIGGERS](#)

```
SHOW CREATE TRIGGER
```

- Trigger Limitations

## 1.1.2.9.1.1.56 Information Schema USER\_PRIVILEGES Table

The [Information Schema](#)

USER\_PRIVILEGES

table contains global user privilege information derived from the

`mysql.user`

grant table.

It contains the following columns:

Column	Description
GRANTEE	In the format <code>user_name@host_name</code>
TABLE_CATALOG	Always def
PRIVILEGE_TYPE	The specific privilege, for example SELECT , INSERT , UPDATE or REFERENCES
IS_GRANTABLE	Whether the user has the <code>GRANT OPTION</code> for this privilege.

Similar information can be accessed with the

```
SHOW GRANTS
```

statement. See the

[GRANT](#)

article for more about privileges.

This information is also stored in the `user` table, in the

`mysql`

system database.

## 1.1.2.9.1.1.57 Information Schema USER\_STATISTICS Table

The [Information Schema](#)

USER\_STATISTICS

table holds statistics about user activity. This is part of the [User Statistics](#) feature, which is not enabled by default.

You can use this table to find out such things as which user is causing the most load and which users are being abusive. You can also use this table to measure how close to capacity the server may be.

It contains the following columns:

Field	Type	Notes
-------	------	-------

USER	varchar(48)	The username. The value '#mysql_system_user#' appears when there is no username (such as for the slave SQL thread).
TOTAL_CONNECTIONS	int(21)	The number of connections created for this user.
CONCURRENT_CONNECTIONS	int(21)	The number of concurrent connections for this user.
CONNECTED_TIME	int(21)	The cumulative number of seconds elapsed while there were connections from this user.
BUSY_TIME	double	The cumulative number of seconds there was activity on connections from this user.
CPU_TIME	double	The cumulative CPU time elapsed while servicing this user's connections.
BYTES_RECEIVED	int(21)	The number of bytes received from this user's connections.
BYTES_SENT	int(21)	The number of bytes sent to this user's connections.
BINLOG_BYTES_WRITTEN	int(21)	The number of bytes written to the <a href="#">binary log</a> from this user's connections.
ROWS_READ	int(21)	The number of rows read by this user's connections.
ROWS_SENT	int(21)	The number of rows sent by this user's connections.
ROWS_DELETED	int(21)	The number of rows deleted by this user's connections.
ROWS_INSERTED	int(21)	The number of rows inserted by this user's connections.
ROWS_UPDATED	int(21)	The number of rows updated by this user's connections.
SELECT_COMMANDS	int(21)	The number of <a href="#">SELECT</a> commands executed from this user's connections.
UPDATE_COMMANDS	int(21)	The number of <a href="#">UPDATE</a> commands executed from this user's connections.
OTHER_COMMANDS	int(21)	The number of other commands executed from this user's connections.
COMMIT_TRANSACTIONS	int(21)	The number of <a href="#">COMMIT</a> commands issued by this user's connections.

ROLLBACK_TRANSACTIONS	int(21)	The number of <a href="#">ROLLBACK</a> commands issued by this user's connections.
DENIED_CONNECTIONS	int(21)	The number of connections denied to this user.
LOST_CONNECTIONS	int(21)	The number of this user's connections that were terminated uncleanly.
ACCESS_DENIED	int(21)	The number of times this user's connections issued commands that were denied.
EMPTY_QUERIES	int(21)	The number of times this user's connections sent empty queries to the server.
TOTAL_SSL_CONNECTIONS	int(21)	The number of <a href="#">TLS connections</a> created for this user. (>= <a href="#">MariaDB 10.1.1</a> )
MAX_STATEMENT_TIME_EXCEEDED	int(21)	The number of times a statement was aborted, because it was executed longer than its <a href="#">MAX_STATEMENT_TIME</a> threshold. (>= <a href="#">MariaDB 10.1.1</a> )

## Example

```
SELECT * FROM information_schema.USER_STATISTICS\G
*****
1. row *****
    USER: root
    TOTAL_CONNECTIONS: 1
    CONCURRENT_CONNECTIONS: 0
    CONNECTED_TIME: 297
        BUSY_TIME: 0.001725

```

## 1.1.2.9.1.1.58 Information Schema USER\_VARIABLES Table

MariaDB 10.2.0

The

USER\_VARIABLES  
table was introduced in [MariaDB 10.2.0](#) as part of the

[user\\_variables](#)

plugin.

## Description

The

USER\_VARIABLES  
table is created when the

[user\\_variables](#)

plugin is enabled, and contains information about [user-defined variables](#).

The table contains the following columns:

Column	Description
VARIABLE_NAME	Variable name.
VARIABLE_VALUE	Variable value.
VARIABLE_TYPE	Variable <a href="#">type</a> .
CHARACTER_SET_NAME	<a href="#">Character set</a> .

## Example

```
SELECT * FROM information_schema.USER_VARIABLES ORDER BY VARIABLE_NAME;
+-----+-----+-----+-----+
| VARIABLE_NAME | VARIABLE_VALUE | VARIABLE_TYPE | CHARACTER_SET_NAME |
+-----+-----+-----+-----+
| var          | 0             | INT           | utf8            |
| var2         | abc           | VARCHAR       | utf8            |
+-----+-----+-----+-----+
```

## 1.1.2.9.1.1.59 Information Schema VIEWS Table

The [Information Schema](#)

VIEWS  
table contains information about [views](#). The  
SHOW VIEW  
[privilege](#) is required to view the table.

It has the following columns:

Column	Description	Added
TABLE_CATALOG	Aways def .	
TABLE_SCHEMA	Database name containing the view.	
TABLE_NAME	View table name.	
VIEW_DEFINITION	Definition of the view.	

CHECK_OPTION	YES if the WITH CHECK_OPTION clause has been specified, NO otherwise.	
IS_UPDATABLE	Whether the view is updatable or not.	
DEFINER	Account specified in the DEFINER clause (or the default when created).	
SECURITY_TYPE	SQL SECURITY characteristic, either DEFINER or INVOKER	
CHARACTER_SET_CLIENT	The client <a href="#">character set</a> when the view was created, from the session value of the <a href="#">character_set_client</a> system variable.	
COLLATION_CONNECTION	The client <a href="#">collation</a> when the view was created, from the session value of the <a href="#">collation_connection</a> system variable.	
ALGORITHM	The algorithm used in the view. See <a href="#">View Algorithms</a> .	MariaDB 10.1.3

## Example

```
SELECT * FROM information_schema.VIEWS\G
*****
1. row ****
  TABLE_CATALOG: def
  TABLE_SCHEMA: test
  TABLE_NAME: v
  VIEW_DEFINITION: select `test`.`t`.`qty` AS `qty`, `test`.`t`.`price` AS `price`,(`test`.`t`.`qty` * `test`.`t`.`price`) AS
  CHECK_OPTION: NONE
  IS_UPDATABLE: YES
  DEFINER: root@localhost
  SECURITY_TYPE: DEFINER
  CHARACTER_SET_CLIENT: utf8
  COLLATION_CONNECTION: utf8_general_ci
  ALGORITHM: UNDEFINED
```

SHOW CREATE VIEWS

## 1.1.2.9.1.1.60 Information Schema WSREP\_MEMBERSHIP Table

The

WSREP\_STATUS

table makes Galera node cluster membership information available through the [Information Schema](#). The same information can be returned using the `SHOW WSREP_MEMBERSHIP` statement. Only users with the `SUPER` can access information from this table.

The

WSREP\_MEMBERSHIP

table is part of the [WSREP\\_INFO plugin](#).

### Example

```
SELECT * FROM information_schema.WSREP_MEMBERSHIP;
+-----+-----+-----+
| INDEX | UUID           | NAME   | ADDRESS      |
+-----+-----+-----+
| 0    | 46da96e3-6e9e-11e4-95a2-f609aa5444b3 | node1  | 10.0.2.15:16000 |
| 1    | 5f6bc72a-6e9e-11e4-84ed-57ec6780a3d3 | node2  | 10.0.2.15:16001 |
| 2    | 7473fd75-6e9e-11e4-91de-0b541ad91bd0 | node3  | 10.0.2.15:16002 |
+-----+-----+-----+
```

## 1.1.2.9.1.1.61 Information Schema WSREP\_STATUS Table

The WSREP\_STATUS table makes Galera node cluster status information available through the [Information Schema](#). The same information can be returned using the `SHOW WSREP_STATUS` statement. Only users with the `SUPER` privilege can access information from this table.

The

WSREP\_STATUS

table is part of the [WSREP\\_INFO plugin](#).

### Example

```
SELECT * FROM information_schema.WSREP_STATUS\G
***** 1. row *****
  NODE_INDEX: 0
  NODE_STATUS: Synced
  CLUSTER_STATUS: Primary
  CLUSTER_SIZE: 3
  CLUSTER_STATE_UUID: 00b0fbad-6e84-11e4-8a8b-376f19ce8ee7
  CLUSTER_STATE_SEQNO: 2
  CLUSTER_CONF_ID: 3
  GAP: NO
  PROTOCOL_VERSION: 3
```

## 1.1.2.9.1.2 Extended SHOW

### 1.1.2.9.1.3 TIME\_MS column in INFORMATION\_SCHEMA.PROCESSLIST

In MariaDB, an extra column

TIME\_MS

has been added to the [INFORMATION\\_SCHEMA.PROCESSLIST](#) table. This column shows the same information as the column 'TIME', but in units of milliseconds with microsecond precision (the unit and precision of the TIME column is one second).

For details about microseconds support in MariaDB, see [microseconds in MariaDB](#).

The value displayed in the

TIME

and

TIME\_MS

columns is the period of time that the given thread has been in its current state. Thus it can be used to check for example how long a thread has been executing the current query, or for how long it has been idle.

```
select id, time, time_ms, command, state from
    information_schema.processlist, (select sleep(2)) t;
+----+----+----+----+
| id | time | time_ms | command | state   |
+----+----+----+----+
| 37 | 2   | 2000.493 | Query   | executing |
+----+----+----+----+
```

Note that as a difference to MySQL, in MariaDB the

TIME

column (and also the

TIME\_MS

column) are not affected by any setting of [@TIMESTAMP](#). This means that it can be reliably used also for threads that change [@TIMESTAMP](#) (such as the [replication](#) SQL thread). See also [MySQL Bug #22047](#).

As a consequence of this, the

TIME

column of

SHOW FULL PROCESSLIST

and

INFORMATION\_SCHEMA.PROCESSLIST

can not be used to determine if a slave is lagging behind. For this, use instead the

Seconds\_Behind\_Master

column in the output of [SHOW SLAVE STATUS](#).

The addition of the TIME\_MS column is based on the microsec\_process patch, developed by [Percona](#).

## 1.1.2.9.2 Performance Schema

### 1.1.2.9.2.1 Performance Schema Tables

#### 1.1.2.9.2.1.1 List of Performance Schema Tables

Below is a list of all [Performance Schema](#) tables as well as a brief description of each of them.

Table	Description
accounts	Client account connection statistics.
cond_instances	Synchronization object instances.
events_stages_current	Current stage events.
events_stages_history	Ten most recent stage events per thread.

<code>events_stages_history_long</code>	Ten thousand most recent stage events.
<code>events_stages_summary_by_account_by_event_name</code>	Summarized stage events per account and event name.
<code>events_stages_summary_by_host_by_event_name</code>	Summarized stage events per host and event name.
<code>events_stages_summary_by_thread_by_event_name</code>	Summarized stage events per thread and event name.
<code>events_stages_summary_by_user_by_event_name</code>	Summarized stage events per user name and event name.
<code>events_stages_summary_global_by_event_name</code>	Summarized stage events per event name.
<code>events_statements_current</code>	Current statement events.
<code>events_statements_history</code>	Ten most recent events per thread.
<code>events_statements_history_long</code>	Ten thousand most recent stage events.
<code>events_statements_summary_by_account_by_event_name</code>	Summarized statement events per account and event name.
<code>events_statements_summary_by_digest</code>	Summarized statement events by scheme and digest.
<code>events_statements_summary_by_host_by_event_name</code>	Summarized statement events by host and event name.

<code>events_statements_summary_by_program</code>	
<code>events_statements_summary_by_thread_by_event_name</code>	Summarized statement events by thread and event name.
<code>events_statements_summary_by_user_by_event_name</code>	Summarized statement events by user and event name.
<code>events_statements_summary_global_by_event_name</code>	Summarized statement events by event name.
<code>events_transactions_current</code>	Current transaction events for each thread.
<code>events_transactions_history</code>	Most recent completed transaction events for each thread.
<code>events_transactions_history_long</code>	Most recent completed transaction events that have ended globally.
<code>events_transactions_summary_by_account_by_event_name</code>	Transaction events aggregated by account and event.
<code>events_transactions_summary_by_host_by_event_name</code>	Transaction events aggregated by host and event..
<code>events_transactions_summary_by_thread_by_event_name</code>	Transaction events aggregated by thread and event..
<code>events_transactions_summary_by_user_by_event_name</code>	Transaction events aggregated by user and event..
<code>events_transactions_summary_global_by_event_name</code>	Transaction events aggregated by event name.

<code>events_waits_current</code>	Current wait events.
<code>events_waits_history</code>	Ten most recent wait events per thread.
<code>events_waits_history_long</code>	Ten thousand most recent wait events per thread.
<code>events_waits_summary_by_account_by_event_name</code>	Summarized wait events by account and event name.
<code>events_waits_summary_by_host_by_event_name</code>	Summarized wait events by host and event name.
<code>events_waits_summary_by_instance</code>	Summarized wait events by instance.
<code>events_waits_summary_by_thread_by_event_name</code>	Summarized wait events by thread and event name.
<code>events_waits_summary_by_user_by_event_name</code>	Summarized wait events by user and event name.
<code>events_waits_summary_global_by_event_name</code>	Summarized wait events by event name.
<code>file_instances</code>	Seen files.
<code>file_summary_by_event_name</code>	File events summarized by event name.
<code>file_summary_by_instance</code>	File events summarized by instance.

<code>global_status</code>	Global status variables and values.
<code>host_cache</code>	Host and IP information.
<code>hosts</code>	Connections by host.
<code>memory_summary_by_account_by_event_name</code>	Memory usage statistics aggregated by account and event.
<code>memory_summary_by_host_by_event_name</code>	Memory usage statistics aggregated by host. and event.
<code>memory_summary_by_thread_by_event_name</code>	Memory usage statistics aggregated by thread and event..
<code>memory_summary_by_user_by_event_name</code>	Memory usage statistics aggregated by user and event..
<code>memory_summary_global_by_event_name</code>	Memory usage statistics aggregated by event.
<code>metadata_locks</code>	<code>Metadata locks</code> .
<code>mutex_instances</code>	Seen mutexes.
<code>objects_summary_global_by_type</code>	Object wait events.
<code>performance_timers</code>	Available event timers.

<code>prepared_statements_instances</code>	Aggregate statistics of prepared statements.
<code>replication_applier_configuration</code>	Configuration settings affecting replica transactions.
<code>replication_applier_status</code>	General transaction execution status on the replica.
<code>replication_applier_status_by_coordinator</code>	Coordinator thread specific information.
<code>replication_applier_status_by_worker</code>	Replica worker thread specific information.
<code>replication_connection_configuration</code>	Replica's configuration settings used for connecting to the primary.
<code>rwlock_instances</code>	Seen read-write locks.
<code>session_account_connect_attrs</code>	Current session connection attributes.
<code>session_connect_attrs</code>	All session connection attributes.
<code>session_status</code>	Session status variables and values.
<code>setup_actors</code>	Details on foreground thread monitoring.
<code>setup_consumers</code>	Consumers for which event information is stored.

<code>setup_instruments</code>	Instrumented objects for which events are collected.
<code>setup_objects</code>	Objects to be monitored.
<code>setup_timers</code>	Currently selected event timers.
<code>socket_instances</code>	Active connections.
<code>socket_summary_by_event_name</code>	Timer and byte count statistics by socket instrument.
<code>socket_summary_by_instance</code>	Timer and byte count statistics by socket instance.
<code>status_by_thread</code>	Status variable info about active foreground threads.
<code>table_io_waits_summary_by_index_usage</code>	Aggregate table I/O wait events by index.
<code>table_io_waits_summary_by_table</code>	Aggregate table I/O wait events by table.
<code>table_lock_waits_summary_by_table</code>	Aggregate table lock wait events by table.
<code>threads</code>	Server thread information.
<code>users</code>	Connection statistics by user.

## 1.1.2.9.2.1.2 Performance Schema accounts Table

## Description

Each account that connects to the server is stored as a row in the accounts table, along with current and total connections.

The table size is determined at startup by the value of the [performance\\_schema\\_accounts\\_size](#) system variable. If this is set to 0, account statistics will be disabled.

Column	Description
USER	The connection's client user name for the connection, or NULL if an internal thread.
HOST	The connection client's host name, or NULL if an internal thread.
CURRENT_CONNECTIONS	Current connections for the account.
TOTAL_CONNECTIONS	Total connections for the account.

The

USER  
and  
HOST

values shown here are the username and host used for user connections, not the patterns used to check permissions.

## Example

```
SELECT * FROM performance_schema.accounts;
+-----+-----+-----+-----+
| USER      | HOST     | CURRENT_CONNECTIONS | TOTAL_CONNECTIONS |
+-----+-----+-----+-----+
| root      | localhost |                1 |                 2 |
| NULL      | NULL      |               20 |                23 |
| debian-sys-maint | localhost |                0 |                35 |
+-----+-----+-----+-----+
```

## 1.1.2.9.2.1.3 Performance Schema cond\_instances Table

### Description

The

cond\_instances

table lists all conditions while the server is executing. A condition, or instrumented condition object, is an internal code mechanism used for signalling that a specific event has occurred so that any threads waiting for this condition can continue.

The maximum number of conditions stored in the performance schema is determined by the [performance\\_schema\\_max\\_cond\\_instances](#) system variable.

Column	Description
NAME	Client user name for the connection, or NULL if an internal thread.
OBJECT_INSTANCE_BEGIN	Address in memory of the instrumented condition.

## 1.1.2.9.2.1.4 Performance Schema events\_stages\_current Table

The

events\_stages\_current

table contains current stage events, with each row being a record of a thread and its most recent stage event.

The table contains the following columns:

Column	Description
THREAD_ID	Thread associated with the event. Together with EVENT_ID uniquely identifies the row.
EVENT_ID	Thread's current event number at the start of the event. Together with THREAD_ID uniquely identifies the row.
END_EVENT_ID	NULL when the event starts, set to the thread's current event number at the end of the event.
EVENT_NAME	Event instrument name and a NAME from the setup_instruments table
SOURCE	Name and line number of the source file containing the instrumented code that produced the event.
TIMER_START	Value in picoseconds when the event timing started or NULL if timing is not collected.
TIMER_END	Value in picoseconds when the event timing ended, or NULL if the event has not ended or timing is not collected.
TIMER_WAIT	Value in picoseconds of the event's duration or NULL if the event has not ended or timing is not collected.
NESTING_EVENT_ID	EVENT_ID of event within which this event nests.
NESTING_EVENT_TYPE	Nesting event type. One of transaction , statement , stage or wait .

It is possible to empty this table with a

```
TRUNCATE TABLE
statement.
```

The related tables, [events\\_stages\\_history](#) and [events\\_stages\\_history\\_long](#) derive their values from the current events.

## 1.1.2.9.2.1.5 Performance Schema events\_stages\_history Table

The

```
events_stages_history
```

table by default contains the ten most recent completed stage events per thread. This number can be adjusted by setting the [performance\\_schema\\_events\\_stages\\_history\\_size](#) system variable when the server starts up.

The table structure is identical to the [events\\_stage\\_current](#) table structure, and contains the following columns:

Column	Description
THREAD_ID	Thread associated with the event. Together with EVENT_ID uniquely identifies the row.
EVENT_ID	Thread's current event number at the start of the event. Together with THREAD_ID uniquely identifies the row.

END_EVENT_ID	NULL when the event starts, set to the thread's current event number at the end of the event.
EVENT_NAME	Event instrument name and a NAME from the setup_instruments table
SOURCE	Name and line number of the source file containing the instrumented code that produced the event.
TIMER_START	Value in picoseconds when the event timing started or NULL if timing is not collected.
TIMER_END	Value in picoseconds when the event timing ended, or NULL if timing is not collected.
TIMER_WAIT	Value in picoseconds of the event's duration or NULL if timing is not collected.
NESTING_EVENT_ID	EVENT_ID of event within which this event nests.
NESTING_EVENT_TYPE	Nesting event type. One of transaction , statement , stage or wait .

It is possible to empty this table with a

```
TRUNCATE TABLE
statement.
```

[events\\_stages\\_current](#) and [events\\_stages\\_history\\_long](#) are related tables.

## 1.1.2.9.2.1.6 Performance Schema [events\\_stages\\_history\\_long](#) Table

The

[events\\_stages\\_history\\_long](#)

table by default contains the ten thousand most recent completed stage events. This number can be adjusted by setting the [performance\\_schema\\_events\\_stages\\_history\\_long\\_size](#) system variable when the server starts up.

The table structure is identical to the

[events\\_stage\\_current](#)

table structure, and contains the following columns:

Column	Description
THREAD_ID	Thread associated with the event. Together with EVENT_ID uniquely identifies the row.
EVENT_ID	Thread's current event number at the start of the event. Together with THREAD_ID uniquely identifies the row.
END_EVENT_ID	NULL when the event starts, set to the thread's current event number at the end of the event.
EVENT_NAME	Event instrument name and a NAME from the setup_instruments table

SOURCE	Name and line number of the source file containing the instrumented code that produced the event.
TIMER_START	Value in picoseconds when the event timing started or NULL if timing is not collected.
TIMER_END	Value in picoseconds when the event timing ended, or NULL if timing is not collected.
TIMER_WAIT	Value in picoseconds of the event's duration or NULL if timing is not collected.
NESTING_EVENT_ID	EVENT_ID of event within which this event nests.
NESTING_EVENT_TYPE	Nesting event type. One of transaction ,
	statement ,
	stage or wait .

It is possible to empty this table with a

```
TRUNCATE TABLE
statement.
```

[events\\_stages\\_current](#) and [events\\_stages\\_history](#) are related tables.

## 1.1.2.9.2.1.7 Performance Schema `events_stages_summary_by_account_by_event_name` Table

The table lists stage events, summarized by account and event name.

It contains the following columns:

Column	Description
USER	User. Used together with HOST and EVENT_NAME for grouping events.
HOST	Host. Used together with USER and EVENT_NAME for grouping events.
EVENT_NAME	Event name. Used together with USER and HOST for grouping events.
COUNT_STAR	Number of summarized events, which includes all timed and untimed events.
SUM_TIMER_WAIT	Total wait time of the timed summarized events.
MIN_TIMER_WAIT	Minimum wait time of the timed summarized events.

AVG_TIMER_WAIT	Average wait time of the timed summarized events.
MAX_TIMER_WAIT	Maximum wait time of the timed summarized events.

## Example

```

SELECT * FROM events_stages_summary_by_account_by_event_name\G
...
***** 325. row *****
    USER: NULL
    HOST: NULL
  EVENT_NAME: stage/sql/Waiting for event metadata lock
  COUNT_STAR: 0
SUM_TIMER_WAIT: 0
MIN_TIMER_WAIT: 0
AVG_TIMER_WAIT: 0
MAX_TIMER_WAIT: 0
***** 326. row *****
    USER: NULL
    HOST: NULL
  EVENT_NAME: stage/sql/Waiting for commit lock
  COUNT_STAR: 0
SUM_TIMER_WAIT: 0
MIN_TIMER_WAIT: 0
AVG_TIMER_WAIT: 0
MAX_TIMER_WAIT: 0
***** 327. row *****
    USER: NULL
    HOST: NULL
  EVENT_NAME: stage/aria/Waiting for a resource
  COUNT_STAR: 0
SUM_TIMER_WAIT: 0
MIN_TIMER_WAIT: 0
AVG_TIMER_WAIT: 0
MAX_TIMER_WAIT: 0

```

### 1.1.2.9.2.1.8 Performance Schema events\_stages\_summary\_by\_host\_by\_event\_name Table

The table lists stage events, summarized by host and event name.

It contains the following columns:

Column	Description
HOST	Host. Used together with EVENT_NAME for grouping events.
EVENT_NAME	Event name. Used together with HOST for grouping events.
COUNT_STAR	Number of summarized events, which includes all timed and untimed events.
SUM_TIMER_WAIT	Total wait time of the timed summarized events.
MIN_TIMER_WAIT	Minimum wait time of the timed summarized events.
AVG_TIMER_WAIT	Average wait time of the timed summarized events.

MAX_TIMER_WAIT	Maximum wait time of the timed summarized events.
----------------	---

## Example

```

SELECT * FROM events_stages_summary_by_host_by_event_name\G
...
***** 216. row *****
HOST: NULL
EVENT_NAME: stage/sql/Waiting for event metadata lock
COUNT_STAR: 0
SUM_TIMER_WAIT: 0
MIN_TIMER_WAIT: 0
AVG_TIMER_WAIT: 0
MAX_TIMER_WAIT: 0
***** 217. row *****
HOST: NULL
EVENT_NAME: stage/sql/Waiting for commit lock
COUNT_STAR: 0
SUM_TIMER_WAIT: 0
MIN_TIMER_WAIT: 0
AVG_TIMER_WAIT: 0
MAX_TIMER_WAIT: 0
***** 218. row *****
HOST: NULL
EVENT_NAME: stage/aria/Waiting for a resource
COUNT_STAR: 0
SUM_TIMER_WAIT: 0
MIN_TIMER_WAIT: 0
AVG_TIMER_WAIT: 0
MAX_TIMER_WAIT: 0

```

### 1.1.2.9.2.1.9 Performance Schema events\_stages\_summary\_by\_thread\_by\_event\_name Table

The table lists stage events, summarized by thread and event name.

It contains the following columns:

Column	Description
THREAD_ID	Thread associated with the event. Together with EVENT_NAME uniquely identifies the row.
EVENT_NAME	Event name. Used together with THREAD_ID for grouping events.
COUNT_STAR	Number of summarized events, which includes all timed and untimed events.
SUM_TIMER_WAIT	Total wait time of the timed summarized events.
MIN_TIMER_WAIT	Minimum wait time of the timed summarized events.
AVG_TIMER_WAIT	Average wait time of the timed summarized events.
MAX_TIMER_WAIT	Maximum wait time of the timed summarized events.

## Example

```
SELECT * FROM events_stages_summary_by_thread_by_event_name\G
...
***** 2287. row *****
    THREAD_ID: 64
    EVENT_NAME: stage/sql/Waiting for event metadata lock
    COUNT_STAR: 0
SUM_TIMER_WAIT: 0
MIN_TIMER_WAIT: 0
AVG_TIMER_WAIT: 0
MAX_TIMER_WAIT: 0
***** 2288. row *****
    THREAD_ID: 64
    EVENT_NAME: stage/sql/Waiting for commit lock
    COUNT_STAR: 0
SUM_TIMER_WAIT: 0
MIN_TIMER_WAIT: 0
AVG_TIMER_WAIT: 0
MAX_TIMER_WAIT: 0
***** 2289. row *****
    THREAD_ID: 64
    EVENT_NAME: stage/aria/Waiting for a resource
    COUNT_STAR: 0
SUM_TIMER_WAIT: 0
MIN_TIMER_WAIT: 0
AVG_TIMER_WAIT: 0
MAX_TIMER_WAIT: 0
```

### 1.1.2.9.2.1.10 Performance Schema events\_stages\_summary\_by\_user\_by\_event\_name Table

The table lists stage events, summarized by user and event name.

It contains the following columns:

Column	Description
USER	User. Used together with EVENT_NAME for grouping events.
EVENT_NAME	Event name. Used together with USER for grouping events.
COUNT_STAR	Number of summarized events, which includes all timed and untimed events.
SUM_TIMER_WAIT	Total wait time of the timed summarized events.
MIN_TIMER_WAIT	Minimum wait time of the timed summarized events.
AVG_TIMER_WAIT	Average wait time of the timed summarized events.
MAX_TIMER_WAIT	Maximum wait time of the timed summarized events.

## Example

```

SELECT * FROM events_stages_summary_by_user_by_event_name\G
...
***** 325. row *****
USER: NULL
EVENT_NAME: stage/sql/Waiting for event metadata lock
COUNT_STAR: 0
SUM_TIMER_WAIT: 0
MIN_TIMER_WAIT: 0
AVG_TIMER_WAIT: 0
MAX_TIMER_WAIT: 0
***** 326. row *****
USER: NULL
EVENT_NAME: stage/sql/Waiting for commit lock
COUNT_STAR: 0
SUM_TIMER_WAIT: 0
MIN_TIMER_WAIT: 0
AVG_TIMER_WAIT: 0
MAX_TIMER_WAIT: 0
***** 327. row *****
USER: NULL
EVENT_NAME: stage/aria/Waiting for a resource
COUNT_STAR: 0
SUM_TIMER_WAIT: 0
MIN_TIMER_WAIT: 0
AVG_TIMER_WAIT: 0
MAX_TIMER_WAIT: 0

```

## 1.1.2.9.2.1.11 Performance Schema events\_stages\_summary\_global\_by\_event\_name Table

The table lists stage events, summarized by thread and event name.

It contains the following columns:

Column	Description
EVENT_NAME	Event name.
COUNT_STAR	Number of summarized events, which includes all timed and untimed events.
SUM_TIMER_WAIT	Total wait time of the timed summarized events.
MIN_TIMER_WAIT	Minimum wait time of the timed summarized events.
AVG_TIMER_WAIT	Average wait time of the timed summarized events.
MAX_TIMER_WAIT	Maximum wait time of the timed summarized events.

### Example

```

SELECT * FROM events_stages_summary_global_by_event_name\G
...
***** 106. row *****
EVENT_NAME: stage/sql/Waiting for trigger metadata lock
COUNT_STAR: 0
SUM_TIMER_WAIT: 0
MIN_TIMER_WAIT: 0
AVG_TIMER_WAIT: 0
MAX_TIMER_WAIT: 0
***** 107. row *****
EVENT_NAME: stage/sql/Waiting for event metadata lock
COUNT_STAR: 0
SUM_TIMER_WAIT: 0
MIN_TIMER_WAIT: 0
AVG_TIMER_WAIT: 0
MAX_TIMER_WAIT: 0
***** 108. row *****
EVENT_NAME: stage/sql/Waiting for commit lock
COUNT_STAR: 0

## 1.1.2.9.2.1.12 Performance Schema events\_statements\_history Table

The

`events_statements_history`  
table by default contains the ten most recent completed statement events per thread. This number can be adjusted by setting the `performance_schema_events_statements_history_size` system variable when the server starts up.

The table structure is identical to the `events_statements_current` table structure, and contains the following columns:

The table contains the following columns:

Column	Description
THREAD_ID	Thread associated with the event. Together with EVENT_ID uniquely identifies the row.
EVENT_ID	Thread's current event number at the start of the event. Together with THREAD_ID uniquely identifies the row.
END_EVENT_ID	NULL when the event starts, set to the thread's current event number at the end of the event.
EVENT_NAME	Event instrument name and a NAME from the setup_instruments table
SOURCE	Name and line number of the source file containing the instrumented code that produced the event.
TIMER_START	Value in picoseconds when the event timing started or NULL if timing is not collected.
TIMER_END	Value in picoseconds when the event timing ended, or NULL if timing is not collected.

TIMER_WAIT	Value in picoseconds of the event's duration or NULL if timing is not collected.
LOCK_TIME	Time in picoseconds spent waiting for locks. The time is calculated in microseconds but stored in picoseconds for compatibility with other timings.
SQL_TEXT	The SQL statement, or NULL if the command is not associated with an SQL statement.
DIGEST	<a href="#">Statement digest</a> .
DIGEST_TEXT	<a href="#">Statement digest text</a> .
CURRENT_SCHEMA	Statement's default database for the statement, or NULL if there was none.
OBJECT_SCHEMA	Reserved, currently NULL
OBJECT_NAME	Reserved, currently NULL
OBJECT_TYPE	Reserved, currently NULL
OBJECT_INSTANCE_BEGIN	Address in memory of the statement object.
MYSQL_ERRNO	Error code. See <a href="#">MariaDB Error Codes</a> for a full list.
RETURNED_SQLSTATE	The <a href="#">SQLSTATE</a> value.
MESSAGE_TEXT	Statement error message. See <a href="#">MariaDB Error Codes</a> .
ERRORS	0 if SQLSTATE signifies completion (starting with 00) or warning (01), otherwise 1 .
WARNINGS	Number of warnings from the diagnostics area.
ROWS_AFFECTED	Number of rows affected the statement affected.
ROWS_SENT	Number of rows returned.
ROWS_EXAMINED	Number of rows read during the statement's execution.

CREATED_TMP_DISK_TABLES	Number of on-disk temp tables created by the statement.
CREATED_TMP_TABLES	Number of temp tables created by the statement.
SELECT_FULL_JOIN	Number of joins performed by the statement which did not use an index.
SELECT_FULL_RANGE_JOIN	Number of joins performed by the statement which used a range search of the first table.
SELECT_RANGE	Number of joins performed by the statement which used a range of the first table.
SELECT_RANGE_CHECK	Number of joins without keys performed by the statement that check for key usage after each row.
SELECT_SCAN	Number of joins performed by the statement which used a full scan of the first table.
SORT_MERGE_PASSES	Number of merge passes by the sort algorithm performed by the statement. If too high, you may need to increase the <code>sort_buffer_size</code> .
SORT_RANGE	Number of sorts performed by the statement which used a range.
SORT_ROWS	Number of rows sorted by the statement.
SORT_SCAN	Number of sorts performed by the statement which used a full table scan.
NO_INDEX_USED	<ul style="list-style-type: none"> <li>0 if the statement performed a table scan with an index,</li> <li>1 if without an index.</li> </ul>
NO_GOOD_INDEX_USED	<ul style="list-style-type: none"> <li>0 if a good index was found for the statement,</li> <li>1 if no good index was found. See the Range checked for each record description in the <a href="#">EXPLAIN</a> article.</li> </ul>
NESTING_EVENT_ID	Reserved, currently NULL .
NESTING_EVENT_TYPE	Reserved, currently NULL .

It is possible to empty this table with a

```
TRUNCATE TABLE
statement.
```

[events\\_statements\\_current](#) and [events\\_statements\\_history\\_long](#) are related tables.

## 1.1.2.9.2.1.13 Performance Schema events\_statements\_history\_long Table

The

`events_statements_history_long`

table by default contains the ten thousand most recent completed statement events. This number can be adjusted by setting the `performance_schema_events_statements_history_long_size` system variable when the server starts up.

The table structure is identical to the `events_statements_current` table structure, and contains the following columns:

Column	Description
THREAD_ID	Thread associated with the event. Together with EVENT_ID uniquely identifies the row.
EVENT_ID	Thread's current event number at the start of the event. Together with THREAD_ID uniquely identifies the row.
END_EVENT_ID	NULL when the event starts, set to the thread's current event number at the end of the event.
EVENT_NAME	Event instrument name and a NAME from the setup_instruments table
SOURCE	Name and line number of the source file containing the instrumented code that produced the event.
TIMER_START	Value in picoseconds when the event timing started or NULL if timing is not collected.
TIMER_END	Value in picoseconds when the event timing ended, or NULL if timing is not collected.
TIMER_WAIT	Value in picoseconds of the event's duration or NULL if timing is not collected.
LOCK_TIME	Time in picoseconds spent waiting for locks. The time is calculated in microseconds but stored in picoseconds for compatibility with other timings.
SQL_TEXT	The SQL statement, or NULL if the command is not associated with an SQL statement.
DIGEST	<code>Statement digest</code> .
DIGEST_TEXT	<code>Statement digest text</code> .
CURRENT_SCHEMA	Statement's default database for the statement, or NULL if there was none.
OBJECT_SCHEMA	Reserved, currently NULL
OBJECT_NAME	Reserved, currently NULL
OBJECT_TYPE	Reserved, currently NULL

OBJECT_INSTANCE_BEGIN	Address in memory of the statement object.
MYSQL_ERRNO	Error code. See <a href="#">MariaDB Error Codes</a> for a full list.
RETURNED_SQLSTATE	The <a href="#">SQLSTATE</a> value.
MESSAGE_TEXT	Statement error message. See <a href="#">MariaDB Error Codes</a> .
ERRORS	<pre> 0 if SQLSTATE signifies completion (starting with 00) or warning (01), otherwise 1 . </pre>
WARNINGS	Number of warnings from the diagnostics area.
ROWS_AFFECTED	Number of rows affected the statement affected.
ROWS_SENT	Number of rows returned.
ROWS_EXAMINED	Number of rows read during the statement's execution.
CREATED_TMP_DISK_TABLES	Number of on-disk temp tables created by the statement.
CREATED_TMP_TABLES	Number of temp tables created by the statement.
SELECT_FULL_JOIN	Number of joins performed by the statement which did not use an index.
SELECT_FULL_RANGE_JOIN	Number of joins performed by the statement which used a range search of the first table.
SELECT_RANGE	Number of joins performed by the statement which used a range of the first table.
SELECT_RANGE_CHECK	Number of joins without keys performed by the statement that check for key usage after each row.
SELECT_SCAN	Number of joins performed by the statement which used a full scan of the first table.
SORT_MERGE_PASSES	Number of merge passes by the sort algorithm performed by the statement. If too high, you may need to increase the <a href="#">sort_buffer_size</a> .

SORT_RANGE	Number of sorts performed by the statement which used a range.
SORT_ROWS	Number of rows sorted by the statement.
SORT_SCAN	Number of sorts performed by the statement which used a full table scan.
NO_INDEX_USED	0 if the statement performed a table scan with an index, 1 if without an index.
NO_GOOD_INDEX_USED	0 if a good index was found for the statement, 1 if no good index was found. See the Range checked for each record description in the <a href="#">EXPLAIN</a> article.
NESTING_EVENT_ID	Reserved, currently NULL .
NESTING_EVENT_TYPE	Reserved, currently NULL .

It is possible to empty this table with a

```
TRUNCATE TABLE
statement.
```

[events\\_statements\\_current](#) and [events\\_statements\\_history](#) are related tables.

## 1.1.2.9.2.1.14 Performance Schema events\_statements\_summary\_by\_account\_by\_event\_name Table

The [Performance Schema](#) events\_statements\_summary\_by\_account\_by\_event\_name table contains statement events summarized by account and event name. It contains the following columns:

Column	Description
USER	User. Used together with HOST and EVENT_NAME for grouping events.
HOST	Host. Used together with USER and EVENT_NAME for grouping events.
EVENT_NAME	Event name. Used together with USER and HOST for grouping events.
COUNT_STAR	Number of summarized events
SUM_TIMER_WAIT	Total wait time of the summarized events that are timed.

MIN_TIMER_WAIT	Minimum wait time of the summarized events that are timed.
AVG_TIMER_WAIT	Average wait time of the summarized events that are timed.
MAX_TIMER_WAIT	Maximum wait time of the summarized events that are timed.
SUM_LOCK_TIME	Sum of the LOCK_TIME column in the events_statements_current table.
SUM_ERRORS	Sum of the ERRORS column in the events_statements_current table.
SUM_WARNINGS	Sum of the WARNINGS column in the events_statements_current table.
SUM_ROWS_AFFECTED	Sum of the ROWS_AFFECTED column in the events_statements_current table.
SUM_ROWS_SENT	Sum of the ROWS_SENT column in the events_statements_current table.
SUM_ROWS_EXAMINED	Sum of the ROWS_EXAMINED column in the events_statements_current table.
SUM_CREATED_TMP_DISK_TABLES	Sum of the CREATED_TMP_DISK_TABLES column in the events_statements_current table.
SUM_CREATED_TMP_TABLES	Sum of the CREATED_TMP_TABLES column in the events_statements_current table.
SUM_SELECT_FULL_JOIN	Sum of the SELECT_FULL_JOIN column in the events_statements_current table.
SUM_SELECT_FULL_RANGE_JOIN	Sum of the SELECT_FULL_RANGE_JOIN column in the events_statements_current table.
SUM_SELECT_RANGE	Sum of the SELECT_RANGE column in the events_statements_current table.

SUM_SELECT_RANGE_CHECK	Sum of the SELECT_RANGE_CHECK column in the events_statements_current table.
SUM_SELECT_SCAN	Sum of the SELECT_SCAN column in the events_statements_current table.
SUM_SORT_MERGE_PASSES	Sum of the SORT_MERGE_PASSES column in the events_statements_current table.
SUM_SORT_RANGE	Sum of the SORT_RANGE column in the events_statements_current table.
SUM_SORT_ROWS	Sum of the SORT_ROWS column in the events_statements_current table.
SUM_SORT_SCAN	Sum of the SORT_SCAN column in the events_statements_current table.
SUM_NO_INDEX_USED	Sum of the NO_INDEX_USED column in the events_statements_current table.
SUM_NO_GOOD_INDEX_USED	Sum of the NO_GOOD_INDEX_USED column in the events_statements_current table.

The

\*\_TIMER\_WAIT  
columns only calculate results for timed events, as non-timed events have a  
NULL  
wait time.

## Example

```

SELECT * FROM events_statements_summary_by_account_by_event_name\G
...
***** 521. row *****
    USER: NULL
    HOST: NULL
    EVENT_NAME: statement/com/Error

    SUM_NO_INDEX_USED: 0
    SUM_NO_GOOD_INDEX_USED: 0

```

## 1.1.2.9.2.1.15 Performance Schema events\_statements\_summary\_by\_digest Table

The [Performance Schema digest](#) is a hashed, normalized form of a statement with the specific data values removed. It allows statistics to be gathered for similar kinds of statements.

The [Performance Schema](#)

`events_statements_summary_by_digest`

table records statement events summarized by schema and digest. It contains the following columns:

Column	Description
SCHEMA NAME	Database name. Records are summarised together with DIGEST

DIGEST	Performance Schema digest . Records are summarised together with SCHEMA NAME .
DIGEST_TEXT	The unhashed form of the digest.
COUNT_STAR	Number of summarized events
SUM_TIMER_WAIT	Total wait time of the summarized events that are timed.
MIN_TIMER_WAIT	Minimum wait time of the summarized events that are timed.
AVG_TIMER_WAIT	Average wait time of the summarized events that are timed.
MAX_TIMER_WAIT	Maximum wait time of the summarized events that are timed.
SUM_LOCK_TIME	Sum of the LOCK_TIME column in the events_statements_current table.
SUM_ERRORS	Sum of the ERRORS column in the events_statements_current table.
SUM_WARNINGS	Sum of the WARNINGS column in the events_statements_current table.
SUM_ROWS_AFFECTED	Sum of the ROWS_AFFECTED column in the events_statements_current table.
SUM_ROWS_SENT	Sum of the ROWS_SENT column in the events_statements_current table.
SUM_ROWS_EXAMINED	Sum of the ROWS_EXAMINED column in the events_statements_current table.
SUM_CREATED_TMP_DISK_TABLES	Sum of the CREATED_TMP_DISK_TABLES column in the events_statements_current table.
SUM_CREATED_TMP_TABLES	Sum of the CREATED_TMP_TABLES column in the events_statements_current table.

SUM_SELECT_FULL_JOIN	Sum of the SELECT_FULL_JOIN column in the events_statements_current table.
SUM_SELECT_FULL_RANGE_JOIN	Sum of the SELECT_FULL_RANGE_JOIN column in the events_statements_current table.
SUM_SELECT_RANGE	Sum of the SELECT_RANGE column in the events_statements_current table.
SUM_SELECT_RANGE_CHECK	Sum of the SELECT_RANGE_CHECK column in the events_statements_current table.
SUM_SELECT_SCAN	Sum of the SELECT_SCAN column in the events_statements_current table.
SUM_SORT_MERGE_PASSES	Sum of the SORT_MERGE_PASSES column in the events_statements_current table.
SUM_SORT_RANGE	Sum of the SORT_RANGE column in the events_statements_current table.
SUM_SORT_ROWS	Sum of the SORT_ROWS column in the events_statements_current table.
SUM_SORT_SCAN	Sum of the SORT_SCAN column in the events_statements_current table.
SUM_NO_INDEX_USED	Sum of the NO_INDEX_USED column in the events_statements_current table.
SUM_NO_GOOD_INDEX_USED	Sum of the NO_GOOD_INDEX_USED column in the events_statements_current table.
FIRST_SEEN	Time at which the digest was first seen.
LAST_SEEN	Time at which the digest was most recently seen.

The

\*\_TIMER\_WAIT  
columns only calculate results for timed events, as non-timed events have a

NULL  
wait time.

The

events\_statements\_summary\_by\_digest

table is limited in size by the [performance\\_schema\\_digests\\_size](#) system variable. Once the limit has been reached and the table is full, all entries are aggregated in a row with a

NULL

digest. The

COUNT\_STAR

value of this

NULL

row indicates how many digests are recorded in the row and therefore gives an indication of whether

[performance\\_schema\\_digests\\_size](#)

should be increased to provide more accurate statistics.

## 1.1.2.9.2.1.16 Performance Schema events\_statements\_summary\_by\_host\_by\_event\_name Table

The [Performance Schema](#) events\_statements\_summary\_by\_host\_by\_event\_name table contains statement events summarized by host and event name. It contains the following columns:

Column	Description
HOST	Host. Used together with EVENT_NAME for grouping events.
EVENT_NAME	Event name. Used together with HOST for grouping events.
COUNT_STAR	Number of summarized events
SUM_TIMER_WAIT	Total wait time of the summarized events that are timed.
MIN_TIMER_WAIT	Minimum wait time of the summarized events that are timed.
AVG_TIMER_WAIT	Average wait time of the summarized events that are timed.
MAX_TIMER_WAIT	Maximum wait time of the summarized events that are timed.
SUM_LOCK_TIME	Sum of the LOCK_TIME column in the events_statements_current table.
SUM_ERRORS	Sum of the ERRORS column in the events_statements_current table.
SUM_WARNINGS	Sum of the WARNINGS column in the events_statements_current table.

SUM_ROWS_AFFECTED	Sum of the ROWS_AFFECTED column in the events_statements_current table.
SUM_ROWS_SENT	Sum of the ROWS_SENT column in the events_statements_current table.
SUM_ROWS_EXAMINED	Sum of the ROWS_EXAMINED column in the events_statements_current table.
SUM_CREATED_TMP_DISK_TABLES	Sum of the CREATED_TMP_DISK_TABLES column in the events_statements_current table.
SUM_CREATED_TMP_TABLES	Sum of the CREATED_TMP_TABLES column in the events_statements_current table.
SUM_SELECT_FULL_JOIN	Sum of the SELECT_FULL_JOIN column in the events_statements_current table.
SUM_SELECT_FULL_RANGE_JOIN	Sum of the SELECT_FULL_RANGE_JOIN column in the events_statements_current table.
SUM_SELECT_RANGE	Sum of the SELECT_RANGE column in the events_statements_current table.
SUM_SELECT_RANGE_CHECK	Sum of the SELECT_RANGE_CHECK column in the events_statements_current table.
SUM_SELECT_SCAN	Sum of the SELECT_SCAN column in the events_statements_current table.
SUM_SORT_MERGE_PASSES	Sum of the SORT_MERGE_PASSES column in the events_statements_current table.
SUM_SORT_RANGE	Sum of the SORT_RANGE column in the events_statements_current table.

SUM_SORT_ROWS	Sum of the SORT_ROWS column in the events_statements_current table.
SUM_SORT_SCAN	Sum of the SORT_SCAN column in the events_statements_current table.
SUM_NO_INDEX_USED	Sum of the NO_INDEX_USED column in the events_statements_current table.
SUM_NO_GOOD_INDEX_USED	Sum of the NO_GOOD_INDEX_USED column in the events_statements_current table.

The

```
* _TIMER_WAIT
columns only calculate results for timed events, as non-timed events have a
NULL
wait time.
```

## Example

```

SELECT * FROM events_statements_summary_by_host_by_event_name\G
...
***** row *****
    HOST: NULL
    EVENT_NAME: statement/com/Error
    COUNT_STAR: 0
    SUM_TIMER_WAIT: 0
    MIN_TIMER_WAIT: 0
    AVG_TIMER_WAIT: 0
    MAX_TIMER_WAIT: 0
    SUM_LOCK_TIME: 0
    SUM_ERRORS: 0
    SUM_WARNINGS: 0
    SUM_ROWS_AFFECTED: 0
    SUM_ROWS_SENT: 0
    SUM_ROWS_EXAMINED: 0

    SUM_SELECT_RANGE: 0
    SUM_SELECT_RANGE_CHECK: 0
    SUM_SELECT_SCAN: 0
SUM_SORT_MERGE_PASSES: 0
    SUM_SORT_RANGE: 0
    SUM_SORT_ROWS: 0
    SUM_SORT_SCAN: 0
    SUM_NO_INDEX_USED: 0
    SUM_NO_GOOD_INDEX_USED: 0

```

## 1.1.2.9.2.1.17 Performance Schema events\_statements\_summary\_by\_program Table

MariaDB starting with 10.5.2

The

`events_statements_summary_by_program`  
table, along with many other new [Performance Schema tables](#), was added in [MariaDB 10.5.2](#).

Each row in the the `Performance Schema events_statements_summary_by_program` table summarizes events for a particular stored program (stored procedure, stored function, trigger or event).

It contains the following fields.

Column	Type	Null	Description
--------	------	------	-------------

OBJECT_TYPE	enum('EVENT', 'FUNCTION', 'PROCEDURE', 'TABLE', 'TRIGGER')	YES	Object type for which the summary is generated.
OBJECT_SCHEMA	varchar(64)	NO	The schema of the object for which the summary is generated.
OBJECT_NAME	varchar(64)	NO	The name of the object for which the summary is generated.
COUNT_STAR	bigint(20) unsigned	NO	The number of summarized events (from events_statements_current). This value includes all events, whether timed or nontimed.
SUM_TIMER_WAIT	bigint(20) unsigned	NO	The number of summarized events (from events_statements_current). This value includes all events, whether timed or nontimed.
MIN_TIMER_WAIT	bigint(20) unsigned	NO	The minimum wait time of the summarized timed events.
AVG_TIMER_WAIT	bigint(20) unsigned	NO	The average wait time of the summarized timed events.
MAX_TIMER_WAIT	bigint(20) unsigned	NO	The maximum wait time of the summarized timed events.
COUNT_STATEMENTS	bigint(20) unsigned	NO	Total number of nested statements invoked during stored program execution.
SUM_STATEMENTS_WAIT	bigint(20) unsigned	NO	The total wait time of the summarized timed statements. This value is calculated only for timed statements because nontimed statements have a wait time of NULL. The same is true for the other xxx_STATEMENT_WAIT values.
MIN_STATEMENTS_WAIT	bigint(20) unsigned	NO	The minimum wait time of the summarized timed statements.
AVG_STATEMENTS_WAIT	bigint(20) unsigned	NO	The average wait time of the summarized timed statements.
MAX_STATEMENTS_WAIT	bigint(20) unsigned	NO	The maximum wait time of the summarized timed statements.
SUM_LOCK_TIME	bigint(20) unsigned	NO	The total time spent (in picoseconds) waiting for table locks for the summarized statements.
SUM_ERRORS	bigint(20) unsigned	NO	The total number of errors that occurred for the summarized statements.
SUM_WARNINGS	bigint(20) unsigned	NO	The total number of warnings that occurred for the summarized statements.
SUM_ROWS_AFFECTED	bigint(20) unsigned	NO	The total number of affected rows by the summarized statements.
SUM_ROWS_SENT	bigint(20) unsigned	NO	The total number of rows returned by the summarized statements.
SUM_ROWS_EXAMINED	bigint(20) unsigned	NO	The total number of rows examined by the summarized statements. The total number of affected rows by the summarized statements.
SUM_CREATED_TMP_DISK_TABLES	bigint(20) unsigned	NO	The total number of on-disk temporary tables created by the summarized statements.
SUM_CREATED_TMP_TABLES	bigint(20) unsigned	NO	The total number of in-memory temporary tables created by the summarized statements.
SUM_SELECT_FULL_JOIN	bigint(20) unsigned	NO	The total number of full joins executed by the summarized statements.
SUM_SELECT_FULL_RANGE_JOIN	bigint(20) unsigned	NO	The total number of range search joins executed by the summarized statements.
SUM_SELECT_RANGE	bigint(20) unsigned	NO	The total number of joins that used ranges on the first table executed by the summarized statements.
SUM_SELECT_RANGE_CHECK	bigint(20) unsigned	NO	The total number of joins that check for key usage after each row executed by the summarized statements.
SUM_SELECT_SCAN	bigint(20) unsigned	NO	The total number of joins that did a full scan of the first table executed by the summarized statements.
SUM_SORT_MERGE_PASSES	bigint(20) unsigned	NO	The total number of merge passes that the sort algorithm has had to do for the summarized statements.
SUM_SORT_RANGE	bigint(20) unsigned	NO	The total number of sorts that were done using ranges for the summarized statements.
SUM_SORT_ROWS	bigint(20) unsigned	NO	The total number of sorted rows that were sorted by the summarized statements.
SUM_SORT_SCAN	bigint(20) unsigned	NO	The total number of sorts that were done by scanning the table by the summarized statements.
SUM_NO_INDEX_USED	bigint(20) unsigned	NO	The total number of statements that performed a table scan without using an index.
SUM_NO_GOOD_INDEX_USED	bigint(20) unsigned	NO	The total number of statements where no good index was found.

## 1.1.2.9.2.1.18 Performance Schema events\_statements\_summary\_by\_thread\_by\_event\_name Table

The [Performance Schema](#)

events\_statements\_summary\_by\_thread\_by\_event\_name

table contains statement events summarized by thread and event name. It contains the following columns:

Column	Description
THREAD_ID	Thread associated with the event. Together with EVENT_NAME uniquely identifies the row.
EVENT_NAME	Event name. Used together with THREAD_ID for grouping events.
COUNT_STAR	Number of summarized events
SUM_TIMER_WAIT	Total wait time of the summarized events that are timed.
MIN_TIMER_WAIT	Minimum wait time of the summarized events that are timed.
AVG_TIMER_WAIT	Average wait time of the summarized events that are timed.
MAX_TIMER_WAIT	Maximum wait time of the summarized events that are timed.
SUM_LOCK_TIME	Sum of the LOCK_TIME column in the events_statements_current table.
SUM_ERRORS	Sum of the ERRORS column in the events_statements_current table.
SUM_WARNINGS	Sum of the WARNINGS column in the events_statements_current table.
SUM_ROWS_AFFECTED	Sum of the ROWS_AFFECTED column in the events_statements_current table.
SUM_ROWS_SENT	Sum of the ROWS_SENT column in the events_statements_current table.
SUM_ROWS_EXAMINED	Sum of the ROWS_EXAMINED column in the events_statements_current table.

SUM_CREATED_TMP_DISK_TABLES	Sum of the CREATED_TMP_DISK_TABLES column in the events_statements_current table.
SUM_CREATED_TMP_TABLES	Sum of the CREATED_TMP_TABLES column in the events_statements_current table.
SUM_SELECT_FULL_JOIN	Sum of the SELECT_FULL_JOIN column in the events_statements_current table.
SUM_SELECT_FULL_RANGE_JOIN	Sum of the SELECT_FULL_RANGE_JOIN column in the events_statements_current table.
SUM_SELECT_RANGE	Sum of the SELECT_RANGE column in the events_statements_current table.
SUM_SELECT_RANGE_CHECK	Sum of the SELECT_RANGE_CHECK column in the events_statements_current table.
SUM_SELECT_SCAN	Sum of the SELECT_SCAN column in the events_statements_current table.
SUM_SORT_MERGE_PASSES	Sum of the SORT_MERGE_PASSES column in the events_statements_current table.
SUM_SORT_RANGE	Sum of the SORT_RANGE column in the events_statements_current table.
SUM_SORT_ROWS	Sum of the SORT_ROWS column in the events_statements_current table.
SUM_SORT_SCAN	Sum of the SORT_SCAN column in the events_statements_current table.
SUM_NO_INDEX_USED	Sum of the NO_INDEX_USED column in the events_statements_current table.

<pre>SUM_NO_GOOD_INDEX_USED</pre>	<p>Sum of the NO_GOOD_INDEX_USED column in the events_statements_current table.</p>
-----------------------------------	---

The

```
*_TIMER_WAIT
columns only calculate results for timed events, as non-timed events have a
NULL
wait time.
```

## Example

```
SELECT * FROM events_statements_summary_by_thread_by_event_name\G
...
***** 3653. row *****
    THREAD_ID: 64
    EVENT_NAME: statement/com/Error
    COUNT_STAR: 0
    SUM_TIMER_WAIT: 0
    MIN_TIMER_WAIT: 0
    AVG_TIMER_WAIT: 0
    MAX_TIMER_WAIT: 0

## 1.1.2.9.2.1.19 Performance Schema

# events\_statements\_summary\_by\_user\_by\_event\_name Table

The [Performance Schema](#)

`events_statements_summary_by_user_by_event_name`

table contains statement events summarized by user and event name. It contains the following columns:

Column	Description
USER	User. Used together with EVENT_NAME for grouping events.
EVENT_NAME	Event name. Used together with USER for grouping events.
COUNT_STAR	Number of summarized events
SUM_TIMER_WAIT	Total wait time of the summarized events that are timed.
MIN_TIMER_WAIT	Minimum wait time of the summarized events that are timed.
AVG_TIMER_WAIT	Average wait time of the summarized events that are timed.
MAX_TIMER_WAIT	Maximum wait time of the summarized events that are timed.
SUM_LOCK_TIME	Sum of the LOCK_TIME column in the events_statements_current table.
SUM_ERRORS	Sum of the ERRORS column in the events_statements_current table.
SUM_WARNINGS	Sum of the WARNINGS column in the events_statements_current table.
SUM_ROWS_AFFECTED	Sum of the ROWS_AFFECTED column in the events_statements_current table.
SUM_ROWS_SENT	Sum of the ROWS_SENT column in the events_statements_current table.
SUM_ROWS_EXAMINED	Sum of the ROWS_EXAMINED column in the events_statements_current table.

SUM_CREATED_TMP_DISK_TABLES	Sum of the CREATED_TMP_DISK_TABLES column in the events_statements_current table.
SUM_CREATED_TMP_TABLES	Sum of the CREATED_TMP_TABLES column in the events_statements_current table.
SUM_SELECT_FULL_JOIN	Sum of the SELECT_FULL_JOIN column in the events_statements_current table.
SUM_SELECT_FULL_RANGE_JOIN	Sum of the SELECT_FULL_RANGE_JOIN column in the events_statements_current table.
SUM_SELECT_RANGE	Sum of the SELECT_RANGE column in the events_statements_current table.
SUM_SELECT_RANGE_CHECK	Sum of the SELECT_RANGE_CHECK column in the events_statements_current table.
SUM_SELECT_SCAN	Sum of the SELECT_SCAN column in the events_statements_current table.
SUM_SORT_MERGE_PASSES	Sum of the SORT_MERGE_PASSES column in the events_statements_current table.
SUM_SORT_RANGE	Sum of the SORT_RANGE column in the events_statements_current table.
SUM_SORT_ROWS	Sum of the SORT_ROWS column in the events_statements_current table.
SUM_SORT_SCAN	Sum of the SORT_SCAN column in the events_statements_current table.
SUM_NO_INDEX_USED	Sum of the NO_INDEX_USED column in the events_statements_current table.

<pre>SUM_NO_GOOD_INDEX_USED</pre>	<p>Sum of the NO_GOOD_INDEX_USED column in the events_statements_current table.</p>
-----------------------------------	---

The

```
*_TIMER_WAIT
columns only calculate results for timed events, as non-timed events have a
NULL
wait time.
```

## Example

```
SELECT * FROM events_statements_summary_by_user_by_event_name\G
...
***** 521. row *****
    USER: NULL
    EVENT_NAME: statement/com/Error
    COUNT_STAR: 0
    SUM_TIMER_WAIT: 0
    MIN_TIMER_WAIT: 0
    AVG_TIMER_WAIT: 0
    MAX_TIMER_WAIT: 0
    SUM_LOCK_TIME: 0
    SUM_ERRORS: 0
    SUM_WARNINGS: 0
    SUM_ROWS_AFFECTED: 0
    SUM_ROWS_SENT: 0
    SUM_ROWS_EXAMINED: 0
SUM_CREATED_TMP_DISK_TABLES: 0
    SUM_CREATED_TMP_TABLES: 0
    SUM_SELECT_FULL_JOIN: 0

    SUM_SORT_SCAN: 0
    SUM_NO_INDEX_USED: 0
    SUM_NO_GOOD_INDEX_USED: 0
```

## 1.1.2.9.2.1.20 Performance Schema

# events\_statements\_summary\_global\_by\_event\_name Table

The [Performance Schema](#)

events\_statements\_summary\_global\_by\_event\_name

table contains statement events summarized by event name. It contains the following columns:

Column	Description
EVENT_NAME	Event name.
COUNT_STAR	Number of summarized events
SUM_TIMER_WAIT	Total wait time of the summarized events that are timed.
MIN_TIMER_WAIT	Minimum wait time of the summarized events that are timed.
AVG_TIMER_WAIT	Average wait time of the summarized events that are timed.
MAX_TIMER_WAIT	Maximum wait time of the summarized events that are timed.
SUM_LOCK_TIME	Sum of the LOCK_TIME column in the events_statements_current table.
SUM_ERRORS	Sum of the ERRORS column in the events_statements_current table.
SUM_WARNINGS	Sum of the WARNINGS column in the events_statements_current table.
SUM_ROWS_AFFECTED	Sum of the ROWS_AFFECTED column in the events_statements_current table.
SUM_ROWS_SENT	Sum of the ROWS_SENT column in the events_statements_current table.
SUM_ROWS_EXAMINED	Sum of the ROWS_EXAMINED column in the events_statements_current table.
SUM_CREATED_TMP_DISK_TABLES	Sum of the CREATED_TMP_DISK_TABLES column in the events_statements_current table.

SUM_CREATED_TMP_TABLES	Sum of the CREATED_TMP_TABLES column in the events_statements_current table.
SUM_SELECT_FULL_JOIN	Sum of the SELECT_FULL_JOIN column in the events_statements_current table.
SUM_SELECT_FULL_RANGE_JOIN	Sum of the SELECT_FULL_RANGE_JOIN column in the events_statements_current table.
SUM_SELECT_RANGE	Sum of the SELECT_RANGE column in the events_statements_current table.
SUM_SELECT_RANGE_CHECK	Sum of the SELECT_RANGE_CHECK column in the events_statements_current table.
SUM_SELECT_SCAN	Sum of the SELECT_SCAN column in the events_statements_current table.
SUM_SORT_MERGE_PASSES	Sum of the SORT_MERGE_PASSES column in the events_statements_current table.
SUM_SORT_RANGE	Sum of the SORT_RANGE column in the events_statements_current table.
SUM_SORT_ROWS	Sum of the SORT_ROWS column in the events_statements_current table.
SUM_SORT_SCAN	Sum of the SORT_SCAN column in the events_statements_current table.
SUM_NO_INDEX_USED	Sum of the NO_INDEX_USED column in the events_statements_current table.
SUM_NO_GOOD_INDEX_USED	Sum of the NO_GOOD_INDEX_USED column in the events_statements_current table.

The

\*\_TIMER\_WAIT  
columns only calculate results for timed events, as non-timed events have a  
NULL

wait time.

## Example

```
SELECT * FROM events_statements_summary_global_by_event_name\G
...
***** 173. row *****
    EVENT_NAME: statement/com/Error
    COUNT_STAR: 0
    SUM_TIMER_WAIT: 0
    MIN_TIMER_WAIT: 0
    AVG_TIMER_WAIT: 0
    MAX_TIMER_WAIT: 0

    SUM_NO_GOOD_INDEX_USED: 0
```

### 1.1.2.9.2.1.21 Performance Schema events\_transactions\_current Table

MariaDB starting with [10.5.2](#)

The events\_transactions\_current table was introduced in [MariaDB 10.5.2](#).

The

events\_transactions\_current  
table contains current transaction events for each thread.

The table size cannot be figured, and always stores one row for each thread, showing the current status of the thread's most recent monitored transaction event.

The table contains the following columns:

Column	Type	Description
THREAD_ID	bigint(20) unsigned	The thread associated with the event.
EVENT_ID	bigint(20) unsigned	The event id associated with the event.
END_EVENT_ID	bigint(20) unsigned	This column is set to NULL when the event starts and updated to the thread current event number when the event ends.
EVENT_NAME	varchar(128)	The name of the instrument from which the event was collected. This is a NAME value from the setup_instruments table.
STATE	enum('ACTIVE', 'COMMITTED', 'ROLLED BACK')	The current transaction state. The value is ACTIVE (after START TRANSACTION or BEGIN), COMMITTED (after COMMIT), or ROLLED BACK (after ROLLBACK).
TRX_ID	bigint(20) unsigned	Unused.
GTID	varchar(64)	Transaction GTID , using the format DOMAIN-SERVER_ID-SEQUENCE_NO.
XID_FORMAT_ID	int(11)	XA transaction format ID for GTRID and BQUAL values.
XID_GTRID	varchar(130)	XA global transaction ID.
XID_BQUAL	varchar(130)	XA transaction branch qualifier.
XA_STATE	varchar(64)	The state of the XA transaction. The value is ACTIVE (after XA START), IDLE (after XA END), PREPARED (after XA PREPARE), ROLLED BACK (after XA ROLLBACK), or COMMITTED (after XA COMMIT).
SOURCE	varchar(64)	The name of the source file containing the instrumented code that produced the event and the line number in the file at which the instrumentation occurs.
TIMER_START	bigint(20) unsigned	The unit is picoseconds. When event timing started. NULL if event has no timing information.
TIMER_END	bigint(20) unsigned	The unit is picoseconds. When event timing ended. NULL if event has no timing information.
TIMER_WAIT	bigint(20) unsigned	The unit is picoseconds. Event duration. NULL if event has not timing information.
ACCESS_MODE	enum('READ ONLY', 'READ WRITE')	Transaction access mode.
ISOLATION_LEVEL	varchar(64)	Transaction isolation level. One of: REPEATABLE READ, READ COMMITTED, READ UNCOMMITTED, or SERIALIZABLE.
AUTOCOMMIT	enum('YES','NO')	Whether autocommit mode was enabled when the transaction started.
NUMBER_OF_SAVEPOINTS	bigint(20) unsigned	The number of SAVEPOINT statements issued during the transaction.
NUMBER_OF_ROLLBACK_TO_SAVEPOINT	bigint(20) unsigned	The number of ROLLBACK_TO_SAVEPOINT statements issued during the transaction.
NUMBER_OF_RELEASE_SAVEPOINT	bigint(20) unsigned	The number of RELEASE_SAVEPOINT statements issued during the transaction.
OBJECT_INSTANCE_BEGIN	bigint(20) unsigned	Unused.
NESTING_EVENT_ID	bigint(20) unsigned	The EVENT_ID value of the event within which this event is nested.
NESTING_EVENT_TYPE	enum('TRANSACTION', 'STATEMENT', 'STAGE', 'WAIT')	The nesting event type.

## 1.1.2.9.2.1.22 Performance Schema events\_transactions\_history Table

MariaDB starting with [10.5.2](#)

The events\_transactions\_history table was introduced in [MariaDB 10.5.2](#).

The

events\_transactions\_history

table contains the most recent completed transaction events for each thread.

The number of records stored per thread in the table is determined by the [performance\\_schema\\_events\\_transactions\\_history\\_size](#) system variable,

which is autosized on startup.

If adding a completed transaction event would cause the table to exceed this limit, the oldest thread row is discarded.

All of a thread's rows are discarded when the thread ends.

The table contains the following columns:

Column	Type	Description
THREAD_ID	bigint(20) unsigned	The thread associated with the event.
EVENT_ID	bigint(20) unsigned	The event id associated with the event.
END_EVENT_ID	bigint(20) unsigned	This column is set to NULL when the event starts and updated to the thread current event number when the event ends.
EVENT_NAME	varchar(128)	The name of the instrument from which the event was collected. This is a NAME value from the setup_instruments table.
STATE	enum('ACTIVE', 'COMMITTED', 'ROLLED BACK')	The current transaction state. The value is ACTIVE (after START TRANSACTION or BEGIN), COMMITTED (after COMMIT), or ROLLED BACK (after ROLLBACK).
TRX_ID	bigint(20) unsigned	Unused.
GTID	varchar(64)	Transaction <a href="#">GTID</a> , using the format DOMAIN-SERVER_ID-SEQUENCE_NO.
XID_FORMAT_ID	int(11)	XA transaction format ID for GTRID and BQUAL values.
XID_GTRID	varchar(130)	XA global transaction ID.
XID_BQUAL	varchar(130)	XA transaction branch qualifier.
XA_STATE	varchar(64)	The state of the XA transaction. The value is ACTIVE (after XA START), IDLE (after XA END), PREPARED (after XA PREPARE), ROLLED BACK (after XA ROLLBACK), or COMMITTED (after XA COMMIT).
SOURCE	varchar(64)	The name of the source file containing the instrumented code that produced the event and the line number in the file at which the instrumentation occurs.
TIMER_START	bigint(20) unsigned	The unit is picoseconds. When event timing started. NULL if event has no timing information.
TIMER_END	bigint(20) unsigned	The unit is picoseconds. When event timing ended. NULL if event has no timing information.
TIMER_WAIT	bigint(20) unsigned	The unit is picoseconds. Event duration. NULL if event has not timing information.
ACCESS_MODE	enum('READ ONLY', 'READ WRITE')	Transaction access mode.
ISOLATION_LEVEL	varchar(64)	Transaction isolation level. One of: REPEATABLE READ, READ COMMITTED, READ UNCOMMITTED, or SERIALIZABLE.
AUTOCOMMIT	enum('YES', 'NO')	NO
NUMBER_OF_SAVEPOINTS	bigint(20) unsigned	The number of SAVEPOINT statements issued during the transaction.
NUMBER_OF_ROLLBACK_TO_SAVEPOINT	bigint(20) unsigned	The number of ROLLBACK_TO_SAVEPOINT statements issued during the transaction.
NUMBER_OF_RELEASE_SAVEPOINT	bigint(20) unsigned	The number of RELEASE_SAVEPOINT statements issued during the transaction.
OBJECT_INSTANCE_BEGIN	bigint(20) unsigned	Unused.
NESTING_EVENT_ID	bigint(20) unsigned	The EVENT_ID value of the event within which this event is nested.
NESTING_EVENT_TYPE	enum('TRANSACTION', 'STATEMENT', 'STAGE', 'WAIT')	The nesting event type.

## 1.1.2.9.2.1.23 Performance Schema events\_transactions\_history\_long Table

MariaDB starting with [10.5.2](#)

The events\_transactions\_history\_long table was introduced in [MariaDB 10.5.2](#).

The

`events_transactions_history_long`

table contains the most recent completed transaction events that have ended globally, across all threads.

The number of records stored in the table is determined by the `performance_schema_events_transactions_history_long_size` system variable, which is autosized on startup.

If adding a completed transaction would cause the table to exceed this limit, the oldest row, regardless of thread, is discarded.

The table contains the following columns:

Column	Type	Description
THREAD_ID	bigint(20) unsigned	The thread associated with the event.
EVENT_ID	bigint(20) unsigned	The event id associated with the event.
END_EVENT_ID	bigint(20) unsigned	This column is set to NULL when the event starts and updated to the thread current event number when the event ends.
EVENT_NAME	varchar(128)	The name of the instrument from which the event was collected. This is a NAME value from the setup_instruments table.
STATE	enum('ACTIVE', 'COMMITTED', 'ROLLED BACK')	The current transaction state. The value is ACTIVE (after START TRANSACTION or BEGIN), COMMITTED (after COMMIT), or ROLLED BACK (after ROLLBACK).
TRX_ID	bigint(20) unsigned	Unused.
GTID	varchar(64)	Transaction GTID , using the format DOMAIN-SERVER_ID-SEQUENCE_NO.
XID_FORMAT_ID	int(11)	XA transaction format ID for GTRID and BQUAL values.
XID_GTRID	varchar(130)	XA global transaction ID.
XID_BQUAL	varchar(130)	XA transaction branch qualifier.
XA_STATE	varchar(64)	The state of the XA transaction. The value is ACTIVE (after XA START), IDLE (after XA END), PREPARED (after XA PREPARE), ROLLED BACK (after XA ROLLBACK), or COMMITTED (after XA COMMIT).
SOURCE	varchar(64)	The name of the source file containing the instrumented code that produced the event and the line number in the file at which the instrumentation occurs.
TIMER_START	bigint(20) unsigned	The unit is picoseconds. When event timing started. NULL if event has no timing information.
TIMER_END	bigint(20) unsigned	The unit is picoseconds. When event timing ended. NULL if event has no timing information.
TIMER_WAIT	bigint(20) unsigned	The unit is picoseconds. Event duration. NULL if event has not timing information.
ACCESS_MODE	enum('READ ONLY', 'READ WRITE')	Transaction access mode.
ISOLATION_LEVEL	varchar(64)	Transaction isolation level. One of: REPEATABLE READ, READ COMMITTED, READ UNCOMMITTED, or SERIALIZABLE.
AUTOCOMMIT	enum('YES', 'NO')	NO
NUMBER_OF_SAVEPOINTS	bigint(20) unsigned	The number of SAVEPOINT statements issued during the transaction.
NUMBER_OF_ROLLBACK_TO_SAVEPOINT	bigint(20) unsigned	The number of ROLLBACK_TO_SAVEPOINT statements issued during the transaction.
NUMBER_OF_RELEASE_SAVEPOINT	bigint(20) unsigned	The number of RELEASE_SAVEPOINT statements issued during the transaction.
OBJECT_INSTANCE_BEGIN	bigint(20) unsigned	Unused.
NESTING_EVENT_ID	bigint(20) unsigned	The EVENT_ID value of the event within which this event is nested.
NESTING_EVENT_TYPE	enum('TRANSACTION', 'STATEMENT', 'STAGE', 'WAIT')	The nesting event type.

## 1.1.2.9.2.1.24 Performance Schema events\_transactions\_summary\_by\_account\_by\_event\_name Table

MariaDB starting with [10.5.2](#)

The `events_transactions_summary_by_account_by_event_name` table was introduced in [MariaDB 10.5.2](#).

The

`events_transactions_summary_by_account_by_event_name`  
table contains information on transaction events aggregated by account and event name.

The table contains the following columns:

Column	Type	Description
USER	char(32)	User for which summary is generated.
HOST	char(60)	Host for which summary is generated.
EVENT_NAME	varchar(128)	Event name for which summary is generated.
COUNT_STAR	bigint(20) unsigned	The number of summarized events. This value includes all events, whether timed or nontimed.
SUM_TIMER_WAIT	bigint(20) unsigned	The total wait time of the summarized timed events. This value is calculated only for timed events because nontimed events have a wait time of NULL. The same is true for the other <code>xxx_TIMER_WAIT</code> values.
MIN_TIMER_WAIT	bigint(20) unsigned	The minimum wait time of the summarized timed events.
AVG_TIMER_WAIT	bigint(20) unsigned	The average wait time of the summarized timed events.
MAX_TIMER_WAIT	bigint(20) unsigned	The maximum wait time of the summarized timed events.
COUNT_READ_WRITE	bigint(20) unsigned	The total number of only READ/WRITE transaction events.
SUM_TIMER_READ_WRITE	bigint(20) unsigned	The total wait time of only READ/WRITE transaction events.
MIN_TIMER_READ_WRITE	bigint(20) unsigned	The minimum wait time of only READ/WRITE transaction events.
AVG_TIMER_READ_WRITE	bigint(20) unsigned	The average wait time of only READ/WRITE transaction events.
MAX_TIMER_READ_WRITE	bigint(20) unsigned	The maximum wait time of only READ/WRITE transaction events.
COUNT_READ_ONLY	bigint(20) unsigned	The total number of only READ ONLY transaction events.
SUM_TIMER_READ_ONLY	bigint(20) unsigned	The total wait time of only READ ONLY transaction events.
MIN_TIMER_READ_ONLY	bigint(20) unsigned	The minimum wait time of only READ ONLY transaction events.
AVG_TIMER_READ_ONLY	bigint(20) unsigned	The average wait time of only READ ONLY transaction events.
MAX_TIMER_READ_ONLY	bigint(20) unsigned	The maximum wait time of only READ ONLY transaction events.

## 1.1.2.9.2.1.25 Performance Schema `events_transactions_summary_by_host_by_event_name` Table

MariaDB starting with [10.5.2](#)

The `events_transactions_summary_by_host_by_event_name` table was introduced in [MariaDB 10.5.2](#).

The

`events_transactions_summary_by_host_by_event_name`  
table contains information on transaction events aggregated by host and event name.

The table contains the following columns:

Column	Type	Description
HOST	char(60)	Host for which summary is generated.
EVENT_NAME	varchar(128)	Event name for which summary is generated.
COUNT_STAR	bigint(20) unsigned	The number of summarized events. This value includes all events, whether timed or nontimed.
SUM_TIMER_WAIT	bigint(20) unsigned	The total wait time of the summarized timed events. This value is calculated only for timed events because nontimed events have a wait time of NULL. The same is true for the other xxx_TIMER_WAIT values.
MIN_TIMER_WAIT	bigint(20) unsigned	The minimum wait time of the summarized timed events.
AVG_TIMER_WAIT	bigint(20) unsigned	The average wait time of the summarized timed events.
MAX_TIMER_WAIT	bigint(20) unsigned	The maximum wait time of the summarized timed events.
COUNT_READ_WRITE	bigint(20) unsigned	The total number of only READ/WRITE transaction events.
SUM_TIMER_READ_WRITE	bigint(20) unsigned	The total wait time of only READ/WRITE transaction events.
MIN_TIMER_READ_WRITE	bigint(20) unsigned	The minimum wait time of only READ/WRITE transaction events.
AVG_TIMER_READ_WRITE	bigint(20) unsigned	The average wait time of only READ/WRITE transaction events.
MAX_TIMER_READ_WRITE	bigint(20) unsigned	The maximum wait time of only READ/WRITE transaction events.
COUNT_READ_ONLY	bigint(20) unsigned	The total number of only READ ONLY transaction events.
SUM_TIMER_READ_ONLY	bigint(20) unsigned	The total wait time of only READ ONLY transaction events.
MIN_TIMER_READ_ONLY	bigint(20) unsigned	The minimum wait time of only READ ONLY transaction events.
AVG_TIMER_READ_ONLY	bigint(20) unsigned	The average wait time of only READ ONLY transaction events.
MAX_TIMER_READ_ONLY	bigint(20) unsigned	The maximum wait time of only READ ONLY transaction events.

## 1.1.2.9.2.1.26 Performance Schema events\_transactions\_summary\_by\_thread\_by\_event\_name Table

MariaDB starting with [10.5.2](#)

The events\_transactions\_summary\_by\_thread\_by\_event\_name table was introduced in [MariaDB 10.5.2](#).

The

events\_transactions\_summary\_by\_thread\_by\_event\_name  
table contains information on transaction events aggregated by thread and event name.

The table contains the following columns:

Field	Type	Null	Key	Default	Extra
THREAD_ID	bigint(20) unsigned	NO		NULL	
EVENT_NAME	varchar(128)	NO		NULL	
COUNT_STAR	bigint(20) unsigned	NO		NULL	
SUM_TIMER_WAIT	bigint(20) unsigned	NO		NULL	
MIN_TIMER_WAIT	bigint(20) unsigned	NO		NULL	
AVG_TIMER_WAIT	bigint(20) unsigned	NO		NULL	
MAX_TIMER_WAIT	bigint(20) unsigned	NO		NULL	
COUNT_READ_WRITE	bigint(20) unsigned	NO		NULL	
SUM_TIMER_READ_WRITE	bigint(20) unsigned	NO		NULL	
MIN_TIMER_READ_WRITE	bigint(20) unsigned	NO		NULL	
AVG_TIMER_READ_WRITE	bigint(20) unsigned	NO		NULL	
MAX_TIMER_READ_WRITE	bigint(20) unsigned	NO		NULL	
COUNT_READ_ONLY	bigint(20) unsigned	NO		NULL	
SUM_TIMER_READ_ONLY	bigint(20) unsigned	NO		NULL	
MIN_TIMER_READ_ONLY	bigint(20) unsigned	NO		NULL	
AVG_TIMER_READ_ONLY	bigint(20) unsigned	NO		NULL	
MAX_TIMER_READ_ONLY	bigint(20) unsigned	NO		NULL	

## 1.1.2.9.2.1.27 Performance Schema events\_transactions\_summary\_by\_user\_by\_event\_name Table

MariaDB starting with [10.5.2](#)

The `events_transactions_summary_by_user_by_event_name` table was introduced in [MariaDB 10.5.2](#).

The

`events_transactions_summary_by_user_by_event_name`  
table contains information on transaction events aggregated by user and event name.

The table contains the following columns:

Field	Type	Null	Key	Default	Extra
USER	char(32)	YES		NULL	
EVENT_NAME	varchar(128)	NO		NULL	
COUNT_STAR	bigint(20) unsigned	NO		NULL	
SUM_TIMER_WAIT	bigint(20) unsigned	NO		NULL	
MIN_TIMER_WAIT	bigint(20) unsigned	NO		NULL	
AVG_TIMER_WAIT	bigint(20) unsigned	NO		NULL	
MAX_TIMER_WAIT	bigint(20) unsigned	NO		NULL	
COUNT_READ_WRITE	bigint(20) unsigned	NO		NULL	
SUM_TIMER_READ_WRITE	bigint(20) unsigned	NO		NULL	
MIN_TIMER_READ_WRITE	bigint(20) unsigned	NO		NULL	
AVG_TIMER_READ_WRITE	bigint(20) unsigned	NO		NULL	
MAX_TIMER_READ_WRITE	bigint(20) unsigned	NO		NULL	
COUNT_READ_ONLY	bigint(20) unsigned	NO		NULL	
SUM_TIMER_READ_ONLY	bigint(20) unsigned	NO		NULL	
MIN_TIMER_READ_ONLY	bigint(20) unsigned	NO		NULL	
AVG_TIMER_READ_ONLY	bigint(20) unsigned	NO		NULL	
MAX_TIMER_READ_ONLY	bigint(20) unsigned	NO		NULL	

## 1.1.2.9.2.1.28 Performance Schema events\_transactions\_summary\_global\_by\_event\_name Table

MariaDB starting with [10.5.2](#)

The `events_transactions_summary_global_by_event_name` table was introduced in [MariaDB 10.5.2](#).

The

`events_transactions_summary_global_by_event_name`  
 table contains information on transaction events aggregated by event name.

The table contains the following columns:

Field	Type	Null	Key	Default	Extra
EVENT_NAME	varchar(128)	NO		NULL	
COUNT_STAR	bigint(20) unsigned	NO		NULL	
SUM_TIMER_WAIT	bigint(20) unsigned	NO		NULL	
MIN_TIMER_WAIT	bigint(20) unsigned	NO		NULL	
AVG_TIMER_WAIT	bigint(20) unsigned	NO		NULL	
MAX_TIMER_WAIT	bigint(20) unsigned	NO		NULL	
COUNT_READ_WRITE	bigint(20) unsigned	NO		NULL	
SUM_TIMER_READ_WRITE	bigint(20) unsigned	NO		NULL	
MIN_TIMER_READ_WRITE	bigint(20) unsigned	NO		NULL	
AVG_TIMER_READ_WRITE	bigint(20) unsigned	NO		NULL	
MAX_TIMER_READ_WRITE	bigint(20) unsigned	NO		NULL	
COUNT_READ_ONLY	bigint(20) unsigned	NO		NULL	
SUM_TIMER_READ_ONLY	bigint(20) unsigned	NO		NULL	
MIN_TIMER_READ_ONLY	bigint(20) unsigned	NO		NULL	
AVG_TIMER_READ_ONLY	bigint(20) unsigned	NO		NULL	
MAX_TIMER_READ_ONLY	bigint(20) unsigned	NO		NULL	

## 1.1.2.9.2.1.29 Performance Schema events\_waits\_current Table

The

`events_waits_current`  
 table contains the status of a thread's most recently monitored wait event, listing one event per thread.

The table contains the following columns:

Column	Description
THREAD_ID	Thread associated with the event. Together with <code>EVENT_ID</code> uniquely identifies the row.
EVENT_ID	Thread's current event number at the start of the event. Together with <code>THREAD_ID</code> uniquely identifies the row.
END_EVENT_ID	NULL when the event starts, set to the thread's current event number at the end of the event.
EVENT_NAME	Event instrument name and a <code>NAME</code> from the <code>setup_instruments</code> table
SOURCE	Name and line number of the source file containing the instrumented code that produced the event.
TIMER_START	Value in picoseconds when the event timing started or <code>NULL</code> if timing is not collected.
TIMER_END	Value in picoseconds when the event timing ended, or <code>NULL</code> if the event has not ended or timing is not collected.
TIMER_WAIT	Value in picoseconds of the event's duration or <code>NULL</code> if the event has not ended or timing is not collected.
SPINS	Number of spin rounds for a mutex, or <code>NULL</code> if spin rounds are not used, or spinning is not instrumented.

OBJECT_SCHEMA	Name of the schema that contains the table for table I/O objects, otherwise NULL for file I/O and synchronization objects.
OBJECT_NAME	File name for file I/O objects, table name for table I/O objects, the socket's IP : PORT value for a socket object or NULL for a synchronization object.
INDEX_NAME	Name of the index, PRIMARY for the primary key, or NULL for no index used.
OBJECT_TYPE	FILE for a file object, TABLE or TEMPORARY TABLE for a table object, or NULL for a synchronization object.
OBJECT_INSTANCE_BEGIN	Address in memory of the object.
NESTING_EVENT_ID	EVENT_ID of event within which this event nests.
NESTING_EVENT_TYPE	Nesting event type. Either statement ,, stage or wait .
OPERATION	Operation type, for example read, write or lock
NUMBER_OF_BYTES	Number of bytes that the operation read or wrote, or NULL for table I/O waits.
FLAGS	Reserved for use in the future.

It is possible to empty this table with a

```
TRUNCATE TABLE
statement.
```

The related tables, [events\\_waits\\_history](#) and [events\\_waits\\_history\\_long](#) derive their values from the current events.

## 1.1.2.9.2.1.30 Performance Schema events\_waits\_history Table

The

```
events_waits_history
table by default contains the ten most recent completed wait events per thread. This number can be adjusted by setting the
performance_schema_events_waits_history_size system variable when the server starts up.
```

The table structure is identical to the [events\\_waits\\_current](#) table structure, and contains the following columns:

Column	Description
THREAD_ID	Thread associated with the event. Together with EVENT_ID uniquely identifies the row.

EVENT_ID	Thread's current event number at the start of the event. Together with THREAD_ID uniquely identifies the row.
END_EVENT_ID	NULL when the event starts, set to the thread's current event number at the end of the event.
EVENT_NAME	Event instrument name and a NAME from the setup_instruments table
SOURCE	Name and line number of the source file containing the instrumented code that produced the event.
TIMER_START	Value in picoseconds when the event timing started or NULL if timing is not collected.
TIMER_END	Value in picoseconds when the event timing ended, or NULL if timing is not collected.
TIMER_WAIT	Value in picoseconds of the event's duration or NULL if timing is not collected.
SPINS	Number of spin rounds for a mutex, or NULL if spin rounds are not used, or spinning is not instrumented.
OBJECT_SCHEMA	Name of the schema that contains the table for table I/O objects, otherwise NULL for file I/O and synchronization objects.
OBJECT_NAME	File name for file I/O objects, table name for table I/O objects, the socket's IP:PORT value for a socket object or NULL for a synchronization object.
INDEX_NAME	Name of the index, PRIMARY for the primary key, or NULL for no index used.
OBJECT_TYPE	FILE for a file object, TABLE or TEMPORARY TABLE for a table object, or NULL for a synchronization object.
OBJECT_INSTANCE_BEGIN	Address in memory of the object.
NESTING_EVENT_ID	EVENT_ID of event within which this event nests.
NESTING_EVENT_TYPE	Nesting event type. Either statement ,, stage or wait .
OPERATION	Operation type, for example read, write or lock

NUMBER_OF_BYTES	Number of bytes that the operation read or wrote, or NULL for table I/O waits.
FLAGS	Reserved for use in the future.

It is possible to empty this table with a

```
TRUNCATE TABLE
```

[events\\_waits\\_current](#) and [events\\_waits\\_history\\_long](#) are related tables.

## 1.1.2.9.2.1.31 Performance Schema events\_waits\_summary\_by\_account\_by\_event\_name Table

The [Performance Schema](#)

[events\\_waits\\_summary\\_by\\_account\\_by\\_event\\_name](#)

table contains wait events summarized by account and event name. It contains the following columns:

Column	Description
USER	User. Used together with HOST and EVENT_NAME for grouping events.
HOST	Host. Used together with USER and EVENT_NAME for grouping events.
EVENT_NAME	Event name. Used together with USER and HOST for grouping events.
COUNT_STAR	Number of summarized events
SUM_TIMER_WAIT	Total wait time of the summarized events that are timed.
MIN_TIMER_WAIT	Minimum wait time of the summarized events that are timed.
AVG_TIMER_WAIT	Average wait time of the summarized events that are timed.
MAX_TIMER_WAIT	Maximum wait time of the summarized events that are timed.

The

```
*_TIMER_WAIT
```

columns only calculate results for timed events, as non-timed events have a  
NULL  
wait time.

## Example

```

SELECT * FROM events_waits_summary_by_account_by_event_name\G
...
***** 915. row *****
    USER: NULL
    HOST: NULL
  EVENT_NAME: wait/io/socket/sql/server_tcpip_socket
  COUNT_STAR: 0
SUM_TIMER_WAIT: 0
MIN_TIMER_WAIT: 0
AVG_TIMER_WAIT: 0
MAX_TIMER_WAIT: 0
***** 916. row *****
    USER: NULL
    HOST: NULL
  EVENT_NAME: wait/io/socket/sql/server_unix_socket
  COUNT_STAR: 0
SUM_TIMER_WAIT: 0
MIN_TIMER_WAIT: 0
AVG_TIMER_WAIT: 0
MAX_TIMER_WAIT: 0
***** 917. row *****
    USER: NULL
    HOST: NULL
  EVENT_NAME: wait/io/socket/sql/client_connection
  COUNT_STAR: 0
SUM_TIMER_WAIT: 0
MIN_TIMER_WAIT: 0
AVG_TIMER_WAIT: 0
MAX_TIMER_WAIT: 0
***** 918. row *****
    USER: NULL
    HOST: NULL
  EVENT_NAME: idle
  COUNT_STAR: 0
SUM_TIMER_WAIT: 0
MIN_TIMER_WAIT: 0
AVG_TIMER_WAIT: 0
MAX_TIMER_WAIT: 0

```

## 1.1.2.9.2.1.32 Performance Schema events\_waits\_summary\_by\_host\_by\_event\_name Table

The [Performance Schema](#)

`events_waits_summary_by_host_by_event_name`

table contains wait events summarized by host and event name. It contains the following columns:

Column	Description
HOST	Host. Used together with EVENT_NAME for grouping events.
EVENT_NAME	Event name. Used together with USER and HOST for grouping events.
COUNT_STAR	Number of summarized events
SUM_TIMER_WAIT	Total wait time of the summarized events that are timed.
MIN_TIMER_WAIT	Minimum wait time of the summarized events that are timed.
AVG_TIMER_WAIT	Average wait time of the summarized events that are timed.

MAX_TIMER_WAIT	Maximum wait time of the summarized events that are timed.
----------------	--

The

```
* _TIMER_WAIT
columns only calculate results for timed events, as non-timed events have a
NULL
wait time.
```

## Example

```
SELECT * FROM events_waits_summary_by_host_by_event_name\G
...
*****
610. row ****
HOST: NULL
EVENT_NAME: wait/io/socket/sql/server_unix_socket
COUNT_STAR: 0
SUM_TIMER_WAIT: 0
MIN_TIMER_WAIT: 0
AVG_TIMER_WAIT: 0
MAX_TIMER_WAIT: 0
*****
611. row ****
HOST: NULL
EVENT_NAME: wait/io/socket/sql/client_connection
COUNT_STAR: 0
SUM_TIMER_WAIT: 0
MIN_TIMER_WAIT: 0
AVG_TIMER_WAIT: 0
MAX_TIMER_WAIT: 0
*****
612. row ****
HOST: NULL
EVENT_NAME: idle
COUNT_STAR: 0
SUM_TIMER_WAIT: 0
MIN_TIMER_WAIT: 0
AVG_TIMER_WAIT: 0
MAX_TIMER_WAIT: 0
```

## 1.1.2.9.2.1.33 Performance Schema events\_waits\_summary\_by\_instance Table

The [Performance Schema](#)

`events_waits_summary_by_instance`  
table contains wait events summarized by instance. It contains the following columns:

Column	Description
EVENT_NAME	Event name. Used together with <code>OBJECT_INSTANCE_BEGIN</code> for grouping events.
OBJECT_INSTANCE_BEGIN	If an instrument creates multiple instances, each instance has a unique <code>OBJECT_INSTANCE_BEGIN</code> value to allow for grouping by instance.
COUNT_STAR	Number of summarized events
SUM_TIMER_WAIT	Total wait time of the summarized events that are timed.
MIN_TIMER_WAIT	Minimum wait time of the summarized events that are timed.
AVG_TIMER_WAIT	Average wait time of the summarized events that are timed.

MAX_TIMER_WAIT	Maximum wait time of the summarized events that are timed.
----------------	--

The

```
*_TIMER_WAIT
columns only calculate results for timed events, as non-timed events have a
NULL
wait time.
```

## Example

```
SELECT * FROM events_waits_summary_by_instance\G
...
***** 202. row *****
EVENT_NAME: wait/io/file/sql/binlog
OBJECT_INSTANCE_BEGIN: 140578961969856
COUNT_STAR: 6
SUM_TIMER_WAIT: 90478331960
MIN_TIMER_WAIT: 263344
AVG_TIMER_WAIT: 15079721848
MAX_TIMER_WAIT: 67760576376
***** 203. row *****
EVENT_NAME: wait/io/file/sql/dbopt
OBJECT_INSTANCE_BEGIN: 140578961970560
COUNT_STAR: 6
SUM_TIMER_WAIT: 39891428472
MIN_TIMER_WAIT: 387168
AVG_TIMER_WAIT: 6648571412
MAX_TIMER_WAIT: 24503293304
***** 204. row *****
EVENT_NAME: wait/io/file/sql/dbopt
OBJECT_INSTANCE_BEGIN: 140578961971264
COUNT_STAR: 6
SUM_TIMER_WAIT: 39902495024
MIN_TIMER_WAIT: 177888
AVG_TIMER_WAIT: 6650415692
MAX_TIMER_WAIT: 21026400404
```

### 1.1.2.9.2.1.34 Performance Schema events\_waits\_summary\_by\_thread\_by\_event\_name Table

The [Performance Schema](#)

`events_waits_summary_by_thread_by_event_name`  
table contains wait events summarized by thread and event name. It contains the following columns:

Column	Description
THREAD_ID	Thread associated with the event. Together with EVENT_NAME uniquely identifies the row.
EVENT_NAME	Event name. Used together with THREAD_ID for grouping events.
COUNT_STAR	Number of summarized events
SUM_TIMER_WAIT	Total wait time of the summarized events that are timed.
MIN_TIMER_WAIT	Minimum wait time of the summarized events that are timed.
AVG_TIMER_WAIT	Average wait time of the summarized events that are timed.

MAX_TIMER_WAIT	Maximum wait time of the summarized events that are timed.
----------------	--

The

```
* _TIMER_WAIT
columns only calculate results for timed events, as non-timed events have a
NULL
wait time.
```

## Example

```
SELECT * FROM events_waits_summary_by_thread_by_event_name\G
...
*****6424. row *****
THREAD_ID: 64
EVENT_NAME: wait/io/socket/sql/server_unix_socket
COUNT_STAR: 0
SUM_TIMER_WAIT: 0
MIN_TIMER_WAIT: 0
AVG_TIMER_WAIT: 0
MAX_TIMER_WAIT: 0
*****6425. row *****
THREAD_ID: 64
EVENT_NAME: wait/io/socket/sql/client_connection
COUNT_STAR: 0
SUM_TIMER_WAIT: 0
MIN_TIMER_WAIT: 0
AVG_TIMER_WAIT: 0
MAX_TIMER_WAIT: 0
*****6426. row *****
THREAD_ID: 64
EVENT_NAME: idle
COUNT_STAR: 73
SUM_TIMER_WAIT: 2200525216200000
MIN_TIMER_WAIT: 300000
AVG_TIMER_WAIT: 30144181000000
MAX_TIMER_WAIT: 491241757300000
```

### 1.1.2.9.2.1.35 Performance Schema events\_waits\_summary\_by\_user\_by\_event\_name Table

The [Performance Schema](#)

`events_waits_summary_by_user_by_event_name`  
table contains wait events summarized by user and event name. It contains the following columns:

Column	Description
USER	User. Used together with EVENT_NAME for grouping events.
EVENT_NAME	Event name. Used together with USER for grouping events.
COUNT_STAR	Number of summarized events
SUM_TIMER_WAIT	Total wait time of the summarized events that are timed.
MIN_TIMER_WAIT	Minimum wait time of the summarized events that are timed.
AVG_TIMER_WAIT	Average wait time of the summarized events that are timed.

MAX_TIMER_WAIT	Maximum wait time of the summarized events that are timed.
----------------	--

The

```
* _TIMER_WAIT
columns only calculate results for timed events, as non-timed events have a
NULL
wait time.
```

## Example

```
SELECT * FROM events_waits_summary_by_user_by_event_name\G
...
*****916. row *****
USER: NULL
EVENT_NAME: wait/io/socket/sql/server_unix_socket
COUNT_STAR: 0
SUM_TIMER_WAIT: 0
MIN_TIMER_WAIT: 0
AVG_TIMER_WAIT: 0
MAX_TIMER_WAIT: 0
*****917. row *****
USER: NULL
EVENT_NAME: wait/io/socket/sql/client_connection
COUNT_STAR: 0
SUM_TIMER_WAIT: 0
MIN_TIMER_WAIT: 0
AVG_TIMER_WAIT: 0
MAX_TIMER_WAIT: 0
*****918. row *****
USER: NULL
EVENT_NAME: idle
COUNT_STAR: 0
SUM_TIMER_WAIT: 0
MIN_TIMER_WAIT: 0
AVG_TIMER_WAIT: 0
MAX_TIMER_WAIT: 0
```

## 1.1.2.9.2.1.36 Performance Schema events\_waits\_summary\_global\_by\_event\_name Table

The [Performance Schema](#)

`events_waits_summary_global_by_event_name`  
table contains wait events summarized by event name. It contains the following columns:

Column	Description
EVENT_NAME	Event name.
COUNT_STAR	Number of summarized events
SUM_TIMER_WAIT	Total wait time of the summarized events that are timed.
MIN_TIMER_WAIT	Minimum wait time of the summarized events that are timed.
AVG_TIMER_WAIT	Average wait time of the summarized events that are timed.
MAX_TIMER_WAIT	Maximum wait time of the summarized events that are timed.

The

```
* _TIMER_WAIT
columns only calculate results for timed events, as non-timed events have a
NULL
wait time.
```

## Example

```
SELECT * FROM events_waits_summary_global_by_event_name\G
...
***** 303. row *****
EVENT_NAME: wait/io/socket/sql/server_tcpip_socket
COUNT_STAR: 0
SUM_TIMER_WAIT: 0
MIN_TIMER_WAIT: 0
AVG_TIMER_WAIT: 0
MAX_TIMER_WAIT: 0
***** 304. row *****
EVENT_NAME: wait/io/socket/sql/server_unix_socket
COUNT_STAR: 0
SUM_TIMER_WAIT: 0
MIN_TIMER_WAIT: 0
AVG_TIMER_WAIT: 0
MAX_TIMER_WAIT: 0
***** 305. row *****
EVENT_NAME: wait/io/socket/sql/client_connection
COUNT_STAR: 0
SUM_TIMER_WAIT: 0
MIN_TIMER_WAIT: 0
AVG_TIMER_WAIT: 0
MAX_TIMER_WAIT: 0
***** 306. row *****
EVENT_NAME: idle
COUNT_STAR: 265
SUM_TIMER_WAIT: 4686112518100000
MIN_TIMER_WAIT: 1000000
AVG_TIMER_WAIT: 17683443400000
MAX_TIMER_WAIT: 491241757300000
```

## 1.1.2.9.2.1.37 Performance Schema file\_instances Table

### Description

The

`file_instances`

table lists instances of instruments seen by the Performance Schema when executing file I/O instrumentation, and the associated files. Only files that have been opened, and that have not been deleted, will be listed in the table.

The `performance_schema_max_file_instances` system variable specifies the maximum number of instrumented file objects.

Column	Description
<code>FILE_NAME</code>	File name.
<code>EVENT_NAME</code>	Instrument name associated with the file.
<code>OPEN_COUNT</code>	Open handles on the file. A value of greater than zero means that the file is currently open.

## Example

```
SELECT * FROM performance_schema.file_instances WHERE OPEN_COUNT>0;
```

FILE_NAME	EVENT_NAME	OPEN_COUNT
/var/log/mysql/mariadb-bin.index	wait/io/file/sql/binlog_index	1
/var/lib/mysql/ibdata1	wait/io/file/innodb/innodb_data_file	2
/var/lib/mysql/ib_logfile0	wait/io/file/innodb/innodb_log_file	2
/var/lib/mysql/ib_logfile1	wait/io/file/innodb/innodb_log_file	2
/var/lib/mysql/mysql/gtid_slave_pos.ibd	wait/io/file/innodb/innodb_data_file	3
/var/lib/mysql/mysql/innodb_index_stats.ibd	wait/io/file/innodb/innodb_data_file	3
/var/lib/mysql/mysql/innodb_table_stats.ibd	wait/io/file/innodb/innodb_data_file	3
...		

## 1.1.2.9.2.1.38 Performance Schema file\_summary\_by\_event\_name Table

The [Performance Schema](#)

`file_summary_by_event_name`

table contains file events summarized by event name. As of [MariaDB 10.0](#), it contains the following columns:

Column	Description
EVENT_NAME	Event name.
COUNT_STAR	Number of summarized events
SUM_TIMER_WAIT	Total wait time of the summarized events that are timed.
MIN_TIMER_WAIT	Minimum wait time of the summarized events that are timed.
AVG_TIMER_WAIT	Average wait time of the summarized events that are timed.
MAX_TIMER_WAIT	Maximum wait time of the summarized events that are timed.
COUNT_READ	Number of all read operations, including FGETS ,FGETC ,FREAD , and READ
SUM_TIMER_READ	Total wait time of all read operations that are timed.
MIN_TIMER_READ	Minimum wait time of all read operations that are timed.
AVG_TIMER_READ	Average wait time of all read operations that are timed.
MAX_TIMER_READ	Maximum wait time of all read operations that are timed.
SUM_NUMBER_OF_BYTES_READ	Bytes read by read operations.

COUNT_WRITE	Number of all write operations, including FPUTS ,, FPUTC ,, FPRINTF ,, VFPRINTF ,, FWRITE , and PWRITE  .
SUM_TIMER_WRITE	Total wait time of all write operations that are timed.
MIN_TIMER_WRITE	Minimum wait time of all write operations that are timed.
AVG_TIMER_WRITE	Average wait time of all write operations that are timed.
MAX_TIMER_WRITE	Maximum wait time of all write operations that are timed.
SUM_NUMBER_OF_BYTES_WRITE	Bytes written by write operations.
COUNT_MISC	Number of all miscellaneous operations not counted above, including CREATE ,, DELETE ,, OPEN ,, CLOSE ,, STREAM_OPEN ,, STREAM_CLOSE ,, SEEK ,, TELL ,, FLUSH ,, STAT ,, FSTAT ,, CHSIZE ,, RENAME , and SYNC  .
SUM_TIMER_MISC	Total wait time of all miscellaneous operations that are timed.
MIN_TIMER_MISC	Minimum wait time of all miscellaneous operations that are timed.
AVG_TIMER_MISC	Average wait time of all miscellaneous operations that are timed.

MAX_TIMER_MISC	Maximum wait time of all miscellaneous operations that are timed.
----------------	---

Before MariaDB 10, the table contained only the

```
EVENT_NAME
,
COUNT_READ
,
COUNT_WRITE
,
SUM_NUMBER_OF_BYTES_READ
and
SUM_NUMBER_OF_BYTES_WRITE
columns.
```

I/O operations can be avoided by caching, in which case they will not be recorded in this table.

You can [TRUNCATE](#) the table, which will reset all counters to zero.

## Example

```
SELECT * FROM file_summary_by_event_name\G
...
***** 49. row *****
    EVENT_NAME: wait/io/file/aria/MAD
    COUNT_STAR: 60
    SUM_TIMER_WAIT: 397234368
    MIN_TIMER_WAIT: 0
    AVG_TIMER_WAIT: 6620224
    MAX_TIMER_WAIT: 16808672
        COUNT_READ: 0
    SUM_TIMER_READ: 0
    MIN_TIMER_READ: 0
    AVG_TIMER_READ: 0
    MAX_TIMER_READ: 0
    SUM_NUMBER_OF_BYTES_READ: 0
        COUNT_WRITE: 0
    SUM_TIMER_WRITE: 0
    MIN_TIMER_WRITE: 0
    AVG_TIMER_WRITE: 0
    MAX_TIMER_WRITE: 0
    SUM_NUMBER_OF_BYTES_WRITE: 0
        COUNT_MISC: 60
    SUM_TIMER_MISC: 397234368
    MIN_TIMER_MISC: 0
    AVG_TIMER_MISC: 6620224
    MAX_TIMER_MISC: 16808672
***** 50. row *****
    EVENT_NAME: wait/io/file/aria/control
    COUNT_STAR: 3
    SUM_TIMER_WAIT: 24055778544
    MIN_TIMER_WAIT: 0
    AVG_TIMER_WAIT: 8018592848
    MAX_TIMER_WAIT: 24027262400
        COUNT_READ: 1
    SUM_TIMER_READ: 24027262400
    MIN_TIMER_READ: 0
    AVG_TIMER_READ: 24027262400
    MAX_TIMER_READ: 24027262400
    SUM_NUMBER_OF_BYTES_READ: 52
        COUNT_WRITE: 0
    SUM_TIMER_WRITE: 0
    MIN_TIMER_WRITE: 0
    AVG_TIMER_WRITE: 0
    MAX_TIMER_WRITE: 0
    SUM_NUMBER_OF_BYTES_WRITE: 0
        COUNT_MISC: 2
    SUM_TIMER_MISC: 28516144
    MIN_TIMER_MISC: 0
    AVG_TIMER_MISC: 14258072
    MAX_TIMER_MISC: 27262208
```

## 1.1.2.9.2.1.39 Performance Schema file\_summary\_by\_instance Table

The [Performance Schema](#)

`file_summary_by_instance`

table contains file events summarized by instance. As of [MariaDB 10.0](#), it contains the following columns:

Column	Description
<code>FILE_NAME</code>	File name.
<code>EVENT_NAME</code>	Event name.
<code>OBJECT_INSTANCE_BEGIN</code>	Address in memory. Together with <code>FILE_NAME</code> and <code>EVENT_NAME</code> uniquely identifies a row.
<code>COUNT_STAR</code>	Number of summarized events
<code>SUM_TIMER_WAIT</code>	Total wait time of the summarized events that are timed.
<code>MIN_TIMER_WAIT</code>	Minimum wait time of the summarized events that are timed.
<code>AVG_TIMER_WAIT</code>	Average wait time of the summarized events that are timed.
<code>MAX_TIMER_WAIT</code>	Maximum wait time of the summarized events that are timed.
<code>COUNT_READ</code>	Number of all read operations, including <code>FGETS</code> , <code>FGETC</code> , <code>FREAD</code> , and <code>READ</code> .
<code>SUM_TIMER_READ</code>	Total wait time of all read operations that are timed.
<code>MIN_TIMER_READ</code>	Minimum wait time of all read operations that are timed.
<code>AVG_TIMER_READ</code>	Average wait time of all read operations that are timed.
<code>MAX_TIMER_READ</code>	Maximum wait time of all read operations that are timed.
<code>SUM_NUMBER_OF_BYTES_READ</code>	Bytes read by read operations.

COUNT_WRITE	Number of all write operations, including FPUTS ,, FPUTC ,, FPRINTF ,, VFPRINTF ,, FWRITE , and PWRITE  .
SUM_TIMER_WRITE	Total wait time of all write operations that are timed.
MIN_TIMER_WRITE	Minimum wait time of all write operations that are timed.
AVG_TIMER_WRITE	Average wait time of all write operations that are timed.
MAX_TIMER_WRITE	Maximum wait time of all write operations that are timed.
SUM_NUMBER_OF_BYTES_WRITE	Bytes written by write operations.
COUNT_MISC	Number of all miscellaneous operations not counted above, including CREATE ,, DELETE ,, OPEN ,, CLOSE ,, STREAM_OPEN ,, STREAM_CLOSE ,, SEEK ,, TELL ,, FLUSH ,, STAT ,, FSTAT ,, CHSIZE ,, RENAME , and SYNC  .
SUM_TIMER_MISC	Total wait time of all miscellaneous operations that are timed.
MIN_TIMER_MISC	Minimum wait time of all miscellaneous operations that are timed.
AVG_TIMER_MISC	Average wait time of all miscellaneous operations that are timed.

MAX_TIMER_MISC	Maximum wait time of all miscellaneous operations that are timed.
----------------	---

Before MariaDB 10, the table contained only the

```
FILE_NAME  
,  
EVENT_NAME  
,  
COUNT_READ  
,  
COUNT_WRITE  
,  
SUM_NUMBER_OF_BYTES_READ  
and  
SUM_NUMBER_OF_BYTES_WRITE  
columns.
```

I/O operations can be avoided by caching, in which case they will not be recorded in this table.

You can [TRUNCATE](#) the table, which will reset all counters to zero.

## Example

```

SELECT * FROM file_summary_by_instance\G
...
***** 204. row *****
    FILE_NAME: /var/lib/mysql/test/db.opt
    EVENT_NAME: wait/io/file/sql/dbopt
OBJECT_INSTANCE_BEGIN: 140578961971264
    COUNT_STAR: 6
    SUM_TIMER_WAIT: 39902495024
    MIN_TIMER_WAIT: 177888
    AVG_TIMER_WAIT: 6650415692
    MAX_TIMER_WAIT: 21026400404
    COUNT_READ: 1
    SUM_TIMER_READ: 21026400404
    MIN_TIMER_READ: 21026400404
    AVG_TIMER_READ: 21026400404
    MAX_TIMER_READ: 21026400404
SUM_NUMBER_OF_BYTES_READ: 65
    COUNT_WRITE: 0
    SUM_TIMER_WRITE: 0
    MIN_TIMER_WRITE: 0
    AVG_TIMER_WRITE: 0
    MAX_TIMER_WRITE: 0

```

## 1.1.2.9.2.1.40 Performance Schema global\_status Table

MariaDB starting with [10.5.2](#)

The

`global_status`  
table was added in [MariaDB 10.5.2](#).

The

`global_status`

table contains a list of status variables and their global values. The table only stores status variable statistics for threads which are instrumented, and does not collect statistics for

`Com_xxx`

variables.

The table contains the following columns:

Column	Description
--------	-------------

VARIABLE_NAME	The global status variable name.
VARIABLE_VALUE	The global status variable value.

`TRUNCATE TABLE` resets global status variables, including thread, account, host, and user status, but not those that are never reset by the server.

## 1.1.2.9.2.1.41 Performance Schema hosts Table

### Description

The  
 hosts  
 table contains a row for each host used by clients to connect to the server, containing current and total connections.  
 The size is determined by the `performance_schema_hosts_size` system variable, which, if set to zero, will disable connection statistics in the hosts table.  
 It contains the following columns:

Column	Description
HOST	Host name used by the client to connect, NULL for internal threads or user sessions that failed to authenticate.
CURRENT_CONNECTIONS	Current number of the host's connections.
TOTAL_CONNECTIONS	Total number of the host's connections

### Example

```
SELECT * FROM hosts;
+-----+-----+-----+
| HOST      | CURRENT_CONNECTIONS | TOTAL_CONNECTIONS |
+-----+-----+-----+
| localhost |              1 |          45 |
| NULL      |             20 |          23 |
+-----+-----+-----+
```

## 1.1.2.9.2.1.42 Performance Schema memory\_summary\_by\_account\_by\_event\_name Table

MariaDB starting with 10.5.2

The `memory_summary_by_account_by_event_name` table was introduced in MariaDB 10.5.2 .

There are five memory summary tables in the Performance Schema that share a number of fields in common. These include:

- `memory_summary_by_account_by_event_name`
- `memory_summary_by_host_by_event_name`
- `memory_summary_by_thread_by_event_name`
- `memory_summary_by_user_by_event_name`
- `memory_global_by_event_name`

The  
`memory_summary_by_account_by_event_name`

table contains memory usage statistics aggregated by account and event.

The table contains the following columns:

Field	Type	Null	Default	Description
USER	char(32)	YES	NULL	User portion of the account.
HOST	char(60)	YES	NULL	Host portion of the account.

EVENT_NAME	varchar(128)	NO	NULL	Event name.
COUNT_ALLOC	bigint(20) unsigned	NO	NULL	Total number of allocations to memory.
COUNT_FREE	bigint(20) unsigned	NO	NULL	Total number of attempts to free the allocated memory.
SUM_NUMBER_OF_BYTES_ALLOC	bigint(20) unsigned	NO	NULL	Total number of bytes allocated.
SUM_NUMBER_OF_BYTES_FREE	bigint(20) unsigned	NO	NULL	Total number of bytes freed
LOW_COUNT_USED	bigint(20)	NO	NULL	Lowest number of allocated blocks (lowest value of CURRENT_COUNT_USED).
CURRENT_COUNT_USED	bigint(20)	NO	NULL	Currently allocated blocks that have not been freed (COUNT_ALLOC minus COUNT_FREE).
HIGH_COUNT_USED	bigint(20)	NO	NULL	Highest number of allocated blocks (highest value of CURRENT_COUNT_USED).
LOW_NUMBER_OF_BYTES_USED	bigint(20)	NO	NULL	Lowest number of bytes used.
CURRENT_NUMBER_OF_BYTES_USED	bigint(20)	NO	NULL	Current number of bytes used (total allocated minus total freed).
HIGH_NUMBER_OF_BYTES_USED	bigint(20)	NO	NULL	Highest number of bytes used.

## 1.1.2.9.2.1.43 Performance Schema memory\_summary\_by\_host\_by\_event\_name Table

MariaDB starting with [10.5.2](#)

The `memory_summary_by_host_by_event_name` table was introduced in [MariaDB 10.5.2](#).

There are five memory summary tables in the Performance Schema that share a number of fields in common. These include:

- [memory\\_summary\\_by\\_account\\_by\\_event\\_name](#)
- [memory\\_summary\\_by\\_host\\_by\\_event\\_name](#)
- [memory\\_summary\\_by\\_thread\\_by\\_event\\_name](#)
- [memory\\_summary\\_by\\_user\\_by\\_event\\_name](#)
- [memory\\_global\\_by\\_event\\_name](#)

The

```
memory_summary_by_host_by_event_name
table contains memory usage statistics aggregated by host and event.
```

The table contains the following columns:

Field	Type	Null	Default	Description
HOST	char(60)	YES	NULL	Host portion of the account.
EVENT_NAME	varchar(128)	NO	NULL	Event name.
COUNT_ALLOC	bigint(20) unsigned	NO	NULL	Total number of allocations to memory.
COUNT_FREE	bigint(20) unsigned	NO	NULL	Total number of attempts to free the allocated memory.
SUM_NUMBER_OF_BYTES_ALLOC	bigint(20) unsigned	NO	NULL	Total number of bytes allocated.
SUM_NUMBER_OF_BYTES_FREE	bigint(20) unsigned	NO	NULL	Total number of bytes freed
LOW_COUNT_USED	bigint(20)	NO	NULL	Lowest number of allocated blocks (lowest value of CURRENT_COUNT_USED).
CURRENT_COUNT_USED	bigint(20)	NO	NULL	Currently allocated blocks that have not been freed (COUNT_ALLOC minus COUNT_FREE).
HIGH_COUNT_USED	bigint(20)	NO	NULL	Highest number of allocated blocks (highest value of CURRENT_COUNT_USED).
LOW_NUMBER_OF_BYTES_USED	bigint(20)	NO	NULL	Lowest number of bytes used.

CURRENT_NUMBEROFBYTESUSED	bigint(20)	NO	NULL	Current number of bytes used (total allocated minus total freed).
HIGH_NUMBER_OF_BYTES_USED	bigint(20)	NO	NULL	Highest number of bytes used.

## 1.1.2.9.2.1.44 Performance Schema memory\_summary\_by\_thread\_by\_event\_name Table

MariaDB starting with [10.5.2](#)

The memory\_summary\_by\_thread\_by\_event\_name table was introduced in [MariaDB 10.5.2](#).

There are five memory summary tables in the Performance Schema that share a number of fields in common. These include:

- [memory\\_summary\\_by\\_account\\_by\\_event\\_name](#)
- [memory\\_summary\\_by\\_host\\_by\\_event\\_name](#)
- [memory\\_summary\\_by\\_thread\\_by\\_event\\_name](#)
- [memory\\_summary\\_by\\_user\\_by\\_event\\_name](#)
- [memory\\_global\\_by\\_event\\_name](#)

The

```
memory_summary_by_thread_by_event_name
table contains memory usage statistics aggregated by thread and event.
```

The table contains the following columns:

Field	Type	Null	Default	Description
THREAD_ID	bigint(20) unsigned	NO	NULL	Thread id.
EVENT_NAME	varchar(128)	NO	NULL	Event name.
COUNT_ALLOC	bigint(20) unsigned	NO	NULL	Total number of allocations to memory.
COUNT_FREE	bigint(20) unsigned	NO	NULL	Total number of attempts to free the allocated memory.
SUM_NUMBER_OF_BYTES_ALLOC	bigint(20) unsigned	NO	NULL	Total number of bytes allocated.
SUM_NUMBER_OF_BYTES_FREE	bigint(20) unsigned	NO	NULL	Total number of bytes freed
LOW_COUNT_USED	bigint(20)	NO	NULL	Lowest number of allocated blocks (lowest value of CURRENT_COUNT_USED).
CURRENT_COUNT_USED	bigint(20)	NO	NULL	Currently allocated blocks that have not been freed (COUNT_ALLOC minus COUNT_FREE).
HIGH_COUNT_USED	bigint(20)	NO	NULL	Highest number of allocated blocks (highest value of CURRENT_COUNT_USED).
LOW_NUMBER_OF_BYTES_USED	bigint(20)	NO	NULL	Lowest number of bytes used.
CURRENT_NUMBER_OF_BYTES_USED	bigint(20)	NO	NULL	Current number of bytes used (total allocated minus total freed).
HIGH_NUMBER_OF_BYTES_USED	bigint(20)	NO	NULL	Highest number of bytes used.

## 1.1.2.9.2.1.45 Performance Schema memory\_summary\_by\_user\_by\_event\_name Table

MariaDB starting with [10.5.2](#)

The memory\_summary\_by\_user\_by\_event\_name table was introduced in [MariaDB 10.5.2](#).

There are five memory summary tables in the Performance Schema that share a number of fields in common. These include:

- [memory\\_summary\\_by\\_account\\_by\\_event\\_name](#)
- [memory\\_summary\\_by\\_host\\_by\\_event\\_name](#)
- [memory\\_summary\\_by\\_thread\\_by\\_event\\_name](#)
- [memory\\_summary\\_by\\_user\\_by\\_event\\_name](#)
- [memory\\_global\\_by\\_event\\_name](#)

The

### `memory_summary_by_user_by_event_name`

table contains memory usage statistics aggregated by user and event.

The table contains the following columns:

Field	Type	Null	Default	Description
USER	char(32)	YES	NULL	User portion of the account.
EVENT_NAME	varchar(128)	NO	NULL	Event name.
COUNT_ALLOC	bigint(20) unsigned	NO	NULL	Total number of allocations to memory.
COUNT_FREE	bigint(20) unsigned	NO	NULL	Total number of attempts to free the allocated memory.
SUM_NUMBER_OF_BYTES_ALLOC	bigint(20) unsigned	NO	NULL	Total number of bytes allocated.
SUM_NUMBER_OF_BYTES_FREE	bigint(20) unsigned	NO	NULL	Total number of bytes freed
LOW_COUNT_USED	bigint(20)	NO	NULL	Lowest number of allocated blocks (lowest value of CURRENT_COUNT_USED).
CURRENT_COUNT_USED	bigint(20)	NO	NULL	Currently allocated blocks that have not been freed (COUNT_ALLOC minus COUNT_FREE).
HIGH_COUNT_USED	bigint(20)	NO	NULL	Highest number of allocated blocks (highest value of CURRENT_COUNT_USED).
LOW_NUMBER_OF_BYTES_USED	bigint(20)	NO	NULL	Lowest number of bytes used.
CURRENT_NUMBER_OF_BYTES_USED	bigint(20)	NO	NULL	Current number of bytes used (total allocated minus total freed).
HIGH_NUMBER_OF_BYTES_USED	bigint(20)	NO	NULL	Highest number of bytes used.

## 1.1.2.9.2.1.46 Performance Schema `memory_summary_global_by_event_name` Table

MariaDB starting with [10.5.2](#)

The `memory_summary_global_by_event_name` table was introduced in [MariaDB 10.5.2](#).

There are five memory summary tables in the Performance Schema that share a number of fields in common. These include:

- [memory\\_summary\\_by\\_account\\_by\\_event\\_name](#)
- [memory\\_summary\\_by\\_host\\_by\\_event\\_name](#)
- [memory\\_summary\\_by\\_thread\\_by\\_event\\_name](#)
- [memory\\_summary\\_by\\_user\\_by\\_event\\_name](#)
- [memory\\_global\\_by\\_event\\_name](#)

The

### `memory_summary_global_by_event_name`

table contains memory usage statistics aggregated by event and event.

The table contains the following columns:

Field	Type	Null	Default	Description
EVENT_NAME	varchar(128)	NO	NULL	Event name.
COUNT_ALLOC	bigint(20) unsigned	NO	NULL	Total number of allocations to memory.
COUNT_FREE	bigint(20) unsigned	NO	NULL	Total number of attempts to free the allocated memory.
SUM_NUMBER_OF_BYTES_ALLOC	bigint(20) unsigned	NO	NULL	Total number of bytes allocated.
SUM_NUMBER_OF_BYTES_FREE	bigint(20) unsigned	NO	NULL	Total number of bytes freed
LOW_COUNT_USED	bigint(20)	NO	NULL	Lowest number of allocated blocks (lowest value of CURRENT_COUNT_USED).
CURRENT_COUNT_USED	bigint(20)	NO	NULL	Currently allocated blocks that have not been freed (COUNT_ALLOC minus COUNT_FREE).

HIGH_COUNT_USED	bigint(20)	NO	NULL	Highest number of allocated blocks (highest value of CURRENT_COUNT_USED).
LOW_NUMBER_OF_BYTES_USED	bigint(20)	NO	NULL	Lowest number of bytes used.
CURRENT_NUMBER_OF_BYTES_USED	bigint(20)	NO	NULL	Current number of bytes used (total allocated minus total freed).
HIGH_NUMBER_OF_BYTES_USED	bigint(20)	NO	NULL	Highest number of bytes used.

## Example

Seeing what memory was most often allocated for:

```
SELECT * FROM memory_summary_global_by_event_name
  ORDER BY count_alloc DESC LIMIT 1\G
***** 1. row *****
  EVENT_NAME: memory/sql/QUICK_RANGE_SELECT::alloc
  COUNT_ALLOC: 147976
  COUNT_FREE: 147976
  SUM_NUMBER_OF_BYTES_ALLOC: 600190656
  SUM_NUMBER_OF_BYTES_FREE: 600190656
  LOW_COUNT_USED: 0
  CURRENT_COUNT_USED: 0
  HIGH_COUNT_USED: 68
  LOW_NUMBER_OF_BYTES_USED: 0
  CURRENT_NUMBER_OF_BYTES_USED: 0
  HIGH_NUMBER_OF_BYTES_USED: 275808
```

## 1.1.2.9.2.1.47 Performance Schema metadata\_locks Table

MariaDB starting with [10.5.2](#)

The metadata\_locks table was introduced in [MariaDB 10.5.2](#).

The

`metadata_locks`  
table contains [metadata lock](#) information.

To enable metadata lock instrumention, at runtime:

```
UPDATE performance_schema.setup_instruments SET enabled='YES', timed='YES'
  WHERE name LIKE 'wait/lock/metadata%';
```

or in the [configuration file](#):

```
performance-schema-instrument='wait/lock/metadata/sql/mdl=ON'
```

The table is by default autosized, but the size can be configured with the [performance\\_schema\\_max\\_metadata\\_locks](#) system variable.

The table is read-only, and [TRUNCATE TABLE](#) cannot be used to empty the table.

The table contains the following columns:

Field	Type	Null	Default	Description
-------	------	------	---------	-------------

OBJECT_TYPE	varchar(64)	NO	NULL	Object type. One of BACKUP , COMMIT , EVENT , FUNCTION , GLOBAL , LOCKING SERVICE , PROCEDURE , SCHEMA , TABLE , TABLESPACE , TRIGGER (unused) or USER LEVEL LOCK .
OBJECT_SCHEMA	varchar(64)	YES	NULL	Object schema.
OBJECT_NAME	varchar(64)	YES	NULL	Object name.
OBJECT_INSTANCE_BEGIN	bigint(20) unsigned	NO	NULL	Address in memory of the instrumented object.
LOCK_TYPE	varchar(32)	NO	NULL	Lock type. One of BACKUP_FTWR1 , BACKUP_START , BACKUP_TRANS_DML , EXCLUSIVE , INTENTION_EXCLUSIVE , SHARED , SHARED_HIGH_PRIO , SHARED_NO_READ_WRITE , SHARED_NO_WRITE , SHARED_READ , SHARED_UPGRADABLE or SHARED_WRITE .
LOCK_DURATION	varchar(32)	NO	NULL	Lock duration. One of EXPLICIT (locks released by explicit action, for example a global lock acquired with <a href="#">FLUSH TABLES WITH READ LOCK</a> ), STATEMENT (locks implicitly released at statement end) or TRANSACTION (locks implicitly released at transaction end).

LOCK_STATUS	varchar(32)	NO	NULL	Lock status. One of GRANTED , KILLED , PENDING , POST_RELEASE_NOTIFY , PRE_ACQUIRE_NOTIFY , TIMEOUT or VICTIM .
SOURCE	varchar(64)	YES	NULL	Source file containing the instrumented code that produced the event, as well as the line number where the instrumentation occurred. This allows one to examine the source code involved.
OWNER_THREAD_ID	bigint(20) unsigned	YES	NULL	Thread that requested the lock.
OWNER_EVENT_ID	bigint(20) unsigned	YES	NULL	Event that requested the lock.

## 1.1.2.9.2.1.48 Performance Schema mutex\_instances Table

### Description

The

```
mutex_instances
```

table lists all mutexes that the Performance Schema seeing while the server is executing.

A mutex is a code mechanism for ensuring that threads can only access resources one at a time. A second thread attempting to access a resource will find it protected by a mutex, and will wait for it to be unlocked.

The [performance\\_schema\\_max\\_mutex\\_instances](#) system variable specifies the maximum number of instrumented mutex instances.

Column	Description
NAME	Instrument name associated with the mutex.
OBJECT_INSTANCE_BEGIN	Memory address of the instrumented mutex.
LOCKED_BY_THREAD_ID	The THREAD_ID of the locking thread if a thread has a mutex locked, otherwise NULL .

## 1.1.2.9.2.1.49 Performance Schema objects\_summary\_global\_by\_type Table

It aggregates object wait events, and contains the following columns:

Column	Description
OBJECT_TYPE	Groups records together with OBJECT_SCHEMA and OBJECT_NAME .

OBJECT_SCHEMA	Groups records together with OBJECT_TYPE and OBJECT_NAME
OBJECT_NAME	Groups records together with OBJECT_SCHEMA and OBJECT_TYPE
COUNT_STAR	Number of summarized events
SUM_TIMER_WAIT	Total wait time of the summarized events that are timed.
MIN_TIMER_WAIT	Minimum wait time of the summarized events that are timed.
AVG_TIMER_WAIT	Average wait time of the summarized events that are timed.
MAX_TIMER_WAIT	Maximum wait time of the summarized events that are timed.

You can [TRUNCATE](#) the table, which will reset all counters to zero.

## Example

```
SELECT * FROM objects_summary_global_by_type\G
...
***** 101. row *****
OBJECT_TYPE: TABLE
OBJECT_SCHEMA: test
OBJECT_NAME: v
COUNT_STAR: 0
SUM_TIMER_WAIT: 0
MIN_TIMER_WAIT: 0
AVG_TIMER_WAIT: 0
MAX_TIMER_WAIT: 0
***** 102. row *****
OBJECT_TYPE: TABLE
OBJECT_SCHEMA: test
OBJECT_NAME: xx2
COUNT_STAR: 2
SUM_TIMER_WAIT: 1621920
MIN_TIMER_WAIT: 481344
AVG_TIMER_WAIT: 810960
MAX_TIMER_WAIT: 1140576
```

## 1.1.2.9.2.1.50 Performance Schema performance\_timers Table

### Description

The

performance\_timers  
table lists available event timers.

It contains the following columns:

Column	Description
--------	-------------

TIMER_NAME	Time name, used in the <a href="#">setup_timers</a> table.
TIMER_FREQUENCY	Number of timer units per second. Dependent on the processor speed.
TIMER_RESOLUTION	Number of timer units by which timed values increase each time.
TIMER_OVERHEAD	Minimum timer overhead, determined during initialization by calling the timer 20 times and selecting the smallest value. Total overhead will be at least double this, as the timer is called at the beginning and end of each timed event.

Any

NULL

values indicate that that particular timer is not available on your platform. Any timer names with a non-NULL value can be used in the [setup\\_timers](#) table.

## Example

```
SELECT * FROM performance_timers;
+-----+-----+-----+-----+
| TIMER_NAME | TIMER_FREQUENCY | TIMER_RESOLUTION | TIMER_OVERHEAD |
+-----+-----+-----+-----+
| CYCLE      | 2293651741 | 1 | 28 |
| NANOSECOND | 1000000000 | 1 | 48 |
| MICROSECOND | 1000000 | 1 | 52 |
| MILLISECOND | 1000 | 1000 | 9223372036854775807 |
| TICK        | 106 | 1 | 496 |
+-----+-----+-----+-----+
```

## 1.1.2.9.2.1.51 Performance Schema prepared\_statements\_instances Table

MariaDB starting with [10.5.2](#)

The `prepared_statements_instances` table was introduced in [MariaDB 10.5.2](#).

The

```
prepared_statements_instances
table contains aggregated statistics of prepared statements.
```

The maximum number of rows in the table is determined by the [performance\\_schema\\_max\\_prepared\\_statement\\_instances](#) system variable, which is by default autosized on startup.

The table contains the following columns:

Field	Type	Null	Key	Default	Extra
OBJECT_INSTANCE_BEGIN	bigint(20) unsigned	NO		NULL	
STATEMENT_ID	bigint(20) unsigned	NO		NULL	
STATEMENT_NAME	varchar(64)	YES		NULL	
SQL_TEXT	longtext	NO		NULL	
OWNER_THREAD_ID	bigint(20) unsigned	NO		NULL	
OWNER_EVENT_ID	bigint(20) unsigned	NO		NULL	
OWNER_OBJECT_TYPE	enum('EVENT','FUNCTION','PROCEDURE','TABLE','TRIGGER')	YES		NULL	
OWNER_OBJECT_SCHEMA	varchar(64)	YES		NULL	
OWNER_OBJECT_NAME	varchar(64)	YES		NULL	
TIMER_PREPARE	bigint(20) unsigned	NO		NULL	
COUNT_REPREPARE	bigint(20) unsigned	NO		NULL	
COUNT_EXECUTE	bigint(20) unsigned	NO		NULL	
SUM_TIMER_EXECUTE	bigint(20) unsigned	NO		NULL	
MIN_TIMER_EXECUTE	bigint(20) unsigned	NO		NULL	
AVG_TIMER_EXECUTE	bigint(20) unsigned	NO		NULL	
MAX_TIMER_EXECUTE	bigint(20) unsigned	NO		NULL	
SUM_LOCK_TIME	bigint(20) unsigned	NO		NULL	
SUM_ERRORS	bigint(20) unsigned	NO		NULL	
SUM_WARNINGS	bigint(20) unsigned	NO		NULL	
SUM_ROWS_AFFECTED	bigint(20) unsigned	NO		NULL	
SUM_ROWS_SENT	bigint(20) unsigned	NO		NULL	
SUM_ROWS_EXAMINED	bigint(20) unsigned	NO		NULL	
SUM_CREATED_TMP_DISK_TABLES	bigint(20) unsigned	NO		NULL	
SUM_CREATED_TMP_TABLES	bigint(20) unsigned	NO		NULL	
SUM_SELECT_FULL_JOIN	bigint(20) unsigned	NO		NULL	
SUM_SELECT_FULL_RANGE_JOIN	bigint(20) unsigned	NO		NULL	
SUM_SELECT_RANGE	bigint(20) unsigned	NO		NULL	
SUM_SELECT_RANGE_CHECK	bigint(20) unsigned	NO		NULL	
SUM_SELECT_SCAN	bigint(20) unsigned	NO		NULL	
SUM_SORT_MERGE_PASSES	bigint(20) unsigned	NO		NULL	
SUM_SORT_RANGE	bigint(20) unsigned	NO		NULL	
SUM_SORT_ROWS	bigint(20) unsigned	NO		NULL	
SUM_SORT_SCAN	bigint(20) unsigned	NO		NULL	
SUM_NO_INDEX_USED	bigint(20) unsigned	NO		NULL	
SUM_NO_GOOD_INDEX_USED	bigint(20) unsigned	NO		NULL	

## 1.1.2.9.2.1.52 Performance Schema replication\_applier\_configuration Table

MariaDB starting with [10.5.2](#)

The

```
replication_applier_configuration
table, along with many other new Performance Schema tables, was added in MariaDB 10.5.2.
```

The [Performance Schema](#) replication\_applier\_configuration table contains configuration settings affecting replica transactions.

It contains the following fields.

Field	Type	Null	Description
CHANNEL_NAME	char(64)	NO	Replication channel name.
DESIRED_DELAY	int(11)	NO	Target number of seconds the replica should be delayed to the master.

## 1.1.2.9.2.1.53 Performance Schema replication\_applier\_status Table

MariaDB starting with [10.5.2](#)

The

```
replication_applier_status
table, along with many other new Performance Schema tables, was added in MariaDB 10.5.2.
```

The [Performance Schema](#) replication\_applier\_status table contains information about the general transaction execution status on the replica.

It contains the following fields.

Field	Type	Null	Description
CHANNEL_NAME	char(64)	NO	The replication channel name.
SERVICE_STATE	enum('ON','OFF')	NO	Shows ON when the replication channel's applier threads are active or idle, OFF means that the applier threads are not active.
REMAINING_DELAY	int(10) unsigned	YES	Seconds the replica needs to wait to reach the desired delay from master.
COUNT_TRANSACTIONS_RETRIES	bigint(20) unsigned	NO	The number of retries that were made because the replication SQL thread failed to apply a transaction.

## 1.1.2.9.2.1.54 Performance Schema replication\_applier\_status\_by\_coordinator Table

MariaDB starting with [10.5.2](#)

The

```
replication_applier_status_by_coordinator
table was added in MariaDB 10.5.2 .
```

The [Performance Schema](#) replication\_applier\_status\_by\_coordinator table displays the status of the coordinator thread used in multi-threaded replicas to manage multiple worker threads.

It contains the following fields.

Column	Type	Null	Description
CHANNEL_NAME	varchar(256)	NO	Replication channel name.
THREAD_ID	bigint(20) unsigned	YES	The SQL/coordinator thread ID.
SERVICE_STATE	enum('ON','OFF')	NO	ON (thread exists and is active or idle) or OFF (thread no longer exists).
LAST_ERROR_NUMBER	int(11)	NO	Last error number that caused the SQL/coordinator thread to stop.
LAST_ERROR_MESSAGE	varchar(1024)	NO	Last error message that caused the SQL/coordinator thread to stop.
LAST_ERROR_TIMESTAMP	timestamp	NO	Timestamp that shows when the most recent SQL/coordinator error occurred.
LAST_SEEN_TRANSACTION	char(57)	NO	The transaction the worker has last seen.
LAST_TRANS_RETRY_COUNT	int(11)	NO	Total number of retries attempted by last transaction.

## 1.1.2.9.2.1.55 Performance Schema replication\_applier\_status\_by\_worker Table

MariaDB starting with [10.6.0](#)

The

```
replication_applier_status_by_worker
table was added in MariaDB 10.6.0 .
```

The [Performance Schema](#) replication\_applier\_status\_by\_worker table displays replica worker thread specific information.

It contains the following fields.

Column	Description
CHANNEL_NAME	Name of replication channel through which the transaction is received.
THREAD_ID	Thread_Id as displayed in the <a href="#">performance_schema.threads</a> table for thread with name 'thread/sql/rpl_parallel_thread'. THREAD_ID will be NULL when worker threads are stopped due to error/force stop.
SERVICE_STATE	Whether or not the thread is running.
LAST_SEEN_TRANSACTION	Last GTID executed by worker
LAST_ERROR_NUMBER	Last Error that occurred on a particular worker.
LAST_ERROR_MESSAGE	Last error specific message.
LAST_ERROR_TIMESTAMP	Time stamp of last error.
WORKER_IDLE_TIME	Total idle time in seconds that the worker thread has spent waiting for work from SQL thread.
LAST_TRANS_RETRY_COUNT	Total number of retries attempted by last transaction.

## 1.1.2.9.2.1.56 Performance Schema replication\_connection\_configuration Table

MariaDB starting with [10.5.2](#)

The

`replication_connection_configuration`  
table was added in [MariaDB 10.6.0](#).

The [Performance Schema](#) `replication_connection_configuration` table displays replica's configuration settings used for connecting to the primary.

It contains the following fields.

Column	Type	Null	Description
CHANNEL_NAME	varchar(256)	NO	The replication channel used.
HOST	char(60)	NO	The host name of the source that the replica is connected to.
PORT	int(11)	NO	The port used to connect to the source.
USER	char(32)	NO	The user name of the replication user account used to connect to the source.
USING_GTID	enum('NO', 'CURRENT_POS', 'SLAVE_POS')	NO	Whether replication is using GTIDs or not.
SSL_ALLOWED	enum('YES', 'NO', 'IGNORED')	NO	Whether SSL is allowed for the replica connection.
SSL_CA_FILE	varchar(512)	NO	Path to the file that contains one or more certificates for trusted Certificate Authorities (CA) to use for TLS.
SSL_CA_PATH	varchar(512)	NO	Path to a directory that contains one or more PEM files that contain X509 certificates for a trusted Certificate Authority (CA) to use for TLS.
SSL_CERTIFICATE	varchar(512)	NO	Path to the certificate used to authenticate the master.
SSL_CIPHER	varchar(512)	NO	Which cipher is used for encryption.
SSL_KEY	varchar(512)	NO	Path to the private key used for TLS.
SSL_VERIFY_SERVER_CERTIFICATE	enum('YES', 'NO')	NO	Whether the server certificate is verified as part of the SSL connection.
SSL_CRL_FILE	varchar(255)	NO	Path to the PEM file containing one or more revoked X.509 certificates.
SSL_CRL_PATH	varchar(255)	NO	PATH to a folder containing PEM files containing one or more revoked X.509 certificates.
CONNECTION_RETRY_INTERVAL	int(11)	NO	The number of seconds between connect retries.
CONNECTION_RETRY_COUNT	bigint(20) unsigned	NO	The number of times the replica can attempt to reconnect to the source in the event of a lost connection.
HEARTBEAT_INTERVAL	double(10,3) unsigned	NO	Number of seconds after which a heartbeat will be sent.
IGNORE_SERVER_IDS	longtext	NO	Binary log events from servers (ids) to ignore.
REPL_DO_DOMAIN_IDS	longtext	NO	Only apply binary logs from these domain ids.
REPL_IGNORE_DOMAIN_IDS	longtext	NO	Binary log events from domains to ignore.

## 1.1.2.9.2.1.57 Performance Schema rwlock\_instances Table

The

`rwlock_instances`

table lists all read write lock (rwlock) instances that the Performance Schema sees while the server is executing. A read write is a mechanism for ensuring threads can either share access to common resources, or have exclusive access.

The [performance\\_schema\\_max\\_rwlock\\_instances](#) system variable specifies the maximum number of instrumented rwlock objects.

The

`rwlock_instances`

table contains the following columns:

Column	Description
--------	-------------

NAME	Instrument name associated with the read write lock
OBJECT_INSTANCE_BEGIN	Address in memory of the instrumented lock
WRITE_LOCKED_BY_THREAD_ID	THREAD_ID of the locking thread if locked in write (exclusive) mode, otherwise NULL
READ_LOCKED_BY_COUNT	Count of current read locks held

## 1.1.2.9.2.1.58 Performance Schema session\_account\_connect\_attrs Table

### Description

The

```
session_account_connect_attrs
```

table shows connection attributes for the current session.

Applications can pass key/value connection attributes to the server when a connection is made. The [session\\_connect\\_attrs](#) and [session\\_account\\_connect\\_attrs](#) tables provide access to this information, for all sessions and the current session respectively.

The C API functions [mysql\\_options\(\)](#) and [mysql\\_optionsv\(\)](#) are used for passing connection attributes to the server.

```
session_account_connect_attrs
```

contains the following columns:

Column	Description
PROCESSLIST_ID	Session connection identifier.
ATTR_NAME	Attribute name.
ATTR_VALUE	Attribute value.
ORDINAL_POSITION	Order in which attribute was added to the connection attributes.

### Example

```
SELECT * FROM performance_schema.session_account_connect_attrs;
+-----+-----+-----+-----+
| PROCESSLIST_ID | ATTR_NAME      | ATTR_VALUE      | ORDINAL_POSITION |
+-----+-----+-----+-----+
|        45 | _os           | debian-linux-gnu |          0 |
|        45 | _client_name   | libmysql        |          1 |
|        45 | _pid           | 7711            |          2 |
|        45 | _client_version | 10.0.5          |          3 |
|        45 | _platform       | x86_64          |          4 |
|        45 | program_name    | mysql           |          5 |
+-----+-----+-----+-----+
```

## 1.1.2.9.2.1.59 Performance Schema session\_connect\_attrs

# Table

## Description

The

```
session_connect_attrs  
table shows connection attributes for all sessions.
```

Applications can pass key/value connection attributes to the server when a connection is made. The

```
session_connect_attrs  
and session_account_connect_attrs tables provide access to this information, for all sessions and the current session respectively.
```

The C API functions [mysql\\_options\(\)](#) and [mysql\\_optionsv\(\)](#) are used for passing connection attributes to the server.

```
session_connect_attrs  
contains the following columns:
```

Column	Description
PROCESSLIST_ID	Session connection identifier.
ATTR_NAME	Attribute name.
ATTR_VALUE	Attribute value.
ORDINAL_POSITION	Order in which attribute was added to the connection attributes.

## Example

Returning the current connection's attributes:

```
SELECT * FROM performance_schema.session_connect_attrs WHERE processlist_id=CONNECTION_ID();  
+-----+-----+-----+-----+  
| PROCESSLIST_ID | ATTR_NAME | ATTR_VALUE | ORDINAL_POSITION |  
+-----+-----+-----+-----+  
| 45 | _os | debian-linux-gnu | 0 |  
| 45 | _client_name | libmysql | 1 |  
| 45 | _pid | 7711 | 2 |  
| 45 | _client_version | 10.0.5 | 3 |  
| 45 | _platform | x86_64 | 4 |  
| 45 | program_name | mysql | 5 |  
+-----+-----+-----+-----+
```

## 1.1.2.9.2.1.60 Performance Schema session\_status Table

MariaDB starting with [10.5.2](#)

The

```
session_status  
table was added in MariaDB 10.5.2.
```

The

```
session_status  
table contains a list of status variables for the current session. The table only stores status variable statistics for threads which are instrumented,  
and does not collect statistics for  
Com_xxx  
variables.
```

The table contains the following columns:

Column	Description
--------	-------------

VARIABLE_NAME	The session status variable name.
VARIABLE_VALUE	The session status variable value.

It is not possible to empty this table with a

```
TRUNCATE TABLE  
statement.
```

## 1.1.2.9.2.1.61 Performance Schema setup\_actors Table

The

```
setup_actors
```

table contains information for determining whether monitoring should be enabled for new client connection threads.

The default size is 100 rows, which can be changed by modifying the

```
performance_schema_setup_actors_size
```

system variable at server startup.

If a row in the table matches a new foreground thread's client and host, the matching

```
INSTRUMENTED  
column in the threads table is set to either  
YES  
or  
NO
```

, which allows selective application of instrumenting by host, by user, or combination thereof.

Column	Description
HOST	Host name, either a literal, or the % wildcard representing any host.
USER	User name, either a literal or the % wildcard representing any name.
ROLE	Unused

Initially, any user and host is matched:

```
SELECT * FROM performance_schema.setup_actors;
+-----+-----+
| HOST | USER | ROLE |
+-----+-----+
| %   | %   | %   |
+-----+-----+
```

## 1.1.2.9.2.1.62 Performance Schema setup\_consumers Table

Lists the types of consumers for which event information is available.

The

```
setup_consumers
```

table contains the following columns:

Column	Description
NAME	Consumer name

ENABLED	YES or NO for whether or not the consumer is enabled. You can modify this column to ensure that event information is added, or is not added.
---------	---

The table can be modified directly, or the server started with the option enabled, for example:

```
performance-schema-consumer-events-waits-history=ON
```

## Example

```
SELECT * FROM performance_schema.setup_consumers;
```

NAME	ENABLED
events_stages_current	NO
events_stages_history	NO
events_stages_history_long	NO
events_statements_current	YES
events_statements_history	NO
events_statements_history_long	NO
events_waits_current	NO
events_waits_history	NO
events_waits_history_long	NO
global_instrumentation	YES
thread_instrumentation	YES
statements_digest	YES

## 1.1.2.9.2.1.63 Performance Schema setup\_instruments Table

The

`setup_instruments`

table contains a list of instrumented object classes for which it is possible to collect events. There is one row for each instrument in the source code. When an instrument is enabled and executed, instances are created which are then stored in the `cond_instances`, `file_instances`, `mutex_instances`, `rwlock_instances` or `socket_instance` tables.

It contains the following columns:

Column	Description
NAME	Instrument name
ENABLED	Whether or not the instrument is enabled. It can be disabled, and the instrument will produce no events.
TIMED	Whether or not the instrument is timed. It can be set, but if disabled, events produced by the instrument will have NULL values for the corresponding TIMER_START , TIMER_END , and TIMER_WAIT values.

## Example

From [MariaDB 10.5.7](#), default settings with the Performance Schema enabled:

```
SELECT * FROM setup_instruments ORDER BY name;
```

NAME	ENABLED	TIMED
events_stages	NO	NO

	YES	YES
idle	YES	YES
memory/csv/blobroot	NO	NO
memory/csv/row	NO	NO

## 1.1.2.9.2.1.64 Performance Schema setup\_objects Table

### Description

The

### setup\_objects

table determines whether objects are monitored by the performance schema or not. By default limited to 100 rows, this can be changed by setting the [performance\\_schema\\_setup\\_objects\\_size](#) system variable when the server starts.

It contains the following columns:

Column	Description
OBJECT_TYPE	Type of object to instrument, currently only . Currently, only TABLE , for base table.
OBJECT_SCHEMA	Schema containing the object, either the literal or % for any schema.
OBJECT_NAME	Name of the instrumented object, either the literal or % for any object.
ENABLED	Whether the object's events are instrumented or not. Can be disabled, in which case monitoring is not enabled for those objects.
TIMED	Whether the object's events are timed or not. Can be modified.

When the Performance Schema looks for matches in the

```
setup_objects
, there may be more than one row matching, with different
ENABLED
and
TIMED
```

values. It looks for the most specific matches first, that is, it will first look for the specific database and table name combination, then the specific database, only then falling back to a wildcard for both.

Rows can be added or removed from the table, while for existing rows, only the

```
TIMED
and
ENABLED
columns can be updated. By default, all tables except those in the
performance_schema
,
information_schema
and
mysql
databases are instrumented.
```

## 1.1.2.9.2.1.65 Performance Schema setup\_timers Table

### Description

The

```
setup_timers
table shows the currently selected event timers.
```

It contains the following columns:

Column	Description
NAME	Type of instrument the timer is used for.
TIMER_NAME	Timer applying to the instrument type. Can be modified.

The

```
TIMER_NAME
value can be changed to choose a different timer, and can be any non-NULL value in the performance\_timers.TIMER\_NAME column.
```

If you modify the table, monitoring is immediately affected, and currently monitored events would use a combination of old and new timers, which is probably undesirable. It is best to reset the Performance Schema statistics if you make changes to this table.

## Example

```
SELECT * FROM setup_timers;
+-----+-----+
| NAME      | TIMER_NAME   |
+-----+-----+
| idle      | MICROSECOND |
| wait      | CYCLE        |
| stage     | NANOSECOND   |
| statement | NANOSECOND   |
+-----+-----+
```

## 1.1.2.9.2.1.66 Performance Schema socket\_instances Table

The

socket\_instances  
table lists active server connections, with each record being a Unix socket file or TCP/IP connection.

The

socket\_instances  
table contains the following columns:

Column	Description
EVENT_NAME	NAME from the setup_instruments table, and the name of the wait/io/socket/* instrument that produced the event.
OBJECT_INSTANCE_BEGIN	Memory address of the object.
THREAD_ID	Thread identifier that the server assigns to each socket.
SOCKET_ID	The socket's internal file handle.
IP	Client IP address. Blank for Unix socket file, otherwise an IPv4 or IPv6 address. Together with the PORT identifies the connection.
PORT	TCP/IP port number, from 0 to 65535. Together with the IP identifies the connection.
STATE	Socket status, either IDLE if waiting to receive a request from a client, or ACTIVE

## 1.1.2.9.2.1.67 Performance Schema socket\_summary\_by\_event\_name Table

It aggregates timer and byte count statistics for all socket I/O operations by socket instrument.

Column	Description
EVENT_NAME	Socket instrument.

COUNT_STAR	Number of summarized events
SUM_TIMER_WAIT	Total wait time of the summarized events that are timed.
MIN_TIMER_WAIT	Minimum wait time of the summarized events that are timed.
AVG_TIMER_WAIT	Average wait time of the summarized events that are timed.
MAX_TIMER_WAIT	Maximum wait time of the summarized events that are timed.
COUNT_READ	<p>Number of all read operations, including</p> <p>RECV ,</p> <p>RECVFROM , and</p> <p>RECVMSG</p>
SUM_TIMER_READ	Total wait time of all read operations that are timed.
MIN_TIMER_READ	Minimum wait time of all read operations that are timed.
AVG_TIMER_READ	Average wait time of all read operations that are timed.
MAX_TIMER_READ	Maximum wait time of all read operations that are timed.
SUM_NUMBER_OF_BYTES_READ	Bytes read by read operations.
COUNT_WRITE	<p>Number of all write operations, including</p> <p>SEND ,</p> <p>SENDTO , and</p> <p>SENDMSG</p>
SUM_TIMER_WRITE	Total wait time of all write operations that are timed.
MIN_TIMER_WRITE	Minimum wait time of all write operations that are timed.
AVG_TIMER_WRITE	Average wait time of all write operations that are timed.
MAX_TIMER_WRITE	Maximum wait time of all write operations that are timed.
SUM_NUMBER_OF_BYTES_WRITE	Bytes written by write operations.

COUNT_MISC	Number of all miscellaneous operations not counted above, including CONNECT , LISTEN , ACCEPT , CLOSE , and SHUTDOWN .
SUM_TIMER_MISC	Total wait time of all miscellaneous operations that are timed.
MIN_TIMER_MISC	Minimum wait time of all miscellaneous operations that are timed.
AVG_TIMER_MISC	Average wait time of all miscellaneous operations that are timed.
MAX_TIMER_MISC	Maximum wait time of all miscellaneous operations that are timed.

You can [TRUNCATE](#) the table, which will reset all counters to zero.

## Example

```

SELECT * FROM socket_summary_by_event_name\G
*****

    SUM_TIMER_MISC: 0
    MIN_TIMER_MISC: 0
    AVG_TIMER_MISC: 0
    MAX_TIMER_MISC: 0
...

```

## 1.1.2.9.2.1.68 Performance Schema socket\_summary\_by\_instance Table

It aggregates timer and byte count statistics for all socket I/O operations by socket instance.

Column	Description
EVENT_NAME	Socket instrument.
OBJECT_INSTANCE_BEGIN	Address in memory.
COUNT_STAR	Number of summarized events
SUM_TIMER_WAIT	Total wait time of the summarized events that are timed.

MIN_TIMER_WAIT	Minimum wait time of the summarized events that are timed.
AVG_TIMER_WAIT	Average wait time of the summarized events that are timed.
MAX_TIMER_WAIT	Maximum wait time of the summarized events that are timed.
COUNT_READ	Number of all read operations, including RECV , RECVFROM , and RECVMSG .
SUM_TIMER_READ	Total wait time of all read operations that are timed.
MIN_TIMER_READ	Minimum wait time of all read operations that are timed.
AVG_TIMER_READ	Average wait time of all read operations that are timed.
MAX_TIMER_READ	Maximum wait time of all read operations that are timed.
SUM_NUMBER_OF_BYTES_READ	Bytes read by read operations.
COUNT_WRITE	Number of all write operations, including SEND , SENDTO , and SENDMSG .
SUM_TIMER_WRITE	Total wait time of all write operations that are timed.
MIN_TIMER_WRITE	Minimum wait time of all write operations that are timed.
AVG_TIMER_WRITE	Average wait time of all write operations that are timed.
MAX_TIMER_WRITE	Maximum wait time of all write operations that are timed.
SUM_NUMBER_OF_BYTES_WRITE	Bytes written by write operations.

COUNT_MISC	Number of all miscellaneous operations not counted above, including CONNECT , LISTEN , ACCEPT , CLOSE , and SHUTDOWN
SUM_TIMER_MISC	Total wait time of all miscellaneous operations that are timed.
MIN_TIMER_MISC	Minimum wait time of all miscellaneous operations that are timed.
AVG_TIMER_MISC	Average wait time of all miscellaneous operations that are timed.
MAX_TIMER_MISC	Maximum wait time of all miscellaneous operations that are timed.

The corresponding row in the table is deleted when a connection terminates.

You can [TRUNCATE](#) the table, which will reset all counters to zero.

## 1.1.2.9.2.1.69 Performance Schema status\_by\_thread Table

MariaDB starting with [10.5.2](#)

The

```
session_status
table was added in MariaDB 10.5.2 .
```

The

```
status_by_thread
table contains status variable information about active foreground threads. The table does not collect statistics for
Com_xxx
variables.
```

The table contains the following columns:

Column	Description
THREAD_ID	The thread identifier of the session in which the status variable is defined.
VARIABLE_NAME	Status variable name.
VARIABLE_VALUE	Aggregated status variable value.

If [TRUNCATE TABLE](#) is run, will aggregate the status for all threads to the global status and account status, then reset the thread status. If account statistics are not collected but host and user status are, the session status is added to host and user status.

## 1.1.2.9.2.1.70 Performance Schema table\_io\_waits\_summary\_by\_index\_usage Table

The

```
table_io_waits_summary_by_index_usage
table records table I/O waits by index.
```

Column	Description
OBJECT_TYPE	TABLE in the case of all indexes.
OBJECT_SCHEMA	Schema name.
OBJECT_NAME	Table name.
INDEX_NAME	Index name, or PRIMARY for the primary index, NULL for no index (inserts are counted in this case).
COUNT_STAR	Number of summarized events and the sum of the x_READ and x_WRITE columns.
SUM_TIMER_WAIT	Total wait time of the summarized events that are timed.
MIN_TIMER_WAIT	Minimum wait time of the summarized events that are timed.
AVG_TIMER_WAIT	Average wait time of the summarized events that are timed.
MAX_TIMER_WAIT	Maximum wait time of the summarized events that are timed.
COUNT_READ	Number of all read operations, and the sum of the equivalent x_FETCH columns.
SUM_TIMER_READ	Total wait time of all read operations that are timed.
MIN_TIMER_READ	Minimum wait time of all read operations that are timed.
AVG_TIMER_READ	Average wait time of all read operations that are timed.
MAX_TIMER_READ	Maximum wait time of all read operations that are timed.
COUNT_WRITE	Number of all write operations, and the sum of the equivalent x_INSERT ,x_UPDATE and x_DELETE columns.
SUM_TIMER_WRITE	Total wait time of all write operations that are timed.
MIN_TIMER_WRITE	Minimum wait time of all write operations that are timed.

AVG_TIMER_WRITE	Average wait time of all write operations that are timed.
MAX_TIMER_WRITE	Maximum wait time of all write operations that are timed.
COUNT_FETCH	Number of all fetch operations.
SUM_TIMER_FETCH	Total wait time of all fetch operations that are timed.
MIN_TIMER_FETCH	Minimum wait time of all fetch operations that are timed.
AVG_TIMER_FETCH	Average wait time of all fetch operations that are timed.
MAX_TIMER_FETCH	Maximum wait time of all fetch operations that are timed.
COUNT_INSERT	Number of all insert operations.
SUM_TIMER_INSERT	Total wait time of all insert operations that are timed.
MIN_TIMER_INSERT	Minimum wait time of all insert operations that are timed.
AVG_TIMER_INSERT	Average wait time of all insert operations that are timed.
MAX_TIMER_INSERT	Maximum wait time of all insert operations that are timed.
COUNT_UPDATE	Number of all update operations.
SUM_TIMER_UPDATE	Total wait time of all update operations that are timed.
MIN_TIMER_UPDATE	Minimum wait time of all update operations that are timed.
AVG_TIMER_UPDATE	Average wait time of all update operations that are timed.
MAX_TIMER_UPDATE	Maximum wait time of all update operations that are timed.
COUNT_DELETE	Number of all delete operations.
SUM_TIMER_DELETE	Total wait time of all delete operations that are timed.

MIN_TIMER_DELETE	Minimum wait time of all delete operations that are timed.
AVG_TIMER_DELETE	Average wait time of all delete operations that are timed.
MAX_TIMER_DELETE	Maximum wait time of all delete operations that are timed.

You can [TRUNCATE](#) the table, which will reset all counters to zero. The table is also truncated if the [table\\_io\\_waits\\_summary\\_by\\_table](#) table is truncated.

If a table's index structure is changed, index statistics recorded in this table may also be reset.

## 1.1.2.9.2.1.71 Performance Schema table\_io\_waits\_summary\_by\_table Table

The

```
table_io_waits_summary_by_table
table records table I/O waits by table.
```

Column	Description
OBJECT_TYPE	Since this table records waits by table, always set to TABLE.
OBJECT_SCHEMA	Schema name.
OBJECT_NAME	Table name.
COUNT_STAR	Number of summarized events and the sum of the x_READ and x_WRITE columns.
SUM_TIMER_WAIT	Total wait time of the summarized events that are timed.
MIN_TIMER_WAIT	Minimum wait time of the summarized events that are timed.
AVG_TIMER_WAIT	Average wait time of the summarized events that are timed.
MAX_TIMER_WAIT	Maximum wait time of the summarized events that are timed.
COUNT_READ	Number of all read operations, and the sum of the equivalent x_FETCH columns.
SUM_TIMER_READ	Total wait time of all read operations that are timed.
MIN_TIMER_READ	Minimum wait time of all read operations that are timed.
AVG_TIMER_READ	Average wait time of all read operations that are timed.

MAX_TIMER_READ	Maximum wait time of all read operations that are timed.
COUNT_WRITE	Number of all write operations, and the sum of the equivalent x_INSERT , x_UPDATE and x_DELETE columns.
SUM_TIMER_WRITE	Total wait time of all write operations that are timed.
MIN_TIMER_WRITE	Minimum wait time of all write operations that are timed.
AVG_TIMER_WRITE	Average wait time of all write operations that are timed.
MAX_TIMER_WRITE	Maximum wait time of all write operations that are timed.
COUNT_FETCH	Number of all fetch operations.
SUM_TIMER_FETCH	Total wait time of all fetch operations that are timed.
MIN_TIMER_FETCH	Minimum wait time of all fetch operations that are timed.
AVG_TIMER_FETCH	Average wait time of all fetch operations that are timed.
MAX_TIMER_FETCH	Maximum wait time of all fetch operations that are timed.
COUNT_INSERT	Number of all insert operations.
SUM_TIMER_INSERT	Total wait time of all insert operations that are timed.
MIN_TIMER_INSERT	Minimum wait time of all insert operations that are timed.
AVG_TIMER_INSERT	Average wait time of all insert operations that are timed.
MAX_TIMER_INSERT	Maximum wait time of all insert operations that are timed.
COUNT_UPDATE	Number of all update operations.
SUM_TIMER_UPDATE	Total wait time of all update operations that are timed.

MIN_TIMER_UPDATE	Minimum wait time of all update operations that are timed.
AVG_TIMER_UPDATE	Average wait time of all update operations that are timed.
MAX_TIMER_UPDATE	Maximum wait time of all update operations that are timed.
COUNT_DELETE	Number of all delete operations.
SUM_TIMER_DELETE	Total wait time of all delete operations that are timed.
MIN_TIMER_DELETE	Minimum wait time of all delete operations that are timed.
AVG_TIMER_DELETE	Average wait time of all delete operations that are timed.
MAX_TIMER_DELETE	Maximum wait time of all delete operations that are timed.

You can [TRUNCATE](#) the table, which will reset all counters to zero. Truncating this table will also truncate the [table\\_io\\_waits\\_summary\\_by\\_index\\_usage](#) table.

## 1.1.2.9.2.1.72 Performance Schema table\_lock\_waits\_summary\_by\_table Table

The

```
table_lock_waits_summary_by_table
table records table lock waits by table.
```

Column	Description
OBJECT_TYPE	Since this table records waits by table, always set to TABLE.
OBJECT_SCHEMA	Schema name.
OBJECT_NAME	Table name.
COUNT_STAR	Number of summarized events and the sum of the x_READ and x_WRITE columns.
SUM_TIMER_WAIT	Total wait time of the summarized events that are timed.
MIN_TIMER_WAIT	Minimum wait time of the summarized events that are timed.
AVG_TIMER_WAIT	Average wait time of the summarized events that are timed.
MAX_TIMER_WAIT	Maximum wait time of the summarized events that are timed.

COUNT_READ	Number of all read operations, and the sum of the equivalent x_READ_NORMAL , x_READ_WITH_SHARED_LOCKS , x_READ_HIGH_PRIORITY and x_READ_NO_INSERT columns.
SUM_TIMER_READ	Total wait time of all read operations that are timed.
MIN_TIMER_READ	Minimum wait time of all read operations that are timed.
AVG_TIMER_READ	Average wait time of all read operations that are timed.
MAX_TIMER_READ	Maximum wait time of all read operations that are timed.
COUNT_WRITE	Number of all write operations, and the sum of the equivalent x_WRITE_ALLOW_WRITE , x_WRITE_CONCURRENT_INSERT , x_WRITE_DELAYED , x_WRITE_LOW_PRIORITY and x_WRITE_NORMAL columns.
SUM_TIMER_WRITE	Total wait time of all write operations that are timed.
MIN_TIMER_WRITE	Minimum wait time of all write operations that are timed.
AVG_TIMER_WRITE	Average wait time of all write operations that are timed.
MAX_TIMER_WRITE	Maximum wait time of all write operations that are timed.
COUNT_READ_NORMAL	Number of all internal read normal locks.
SUM_TIMER_READ_NORMAL	Total wait time of all internal read normal locks that are timed.
MIN_TIMER_READ_NORMAL	Minimum wait time of all internal read normal locks that are timed.
AVG_TIMER_READ_NORMAL	Average wait time of all internal read normal locks that are timed.
MAX_TIMER_READ_NORMAL	Maximum wait time of all internal read normal locks that are timed.
COUNT_READ_WITH_SHARED_LOCKS	Number of all internal read with shared locks.

SUM_TIMER_READ_WITH_SHARED_LOCKS	Total wait time of all internal read with shared locks that are timed.
MIN_TIMER_READ_WITH_SHARED_LOCKS	Minimum wait time of all internal read with shared locks that are timed.
AVG_TIMER_READ_WITH_SHARED_LOCKS	Average wait time of all internal read with shared locks that are timed.
MAX_TIMER_READ_WITH_SHARED_LOCKS	Maximum wait time of all internal read with shared locks that are timed.
COUNT_READ_HIGH_PRIORITY	Number of all internal read high priority locks.
SUM_TIMER_READ_HIGH_PRIORITY	Total wait time of all internal read high priority locks that are timed.
MIN_TIMER_READ_HIGH_PRIORITY	Minimum wait time of all internal read high priority locks that are timed.
AVG_TIMER_READ_HIGH_PRIORITY	Average wait time of all internal read high priority locks that are timed.
MAX_TIMER_READ_HIGH_PRIORITY	Maximum wait time of all internal read high priority locks that are timed.
COUNT_READ_NO_INSERT	Number of all internal read no insert locks.
SUM_TIMER_READ_NO_INSERT	Total wait time of all internal read no insert locks that are timed.
MIN_TIMER_READ_NO_INSERT	Minimum wait time of all internal read no insert locks that are timed.
AVG_TIMER_READ_NO_INSERT	Average wait time of all internal read no insert locks that are timed.
MAX_TIMER_READ_NO_INSERT	Maximum wait time of all internal read no insert locks that are timed.
COUNT_READ_EXTERNAL	Number of all external read locks.
SUM_TIMER_READ_EXTERNAL	Total wait time of all external read locks that are timed.
MIN_TIMER_READ_EXTERNAL	Minimum wait time of all external read locks that are timed.
AVG_TIMER_READ_EXTERNAL	Average wait time of all external read locks that are timed.
MAX_TIMER_READ_EXTERNAL	Maximum wait time of all external read locks that are timed.
COUNT_WRITE_ALLOW_WRITE	Number of all internal read normal locks.

SUM_TIMER_WRITE_ALLOW_WRITE	Total wait time of all internal write allow write locks that are timed.
MIN_TIMER_WRITE_ALLOW_WRITE	Minimum wait time of all internal write allow write locks that are timed.
AVG_TIMER_WRITE_ALLOW_WRITE	Average wait time of all internal write allow write locks that are timed.
MAX_TIMER_WRITE_ALLOW_WRITE	Maximum wait time of all internal write allow write locks that are timed.
COUNT_WRITE_CONCURRENT_INSERT	Number of all internal concurrent insert write locks.
SUM_TIMER_WRITE_CONCURRENT_INSERT	Total wait time of all internal concurrent insert write locks that are timed.
MIN_TIMER_WRITE_CONCURRENT_INSERT	Minimum wait time of all internal concurrent insert write locks that are timed.
AVG_TIMER_WRITE_CONCURRENT_INSERT	Average wait time of all internal concurrent insert write locks that are timed.
MAX_TIMER_WRITE_CONCURRENT_INSERT	Maximum wait time of all internal concurrent insert write locks that are timed.
COUNT_WRITE_DELAYED	Number of all internal write delayed locks.
SUM_TIMER_WRITE_DELAYED	Total wait time of all internal write delayed locks that are timed.
MIN_TIMER_WRITE_DELAYED	Minimum wait time of all internal write delayed locks that are timed.
AVG_TIMER_WRITE_DELAYED	Average wait time of all internal write delayed locks that are timed.
MAX_TIMER_WRITE_DELAYED	Maximum wait time of all internal write delayed locks that are timed.
COUNT_WRITE_LOW_PRIORITY	Number of all internal write low priority locks.
SUM_TIMER_WRITE_LOW_PRIORITY	Total wait time of all internal write low priority locks that are timed.
MIN_TIMER_WRITE_LOW_PRIORITY	Minimum wait time of all internal write low priority locks that are timed.
AVG_TIMER_WRITE_LOW_PRIORITY	Average wait time of all internal write low priority locks that are timed.
MAX_TIMER_WRITE_LOW_PRIORITY	Maximum wait time of all internal write low priority locks that are timed.
COUNT_WRITE_NORMAL	Number of all internal write normal locks.

SUM_TIMER_WRITE_NORMAL	Total wait time of all internal write normal locks that are timed.
MIN_TIMER_WRITE_NORMAL	Minimum wait time of all internal write normal locks that are timed.
AVG_TIMER_WRITE_NORMAL	Average wait time of all internal write normal locks that are timed.
MAX_TIMER_WRITE_NORMAL	Maximum wait time of all internal write normal locks that are timed.
COUNT_WRITE_EXTERNAL	Number of all external write locks.
SUM_TIMER_WRITE_EXTERNAL	Total wait time of all external write locks that are timed.
MIN_TIMER_WRITE_EXTERNAL	Minimum wait time of all external write locks that are timed.
AVG_TIMER_WRITE_EXTERNAL	Average wait time of all external write locks that are timed.
MAX_TIMER_WRITE_EXTERNAL	Maximum wait time of all external write locks that are timed.

You can [TRUNCATE](#) the table, which will reset all counters to zero.

## 1.1.2.9.2.1.73 Performance Schema threads Table

Each server thread is represented as a row in the

threads  
table.

The

threads  
table contains the following columns:

Column	Description
THREAD_ID	A unique thread identifier.
NAME	Name associated with the server's thread instrumentation code, for example thread/sql/main for the server's main() function, and thread/sql/one_connection for a user connection.
TYPE	FOREGROUND or BACKGROUND , depending on the thread type. User connection threads are FOREGROUND , internal server threads are BACKGROUND .

PROCESSLIST_ID	The PROCESSLIST.ID value for threads displayed in the INFORMATION_SCHEMA.PROCESSLIST table, or 0 for background threads. Also corresponds with the CONNECTION_ID() return value for the thread.
PROCESSLIST_USER	Foreground thread user, or NULL for a background thread.
PROCESSLIST_HOST	Foreground thread host, or NULL for a background thread.
PROCESSLIST_DB	Thread's default database, or NULL if none exists.
PROCESSLIST_COMMAND	Type of command executed by the thread. These correspond to the the COM_xxx client/server protocol commands, and the Com_xxx status variables . See <a href="#">Thread Command Values</a> .
PROCESSLIST_TIME	Time in seconds the thread has been in its current state.
PROCESSLIST_STATE	Action, event or state indicating what the thread is doing.
PROCESSLIST_INFO	Statement being executed by the thread, or NULL if a statement is not being executed. If a statement results in calling other statements, such as for a <a href="#">stored procedure</a> , the innermost statement from the stored procedure is shown here.
PARENT_THREAD_ID	THREAD_ID of the parent thread, if any. Subthreads can for example be spawned as a result of <a href="#">INSERT DELAYED</a> statements.
ROLE	Unused.
INSTRUMENTED	YES or NO for Whether the thread is instrumented or not. For foreground threads, the initial value is determined by whether there's a user/host match in the <a href="#">setup_actors</a> table. Subthreads are again matched, while for background threads, this will be set to YES by default. To monitor events that the thread executes, INSTRUMENTED must be YES and the thread_instrumentation consumer in the <a href="#">setup_consumers</a> table must also be YES

HISTORY	<p>YES or NO</p> <p>for Whether to log historical events for the thread. For foreground threads, the initial value is determined by whether there's a user/host match in the <code>setup_actors</code> table. Subthreads are again matched, while for background threads, this will be set to</p> <p>YES by default. To monitor events that the thread executes, INSTRUMENTED must be YES and the thread_instrumentation consumer in the <code>setup_consumers</code> table must also be YES . Added in <a href="#">MariaDB 10.5</a>.</p>
CONNECTION_TYPE	The protocol used to establish the connection, or NULL for background threads. Added in <a href="#">MariaDB 10.5</a> .
THREAD_OS_ID	The thread or task identifier as defined by the underlying operating system, if there is one. Added in <a href="#">MariaDB 10.5</a>

## Example

```
SELECT * FROM performance_schema.threads\G;
*****
1. row ****
    THREAD_ID: 1
        NAME: thread/sql/main
        TYPE: BACKGROUND
    PROCESSLIST_ID: NULL
    PROCESSLIST_USER: NULL
    PROCESSLIST_HOST: NULL
    PROCESSLIST_DB: NULL
PROCESSLIST_COMMAND: NULL
PROCESSLIST_TIME: 215859
PROCESSLIST_STATE: Table lock
PROCESSLIST_INFO: INTERNAL DDL LOG RECOVER IN PROGRESS
PARENT_THREAD_ID: NULL
        ROLE: NULL
    INSTRUMENTED: YES
...
*****
21. row ****
    THREAD_ID: 64
        NAME: thread/sql/one_connection
        TYPE: FOREGROUND
    PROCESSLIST_ID: 44
    PROCESSLIST_USER: root
    PROCESSLIST_HOST: localhost
    PROCESSLIST_DB: NULL
PROCESSLIST_COMMAND: Query
PROCESSLIST_TIME: 0
PROCESSLIST_STATE: Sending data
PROCESSLIST_INFO: SELECT * FROM performance_schema.threads
PARENT_THREAD_ID: NULL
        ROLE: NULL
    INSTRUMENTED: YES
```

## 1.1.2.9.2.1.74 Performance Schema users Table

### Description

Each user that connects to the server is stored as a row in the

`users`  
table, along with current and total connections.

The table size is determined at startup by the value of the `performance_schema_users_size` system variable. If this is set to

0

, user statistics will be disabled.

Column	Description
USER	The connection's client user name for the connection, or NULL if an internal thread.
CURRENT_CONNECTIONS	Current connections for the user.
TOTAL_CONNECTIONS	Total connections for the user.

## Example

```
SELECT * FROM performance_schema.users;
+-----+-----+-----+
| USER      | CURRENT_CONNECTIONS | TOTAL_CONNECTIONS |
+-----+-----+-----+
| debian-sys-maint |          0 |          35 |
| NULL       |         20 |          23 |
| root        |          1 |           2 |
+-----+-----+-----+
```

## 1.1.2.9.2.2 Performance Schema Overview

### Contents

1. [Introduction](#)
2. [Activating the Performance Schema](#)
3. [Enabling the Performance Schema](#)
4. [Listing Performance Schema Variables](#)
5. [Column Comments](#)
6. [See Also](#)

The Performance Schema is a feature for monitoring server performance.

## Introduction

It is implemented as a storage engine, and so will appear in the list of storage engines available.

```
SHOW ENGINES;
+-----+-----+-----+-----+-----+-----+
| Engine      | Support | Comment           | Transactions | XA   | Savepoints |
+-----+-----+-----+-----+-----+-----+
| ...         |     |     |     |     |     |
| PERFORMANCE_SCHEMA | YES    | Performance Schema | NO        | NO  | NO
| ...         |     |     |     |     |     |
+-----+-----+-----+-----+-----+-----+
```

However,

```
performance_schema
is not a regular storage engine for storing data, it's a mechanism for implementing the Performance Schema feature.
```

The storage engine contains a database called

```
performance_schema
, which in turn consists of a number of tables that can be queried with regular SQL statements, returning specific performance information.
```

```
USE performance_schema
```

```
SHOW TABLES;
+-----+
| Tables_in_performance_schema |
+-----+
| accounts                      |
...
| users                         |
+-----+
80 rows in set (0.00 sec)
```

See [List of Performance Schema Tables](#) for a full list and links to detailed descriptions of each table. From [MariaDB 10.5](#), there are 80 Performance Schema tables, while until [MariaDB 10.4](#), there are 52.

## Activating the Performance Schema

The performance schema is disabled by default for performance reasons. You can check its current status by looking at the value of the `performance_schema` system variable.

```
SHOW VARIABLES LIKE 'performance_schema';
+-----+
| Variable_name      | Value   |
+-----+
| performance_schema | ON      |
+-----+
```

The performance schema cannot be activated at runtime - it must be set when the server starts by adding the following line in your `my.cnf` configuration file.

```
performance_schema=ON
```

Until [MariaDB 10.4](#), all memory used by the Performance Schema is allocated at startup. From [MariaDB 10.5](#), some memory is allocated dynamically, depending on load, number of connections, number of tables open etc.

## Enabling the Performance Schema

You need to set up all consumers (starting collection of data) and instrumentations (what to collect):

```
UPDATE performance_schema.setup_consumers SET ENABLED = 'YES';
UPDATE performance_schema.setup_instruments SET ENABLED = 'YES', TIMED = 'YES';
```

You can decide what to enable/disable with

```
WHERE NAME like "%what_to_enable"
; You can disable instrumentations by setting
ENABLED
to
"NO"
```

You can also do this in your `my.cnf` file. The following enables all instrumentation of all stages (computation units) in MariaDB:

```
[mysqld]
performance_schema=ON
performance-schema-instrument='stage/%=ON'
performance-schema-consumer-events-stages-current=ON
performance-schema-consumer-events-stages-history=ON
performance-schema-consumer-events-stages-history-long=ON
```

## Listing Performance Schema Variables

```
SHOW VARIABLES LIKE "perf%";
+-----+
| Variable_name          | Value   |
+-----+
| performance_schema     | ON      |
...
| performance_schema_users_size | 100    |
+-----+
```

See [Performance Schema System Variables](#) for a full list of available system variables.

Note that the "consumer" events are not shown on this list, as they are only available as options, not as system variables, and they can only be enabled at [startup](#).

## Column Comments

MariaDB starting with 10.7.1

From [MariaDB 10.7.1](#), comments have been added to table columns in the Performance Schema. These can be viewed with, for example:

```
SELECT column_name, column_comment FROM information_schema.columns
  WHERE table_schema='performance_schema' AND table_name='file_instances';
...
***** 2. row *****
column_name: EVENT_NAME
column_comment: Instrument name associated with the file.
***** 3. row *****
column_name: OPEN_COUNT
column_comment: Open handles on the file. A value of greater than zero means
                that the file is currently open.
...
```

This page documents status variables related to the [Performance Schema](#). See [Server Status Variables](#) for a complete list of status variables that can be viewed with [SHOW STATUS](#).

See also the [Full list of MariaDB options, system and status variables](#).

## `Performance_schema_accounts_lost`

- **Description:** Number of times a row could not be added to the performance schema accounts table due to it being full. The global value can be flushed by [FLUSH STATUS](#) .
  - **Scope:** Global, Session
  - **Data Type:**  
    numeric
- 

## `Performance_schema_cond_classes_lost`

- **Description:** Number of condition instruments that could not be loaded.
  - **Scope:** Global, Session
  - **Data Type:**  
    numeric
- 

## `Performance_schema_cond_instances_lost`

- **Description:** Number of instances a condition object could not be created. The global value can be flushed by [FLUSH STATUS](#) .
  - **Scope:** Global, Session
  - **Data Type:**  
    numeric
- 

## `Performance_schema_digest_lost`

- **Description:** The global value can be flushed by [FLUSH STATUS](#) .
  - **Scope:** Global, Session
  - **Data Type:**  
    numeric
- 

## `Performance_schema_file_classes_lost`

- **Description:** Number of file instruments that could not be loaded.
  - **Scope:** Global, Session
  - **Data Type:**  
    numeric
- 

## `Performance_schema_file_handles_lost`

- **Description:** Number of instances a file object could not be opened. The global value can be flushed by [FLUSH STATUS](#) .
  - **Scope:** Global, Session
  - **Data Type:**  
    numeric
- 

## `Performance_schema_file_instances_lost`

- **Description:** Number of instances a file object could not be created. The global value can be flushed by [FLUSH STATUS](#) .

- **Scope:** Global, Session

- **Data Type:**

numeric

---

#### Performance\_schema\_hosts\_lost

- **Description:** Number of times a row could not be added to the performance schema hosts table due to it being full. The global value can be flushed by [FLUSH STATUS](#) .

- **Scope:** Global, Session

- **Data Type:**

numeric

---

#### Performance\_schema\_index\_stat\_lost

- **Description:**

- **Scope:** Global, Session

- **Data Type:**

numeric

- **Introduced:** MariaDB 10.5.2
- 

#### Performance\_schema\_locker\_lost

- **Description:** Number of events not recorded, due to either being recursive, or having a deeper nested events stack than the implementation limit. The global value can be flushed by [FLUSH STATUS](#) .

- **Scope:** Global, Session

- **Data Type:**

numeric

---

#### Performance\_schema\_memory\_classes\_lost

- **Description:**

- **Scope:** Global, Session

- **Data Type:**

numeric

- **Introduced:** MariaDB 10.5.2
- 

#### Performance\_schema\_metadata\_lock\_lost

- **Description:**

- **Scope:** Global, Session

- **Data Type:**

numeric

- **Introduced:** MariaDB 10.5.2
- 

#### Performance\_schema\_mutex\_classes\_lost

- **Description:** Number of mutual exclusion instruments that could not be loaded.
  - **Scope:** Global, Session
  - **Data Type:**  
numeric
- 

#### Performance\_schema\_mutex\_instances\_lost

- **Description:** Number of instances a mutual exclusion object could not be created. The global value can be flushed by [FLUSH STATUS](#).
  - **Scope:** Global, Session
  - **Data Type:**  
numeric
- 

#### Performance\_schema\_nested\_statement\_lost

- **Description:**
  - **Scope:** Global, Session
  - **Data Type:**  
numeric
- **Introduced:** [MariaDB 10.5.2](#)
- 

#### Performance\_schema\_prepared\_statements\_lost

- **Description:**
  - **Scope:** Global, Session
  - **Data Type:**  
numeric
- **Introduced:** [MariaDB 10.5.2](#)
- 

#### Performance\_schema\_program\_lost

- **Description:**
  - **Scope:** Global, Session
  - **Data Type:**  
numeric
- **Introduced:** [MariaDB 10.5.2](#)
- 

#### Performance\_schema\_rwlock\_classes\_lost

- **Description:** Number of read/write lock instruments that could not be loaded.
  - **Scope:** Global, Session
  - **Data Type:**  
numeric
- 

#### Performance\_schema\_rwlock\_instances\_lost

- **Description:** Number of instances a read/write lock object could not be created. The global value can be flushed by [FLUSH STATUS](#).
- **Scope:** Global, Session

- **Data Type:**

numeric

---

#### Performance\_schema\_session\_connect\_attrs\_lost

- **Description:** Number of connections for which connection attribute truncation has occurred. The global value can be flushed by [FLUSH STATUS](#).
- **Scope:** Global, Session
- **Data Type:**

numeric

---

#### Performance\_schema\_socket\_classes\_lost

- **Description:**
- **Scope:** Global, Session
- **Data Type:**

numeric

---

#### Performance\_schema\_socket\_instances\_lost

- **Description:** Number of instances a socket object could not be created. The global value can be flushed by [FLUSH STATUS](#).
- **Scope:** Global, Session
- **Data Type:**

numeric

---

#### Performance\_schema\_stage\_classes\_lost

- **Description:** Number of stage event instruments that could not be loaded. The global value can be flushed by [FLUSH STATUS](#).
- **Scope:** Global, Session
- **Data Type:**

numeric

---

#### Performance\_schema\_statement\_classes\_lost

- **Description:** Number of statement instruments that could not be loaded. The global value can be flushed by [FLUSH STATUS](#).
- **Scope:** Global, Session
- **Data Type:**

numeric

---

#### Performance\_schema\_table\_handles\_lost

- **Description:** Number of instances a table object could not be opened. The global value can be flushed by [FLUSH STATUS](#).
- **Scope:** Global, Session
- **Data Type:**

numeric

---

#### `Performance_schema_table_instances_lost`

- **Description:** Number of instances a table object could not be created. The global value can be flushed by [FLUSH STATUS](#) .
  - **Scope:** Global, Session
  - **Data Type:**  
    numeric
- 

#### `Performance_schema_table_lock_stat_lost`

- **Description:**
  - **Scope:** Global, Session
  - **Data Type:**  
    numeric
- **Introduced:** [MariaDB 10.5.2](#)
- 

#### `Performance_schema_thread_classes_lost`

- **Description:** Number of thread instruments that could not be loaded.
  - **Scope:** Global, Session
  - **Data Type:**  
    numeric
- 

#### `Performance_schema_thread_instances_lost`

- **Description:** Number of instances thread object could not be created. The global value can be flushed by [FLUSH STATUS](#) .
  - **Scope:** Global, Session
  - **Data Type:**  
    numeric
- 

#### `Performance_schema_users_lost`

- **Description:** Number of times a row could not be added to the performance schema users table due to it being full. The global value can be flushed by [FLUSH STATUS](#) .
  - **Scope:** Global, Session
  - **Data Type:**  
    numeric
-

42. performance\_schema\_users\_size

The following variables are used with MariaDB's [Performance Schema](#). See [Performance Schema Options](#) for Performance Schema options that are not system variables. See [Server System Variables](#) for a complete list of system variables and instructions on setting them.

See also the [Full list of MariaDB options, system and status variables](#).

### performance\_schema

- **Description:** If set to

1  
(  
0

is default), enables the Performance Schema

- **Commandline:**

--performance-schema=#

- **Scope:** Global

- **Dynamic:** No

- **Data Type:**

boolean

- **Default Value:**

OFF

## performance\_schema\_accounts\_size

- **Description:** Maximum number of rows in the [performance\\_schema.accounts](#) table. If set to 0, the Performance Schema will not store statistics in the accounts table. Use

-1  
(the default) for automated sizing.

- **Commandline:**

--performance-schema-accounts-size=#

- **Scope:** Global

- **Dynamic:** No

- **Data Type:**

numeric

- **Default Value:**

-1

- **Range:**

-1  
to  
1048576

## performance\_schema\_digests\_size

- **Description:** Maximum number of rows that can be stored in the [events\\_statements\\_summary\\_by\\_digest](#) table.

0  
for disabling,  
-1  
(the default) for automated sizing.

- **Commandline:**

--performance-schema-digests-size=#

- **Scope:** Global

- **Dynamic:** No

- **Data Type:**

numeric

- **Default Value:**

-1

- **Range:**

-1  
to  
200

## performance\_schema\_events\_stages\_history\_long\_size

- **Description:** Number of rows in the [events\\_stages\\_history\\_long](#) table.

0  
for disabling,  
-1  
(the default) for automated sizing.

- **Commandline:**

--performance-schema-events-stages-history-long-size=#

- **Scope:** Global

- **Dynamic:** No

- **Data Type:**

numeric

- **Default Value:**

-1

- **Range:**

```
-1  
to  
1048576
```

---

performance\_schema\_events\_stages\_history\_size

- **Description:** Number of rows per thread in the [events\\_stages\\_history](#) table.

```
0  
for disabling,  
-1  
(the default) for automated sizing.
```

- **Commandline:**

```
--performance-schema-events-stages-history-size=#
```

- **Scope:** Global

- **Dynamic:** No

- **Data Type:**

```
numeric
```

- **Default Value:**

```
-1
```

- **Range:**

```
-1  
to  
1024
```

---

performance\_schema\_events\_statements\_history\_long\_size

- **Description:** Number of rows in the [events\\_statements\\_history\\_long](#) table.

```
0  
for disabling,  
-1  
(the default) for automated sizing.
```

- **Commandline:**

```
--performance-schema-events-statements-history-long-size=#
```

- **Scope:** Global

- **Dynamic:** No

- **Data Type:**

```
numeric
```

- **Default Value:**

```
-1
```

- **Range:**

```
-1  
to  
1048576
```

---

performance\_schema\_events\_statements\_history\_size

- **Description:** Number of rows per thread in the [events\\_statements\\_history](#) table.

```
0  
for disabling,  
-1  
(the default) for automated sizing.
```

- **Commandline:**

```
--performance-schema-events-statements-history-size=#
```

- **Scope:** Global

- **Dynamic:** No

- **Data Type:**

    numeric

- **Default Value:**

    -1

- **Range:**

    -1

    to

    1024

---

## performance\_schema\_events\_transactions\_history\_long\_size

- **Description:** Number of rows in [events\\_transactions\\_history\\_long](#) table. Use

    0

    to disable,

    -1

    for automated sizing.

- **Commandline:**

```
--performance-schema-events-transactions-history-long-size=#
```

- **Scope:** Global

- **Dynamic:** No

- **Data Type:**

    numeric

- **Default Value:**

    -1

- **Range:**

    -1

    to

    1048576

- **Introduced:** [MariaDB 10.5.2](#)

---

## performance\_schema\_events\_transactions\_history\_size

- **Description:** Number of rows per thread in [events\\_transactions\\_history](#). Use 0 to disable, -1 for automated sizing.

- **Commandline:**

```
--performance-schema-events-transactions-history-size=#
```

- **Scope:** Global

- **Dynamic:** No

- **Data Type:**

    numeric

- **Default Value:**

    -1

- **Range:**

    -1

    to

    1024

- **Introduced:** [MariaDB 10.5.2](#)

---

## performance\_schema\_events\_waits\_history\_long\_size

- **Description:** Number of rows contained in the [events\\_waits\\_history\\_long](#) table.

0  
for disabling,  
-1  
(the default) for automated sizing.

- **Commandline:**

```
--performance-schema-events-waits-history-long-size=#
```

- **Scope:** Global

- **Dynamic:** No

- **Data Type:**

numeric

- **Default Value:**

-1

- **Range:**

-1  
to  
1048576

---

## performance\_schema\_events\_waits\_history\_size

- **Description:** Number of rows per thread contained in the [events\\_waits\\_history](#) table.

0  
for disabling,  
-1  
(the default) for automated sizing.

- **Commandline:**

```
--performance-schema-events-waits-history-size=#
```

- **Scope:** Global

- **Dynamic:** No

- **Data Type:**

numeric

- **Default Value:**

-1

- **Range:**

-1  
to  
1024

---

## performance\_schema\_hosts\_size

- **Description:** Number of rows stored in the [hosts](#) table. If set to zero, no connection statistics are kept for the hosts table.

-1  
(the default) for automated sizing.

- **Commandline:**

```
--performance-schema-hosts-size=#
```

- **Scope:** Global

- **Dynamic:** No

- **Data Type:**

numeric

- **Default Value:**

-1

- **Range:**

-1  
to  
1048576

---

## performance\_schema\_max\_cond\_classes

- **Description:** Specifies the maximum number of condition instruments.
- **Commandline:**

--performance-schema-max-cond-classes=#

- **Scope:** Global
- **Dynamic:** No
- **Data Type:**

numeric

- **Default Value:**

90  
(>= MariaDB 10.5.1 ),  
80  
(<= MariaDB 10.5.0 )

- **Range:**

0  
to  
256

---

## performance\_schema\_max\_cond\_instances

- **Description:** Specifies the maximum number of instrumented condition objects.

0  
for disabling,  
-1  
(the default) for automated sizing.

- **Commandline:**

--performance-schema-max-cond-instances=#

- **Scope:** Global
- **Dynamic:** No
- **Data Type:**

numeric

- **Default Value:**

-1

- **Range:**

-1  
to  
1048576

---

## performance\_schema\_max\_digest\_length

- **Description:** Maximum length considered for digest text, when stored in performance\_schema tables.
- **Commandline:**

--performance-schema-max-digest-length=#

- **Scope:** Global
- **Dynamic:** No
- **Data Type:**

numeric

- **Default Value:**

1024

- **Range:**

0

to

1048576

---

### performance\_schema\_max\_file\_classes

- **Description:** Specifies the maximum number of file instruments.

- **Commandline:**

--performance-schema-max-file-classes=#

- **Scope:** Global

- **Dynamic:** No

- **Data Type:**

numeric

- **Default Value:**

80

(>= MariaDB 10.5.2 ),

50

(<= MariaDB 10.5.1 )

- **Range:**

0

to

256

---

### performance\_schema\_max\_file\_handles

- **Description:** Specifies the maximum number of opened file objects. Should always be higher than [open\\_files\\_limit](#).

- **Commandline:**

--performance-schema-max-file-handles=#

- **Scope:** Global

- **Dynamic:** No

- **Data Type:**

numeric

- **Default Value:**

32768

- **Range:**

-1

to

32768

---

### performance\_schema\_max\_file\_instances

- **Description:** Specifies the maximum number of instrumented file objects.

0

for disabling,

-1

(the default) for automated sizing.

- **Commandline:**

--performance-schema-max-file-instances=#

- **Scope:** Global

- **Dynamic:** No
- **Data Type:** numeric

- **Default Value:**

-1

- **Range:**

-1

to

1048576

---

### performance\_schema\_max\_index\_stat

- **Description:** Maximum number of index statistics for instrumented tables. Use 0 to disable, -1 for automated scaling.

- **Commandline:**

--performance-schema-max-index-stat=#

- **Scope:** Global

- **Dynamic:** No

- **Data Type:**

numeric

- **Default Value:**

-1

- **Range:**

-1

to

1048576

- **Introduced:** MariaDB 10.5.2
- 

### performance\_schema\_max\_memory\_classes

- **Description:** Maximum number of memory pool instruments.

- **Commandline:**

--performance-schema-max-memory-classes=#

- **Scope:** Global

- **Dynamic:** No

- **Data Type:**

numeric

- **Default Value:**

320

- **Range:**

0

to

1024

- **Introduced:** MariaDB 10.5.2
- 

### performance\_schema\_max\_metadata\_locks

- **Description:** Maximum number of [Performance Schema metadata locks](#). Use 0 to disable, -1 for automated scaling.

- **Commandline:**

--performance-schema-max-metadata-locks=#

- **Scope:** Global

- **Dynamic:** No
- **Data Type:**  
numeric

- **Default Value:**  
-1

- **Range:**  
-1  
to  
104857600

- **Introduced:** MariaDB 10.5.2
- 

### performance\_schema\_max\_mutex\_classes

- **Description:** Specifies the maximum number of mutex instruments.

- **Commandline:**  
--performance-schema-max-mutex-classes=#

- **Scope:** Global
- **Dynamic:** No
- **Data Type:**  
numeric

- **Default Value:**  
210  
(>= MariaDB 10.5.2 ),  
200  
(<= MariaDB 10.5.1 )

- **Range:**  
0  
to  
256
- 

### performance\_schema\_max\_mutex\_instances

- **Description:** Specifies the maximum number of instrumented mutex instances.

0  
for disabling,  
-1  
(the default) for automated sizing.

- **Commandline:**  
--performance-schema-max-mutex-instances=#

- **Scope:** Global
- **Dynamic:** No
- **Data Type:**  
numeric

- **Default Value:**  
-1

- **Range:**  
-1  
to  
104857600
- 

### performance\_schema\_max\_prepared\_statement\_instances

- **Description:** Maximum number of instrumented prepared statements. Use 0 to disable, -1 for automated scaling.
  - **Commandline:**

```
--performance-schema-max-prepared-statement-instances=#
```
  - **Scope:** Global
  - **Dynamic:** No
  - **Data Type:**

```
numeric
```
  - **Default Value:**

```
-1
```
  - **Range:**

```
-1  
to  
1048576
```
  - **Introduced:** [MariaDB 10.5.2](#)
- 

### performance\_schema\_max\_program\_instances

- **Description:** Maximum number of instrumented programs. Use 0 to disable, -1 for automated scaling.
  - **Commandline:**

```
--performance-schema-max-program-instances=#
```
  - **Scope:** Global
  - **Dynamic:** No
  - **Data Type:**

```
numeric
```
  - **Default Value:**

```
-1
```
  - **Range:**

```
-1  
to  
1048576
```
  - **Introduced:** [MariaDB 10.5.2](#)
- 

### performance\_schema\_max\_rwlock\_classes

- **Description:** Specifies the maximum number of rwlock instruments.
  - **Commandline:**

```
--performance-schema-max-rwlock-classes=#
```
  - **Scope:** Global
  - **Dynamic:** No
  - **Data Type:**

```
numeric
```
  - **Default Value:**

```
50  
(>= MariaDB 10.5.2 ),  
40  
(<= MariaDB 10.5.1 )
```
  - **Range:**

```
0  
to  
256
```
- 

### performance\_schema\_max\_rwlock\_instances

- **Description:** Specifies the maximum number of instrumented rwlock objects.

0  
for disabling,  
-1  
(the default) for automated sizing.

- **Commandline:**

--performance-schema-max-rwlock-instances=#

- **Scope:** Global

- **Dynamic:** No

- **Data Type:**

numeric

- **Default Value:**

-1

- **Range:**

-1  
to  
104857600

---

#### performance\_schema\_max\_socket\_classes

- **Description:** Specifies the maximum number of socket instruments.

- **Commandline:**

--performance-schema-max-socket-classes=#

- **Scope:** Global

- **Dynamic:** No

- **Data Type:**

numeric

- **Default Value:**

10

- **Range:**

0  
to  
256

---

#### performance\_schema\_max\_socket\_instances

- **Description:** Specifies the maximum number of instrumented socket objects.

0  
for disabling,  
-1  
(the default) for automated sizing.

- **Commandline:**

--performance-schema-max-socket-instances=#

- **Scope:** Global

- **Dynamic:** No

- **Data Type:**

numeric

- **Default Value:**

-1

- **Range:**

-1  
to  
1048576

---

## performance\_schema\_max\_sql\_text\_length

- **Description:** Maximum length of displayed sql text.

- **Commandline:**

```
--performance-schema-max-sql-text-length=#
```

- **Scope:** Global

- **Dynamic:** No

- **Data Type:**

```
numeric
```

- **Default Value:**

```
1024
```

- **Range:**

```
0
```

```
to
```

```
1048576
```

- **Introduced:** [MariaDB 10.5.2](#)
- 

## performance\_schema\_max\_stage\_classes

- **Description:** Specifies the maximum number of stage instruments.

- **Commandline:**

```
--performance-schema-max-stage-classes=#
```

- **Scope:** Global

- **Dynamic:** No

- **Data Type:**

```
numeric
```

- **Default Value:**

```
160  
(>= MariaDB 10.3.3 ),
```

```
150  
(<= MariaDB 10.3.2 )
```

- **Range:**

```
0
```

```
to
```

```
256
```

---

## performance\_schema\_max\_statement\_classes

- **Description:** Specifies the maximum number of statement instruments. Automatically calculated at server build based on the number of available statements. Should be left as either autosized or disabled, as changing to any positive value has no benefit and will most likely allocate unnecessary memory. Setting to zero disables all statement instrumentation, and no memory will be allocated for this purpose.

- **Commandline:**

```
--performance-schema-max-statement-classes=#
```

- **Scope:** Global

- **Dynamic:** No

- **Data Type:**

```
numeric
```

- **Default Value:** Autosized (see description)

- **Range:**

```
0
```

```
to
```

---

`performance_schema_max_statement_stack`

- **Description:** Number of rows per thread in EVENTS\_STATEMENTS\_CURRENT.
- **Commandline:**

--performance-schema-max-statement-stack=#

- **Scope:** Global

- **Dynamic:** No

- **Data Type:**

numeric

- **Default Value:**

10

- **Range:**

1

to

256

- **Introduced:** MariaDB 10.5.2
- 

`performance_schema_max_table_handles`

- **Description:** Specifies the maximum number of opened table objects.

0

for disabling,

-1

(the default) for automated sizing.

- **Commandline:**

--performance-schema-max-table-handles=#

- **Scope:** Global

- **Dynamic:** No

- **Data Type:**

numeric

- **Default Value:**

-1

- **Range:**

-1

to

1048576

---

`performance_schema_max_table_instances`

- **Description:** Specifies the maximum number of instrumented table objects.

0

for disabling,

-1

(the default) for automated sizing.

- **Commandline:**

--performance-schema-max-table-instances=#

- **Scope:** Global

- **Dynamic:** No

- **Data Type:**

numeric

- **Default Value:**

-1

- **Range:**

-1

to

1048576

---

### performance\_schema\_max\_table\_lock\_stat

- **Description:** Maximum number of lock statistics for instrumented tables. Use 0 to disable, -1 for automated scaling.

- **Commandline:**

--performance-schema-max-table-lock-stat=#

- **Scope:** Global

- **Dynamic:** No

- **Data Type:**

numeric

- **Default Value:**

-1

- **Range:**

-1

to

1048576

- **Introduced:** MariaDB 10.5.2
- 

### performance\_schema\_max\_thread\_classes

- **Description:** Specifies the maximum number of thread instruments.

- **Commandline:**

--performance-schema-max-thread-classes=#

- **Scope:** Global

- **Dynamic:** No

- **Data Type:**

numeric

- **Default Value:**

50

- **Range:**

0

to

256

---

### performance\_schema\_max\_thread\_instances

- **Description:** Specifies how many of the running server threads (see [max\\_connections](#) and [max\\_delayed\\_threads](#) ) can be instrumented. Should be greater than the sum of max\_connections and max\_delayed\_threads.

0

for disabling,

-1

(the default) for automated sizing.

- **Commandline:**

--performance-schema-max-thread-instances=#

---

- **Scope:** Global
- **Dynamic:** No
- **Data Type:**  
    numeric

- **Default Value:**  
    -1

- **Range:**

-1  
to  
1048576

---

### performance\_schema\_session\_connect\_attrs\_size

- **Description:** Per thread preallocated memory for holding connection attribute strings. Incremented if the strings are larger than the reserved space.

0  
for disabling,  
-1  
(the default) for automated sizing.

- **Commandline:**

--performance-schema-session-connect-attrs-size=#

- **Scope:** Global
- **Dynamic:** No
- **Data Type:**  
    numeric

- **Default Value:**  
    -1

- **Range:**

-1  
to  
1048576

---

### performance\_schema\_setup\_actors\_size

- **Description:** The maximum number of rows to store in the performance schema `setup_actors` table.

-1  
(from [MariaDB 10.5.2](#) ) denotes automated sizing.

- **Commandline:**

--performance-schema-setup-actors-size=#

- **Scope:** Global
- **Dynamic:** No
- **Data Type:**  
    numeric

- **Default Value:**

-1  
(>= [MariaDB 10.5.2](#) ),  
100  
(<= [MariaDB 10.5.1](#) )

- **Range:**

-1  
to  
1024  
(>= [MariaDB 10.5.2](#) ),  
0  
to  
1024

### performance\_schema\_setup\_objects\_size

- **Description:** The maximum number of rows that can be stored in the performance schema `setup_objects` table.
    - 1
      - (from MariaDB 10.5.2) denotes automated sizing.
  - **Commandline:**

```
--performance-schema-setup-objects-size=#
```
  - **Scope:** Global
  - **Dynamic:** No
  - **Data Type:**

```
numeric
```
  - **Default Value:**

```
-1  
(>= MariaDB 10.5.2),  
100  
(<= MariaDB 10.5.1)
```
  - **Range:**

```
-1  
to  
1048576  
(>= MariaDB 10.5.2),  
0  
to  
1048576  
(<= MariaDB 10.5.1)
```
- 

### performance\_schema\_users\_size

- **Description:** Number of rows in the `performance_schema.users` table. If set to 0, the Performance Schema will not store connection statistics in the users table.
  - 1
    - (the default) for automated sizing.
- **Commandline:**

```
--performance-schema-users-size=#
```
- **Scope:** Global
- **Dynamic:** No
- **Data Type:**

```
numeric
```
- **Default Value:**

```
-1
```
- **Range:**

```

## 1.1.2.9.2.5 Performance Schema Digests

The Performance Schema digest is a normalized form of a statement, with the specific data values removed. It allows statistics to be gathered for similar kinds of statements.

For example:

```
SELECT * FROM customer WHERE age < 20
SELECT * FROM customer WHERE age < 30
```

With the data values removed, both of these statements normalize to:

```
SELECT * FROM customer WHERE age < ?
```

which is the digest text. The digest text is then MD5 hashed, resulting in a digest. For example:

```
DIGEST_TEXT: SELECT * FROM `performance_schema` . `users`  
DIGEST: 0f70cec4015f2a346df4ac0e9475d9f1
```

By contrast, the following two statements would not have the same digest as, while the data values are the same, they call upon different tables.

```
SELECT * FROM customer1 WHERE age < 20  
SELECT * FROM customer2 WHERE age < 20
```

The digest text is limited to 1024 bytes. Queries exceeding this limit are truncated with '...', meaning that long queries that would otherwise have different digests may share the same digest.

Digest information is used in a number of performance scheme tables. These include

- `events_statements_current`
- `events_statements_history`
- `events_statements_history_long`
- `events_statements_summary_by_digest` (a summary table by schema and digest)

## 1.1.2.9.2.6 PERFORMANCE\_SCHEMA Storage Engine

If you run `SHOW ENGINES`, you'll see the following storage engine listed.

```
SHOW ENGINES\G  
...  
Engine: PERFORMANCE_SCHEMA  
Support: YES  
Comment: Performance Schema  
Transactions: NO  
XA: NO  
Savepoints: NO  
...
```

The PERFORMANCE\_SCHEMA is not a regular storage engine for storing data, it's a mechanism for implementing the [Performance Schema](#) feature.

The `SHOW ENGINE PERFORMANCE_SCHEMA STATUS` statement is also available, which shows how much memory is used by the tables and internal buffers.

See [Performance Schema](#) for more details.

## 1.1.2.9.3 The mysql Database Tables

### 1.1.2.9.3.1 mysql.column\_stats Table

The

`mysql.column_stats` table is one of three tables storing data used for [Engine-independent table statistics](#). The others are `mysql.table_stats` and `mysql.index_stats`.

Note that statistics for blob and text columns are not collected. If explicitly specified, a warning is returned.

MariaDB starting with 10.4

In MariaDB 10.4 and later, this table uses the [Aria](#) storage engine.

MariaDB until 10.3

In MariaDB 10.3 and before, this table uses the [MyISAM](#) storage engine.

The

`mysql.column_stats` table contains the following fields:

Field	Type	Null	Key	Default	Description
-------	------	------	-----	---------	-------------

db_name	varchar(64)	NO	PRI	NULL	Database the table is in.
table_name	varchar(64)	NO	PRI	NULL	Table name.
column_name	varchar(64)	NO	PRI	NULL	Name of the column.
min_value	varchar(255)	YES		NULL	Minimum value in the table (in text form).
max_value	varchar(255)	YES		NULL	Maximum value in the table (in text form).
nulls_ratio	decimal(12,4)	YES		NULL	Fraction of NULL values (0- no NULL s, 0.5 - half values are NULL s, 1 - all values are NULL s).
avg_length	decimal(12,4)	YES		NULL	Average length of column value, in bytes. Counted as if one ran  SELECT AVG(LENGTH(col)) . This doesn't count NULL bytes, assumes endspace removal for CHAR(n) , etc.
avg_frequency	decimal(12,4)	YES		NULL	Average number of records with the same value
hist_size	tinyint(3) unsigned	YES		NULL	Histogram size in bytes, from 0-255, or, from MariaDB 10.7 , number of buckets if the histogram type is JSON_HB .
hist_type	enum('SINGLE_PREC_HB', 'DOUBLE_PREC_HB') (>= MariaDB 10.7 )  enum('SINGLE_PREC_HB', 'DOUBLE_PREC_HB','JSON_HB') (<= MariaDB 10.6 )	YES		NULL	Histogram type. See the histogram_type system variable.
histogram	blob (>= MariaDB 10.7 )  varbinary(255) (<= MariaDB 10.6 )	YES		NULL	

It is possible to manually update the table. See [Manual updates to statistics tables](#) for details.

## 1.1.2.9.3.2 mysql.columns\_priv Table

The

### `mysql.columns_priv`

table contains information about column-level privileges. The table can be queried and although it is possible to directly update it, it is best to use [GRANT](#) for setting privileges.

Note that the MariaDB privileges occur at many levels. A user may be granted a privilege at the column level, but may still not have permission on a table level, for example. See [privileges](#) for a more complete view of the MariaDB privilege system.

The [INFORMATION\\_SCHEMA.COLUMN\\_PRIVILEGES](#) table derives its contents from

### `mysql.columns_priv`

MariaDB starting with 10.4

In MariaDB 10.4 and later, this table uses the [Aria](#) storage engine.

MariaDB until 10.3

In MariaDB 10.3 and before, this table uses the [MyISAM](#) storage engine.

The

### `mysql.columns_priv`

table contains the following fields:

Field	Type	Null	Key	Default	Description
Host	char(60)	NO	PRI		Host (together with User, Db, Table_name and Column_name makes up the unique identifier for this record.)
Db	char(64)	NO	PRI		Database name (together with User, Host, Table_name and Column_name makes up the unique identifier for this record.)
User	char(80)	NO	PRI		User (together with Host, Db, Table_name and Column_name makes up the unique identifier for this record.)
Table_name	char(64)	NO	PRI		Table name (together with User, Db, Host and Column_name makes up the unique identifier for this record.)

Column_name	char(64)	NO	PRI		Column name (together with User , Db , Table_name and Host makes up the unique identifier for this record.)
Timestamp	timestamp	NO		CURRENT_TIMESTAMP	
Column_priv	set('Select', 'Insert', 'Update', 'References')	NO			The privilege type. See <a href="#">Column Privileges</a> for details.

The [Acl\\_column\\_grants](#) status variable, added in [MariaDB 10.1.4](#), indicates how many rows the

```
mysql.columns_priv
table contains.
```

## 1.1.2.9.3.3 mysql.db Table

The

```
mysql.db
```

table contains information about database-level privileges. The table can be queried and although it is possible to directly update it, it is best to use [GRANT](#) for setting privileges.

Note that the MariaDB privileges occur at many levels. A user may not be granted a privilege at the database level, but may still have permission on a table level, for example. See [privileges](#) for a more complete view of the MariaDB privilege system.

MariaDB starting with [10.4](#)

In [MariaDB 10.4](#) and later, this table uses the [Aria](#) storage engine.

MariaDB until [10.3](#)

In [MariaDB 10.3](#) and before, this table uses the [MyISAM](#) storage engine.

The

```
mysql.db
```

table contains the following fields:

Field	Type	Null	Key	Default	Description	Introduced
Host	char(60)	NO	PRI		Host (together with User and Db makes up the unique identifier for this record. Until <a href="#">MariaDB 5.5</a> , if the host field was blank, the corresponding record in the <a href="#">mysql.host</a> table would be examined. From <a href="#">MariaDB 10.0</a> , a blank host field is the same as the % wildcard.)	
Db	char(64)	NO	PRI		Database (together with User and Host makes up the unique identifier for this record.)	
User	char(80)	NO	PRI		User (together with Host and Db makes up the unique identifier for this record.)	

Select_priv	enum('N','Y')	NO	N	Can perform <b>SELECT</b> statements.	
Insert_priv	enum('N','Y')	NO	N	Can perform <b>INSERT</b> statements.	
Update_priv	enum('N','Y')	NO	N	Can perform <b>UPDATE</b> statements.	
Delete_priv	enum('N','Y')	NO	N	Can perform <b>DELETE</b> statements.	
Create_priv	enum('N','Y')	NO	N	Can <b>CREATE TABLE</b> 's .	
Drop_priv	enum('N','Y')	NO	N	Can <b>DROP DATABASE</b> 's or <b>DROP TABLE</b> 's .	
Grant_priv	enum('N','Y')	NO	N	User can <b>grant</b> privileges they possess.	
References_priv	enum('N','Y')	NO	N	Unused	
Index_priv	enum('N','Y')	NO	N	Can create an index on a table using the <b>CREATE INDEX</b> statement. Without the <b>INDEX</b> privilege, user can still create indexes when creating a table using the <b>CREATE TABLE</b> statement if the user has have the <b>CREATE</b> privilege, and user can create indexes using the <b>ALTER</b> <b>TABLE</b> statement if they have the <b>ALTER</b> privilege.	
Alter_priv	enum('N','Y')	NO	N	Can perform <b>ALTER TABLE</b> statements.	
Create_tmp_table_priv	enum('N','Y')	NO	N	Can create temporary tables with the <b>CREATE TEMPORARY TABLE</b> statement.	
Lock_tables_priv	enum('N','Y')	NO	N	Acquire explicit locks using the <b>LOCK TABLES</b> statement; user also needs to have the <b>SELECT</b> privilege on a table in order to lock it.	
Create_view_priv	enum('N','Y')	NO	N	Can create a view using the <b>CREATE_VIEW</b> statement.	
Show_view_priv	enum('N','Y')	NO	N	Can show the <b>CREATE VIEW</b> statement to create a view using the <b>SHOW</b> <b>CREATE VIEW</b> statement.	

Create_routine_priv	enum('N','Y')	NO	N	Can create stored programs using the <a href="#">CREATE PROCEDURE</a> and <a href="#">CREATE FUNCTION</a> statements.	
Alter_routine_priv	enum('N','Y')	NO	N	Can change the characteristics of a stored function using the <a href="#">ALTER FUNCTION</a> statement.	
Execute_priv	enum('N','Y')	NO	N	Can execute <a href="#">stored procedure</a> or functions.	
Event_priv	enum('N','Y')	NO	N	Create, drop and alter <a href="#">events</a> .	
Trigger_priv	enum('N','Y')	NO	N	Can execute <a href="#">triggers</a> associated with tables the user updates, execute the <a href="#">CREATE TRIGGER</a> and <a href="#">DROP TRIGGER</a> statements.	
Delete_history_priv	enum('N','Y')	NO	N	Can delete rows created through <a href="#">system versioning</a> .	MariaDB 10.3.5

The [Acl\\_database\\_grants](#) status variable, added in [MariaDB 10.1.4](#), indicates how many rows the `mysql.db` table contains.

## 1.1.2.9.3.4 mysql.event Table

The

`mysql.event`

table contains information about MariaDB [events](#). Similar information can be obtained by viewing the [INFORMATION\\_SCHEMA.EVENTS](#) table, or with the [SHOW EVENTS](#) and [SHOW CREATE EVENT](#) statements.

The table is upgraded live, and there is no need to restart the server if the table has changed.

MariaDB starting with [10.4](#)

In [MariaDB 10.4](#) and later, this table uses the [Aria](#) storage engine.

MariaDB until [10.3](#)

In [MariaDB 10.3](#) and before, this table uses the [MyISAM](#) storage engine.

The

`mysql.event`

table contains the following fields:

Field	Type	Null	Key	Default	Description
db	char(64)	NO	PRI		
name	char(64)	NO	PRI		
body	longblob	NO		NULL	
definer	char(141)	NO			

execute_at	datetime	YES		NULL	
interval_value	int(11)	YES		NULL	
interval_field	enum('YEAR', 'QUARTER', 'MONTH', 'DAY', 'HOUR', 'MINUTE', 'WEEK', 'SECOND', 'MICROSECOND', 'YEAR_MONTH', 'DAY_HOUR', 'DAY_MINUTE', 'DAY_SECOND', 'HOUR_MINUTE', 'HOUR_SECOND', 'MINUTE_SECOND', 'DAY_MICROSECOND', 'HOUR_MICROSECOND', 'MINUTE_MICROSECOND', 'SECOND_MICROSECOND')	YES		NULL	
created	timestamp	NO		CURRENT_TIMESTAMP	
modified	timestamp	NO		0000-00-00 00:00:00	
last_executed	datetime	YES		NULL	
starts	datetime	YES		NULL	
ends	datetime	YES		NULL	
status	enum('ENABLED', 'DISABLED', 'SLAVESIDE_DISABLED')	NO		ENABLED	Current status of the event, one of enabled, disabled, or disabled on the slaveside.
on_completion	enum('DROP', 'PRESERVE')	NO		DROP	
sql_mode	set('REAL_AS_FLOAT', 'PIPES_AS_CONCAT', 'ANSI_QUOTES', 'IGNORE_SPACE', 'IGNORE_BAD_TABLE_OPTIONS', 'ONLY_FULL_GROUP_BY', 'NO_UNSIGNED_SUBTRACTION', 'NO_DIR_IN_CREATE', 'POSTGRESQL', 'ORACLE', 'MSSQL', 'DB2', 'MAXDB', 'NO_KEY_OPTIONS', 'NO_TABLE_OPTIONS', 'NO_FIELD_OPTIONS', 'MYSQL323', 'MYSQL40', 'ANSI', 'NO_AUTO_VALUE_ON_ZERO', 'NO_BACKSLASH_ESCAPES', 'STRICT_TRANS_TABLES', 'STRICT_ALL_TABLES', 'NO_ZERO_IN_DATE', 'NO_ZERO_DATE', 'INVALID_DATES', 'ERROR_FOR_DIVISION_BY_ZERO', 'TRADITIONAL', 'NO_AUTO_CREATE_USER', 'HIGH_NOT_PRECEDENCE', 'NO_ENGINE_SUBSTITUTION', 'PAD_CHAR_TO_FULL_LENGTH')	NO			The <a href="#">SQL_MODE</a> at the time the event was created.
comment	char(64)	NO			
originator	int(10) unsigned	NO		NULL	

time_zone	char(64)	NO		SYSTEM	
character_set_client	char(32)	YES		NULL	
collation_connection	char(32)	YES		NULL	
db_collation	char(32)	YES		NULL	
body_utf8	longblob	YES		NULL	

## 1.1.2.9.3.5 mysql.func Table

The

`mysql.func`

table stores information about [user-defined functions](#) (UDFs) created with the [CREATE FUNCTION UDF](#) statement.

MariaDB starting with [10.4](#)

In [MariaDB 10.4](#) and later, this table uses the [Aria](#) storage engine.

MariaDB until [10.3](#)

In [MariaDB 10.3](#) and before, this table uses the [MyISAM](#) storage engine.

The

`mysql.func`

table contains the following fields:

Field	Type	Null	Key	Default	Description
name	char(64)	NO	PRI		UDF name
ret	tinyint(1)	NO		0	
d1	char(128)	NO			Shared library name
type	enum('function','aggregate')	NO		NULL	Type, either function or aggregate . Aggregate functions are summary functions such as <a href="#">SUM()</a> and <a href="#">AVG()</a> .

## Example

```
SELECT * FROM mysql.func;
+-----+-----+-----+
| name | ret | dl | type |
+-----+-----+-----+
| spider_direct_sql | 2 | ha_spider.so | function |
| spider_bg_direct_sql | 2 | ha_spider.so | aggregate |
| spider_ping_table | 2 | ha_spider.so | function |
| spider_copy_tables | 2 | ha_spider.so | function |
| spider_flush_table_mon_cache | 2 | ha_spider.so | function |
+-----+-----+-----+
```

## 1.1.2.9.3.6 mysql.general\_log Table

The

`mysql.general_log`

table stores the contents of the [General Query Log](#) if general logging is active and the output is being written to table (see [Writing logs into tables](#)).

It contains the following fields:

Field	Type	Null	Key	Default	Description
event_time	timestamp(6)	NO		CURRENT_TIMESTAMP(6)	Time the query was executed.
user_host	mediumtext	NO		NULL	User and host combination.
thread_id	int(11)	NO		NULL	Thread id.
server_id	int(10) unsigned	NO		NULL	Server id.
command_type	varchar(64)	NO		NULL	Type of command.
argument	mediumtext	NO		NULL	Full query.

## Example

```
SELECT * FROM mysql.general_log\G
*****
1. row *****
event_time: 2014-11-11 08:40:04.117177
user_host: root[root] @ localhost []
thread_id: 74
server_id: 1
command_type: Query
argument: SELECT * FROM test.s
*****
2. row *****
event_time: 2014-11-11 08:40:10.501131
user_host: root[root] @ localhost []
thread_id: 74
server_id: 1
command_type: Query
argument: SELECT * FROM mysql.general_log
...
```

## 1.1.2.9.3.7 mysql.global\_priv Table

MariaDB starting with [10.4.1](#)

The

`mysql.global_priv`

table was introduced in [MariaDB 10.4.1](#) to replace the `mysql.user` table.

The

**mysql.global\_priv**  
table contains information about users that have permission to access the MariaDB server, and their global privileges.

Note that the MariaDB privileges occur at many levels. A user may not be granted

privilege at the user level, but may still have  
create  
permission on certain tables or databases, for example. See [privileges](#) for a more complete view of the MariaDB privilege system.

The

`mysql.global_priv`  
table contains the following fields:

Field	Type	Null	Key	Default	Description
Host	char(60)	NO	PRI		Host (together with User makes up the unique identifier for this account).
User	char(80)	NO	PRI		User (together with Host makes up the unique identifier for this account).
Priv	longtext	NO			Global privileges, granted to the account and other account properties

From MariaDB 10.5.2, in order to help the server understand which version a privilege record was written by, the

```
priv  
field contains a new JSON field,  
version_id  
( MDEV-21704 ).
```

## Examples

```
select * from mysql.global_priv;
+-----+-----+-----+
| Host      | User       | Priv
+-----+-----+-----+
| localhost | root        | {"access": 18446744073709551615,"plugin":"mysql_native_password","authentication_string":"*6C387FC38
| 127.%     | msandbox    | {"access":1073740799,"plugin":"mysql_native_password","authentication_string":"*6C387FC3893DBA1E3BA1
| localhost | msandbox    | {"access":1073740799,"plugin":"mysql_native_password","authentication_string":"*6C387FC3893DBA1E3BA1
| localhost | msandbox_rw | {"access":487487,"plugin":"mysql_native_password","authentication_string":"*6C387FC3893DBA1E3BA155E7
| 127.%     | msandbox_rw | {"access":487487,"plugin":"mysql_native_password","authentication_string":"*6C387FC3893DBA1E3BA155E7
| 127.%     | msandbox_ro | {"access":262145,"plugin":"mysql_native_password","authentication_string":"*6C387FC3893DBA1E3BA155E7
| localhost | msandbox_ro | {"access":262145,"plugin":"mysql_native_password","authentication_string":"*6C387FC3893DBA1E3BA155E7
| 127.%     | rsandbox    | {"access":524288,"plugin":"mysql_native_password","authentication_string":"*B07EB15A2E7BD9620DAE47B1
+-----+-----+-----+
```

Readable format:

A particular user:

```

SELECT CONCAT(user, '@', host, ' => ', JSON_DETAILED(priv)) FROM mysql.global_priv
WHERE user='marijn';
+-----+
| CONCAT(user, '@', host, ' => ', JSON_DETAILED(priv)) |
+-----+
| marijn@localhost => {
  "access": 0,
  "plugin": "mysql_native_password",
  "authentication_string": "",
  "account_locked": true,
  "password_last_changed": 1558017158
} |
+-----+

```

From MariaDB 10.5.2 :

```

GRANT FILE ON *.* TO user1@localhost;
SELECT Host, User, JSON_DETAILED(Priv) FROM mysql.global_priv WHERE user='user1'\G

***** 1. row *****
    Host: localhost
    User: user1
JSON_DETAILED(Priv): {
  "access": 512,
  "plugin": "mysql_native_password",
  "authentication_string": "",
  "password_last_changed": 1581070979,
  "version_id": 100502
}

```

## 1.1.2.9.3.8 mysql.gtid\_slave\_pos Table

The

`mysql.gtid_slave_pos`

table is used in [replication](#) by replica servers to keep track of their current position (the [global transaction ID](#) of the last transaction applied).

Using the table allows the replica to maintain a consistent value for the `gtid_slave_pos` system variable across server restarts. See [Global Transaction ID](#).

You should never attempt to modify the table directly. If you do need to change the global `gtid_slave_pos` value, use

```
SET GLOBAL gtid_slave_pos = ...
instead.
```

The table is updated with the new position as part of each transaction committed during replication. This makes it preferable that the table is using the same storage engine as the tables otherwise being modified in the transaction, since otherwise a multi-engine transaction is needed that can reduce performance.

Starting from MariaDB 10.3.1 , multiple versions of this table are supported, each using a different storage engine. This is selected with the [gtid\\_pos\\_auto\\_engines option](#) , by giving a comma-separated list of engine names. The server will then on-demand create an extra version of the table using the appropriate storage engine, and select the table version using the same engine as the rest of the transaction, avoiding multi-engine transactions.

For example, when

```
gtid_pos_auto_engines=innodb,rocksdb
, tables
mysql.gtid_slave_pos_InnoDB
and
mysql.gtid_slave_pos_RocksDB
will be created and used, if needed. If there is no match to the storage engine, the default
mysql.gtid_slave_pos
table will be used; this also happens if non-transactional updates (like MyISAM) are replicated, since there is then no active transaction at the
time of the
mysql.gtid_slave_pos
table update.
```

Prior to MariaDB 10.3.1 , only the default

```
mysql.gtid_slave_pos
table is available. In these versions, the table should preferably be using the storage engine that is used for most replicated transactions.
```

The default

```
mysql.gtid_slave_pos
table will be initially created using the default storage engine set for the server (which itself defaults to InnoDB). If the application load is primarily
non-transactional MyISAM or Aria tables, it can be beneficial to change the storage engine to avoid including an InnoDB update with every operation:
```

```
ALTER TABLE mysql.gtid_slave_pos ENGINE=MyISAM;
```

The

```
mysql.gtid_slave_pos
```

table should not be changed manually in any other way. From [MariaDB 10.3.1](#), it is preferable to use the `gtid_pos_auto_engines` server variable to get the GTID position updates to use the TokuDB or RocksDB storage engine.

Note that for scalability reasons, the automatic creation of a new

```
mysql.gtid_slave_posXXX
```

table happens asynchronously when the first transaction with the new storage engine is committed. So the very first few transactions will update the old version of the table, until the new version is created and available.

The table

```
mysql.gtid_slave_pos
```

contains the following fields

Field	Type	Null	Key	Default	Description
domain_id	unsigned int(10)	NO	PRI	NULL	Domain id (see <a href="#">Global Transaction ID domain ID</a> ).
sub_id	bigint(20) unsigned	NO	PRI	NULL	This field enables multiple parallel transactions within same domain_id to update this table without contention. At any instant, the replication state corresponds to records with largest sub_id for each domain_id
server_id	unsigned int(10)	NO		NULL	<a href="#">Server id</a> .
seq_no	bigint(20) unsigned	NO		NULL	Sequence number, an integer that is monotonically increasing for each new event group logged into the binlog.

From [MariaDB 10.3.1](#), some status variables are available to monitor the use of the different

```
gtid_slave_pos
```

table versions:

#### [Transactions\\_gtid\\_foreign\\_engine](#)

Number of replicated transactions where the update of the

```
gtid_slave_pos
```

table had to choose a storage engine that did not otherwise participate in the transaction. This can indicate that setting `gtid_pos_auto_engines` might be useful.

#### [Rpl\\_transactions\\_multi\\_engine](#)

Number of replicated transactions that involved changes in multiple (transactional) storage engines, before considering the update of

```
gtid_slave_pos
```

. These are transactions that were already cross-engine, independent of the GTID position update introduced by replication

#### [Transactions\\_multi\\_engine](#)

Number of transactions that changed data in multiple (transactional) storage engines. If this is significantly larger than [Rpl\\_transactions\\_multi\\_engine](#), it indicates that setting

```
gtid_pos_auto_engines
```

could reduce the need for cross-engine transactions.

## 1.1.2.9.3.9 mysql.help\_category Table

```
mysql.help_category
```

is one of the four tables used by the [HELP command](#). It is populated when the server is installed by the `fill_help_table.sql` script. The other help tables are [help\\_relation](#), [help\\_topic](#) and [help\\_keyword](#).

MariaDB starting with 10.4

In MariaDB 10.4 and later, this table uses the [Aria](#) storage engine.

MariaDB until 10.3

In MariaDB 10.3 and before, this table uses the MyISAM storage engine.

The

mysql.help\_category

table contains the following fields:

Field	Type	Null	Key	Default	Description
help_category_id	smallint(5) unsigned	NO	PRI	NULL	
name	char(64)	NO	UNI	NULL	
parent_category_id	smallint(5) unsigned	YES		NULL	
url	char(128)	NO		NULL	

## Example

```
SELECT * FROM help_category;
```

help_category_id	name	parent_category_id	url
1	Geographic	0	
2	Polygon properties	34	
3	WKT	34	
4	Numeric Functions	38	
5	Plugins	35	
6	MBR	34	
7	Control flow functions	38	
8	Transactions	35	
9	Help Metadata	35	
10	Account Management	35	
11	Point properties	34	
12	Encryption Functions	38	
13	LineString properties	34	
14	Miscellaneous Functions	38	
15	Logical operators	38	
16	Functions and Modifiers for Use with GROUP BY	35	
17	Information Functions	38	
18	Comparison operators	38	
19	Bit Functions	38	
20	Table Maintenance	35	
21	User-Defined Functions	35	
22	Data Types	35	
23	Compound Statements	35	
24	Geometry constructors	34	
25	GeometryCollection properties	1	
26	Administration	35	
27	Data Manipulation	35	
28	Utility	35	
29	Language Structure	35	
30	Geometry relations	34	
31	Date and Time Functions	38	
32	WKB	34	
33	Procedures	35	
34	Geographic Features	35	
35	Contents	0	
36	Geometry properties	34	
37	String Functions	38	
38	Functions	35	
39	Data Definition	35	

## 1.1.2.9.3.10 mysql.help\_keyword Table

`mysql.help_keyword` is one of the four tables used by the [HELP command](#). It is populated when the server is installed by the `fill_help_table.sql` script. The other help tables are `help_relation`, `help_category` and `help_topic`.

MariaDB starting with 10.4

In MariaDB 10.4 and later, this table uses the [Aria](#) storage engine.

MariaDB until 10.3

In MariaDB 10.3 and before, this table uses the [MyISAM](#) storage engine.

The

`mysql.help_keyword` table contains the following fields:

Field	Type	Null	Key	Default	Description
<code>help_keyword_id</code>	<code>int(10) unsigned</code>	NO	PRI	NULL	
<code>name</code>	<code>char(64)</code>	NO	UNI	NULL	

### Example

```
SELECT * FROM help_keyword;
+-----+-----+
| help_keyword_id | name      |
+-----+-----+
|     0 | JOIN    |
|     1 | HOST    |
|     2 | REPEAT  |
|     3 | SERIALIZABLE |
|     4 | REPLACE |
|     5 | AT      |
|     6 | SCHEDULE |
|     7 | RETURNS |
|     8 | STARTS  |
|     9 | MASTER_SSL_CA |
|    10 | NCHAR   |
|    11 | COLUMNS |
|    12 | COMPLETION |
...
...
```

## 1.1.2.9.3.11 mysql.help\_relation Table

`mysql.help_relation` is one of the four tables used by the [HELP command](#). It is populated when the server is installed by the `fill_help_table.sql` script. The other help tables are `help_topic`, `help_category` and `help_keyword`.

MariaDB starting with 10.4

In MariaDB 10.4 and later, this table uses the [Aria](#) storage engine.

MariaDB until 10.3

In MariaDB 10.3 and before, this table uses the [MyISAM](#) storage engine.

The

`mysql.help_relation`

table contains the following fields:

Field	Type	Null	Key	Default	Description
help_topic_id	int(10) unsigned	NO	PRI	NULL	
help_keyword_id	int(10) unsigned	NO	PRI	NULL	

## Example

```
...  
| 106 | 456 |  
| 463 | 456 |  
| 468 | 456 |  
| 463 | 457 |  
| 194 | 458 |  
| 478 | 458 |  
| 374 | 459 |  
| 459 | 459 |  
| 39 | 460 |  
| 58 | 460 |  
| 185 | 460 |  
| 264 | 460 |  
| 269 | 460 |  
| 209 | 461 |  
| 468 | 461 |  
| 201 | 462 |  
| 468 | 463 |  
+-----+-----+
```

## 1.1.2.9.3.12 mysql.help\_topic Table

`mysql.help_topic` is one of the four tables used by the [HELP command](#). It is populated when the server is installed by the `fill_help_table.sql` script. The other help tables are `help_relation`, `help_category` and `help_keyword`.

MariaDB starting with 10.4

In MariaDB 10.4 and later, this table uses the [Aria](#) storage engine.

MariaDB until 10.3

In MariaDB 10.3 and before, this table uses the [MyISAM](#) storage engine.

The

`mysql.help_topic`

table contains the following fields:

Field	Type	Null	Key	Default	Description
help_topic_id	int(10) unsigned	NO	PRI	NULL	
name	char(64)	NO	UNI	NULL	
help_category_id	smallint(5) unsigned	NO		NULL	
description	text	NO		NULL	

example	text	NO		NULL	
url	char(128)	NO		NULL	

## Example

```

SELECT * FROM help_topic\G;
...
***** row *****
help_topic_id: 692
    name: JSON_DEPTH
help_category_id: 41
    description: JSON functions were added in MariaDB 10.2.3.

Syntax
-----
JSON_DEPTH(json_doc)

Description
-----
Returns the maximum depth of the given JSON document, or
NULL if the argument is null. An error will occur if the
argument is an invalid JSON document.
Scalar values or empty arrays or objects have a depth of 1.
Arrays or objects that are not empty but contain only
elements or member values of depth 1 will have a depth of 2.
In other cases, the depth will be greater than 2.

Examples
-----
SELECT JSON_DEPTH('[]'), JSON_DEPTH('true'),
JSON_DEPTH('{}');
+-----+-----+
| JSON_DEPTH('[]') | JSON_DEPTH('true') |
| JSON_DEPTH('{}') |
+-----+-----+
| 1 | 1 | 1 |
+-----+-----+

SELECT JSON_DEPTH('[1, 2, 3]'), JSON_DEPTH('[], {}, []');
+-----+-----+
| JSON_DEPTH('[1, 2, 3]') | JSON_DEPTH('[], {}, []') |
+-----+-----+
| 2 | 2 |
+-----+-----+

SELECT JSON_DEPTH('1, 2, [3, 4, 5, 6], 7');
+-----+
| JSON_DEPTH('1, 2, [3, 4, 5, 6], 7') |
+-----+
| 3 |
+-----+

URL: https://mariadb.com/kb/en/json_depth/
example:
    url: https://mariadb.com/kb/en/json_depth/

```

## 1.1.2.9.3.13 mysql.index\_stats Table

The

`mysql.index_stats`  
 table is one of three tables storing data used for [Engine-independent table statistics](#). The others are `mysql.column_stats` and `mysql.table_stats`.

MariaDB starting with [10.4](#)

In [MariaDB 10.4](#) and later, this table uses the [Aria](#) storage engine.

MariaDB until 10.3

In MariaDB 10.3 and before, this table uses the MyISAM storage engine.

The

`mysql.index_stats`

table contains the following fields:

Field	Type	Null	Key	Default	Description
db_name	varchar(64)	NO	PRI	NULL	Database the table is in.
table_name	varchar(64)	NO	PRI	NULL	Table name
index_name	varchar(64)	NO	PRI	NULL	Name of the index
prefix_arity	int(11) unsigned	NO	PRI	NULL	Index prefix length. 1 for the first keypart, 2 for the first two, and so on. InnoDB's extended keys are supported.
avg_frequency	decimal(12,4)	YES		NULL	Average number of records one will find for given values of (keypart1, keypart2, ...), provided the values will be found in the table.

It is possible to manually update the table. See [Manual updates to statistics tables](#) for details.

## 1.1.2.9.3.14 mysql.innodb\_index\_stats

### Contents

1. [Example](#)
2. [See Also](#)

The

`mysql.innodb_index_stats`

table stores data related to particular [InnoDB Persistent Statistics](#), and contains multiple rows for each index.

This table, along with the related `mysql.innodb_table_stats` table, can be manually updated in order to force or test differing query optimization plans. After updating,

```
FLUSH TABLE innodb_index_stats  
is required to load the changes.
```

`mysql.innodb_index_stats`

is not replicated, although any [ANALYZE TABLE](#) statements on the table will be by default..

It contains the following fields:

Field	Type	Null	Key	Default	Description
database_name	varchar(64)	NO	PRI	NULL	Database name.
table_name	varchar(64)	NO	PRI	NULL	Table, partition or subpartition name.
index_name	varchar(64)	NO	PRI	NULL	Index name.

last_update	timestamp	NO		current_timestamp()	Time that this row was last updated.
stat_name	varchar(64)	NO	PRI	NULL	Statistic name.
stat_value	bigint(20) unsigned	NO		NULL	Estimated statistic value.
sample_size	bigint(20) unsigned	YES		NULL	Number of pages sampled for the estimated statistic value.
stat_description	varchar(1024)	NO		NULL	Statistic description.

## Example

```

SELECT * FROM mysql.innodb_index_stats\G
***** 1. row *****
database_name: mysql
  table_name: gtid_slave_pos
  index_name: PRIMARY
last_update: 2017-08-19 20:38:34
    stat_name: n_diff_pfx01
    stat_value: 0
  sample_size: 1
stat_description: domain_id
***** 2. row *****
database_name: mysql
  table_name: gtid_slave_pos
  index_name: PRIMARY
last_update: 2017-08-19 20:38:34
    stat_name: n_diff_pfx02
    stat_value: 0
  sample_size: 1
stat_description: domain_id,sub_id
***** 3. row *****
database_name: mysql
  table_name: gtid_slave_pos
  index_name: PRIMARY
last_update: 2017-08-19 20:38:34
    stat_name: n_leaf_pages
    stat_value: 1
  sample_size: NULL
stat_description: Number of leaf pages in the index
***** 4. row *****
database_name: mysql
  table_name: gtid_slave_pos
  index_name: PRIMARY
last_update: 2017-08-19 20:38:34
    stat_name: size
    stat_value: 1
  sample_size: NULL
stat_description: Number of pages in the index
***** 5. row *****
database_name: test
  table_name: ft
  index_name: FTS_DOC_ID_INDEX
last_update: 2017-09-15 12:58:39
    stat_name: n_diff_pfx01
    stat_value: 0
  sample_size: 1
stat_description: FTS_DOC_ID
***** 6. row *****
database_name: test
  table_name: ft
  index_name: FTS_DOC_ID_INDEX
last_update: 2017-09-15 12:58:39
    stat_name: n_leaf_pages
    stat_value: 1
  sample_size: NULL
stat_description: Number of leaf pages in the index
...

```

## 1.1.2.9.3.15 mysql.innodb\_table\_stats

### Contents

1. [Example](#)
2. [See Also](#)

The

`mysql.innodb_table_stats`  
table stores data related to [InnoDB Persistent Statistics](#), and contains one row per table.

This table, along with the related `mysql.innodb_index_stats` table, can be manually updated in order to force or test differing query optimization plans.

After updating,

```
FLUSH TABLE innodb_table_stats  
is required to load the changes.
```

`mysql.innodb_table_stats`  
is not replicated, although any [ANALYZE TABLE](#) statements on the table will be by default..

It contains the following fields:

Field	Type	Null	Key	Default	Description
database_name	varchar(64)	NO	PRI	NULL	Database name.
table_name	varchar(64)	NO	PRI	NULL	Table, partition or subpartition name.
last_update	timestamp	NO		current_timestamp()	Time that this row was last updated.
n_rows	bigint(20) unsigned	NO		NULL	Number of rows in the table.
clustered_index_size	bigint(20) unsigned	NO		NULL	Size, in pages, of the primary index.
sum_of_other_index_sizes	bigint(20) unsigned	NO		NULL	Size, in pages, of non-primary indexes.

## Example

```
SELECT * FROM mysql.innodb_table_stats\G  
***** 1. row *****  
    database_name: mysql  
    table_name: gtid_slave_pos  
    last_update: 2017-08-19 20:38:34  
        n_rows: 0  
    clustered_index_size: 1  
sum_of_other_index_sizes: 0  
***** 2. row *****  
    database_name: test  
    table_name: ft  
    last_update: 2017-09-15 12:58:39  
        n_rows: 0  
    clustered_index_size: 1  
sum_of_other_index_sizes: 2  
...
```

## 1.1.2.9.3.16 mysql.password\_reuse\_check\_history Table

MariaDB starting with 10.7.0

The `mysql.password_reuse_check_history` Table is installed as part of the [password\\_reuse\\_check plugin](#), available from [MariaDB 10.7.0](#).

The

`mysql.password_reuse_check_history`

table stores old passwords, so that when a user sets a new password, it can be checked for purposes of preventing password reuse.

It contains the following fields:

Field	Type	Null	Key	Default	Description
hash	binary(64)	NO	PRI	NULL	
time	timestamp	NO	MUL	current_timestamp()	

## 1.1.2.9.3.17 mysql.plugin Table

The

`mysql.plugin`  
table can be queried to get information about installed [plugins](#).

This table only contains information about [plugins](#) that have been installed via the following methods:

- The

`INSTALL SONAME`

statement.

- The

`INSTALL PLUGIN`

statement.

- The

`mysql_plugin`

utility.

This table does not contain information about:

- Built-in plugins.
- Plugins loaded with the

`--plugin-load-add`

option.

- Plugins loaded with the

`--plugin-load`

option.

This table only contains enough information to reload the plugin when the server is restarted, which means it only contains the plugin name and the plugin library.

MariaDB starting with [10.4](#)

In [MariaDB 10.4](#) and later, this table uses the [Aria](#) storage engine.

MariaDB until [10.3](#)

In [MariaDB 10.3](#) and before, this table uses the [MyISAM](#) storage engine.

The

`mysql.plugin`  
table contains the following fields:

Field	Type	Null	Key	Default	Description
name	varchar(64)	NO	PRI		Plugin name.
d1	varchar(128)	NO			Name of the plugin library.

## Example

```

SELECT * FROM mysql.plugin;
+-----+-----+
| name      | dl          |
+-----+-----+
| spider    | ha_spider.so |
| spider_alloc_mem | ha_spider.so |
| METADATA_LOCK_INFO | metadata_lock_info.so |
| OQGRAPH   | ha_oqgraph.so |
| cassandra | ha_cassandra.so |
| QUERY_RESPONSE_TIME | query_response_time.so |
| QUERY_RESPONSE_TIME_AUDIT | query_response_time.so |
| LOCALES    | locales.so |
| sequence   | ha_sequence.so |
+-----+-----+

```

## 1.1.2.9.3.18 mysql.proc Table

The

`mysql.proc`

table contains information about [stored procedures](#) and [stored functions](#). It contains similar information to that stored in the [INFORMATION SCHEMA.ROUTINES](#) table.

MariaDB starting with 10.4

In MariaDB 10.4 and later, this table uses the [Aria](#) storage engine.

MariaDB until 10.3

In MariaDB 10.3 and before, this table uses the [MyISAM](#) storage engine.

The

`mysql.proc`

table contains the following fields:

Field	Type	Null	Key	Default	Description
db	char(64)	NO	PRI		Database name.
name	char(64)	NO	PRI		Routine name.
type	enum('FUNCTION','PROCEDURE','PACKAGE', 'PACKAGE BODY')	NO	PRI	NULL	Whether <a href="#">stored procedure</a> , <a href="#">stored function</a> or, from MariaDB 10.3.5, a <a href="#">package</a> or <a href="#">package body</a> .
specific_name	char(64)	NO			
language	enum('SQL')	NO		SQL	Always SQL
sql_data_access	enum('CONTAINS_SQL', 'NO_SQL', 'READS_SQL_DATA', 'MODIFIES_SQL_DATA')	NO		CONTAINS_SQL	

is_deterministic	enum('YES','NO')	NO	NO	Whether the routine is deterministic (can produce only one result for a given list of parameters) or not.
security_type	enum('INVOKER','DEFINER')	NO	DEFINER	INVOKER or DEFINER Indicates which user's privileges apply to this routine.
param_list	blob	NO	NULL	List of parameters.
returns	longblob	NO	NULL	What the routine returns.
body	longblob	NO	NULL	Definition of the routine.
definer	char(141)	NO		If the security_type is DEFINER , this value indicates which user defined this routine.
created	timestamp	NO	CURRENT_TIMESTAMP	Date and time the routine was created.
modified	timestamp	NO	0000-00-00 00:00:00	Date and time the routine was modified.
sql_mode	<pre>set('REAL_AS_FLOAT', 'PIPES_AS_CONCAT', 'ANSI_QUOTES', 'IGNORE_SPACE', 'IGNORE_BAD_TABLE_OPTIONS', 'ONLY_FULL_GROUP_BY', 'NO_UNSIGNED_SUBTRACTION', 'NO_DIR_IN_CREATE', 'POSTGRESQL', 'ORACLE', 'MSSQL', 'DB2', 'MAXDB', 'NO_KEY_OPTIONS', 'NO_TABLE_OPTIONS', 'NO_FIELD_OPTIONS', 'MYSQL323', 'MYSQL40', 'ANSI', 'NO_AUTO_VALUE_ON_ZERO', 'NO_BACKSLASH_ESCAPES', 'STRICT_TRANS_TABLES', 'STRICT_ALL_TABLES', 'NO_ZERO_IN_DATE', 'NO_ZERO_DATE', 'INVALID_DATES', 'ERROR_FOR_DIVISION_BY_ZERO', 'TRADITIONAL', 'NO_AUTO_CREATE_USER', 'HIGH_NOT_PRECEDENCE', 'NO_ENGINE_SUBSTITUTION', 'PAD_CHAR_TO_FULL_LENGTH', 'EMPTY_STRING_IS_NULL', 'SIMULTANEOUS_ASSIGNMENT')</pre>	NO		The <a href="#">SQL_MODE</a> at the time the routine was created.

Field	Type	Null	Key	Default	Description
comment	text	NO		NULL	Comment associated with the routine.
character_set_client	char(32)	YES		NULL	The character set used by the client that created the routine.
collation_connection	char(32)	YES		NULL	The collation (and character set) used by the connection that created the routine.
db_collation	char(32)	YES		NULL	The default collation (and character set) for the database, at the time the routine was created.
body_utf8	longblob	YES		NULL	Definition of the routine in utf8.
aggregate	enum('NONE', 'GROUP')	NO		NONE	From MariaDB 10.3.3

## 1.1.2.9.3.19 mysql.procs\_priv Table

The

`mysql.procs_priv`

table contains information about [stored procedure](#) and [stored function](#) privileges. See [CREATE PROCEDURE](#) and [CREATE FUNCTION](#) on creating these.

The [INFORMATION\\_SCHEMA.ROUTINES](#) table derives its contents from

`mysql.procs_priv`

MariaDB starting with [10.4](#)

In [MariaDB 10.4](#) and later, this table uses the [Aria](#) storage engine.

MariaDB until [10.3](#)

In [MariaDB 10.3](#) and before, this table uses the [MyISAM](#) storage engine.

The

`mysql.procs_priv`

table contains the following fields:

Field	Type	Null	Key	Default	Description
-------	------	------	-----	---------	-------------

Host	char(60)	NO	PRI		Host (together with Db , User , Routine_name and Routine_type makes up the unique identifier for this record).
Db	char(64)	NO	PRI		Database (together with Host , User , Routine_name and Routine_type makes up the unique identifier for this record).
User	char(80)	NO	PRI		User (together with Host , Db , Routine_name and Routine_type makes up the unique identifier for this record).
Routine_name	char(64)	NO	PRI		Routine_name (together with Host , Db  User and Routine_type makes up the unique identifier for this record).
Routine_type	enum('FUNCTION','PROCEDURE','PACKAGE', 'PACKAGE BODY')	NO	PRI	NULL	Whether the routine is a <a href="#">stored procedure</a> , <a href="#">stored function</a> , or, from <a href="#">MariaDB 10.3.5</a> , a <a href="#">package</a> or <a href="#">package body</a> .
Grantor	char(141)	NO	MUL		
Proc_priv	set('Execute','Alter Routine','Grant')	NO			The routine privilege. See <a href="#">Function Privileges</a> and <a href="#">Procedure Privileges</a> for details.
Timestamp	timestamp	NO		CURRENT_TIMESTAMP	

The [Acl\\_function\\_grants](#) status variable, added in [MariaDB 10.1.4](#) , indicates how many rows the

```
mysql.columns_priv
table contains with the
FUNCTION
routine type.
```

The [Acl\\_procedure\\_grants](#) status variable, added in [MariaDB 10.1.4](#) , indicates how many rows the

```
mysql.columns_priv
table contains with the
PROCEDURE
routine type.
```

## 1.1.2.9.3.20 mysql.roles\_mapping Table

The

`mysql.roles_mapping`  
table contains information about mariaDB roles .

MariaDB starting with 10.4

In MariaDB 10.4 and later, this table uses the Aria storage engine.

MariaDB until 10.3

In MariaDB 10.3 and before, this table uses the MyISAM storage engine.

The

`mysql.roles_mapping`  
table contains the following fields:

Field	Type	Null	Key	Default	Description
Host	char(60)	NO	PRI		Host (together with User and Role makes up the unique identifier for this record.)
User	char(80)	NO	PRI		User (together with Host and Role makes up the unique identifier for this record.)
Role	char(80)	NO	PRI		Role (together with Host and User makes up the unique identifier for this record.)
Admin_option	enum('N','Y')	NO		N	Whether the role can be granted (see the CREATE ROLE WITH ADMIN clause).

The `Acl_role_grants` status variable, added in MariaDB 10.1.4 , indicates how many rows the

`mysql.roles_mapping`  
table contains.

## 1.1.2.9.3.21 mysql.servers Table

The

`mysql.servers`  
table contains information about servers as used by the Spider , FEDERATED or FederatedX , Connect storage engines (see CREATE SERVER ).

MariaDB starting with 10.4

In MariaDB 10.4 and later, this table uses the Aria storage engine.

MariaDB until 10.3

In MariaDB 10.3 and before, this table uses the MyISAM storage engine.

The

`mysql.servers`  
table contains the following fields:

Field	Type	Null	Key	Default	Description
Server_name	char(64)	NO	PRI		
Host	char(64)	NO			

Db	char(64)	NO			
Username	char(80)	NO			
Password	char(64)	NO			
Port	int(4)	NO	0		
Socket	char(64)	NO			
Wrapper	char(64)	NO			mysql or mariadb
Owner	char(64)	NO			

## 1.1.2.9.3.22 mysql.slow\_log Table

The

`mysql.slow_log`

table stores the contents of the [Slow Query Log](#) if slow logging is active and the output is being written to table (see [Writing logs into tables](#) ).

It contains the following fields:

Field	Type	Null	Key	Default	Description
start_time	timestamp(6)	NO		CURRENT_TIMESTAMP(6)	Time the query began.
user_host	mediumtext	NO		NULL	User and host combination.
query_time	time(6)	NO		NULL	Total time the query took to execute.
lock_time	time(6)	NO		NULL	Total time the query was locked.
rows_sent	int(11)	NO		NULL	Number of rows sent.
rows_examined	int(11)	NO		NULL	Number of rows examined.
db	varchar(512)	NO		NULL	Default database.

last_insert_id	int(11)	NO		NULL	<a href="#">last_insert_id</a> .
insert_id	int(11)	NO		NULL	Insert id.
server_id	unsigned int(10)	NO		NULL	The server's id.
sql_text	mediumtext	NO		NULL	Full query.
thread_id	unsigned bigint(21)	NO		NULL	Thread id.
rows_affected	int(11)	NO		NULL	Number of rows affected by an <a href="#">UPDATE</a> or <a href="#">DELETE</a> (from <a href="#">MariaDB 10.1.2</a> )

## Example

```
SELECT * FROM mysql.slow_log\G
...
*****2. row *****
start_time: 2014-11-11 07:56:28.721519
user_host: root[root] @ localhost []
query_time: 00:00:12.000215
lock_time: 00:00:00.000000
rows_sent: 1
rows_examined: 0
db: test
last_insert_id: 0
insert_id: 0
server_id: 1
sql_text: SELECT SLEEP(12)
thread_id: 74
...
```

## 1.1.2.9.3.23 mysql.tables\_priv Table

The

`mysql.tables_priv`  
table contains information about table-level privileges. The table can be queried and although it is possible to directly update it, it is best to use [GRANT](#) for setting privileges.

Note that the MariaDB privileges occur at many levels. A user may be granted a privilege at the table level, but may still not have permission on a database level, for example. See [privileges](#) for a more complete view of the MariaDB privilege system.

The [INFORMATION\\_SCHEMA.TABLE\\_PRIVILEGES](#) table derives its contents from

`mysql.tables_priv`

MariaDB starting with [10.4](#)

In [MariaDB 10.4](#) and later, this table uses the [Aria](#) storage engine.

MariaDB until [10.3](#)

In [MariaDB 10.3](#) and before, this table uses the [MyISAM](#) storage engine.

The

`mysql.tables_priv`

table contains the following fields:

Field	Type	Null	Key	Default	Description
Host	char(60)	NO	PRI		Host (together with User Db and Table_name makes up the unique identifier for this record.)
Db	char(64)	NO	PRI		Database (together with User Host and Table_name makes up the unique identifier for this record.)
User	char(80)	NO	PRI		User (together with Host Db and Table_name makes up the unique identifier for this record.)

Table_name	char(64)		NO	PRI		Table name (together with User, Db and Table makes up the unique identifier for this record.)
Grantor	char(141)		NO	MUL		
Timestamp	timestamp		NO		CURRENT_TIMESTAMP	
Table_priv	set('Select', 'Insert', 'Update', 'Delete', 'Create', 'Drop', 'Grant', 'References', 'Index', 'Alter', 'Create View', 'Show view', 'Trigger', 'Delete versioning rows')		NO			The table privilege type. See <a href="#">Table Privileges</a> for details.
Column_priv	set('Select', 'Insert', 'Update', 'References')		NO			The column privilege type. See <a href="#">Column Privileges</a> for details.

The [Acl\\_table\\_grants](#) status variable, added in [MariaDB 10.1.4](#), indicates how many rows the

```
mysql.tables_priv
```

table contains.

## 1.1.2.9.3.24 mysql.table\_stats Table

The

```
mysql.table_stats
```

table is one of three tables storing data used for [Engine-independent table statistics](#). The others are [mysql.column\\_stats](#) and [mysql.index\\_stats](#).

MariaDB starting with 10.4

In [MariaDB 10.4](#) and later, this table uses the [Aria](#) storage engine.

MariaDB until 10.3

In [MariaDB 10.3](#) and before, this table uses the [MyISAM](#) storage engine.

The

```
mysql.table_stats
```

table contains the following fields:

Field	Type	Null	Key	Default	Description
db_name	varchar(64)	NO	PRI	NULL	Database the table is in.
table_name	varchar(64)	NO	PRI	NULL	Table name.

cardinality	bigint(21) unsigned	YES		NULL	Number of records in the table.
-------------	---------------------	-----	--	------	---------------------------------

It is possible to manually update the table. See [Manual updates to statistics tables](#) for details.

## 1.1.2.9.3.25 mysql.time\_zone Table

The

`mysql.time_zone`

table is one of the mysql system tables that can contain [time zone](#) information. It is usually preferable for the system to handle the time zone, in which case the table will be empty (the default), but you can populate the mysql time zone tables using the `mysql_tzinfo_to_sql` utility. See [Time Zones](#) for details.

MariaDB starting with 10.4

In MariaDB 10.4 and later, this table uses the [Aria](#) storage engine.

MariaDB until 10.3

In MariaDB 10.3 and before, this table uses the [MyISAM](#) storage engine.

The

`mysql.time_zone`

table contains the following fields:

Field	Type	Null	Key	Default	Description
Time_zone_id	int(10) unsigned	NO	PRI	NULL	ID field, auto_increments.
Use_leap_seconds	enum('Y','N')	NO		N	Whether or not leap seconds are used.

## Example

```
SELECT * FROM mysql.time_zone;
+-----+-----+
| Time_zone_id | Use_leap_seconds |
+-----+-----+
|      1 | N           |
|      2 | N           |
|      3 | N           |
|      4 | N           |
|      5 | N           |
|      6 | N           |
|      7 | N           |
|      8 | N           |
|      9 | N           |
|     10 | N           |
...
+-----+-----+
```

## See Also

- [mysql.time\\_zone\\_leap\\_second table](#)
- [mysql.time\\_zone\\_name table](#)
- [mysql.time\\_zone\\_transition table](#)
- [mysql.time\\_zone\\_transition\\_type table](#)

## 1.1.2.9.3.26 mysql.time\_zone\_leap\_second Table

The

`mysql.time_zone_leap_second`

table is one of the mysql system tables that can contain [time zone](#) information. It is usually preferable for the system to handle the time zone, in which case the table will be empty (the default), but you can populate the mysql time zone tables using the `mysql_tzinfo_to_sql` utility. See [Time Zones](#) for details.

MariaDB starting with 10.4

In MariaDB 10.4 and later, this table uses the [Aria](#) storage engine.

MariaDB until 10.3

In MariaDB 10.3 and before, this table uses the [MyISAM](#) storage engine.

The

`mysql.time_zone_leap_second`

table contains the following fields:

Field	Type	Null	Key	Default	Description
Transition_time	bigint(20)	NO	PRI	NULL	
Correction	int(11)	NO		NULL	

## See Also

- [mysql.time\\_zone table](#)
- [mysql.time\\_zone\\_name table](#)
- [mysql.time\\_zone\\_transition table](#)
- [mysql.time\\_zone\\_transition\\_type table](#)

## 1.1.2.9.3.27 mysql.time\_zone\_name Table

The

`mysql.time_zone_name`

table is one of the mysql system tables that can contain [time zone](#) information. It is usually preferable for the system to handle the time zone, in which case the table will be empty (the default), but you can populate the mysql time zone tables using the [mysql\\_tzinfo\\_to\\_sql](#) utility. See [Time Zones](#) for details.

MariaDB starting with 10.4

In MariaDB 10.4 and later, this table uses the [Aria](#) storage engine.

MariaDB until 10.3

In MariaDB 10.3 and before, this table uses the [MyISAM](#) storage engine.

The

`mysql.time_zone_name`

table contains the following fields:

Field	Type	Null	Key	Default	Description
Name	char(64)	NO	PRI	NULL	Name of the time zone.
Time_zone_id	int(10) unsigned	NO	PRI	NULL	ID field, auto_increments.

## Example

```

SELECT * FROM mysql.time_zone_name;
+-----+-----+
| Name          | Time_zone_id |
+-----+-----+
| Africa/Abidjan |      1 |
| Africa/Accra   |      2 |
| Africa/Addis_Ababa | 3 |
| Africa/Algiers  |      4 |
| Africa/Asmara   |      5 |
| Africa/Asmera   |      6 |
| Africa/Bamako   |      7 |
| Africa/Bangui   |      8 |
| Africa/Banjul   |      9 |
| Africa/Bissau   |     10 |
...
+-----+-----+

```

## See Also

- [mysql.time\\_zone table](#)
- [mysql.time\\_zone\\_leap\\_second table](#)
- [mysql.time\\_zone\\_transition table](#)
- [mysql.time\\_zone\\_transition\\_type table](#)

## 1.1.2.9.3.28 mysql.time\_zone\_transition Table

The

`mysql.time_zone_transition`

table is one of the

`mysql`

system tables that can contain [time zone](#) information. It is usually preferable for the system to handle the time zone, in which case the table will be empty (the default), but you can populate the

`mysql`

time zone tables using the [mysql\\_tzinfo\\_to\\_sql](#) utility. See [Time Zones](#) for details.

MariaDB starting with 10.4

In MariaDB 10.4 and later, this table uses the [Aria](#) storage engine.

MariaDB until 10.3

In MariaDB 10.3 and before, this table uses the [MyISAM](#) storage engine.

The

`mysql.time_zone_transition`

table contains the following fields:

Field	Type	Null	Key	Default	Description
Time_zone_id	int(10) unsigned	NO	PRI	NULL	
Transition_time	bigint(20)	NO	PRI	NULL	
Transition_type_id	int(10) unsigned	NO		NULL	

## Example

```

SELECT * FROM mysql.time_zone_transition;
+-----+-----+-----+
| Time_zone_id | Transition_time | Transition_type_id |
+-----+-----+-----+
| 1 | -1830383032 | 1 |
| 2 | -1640995148 | 2 |
| 2 | -1556841600 | 1 |
| 2 | -1546388400 | 2 |
| 2 | -1525305600 | 1 |
| 2 | -1514852400 | 2 |
| 2 | -1493769600 | 1 |
| 2 | -1483316400 | 2 |
| 2 | -1462233600 | 1 |
| 2 | -1451780400 | 2 |
...
+-----+-----+-----+

```

## See Also

- [mysql.time\\_zone table](#)
- [mysql.time\\_zone\\_leap\\_second table](#)
- [mysql.time\\_zone\\_name table](#)
- [mysql.time\\_zone\\_transition\\_type table](#)

## 1.1.2.9.3.29 mysql.time\_zone\_transition\_type Table

The

`mysql.time_zone_transition_type`

table is one of the

`mysql`

system tables that can contain [time zone](#) information. It is usually preferable for the system to handle the time zone, in which case the table will be empty (the default), but you can populate the

`mysql`

time zone tables using the [mysql\\_tzinfo\\_to\\_sql](#) utility. See [Time Zones](#) for details.

MariaDB starting with 10.4

In MariaDB 10.4 and later, this table uses the [Aria](#) storage engine.

MariaDB until 10.3

In MariaDB 10.3 and before, this table uses the [MyISAM](#) storage engine.

The

`mysql.time_zone_transition_type`

table contains the following fields:

Field	Type	Null	Key	Default	Description
Time_zone_id	int(10) unsigned	NO	PRI	NULL	
Transition_type_id	int(10) unsigned	NO	PRI	NULL	
Offset	int(11)	NO		0	
Is_DST	tinyint(3) unsigned	NO		0	
Abbreviation	char(8)	NO			

## Example

```

SELECT * FROM mysql.time_zone_transition_type;
+-----+-----+-----+-----+
| Time_zone_id | Transition_type_id | Offset | Is_DST | Abbreviation |
+-----+-----+-----+-----+
| 1 | 0 | -968 | 0 | LMT |
| 1 | 1 | 0 | 0 | GMT |
| 2 | 0 | -52 | 0 | LMT |
| 2 | 1 | 1200 | 1 | GHST |
| 2 | 2 | 0 | 0 | GMT |
| 3 | 0 | 8836 | 0 | LMT |
| 3 | 1 | 10800 | 0 | EAT |
| 3 | 2 | 9000 | 0 | BEAT |
| 3 | 3 | 9900 | 0 | BEAUT |
| 3 | 4 | 10800 | 0 | EAT |
...
+-----+-----+-----+-----+

```

## See Also

- [mysql.time\\_zone table](#)
- [mysql.time\\_zone\\_leap\\_second table](#)
- [mysql.time\\_zone\\_name table](#)
- [mysql.time\\_zone\\_transition table](#)

## 1.1.2.9.3.30 mysql.transaction\_registry Table

MariaDB starting with [10.3.4](#)

The

`mysql.transaction_registry`  
table was introduced in [MariaDB 10.3.4](#) as part of [system-versioned tables](#).

The

`mysql.transaction_registry`  
table is used for transaction-precise versioning, and contains the following fields:

Field	Type	Null	Key	Default	Description
transaction_id	bigint(20) unsigned	NO	Primary	NULL	
commit_id	bigint(20) unsigned	NO	Unique	NULL	
begin_timestamp	timestamp(6)	NO	Multiple	0000-00-00 00:00:00.000000	Timestamp when the transaction began (BEGIN statement), however see <a href="#">MDEV-16024</a> .
commit	timestamp(6)	NO	Multiple	0000-00-00 00:00:00.000000	Timestamp when the transaction was committed.
isolation_level	enum('READ-UNCOMMITTED','READ-COMMITTED','REPEATABLE-READ','SERIALIZABLE')	NO		NULL	Transaction <a href="#">isolation level</a> .

## 1.1.2.9.3.31 mysql.user Table

The

`mysql.user`  
table contains information about users that have permission to access the MariaDB server, and their global privileges. The table can be queried and although it is possible to directly update it, it is best to use [GRANT](#) and [CREATE USER](#) for adding users and privileges.

Note that the MariaDB privileges occur at many levels. A user may not be granted

`create`  
`privilege` at the user level, but may still have  
`create`  
`permission` on certain tables or databases, for example. See [privileges](#) for a more complete view of the MariaDB privilege system.

MariaDB until [10.3](#)

In [MariaDB 10.3](#) and before, this table uses the [MyISAM](#) storage engine.

MariaDB starting with [10.4](#)

In MariaDB 10.4 and later, the [mysql.global\\_priv](#) table has replaced the [mysql.user](#) table, and [mysql.user](#) should be considered obsolete. It is now a [view](#) into [mysql.global\\_priv](#) created for compatibility with older applications and monitoring scripts. New tools are supposed to use [INFORMATION\\_SCHEMA](#) tables. From [MariaDB 10.4.13](#), the dedicated [mariadb.sys](#) user is created as the definer of the view. Previously, [root](#) was the definer, which resulted in privilege problems when this username was changed ([MDEV-19650](#)).

The

[mysql.user](#) table contains the following fields:

Field	Type	Null	Key	Default	Description	Introduced
Host	char(60)	NO	PRI		Host (together with User makes up the unique identifier for this account.)	
User	char(80)	NO	PRI		User (together with Host makes up the unique identifier for this account.)	
Password	longtext (>= <a href="#">MariaDB 10.4.1</a> ), char(41) (<= <a href="#">MariaDB 10.4.0</a> )	NO			Hashed password, generated by the <a href="#">PASSWORD()</a> function.	
Select_priv	enum('N','Y')	NO		N	Can perform <a href="#">SELECT</a> statements.	
Insert_priv	enum('N','Y')	NO		N	Can perform <a href="#">INSERT</a> statements.	
Update_priv	enum('N','Y')	NO		N	Can perform <a href="#">UPDATE</a> statements.	
Delete_priv	enum('N','Y')	NO		N	Can perform <a href="#">DELETE</a> statements.	
Create_priv	enum('N','Y')	NO		N	Can <a href="#">CREATE DATABASE</a> 's or <a href="#">CREATE TABLE</a> 's .	
Drop_priv	enum('N','Y')	NO		N	Can <a href="#">DROP DATABASE</a> 's or <a href="#">DROP TABLE</a> 's .	

Reload_priv	enum('N','Y')	NO	N	Can execute <a href="#">FLUSH</a> statements or equivalent <a href="#">mysqladmin</a> commands.	
Shutdown_priv	enum('N','Y')	NO	N	Can shut down the server with <a href="#">SHUTDOWN</a> or <a href="#">mysqladmin shutdown</a> .	
Process_priv	enum('N','Y')	NO	N	Can show information about active processes, via <a href="#">SHOW PROCESSLIST</a> or <a href="#">mysqladmin processlist</a> .	
File_priv	enum('N','Y')	NO	N	Read and write files on the server, using statements like <a href="#">LOAD DATA INFILE</a> or functions like <a href="#">LOAD_FILE()</a> . Also needed to create <a href="#">CONNECT</a> outward tables. MariaDB server must have permission to access those files.	
Grant_priv	enum('N','Y')	NO	N	User can <a href="#">grant</a> privileges they possess.	
References_priv	enum('N','Y')	NO	N	Unused	
Index_priv	enum('N','Y')	NO	N	Can create an index on a table using the <a href="#">CREATE INDEX</a> statement. Without the <a href="#">INDEX</a> privilege, user can still create indexes when creating a table using the <a href="#">CREATE TABLE</a> statement if the user has the <a href="#">CREATE</a> privilege, and user can create indexes using the <a href="#">ALTER TABLE</a> statement if they have the <a href="#">ALTER</a> privilege.	
Alter_priv	enum('N','Y')	NO	N	Can perform <a href="#">ALTER TABLE</a> statements.	
Show_db_priv	enum('N','Y')	NO	N	Can list all databases using the <a href="#">SHOW DATABASES</a> statement. Without the <a href="#">SHOW DATABASES</a> privilege, user can still issue the <a href="#">SHOW DATABASES</a> statement, but it will only list databases containing tables on which they have privileges.	
Super_priv	enum('N','Y')	NO	N	Can execute superuser statements: <a href="#">CHANGE MASTER TO</a> , <a href="#">KILL</a> (users who do not have this privilege can only <a href="#">KILL</a> their own threads), <a href="#">PURGE LOGS</a> , <a href="#">SET global system variables</a> , or the <a href="#">mysqladmin debug</a> command. Also, this permission allows the user to write data even if the <a href="#">read_only</a> startup option is set, enable or disable logging, enable or disable replication on slaves, specify a <a href="#">DEFINER</a> for statements that support that clause, connect once after reaching the <a href="#">MAX_CONNECTIONS</a> . If a statement has been specified for the <a href="#">init-connect</a> mysqld option, that command will not be executed when a user with <a href="#">SUPER</a> privileges connects to the server.	
Create_tmp_table_priv	enum('N','Y')	NO	N	Can create temporary tables with the <a href="#">CREATE TEMPORARY TABLE</a> statement.	

Lock_tables_priv	enum('N','Y')	NO		N	Acquire explicit locks using the <a href="#">LOCK TABLES</a> statement; user also needs to have the SELECT privilege on a table in order to lock it.	
Execute_priv	enum('N','Y')	NO		N	Can execute <a href="#">stored procedure</a> or functions.	
Repl_slave_priv	enum('N','Y')	NO		N	Accounts used by slave servers on the master need this privilege. This is needed to get the updates made on the master.	
Repl_client_priv	enum('N','Y')	NO		N	Can execute <a href="#">SHOW MASTER STATUS</a> and <a href="#">SHOW SLAVE STATUS</a> statements.	
Create_view_priv	enum('N','Y')	NO		N	Can create a view using the <a href="#">CREATE_VIEW</a> statement.	
Show_view_priv	enum('N','Y')	NO		N	Can show the <a href="#">CREATE VIEW</a> statement to create a view using the <a href="#">SHOW CREATE VIEW</a> statement.	
Create_routine_priv	enum('N','Y')	NO		N	Can create stored programs using the <a href="#">CREATE PROCEDURE</a> and <a href="#">CREATE FUNCTION</a> statements.	
Alter_routine_priv	enum('N','Y')	NO		N	Can change the characteristics of a stored function using the <a href="#">ALTER FUNCTION</a> statement.	
Create_user_priv	enum('N','Y')	NO		N	Can create a user using the <a href="#">CREATE USER</a> statement, or implicitly create a user with the <a href="#">GRANT</a> statement.	
Event_priv	enum('N','Y')	NO		N	Create, drop and alter <a href="#">events</a> .	
Trigger_priv	enum('N','Y')	NO		N	Can execute <a href="#">triggers</a> associated with tables the user updates, execute the <a href="#">CREATE TRIGGER</a> and <a href="#">DROP TRIGGER</a> statements.	
Create_tablespace_priv	enum('N','Y')	NO		N		
Delete_history_priv	enum('N','Y')	NO		N	Can delete rows created through <a href="#">system versioning</a> .	MariaDB 10.3.5
ssl_type	enum('', 'ANY', 'X509', 'SPECIFIED')	NO			TLS type - see <a href="#">TLS options</a> .	

Field	Type	Null	Key	Default	Description	Introduced
ssl_cipher	blob	NO		NULL	TLS cipher - see <a href="#">TLS options</a> .	
x509_issuer	blob	NO		NULL	X509 cipher - see <a href="#">TLS options</a> .	
x509_subject	blob	NO		NULL	SSL subject - see <a href="#">TLS options</a> .	
max_questions	int(11) unsigned	NO		0	Number of queries the user can perform per hour. Zero is unlimited. See <a href="#">per-account resource limits</a> .	
max_updates	int(11) unsigned	NO		0	Number of updates the user can perform per hour. Zero is unlimited. See <a href="#">per-account resource limits</a> .	
max_connections	int(11) unsigned	NO		0	Number of connections the account can start per hour. Zero is unlimited. See <a href="#">per-account resource limits</a> .	
max_user_connections	int(11)	NO		0	Number of simultaneous connections the account can have. Zero is unlimited. See <a href="#">per-account resource limits</a> .	
plugin	char(64)	NO			Authentication plugin used on connection. If empty, uses the <a href="#">default</a> .	<a href="#">MariaDB 5.5</a>
authentication_string	text	NO		NULL	Authentication string for the authentication plugin.	<a href="#">MariaDB 5.5</a>
password_expired	enum('N','Y')	NO		N	MySQL-compatibility option, not implemented in MariaDB.	
is_role	enum('N','Y')	NO		N	Whether the user is a <a href="#">role</a> .	<a href="#">MariaDB 10.0.5</a>
default_role	char(80)	NO		N	Role which will be enabled on user login automatically.	<a href="#">MariaDB 10.1.1</a>
max_statement_time	decimal(12,6)	NO		0.000000	If non-zero, how long queries can run before being killed automatically.	<a href="#">MariaDB 10.1.1</a>

The [Acl\\_roles](#) status variable, added in [MariaDB 10.1.4](#), indicates how many rows the

```
mysql.user
table contains where
is_role='Y'
```

The [Acl\\_users](#) status variable, added in [MariaDB 10.1.4](#), indicates how many rows the

```
mysql.user
```

table contains where

is\_role='N'

.

## Authentication Plugin

When the

plugin

column is empty, MariaDB defaults to authenticating accounts with either the

`mysql_native_password`

or the

`mysql_old_password`

plugins. It decides which based on the hash used in the value for the

Password

column. When there's no password set or when the 4.1 password hash is used, (which is 41 characters long), MariaDB uses the

`mysql_native_password`

plugin. The

`mysql_old_password`

plugin is used with pre-4.1 password hashes, (which are 16 characters long).

MariaDB also supports the use of alternative [authentication plugins](#). When the

plugin

column is not empty for the given account, MariaDB uses it to authenticate connection attempts. The specific plugin then uses the value of either the

Password

column or the

`authentication_string`

column to authenticate the user.

A specific authentication plugin can be used for an account by providing the

`IDENTIFIED VIA authentication_plugin`

clause with the

`CREATE USER`

,

`ALTER USER`

, or

`GRANT`

statements.

For example, the following statement would create an account that authenticates with the [PAM authentication plugin](#):

```
CREATE USER foo2@test IDENTIFIED VIA pam;
```

If the specific authentication plugin uses the

`authentication_string`

column, then this value for the account can be specified after a

`USING`

or

`AS`

keyword. For example, the [PAM authentication plugin](#) accepts a `service name` that would go into the

`authentication_string`

column for the account:

```
CREATE USER foo2@test IDENTIFIED VIA pam USING 'mariadb';
```

## 1.1.2.9.3.32 Spider mysql Database Tables

### 1.1.2.9.3.32.1 mysql.spider\_link\_failed\_log Table

The

`mysql.spider_link_failed_log`  
table is installed by the [Spider storage engine](#).

MariaDB starting with [10.4](#)

In MariaDB 10.4 and later, this table uses the [Aria](#) storage engine.

MariaDB until [10.3](#)

In MariaDB 10.3 and before, this table uses the [MyISAM](#) storage engine.

It contains the following fields:

Field	Type	Null	Key	Default	Description
db_name	char(64)	NO			
table_name	char(199)	NO			
link_id	char(64)	NO			
failed_time	timestamp	NO		current_timestamp()	

### 1.1.2.9.3.32.2 mysql.spider\_link\_mon\_servers Table

The

`mysql.spider_link_mon_servers`  
table is installed by the [Spider storage engine](#).

MariaDB starting with [10.4](#)

In MariaDB 10.4 and later, this table uses the [Aria](#) storage engine.

MariaDB until [10.3](#)

In MariaDB 10.3 and before, this table uses the [MyISAM](#) storage engine.

It contains the following fields:

Field	Type	Null	Key	Default	Description
db_name	char(64)	NO	PRI		
table_name	char(199)	NO	PRI		
link_id	char(64)	NO	PRI		
sid	int(10) unsigned	NO	PRI	0	
server	char(64)	YES		NULL	
scheme	char(64)	YES		NULL	
host	char(64)	YES		NULL	
port	char(5)	YES		NULL	
socket	text	YES		NULL	
username	char(64)	YES		NULL	
password	char(64)	YES		NULL	
ssl_ca	text	YES		NULL	
ssl_capath	text	YES		NULL	
ssl_cert	text	YES		NULL	
ssl_cipher	char(64)	YES		NULL	
ssl_key	text	YES		NULL	

ssl_verify_server_cert	tinyint(4)	NO	0	
default_file	text	YES	NULL	
default_group	char(64)	YES	NULL	
dsn	char(64)	YES	NULL	
filedsn	text	YES	NULL	
driver	char(64)	YES	NULL	

## 1.1.2.9.3.32.3 mysql.spider\_tables Table

The

`mysql.spider_tables`  
table is installed by the [Spider storage engine](#).

MariaDB starting with [10.4](#)

In [MariaDB 10.4](#) and later, this table uses the [Aria](#) storage engine.

MariaDB until [10.3](#)

In [MariaDB 10.3](#) and before, this table uses the [MyISAM](#) storage engine.

It contains the following fields:

Field	Type	Null	Key	Default	Description
db_name	char(64)	NO	PRI		
table_name	char(199)	NO	PRI		
link_id	int(11)	NO	PRI	0	
priority	bigint(20)	NO	MUL	0	
server	char(64)	YES		NULL	
schema	char(64)	YES		NULL	
host	char(64)	YES		NULL	
port	char(5)	YES		NULL	
socket	text	YES		NULL	
username	char(64)	YES		NULL	
password	char(64)	YES		NULL	
ssl_ca	text	YES		NULL	
ssl_capath	text	YES		NULL	
ssl_cert	text	YES		NULL	
ssl_cipher	char(64)	YES		NULL	
ssl_key	text	YES		NULL	
ssl_verify_server_cert	tinyint(4)	NO		0	
monitoring_binlog_pos_at_failing	tinyint(4)	NO		0	
default_file	text	YES		NULL	
default_group	char(64)	YES		NULL	
dsn	char(64)	YES		NULL	
filedsn	text	YES		NULL	
driver	char(64)	YES		NULL	
tgt_db_name	char(64)	YES		NULL	
tgt_table_name	char(64)	YES		NULL	
link_status	tinyint(4)	NO		1	
block_status	tinyint(4)	NO		0	

static_link_id	char(64)	YES	NULL	
----------------	----------	-----	------	--

## 1.1.2.9.3.32.4 mysql.spider\_table\_crd Table

The

`mysql.spider_table_crd`  
table is installed by the [Spider storage engine](#).

MariaDB starting with 10.4

In MariaDB 10.4 and later, this table uses the [Aria](#) storage engine.

MariaDB until 10.3

In MariaDB 10.3 and before, this table uses the [MyISAM](#) storage engine.

It contains the following fields:

Field	Type	Null	Key	Default	Description
db_name	char(64)	NO	PRI		
table_name	char(199)	NO	PRI		
key_seq	int(10) unsigned	NO	PRI	0	
cardinality	bigint(20)	NO		0	

## 1.1.2.9.3.32.5 mysql.spider\_table\_position\_for\_recovery Table

The

`mysql.spider_table_position_for_recovery`  
table is installed by the [Spider storage engine](#).

MariaDB starting with 10.4

In MariaDB 10.4 and later, this table uses the [Aria](#) storage engine.

MariaDB until 10.3

In MariaDB 10.3 and before, this table uses the [MyISAM](#) storage engine.

It contains the following fields:

Field	Type	Null	Key	Default	Description
db_name	char(64)	NO	PRI		
table_name	char(199)	NO	PRI		
failed_link_id	int(11)	NO	PRI	0	
source_link_id	int(11)	NO	PRI	0	
file	text	YES		NULL	
position	text	YES		NULL	
gtid	text	YES		NULL	

## 1.1.2.9.3.32.6 mysql.spider\_table\_sts Table

The

`mysql.spider_table_sts`  
table is installed by the [Spider storage engine](#).

MariaDB starting with 10.4

In MariaDB 10.4 and later, this table uses the [Aria](#) storage engine.

MariaDB until 10.3

In MariaDB 10.3 and before, this table uses the [MyISAM](#) storage engine.

It contains the following fields:

Field	Type	Null	Key	Default	Description
db_name	char(64)	NO	PRI		
table_name	char(199)	NO	PRI		
data_file_length	bigint(20) unsigned	NO		0	
max_data_file_length	bigint(20) unsigned	NO		0	
index_file_length	bigint(20) unsigned	NO		0	
records	bigint(20) unsigned	NO		0	
mean_rec_length	bigint(20) unsigned	NO		0	
check_time	datetime	NO		0000-00-00 00:00:00	
create_time	datetime	NO		0000-00-00 00:00:00	
update_time	datetime	NO		0000-00-00 00:00:00	
checksum	bigint(20) unsigned	YES		NULL	

## 1.1.2.9.3.32.7 mysql.spider\_xa Table

The

`mysql.spider_xa`  
table is installed by the [Spider storage engine](#).

MariaDB starting with [10.4](#)

In MariaDB 10.4 and later, this table uses the [Aria](#) storage engine.

MariaDB until [10.3](#)

In MariaDB 10.3 and before, this table uses the [MyISAM](#) storage engine.

It contains the following fields:

Field	Type	Null	Key	Default	Description
format_id	int(11)	NO	PRI	0	
gtrid_length	int(11)	NO	PRI	0	
bqual_length	int(11)	NO		0	
data	binary(128)	NO	PRI		
status	char(8)	NO	MUL		

## 1.1.2.9.3.32.8 mysql.spider\_xa\_failed\_log Table

The

`mysql.spider_xa_failed_log`  
table is installed by the [Spider storage engine](#).

MariaDB starting with [10.4](#)

In MariaDB 10.4 and later, this table uses the [Aria](#) storage engine.

MariaDB until [10.3](#)

In MariaDB 10.3 and before, this table uses the [MyISAM](#) storage engine.

It contains the following fields:

Field	Type	Null	Key	Default	Description
format_id	int(11)	NO		0	
gtrid_length	int(11)	NO		0	

bqual_length	int(11)	NO		0	
data	binary(128)	NO	MUL		
scheme	char(64)	NO			
host	char(64)	NO			
port	char(5)	NO			
socket	text	NO		NULL	
username	char(64)	NO			
password	char(64)	NO			
ssl_ca	text	YES		NULL	
ssl_capath	text	YES		NULL	
ssl_cert	text	YES		NULL	
ssl_cipher	char(64)	YES		NULL	
ssl_key	text	YES		NULL	
ssl_verify_server_cert	tinyint(4)	NO		0	
default_file	text	YES		NULL	
default_group	char(64)	YES		NULL	
dsn	char(64)	YES		NULL	
filedsn	text	YES		NULL	
driver	char(64)	YES		NULL	
thread_id	int(11)	YES		NULL	
status	char(8)	NO			
failed_time	timestamp	NO		current_timestamp()	

## 1.1.2.9.3.32.9 mysql.spider\_xa\_member Table

The

`mysql.spider_xa_member`  
table is installed by the [Spider storage engine](#).

MariaDB starting with [10.4](#)

In [MariaDB 10.4](#) and later, this table uses the [Aria storage engine](#).

MariaDB until [10.3](#)

In [MariaDB 10.3](#) and before, this table uses the [MyISAM storage engine](#).

It contains the following fields:

Field	Type	Null	Key	Default	Description
format_id	int(11)	NO		0	
gtrid_length	int(11)	NO		0	
bqual_length	int(11)	NO		0	
data	binary(128)	NO	MUL		
scheme	char(64)	NO			
host	char(64)	NO			
port	char(5)	NO			
socket	text	NO		NULL	
username	char(64)	NO			
password	char(64)	NO			
ssl_ca	text	YES		NULL	

ssl_capath	text	YES		NULL	
ssl_cert	text	YES		NULL	
ssl_cipher	char(64)	YES		NULL	
ssl_key	text	YES		NULL	
ssl_verify_server_cert	tinyint(4)	NO		0	
default_file	text	YES		NULL	
default_group	char(64)	YES		NULL	
dsn	char(64)	YES		NULL	
filedsn	text	YES		NULL	
driver	char(64)	YES		NULL	

## 1.1.2.9.4 Sys Schema

### 1.1.2.9.4.1 Sys Schema sys\_config Table

MariaDB starting with 10.6.0

The sys schema `sys_config` table was added in [MariaDB 10.6.0](#).

The `sys_config` table holds configuration options for the [sys schema](#).

This is a persistent table (using the `InnoDB` storage engine), with the configuration persisting across upgrades (new options are added with [INSERT IGNORE](#)).

The table also has two related triggers, which maintain the user that INSERTs or UPDATEs the configuration - `sys_config_insert_set_user` and `sys_config_update_set_user` respectively.

Its structure is as follows:

Field	Type	Null	Key	Default	Extra
variable	varchar(128)	NO	PRI	NULL	
value	varchar(128)	YES		NULL	
set_time	timestamp	NO		CURRENT_TIMESTAMP	on update CURRENT_TIMESTAMP
set_by	varchar(128)	YES		NULL	

Note, when functions check for configuration options, they first check whether a similar named user variable exists with a value, and if this is not set then pull the configuration option from this table in to that named user variable. This is done for performance reasons (to not continually SELECT from the table), however this comes with the side effect that once init'd, the values last with the session, somewhat like how session variables are init'd from global variables. If the values within this table are changed, they will not take effect until the user logs in again.

## Options Included

Variable	Default Value	Description
statement_truncate_len	64	Sets the size to truncate statements to, for the <code>format_statement()</code> function.
statement_performance_analyzer.limit	100	The maximum number of rows to include for the views that does not have a built-in limit (e.g. the 95th percentile view). If not set the limit is 100.
statement_performance_analyzer.view	NULL	Used together with the 'custom' view. If the value contains a space, it is considered a query, otherwise it must be an existing view querying the <code>performance_schema.events_statements_summary_by_digest</code> table.
diagnostics.allow_i_s_tables	OFF	Specifies whether it is allowed to do table scan queries on <code>information_schema.TABLES</code> for the diagnostics procedure.
diagnostics.include_raw	OFF	Set to 'ON' to include the raw data (e.g. the original output of "SELECT * FROM sys.metrics") for the diagnostics procedure.
ps_thread_trx_info.max_length	65535	Sets the maximum output length for JSON object output by the <code>ps_thread_trx_info()</code> function.

## 1.1.2.9.5 mariadb\_schema

## Contents

### 1. History

mariadb\_schema

is a data type qualifier that allows one to create MariaDB native date types in an [SQL\\_MODE](#) that has conflicting data type translations.

mariadb\_schema

was introduced in [MariaDB 10.3.24](#), [MariaDB 10.4.14](#) and [MariaDB 10.5.5](#).

For example, in [SQL\\_MODE=ORACLE](#), if one creates a table with the [DATE](#) type, it will actually create a [DATETIME](#) column to match what an Oracle user is expecting. To be able to create a MariaDB DATE in Oracle mode one would have to use

mariadb\_schema

:

```
CREATE TABLE t1 (d mariadb_schema.DATE);
```

mariadb\_schema

is also shown if one creates a table with

DATE

in MariaDB native mode and then does a [SHOW CREATE TABLE](#) in

ORACLE

mode:

```
SET sql_mode=DEFAULT;
CREATE OR REPLACE TABLE t1 (
  d DATE
);
SET SQL_mode=ORACLE;
SHOW CREATE TABLE t1;
+-----+
| Table | Create Table
+-----+
| t1    | CREATE TABLE "t1" (
  "d" mariadb_schema.date DEFAULT NULL
) |
+-----+
```

When the server sees the

mariadb\_schema

qualifier, it disables sql\_mode-specific data type translation and interprets the data type literally, so for example

mariadb\_schema.DATE

is interpreted as the traditional MariaDB

DATE

data type, no matter what the current sql\_mode is.

The

mariadb\_schema

prefix is displayed only when the data type name would be ambiguous otherwise. The prefix is displayed together with MariaDB

DATE

when [SHOW CREATE TABLE](#) is executed in [SQL\\_MODE=ORACLE](#). The prefix is not displayed when [SHOW CREATE TABLE](#) is executed in [SQL\\_MODE=DEFAULT](#), or when a non-ambiguous data type is displayed.

Note, the

mariadb\_schema

prefix can be used with any data type, including non-ambiguous ones:

```
CREATE OR REPLACE TABLE t1 (a mariadb_schema.INT);
SHOW CREATE TABLE t1;
+-----+
| Table | Create Table
+-----+
| t1    | CREATE TABLE "t1" (
  "a" int(11) DEFAULT NULL
) |
+-----+
```

Currently the

mariadb\_schema

prefix is only used in the following case:

- For a MariaDB native DATE type when running SHOW CREATE TABLE in Oracle mode .

## History

When running with `SQL_MODE=ORACLE` , MariaDB server translates the data type

```
DATE
to
DATETIME
, for better Oracle compatibility:
```

```
SET SQL_mode=ORACLE;
CREATE OR REPLACE TABLE t1 (
  d DATE
);
SHOW CREATE TABLE t1;
+-----+
| Table | Create Table |
+-----+
| t1    | CREATE TABLE "t1" (
  "d" datetime DEFAULT NULL
) |
```

Notice,

```
DATE
was translated to
DATETIME
.
```

This translation may cause some ambiguity. Suppose a user creates a table with a column of the traditional MariaDB

```
DATE
data type using the default sql_mode, but then switches to SQL_MODE=ORACLE and runs a SHOW CREATE TABLE statement:
```

```
SET sql_mode=DEFAULT;
CREATE OR REPLACE TABLE t1 (
  d DATE
);
SET SQL_mode=ORACLE;
SHOW CREATE TABLE t1;
```

Before

```
mariadb_schema
was introduced, the above script displayed:
```

```
CREATE TABLE "t1" (
  "d" date DEFAULT NULL
);
```

which had two problems:

- It was confusing for the reader: its not clear if it is the traditional MariaDB  
DATE  
, or is it Oracle-alike date (which is actually  
DATETIME  
);
- It broke replication and caused data type mismatch on the master and on the slave (see [MDEV-19632](#) ).

To address this problem, starting from the mentioned versions, MariaDB uses the idea of qualified data types:

```
SET sql_mode=DEFAULT;
CREATE OR REPLACE TABLE t1 (
  d DATE
);
SET SQL_mode=ORACLE;
SHOW CREATE TABLE t1;
+-----+
| Table | Create Table |
+-----+
| t1    | CREATE TABLE "t1" (
  "d" mariadb_schema.date DEFAULT NULL
) |
```

## 1.1.2.9.6 Writing Logs Into Tables

By default, all logs are disabled or written into files. The [general query log](#) and the [slow query log](#) can also be written to special tables in the `mysql` database. During the startup, entries will always be written into files.

Note that [EXPLAIN output](#) will only be recorded if the slow query log is written to a file and not to a table.

To write logs into tables, the [log\\_output](#) server system variable is used. Allowed values are

```
FILE  
,  
TABLE  
and  
NONE  
. It is possible to specify multiple values, separated with commas, to write the logs into both tables and files.  
NONE  
disables logging and has precedence over the other values.
```

So, to write logs into tables, one of the following settings can be used:

```
SET GLOBAL log_output = 'TABLE';  
SET GLOBAL log_output = 'FILE, TABLE';
```

The general log will be written into the [general\\_log](#) table, and the slow query log will be written into the [slow\\_log](#) table. Only a limited set of operations are supported for those special tables. For example, direct DML statements (like

```
INSERT  
) on those tables will fail with an error similar to the following:
```

```
ERROR 1556 (HY000): You can't use locks with log tables.
```

To flush data to the tables, use [FLUSH TABLES](#) instead of [FLUSH LOGS](#).

To empty the contents of the log tables, [TRUNCATE TABLE](#) can be used.

The log tables use the [CSV](#) storage engine by default. This allows an external program to read the files if needed: normal CSV files are stored in the

```
mysql  
subdirectory, in the data dir. However that engine is slow because it does not support indexes, so you can convert the tables to MyISAM (but not other storage engines). To do so, first temporarily disable logging:
```

```
SET GLOBAL general_log = 'OFF';  
ALTER TABLE mysql.general_log ENGINE = MyISAM;  
ALTER TABLE mysql.slow_log ENGINE = MyISAM;  
SET GLOBAL general_log = @old_log_state;
```

[CHECK TABLE](#) and [CHECKSUM TABLE](#) are supported.

[CREATE TABLE](#) is supported. [ALTER TABLE](#), [RENAME TABLE](#) and [DROP TABLE](#) are supported when logging is disabled, but log tables cannot be partitioned.

The contents of the log tables is not logged in the [binary log](#) thus cannot be replicated.

## 1.1.2.10 BINLOG

### Syntax

```
BINLOG 'str'
```

### Description

`BINLOG` is an internal-use statement. It is generated by the [mariadb-binlog/mysqlbinlog](#) program as the printable representation of certain events in [binary log](#) files. The `'str'` value is a base 64-encoded string that the server decodes to determine the data change indicated by the corresponding event. This statement requires the [SUPER](#) privilege (<= MariaDB 10.5.1) or the [BINLOG REPLAY](#) privilege (>= MariaDB 10.5.2).

### See also

- [MariaDB replication](#)

## 1.1.2.11 PURGE BINARY LOGS

### Syntax

```
PURGE { BINARY | MASTER } LOGS  
      { TO 'log_name' | BEFORE datetime_expr }
```

### Description

The

PURGE BINARY LOGS

statement deletes all the [binary log](#) files listed in the log index file prior to the specified log file name or date.

BINARY

and

MASTER

are synonyms. Deleted log files also are removed from the list recorded in the index file, so that the given log file becomes the first in the list.

The datetime expression is in the format 'YYYY-MM-DD hh:mm:ss'.

If a replica is active but has yet to read from a binary log file you attempt to delete, the statement will fail with an error. However, if the replica is not connected and has yet to read from a log file you delete, the file will be deleted, but the replica will be unable to continue replicating once it connects again.

This statement has no effect if the server was not started with the [--log-bin](#) option to enable binary logging.

To list the binary log files on the server, use [SHOW BINARY LOGS](#). To see which files they are reading, use [SHOW SLAVE STATUS](#) (or [SHOW REPLICAS STATUS](#) from [MariaDB 10.5.1](#)). You can only delete the files that are older than the oldest file that is used by the slaves.

To delete all binary log files, use [RESET MASTER](#). To move to a new log file (for example if you want to remove the current log file), use [FLUSH LOGS](#) before you execute

```
PURGE LOGS
```

If the [expire\\_logs\\_days](#) server system variable is not set to 0, the server automatically deletes binary log files after the given number of days. From [MariaDB 10.6](#), the [binlog\\_expire\\_logs\\_seconds](#) variable allows more precise control over binlog deletion, and takes precedence if both are non-zero.

Requires the [SUPER](#) privilege or, from [MariaDB 10.5.2](#), the [BINLOG ADMIN](#) privilege, to run.

### Examples

```
PURGE BINARY LOGS TO 'mariadb-bin.000063';
```

```
PURGE BINARY LOGS BEFORE '2013-04-21';
```

```
PURGE BINARY LOGS BEFORE '2013-04-22 09:55:22';
```

### See Also

- [Using and Maintaining the Binary Log](#)
- [FLUSH LOGS](#).

## 1.1.2.12 CACHE INDEX

### Syntax

```
CACHE INDEX  
tbl_index_list [, tbl_index_list] ...  
IN key_cache_name  
  
tbl_index_list:  
tbl_name [[INDEX|KEY] (index_name[, index_name] ...)]
```

# Description

The

```
CACHE INDEX  
statement assigns table indexes to a specific key cache. It is used only for MyISAM tables.
```

A default key cache exists and cannot be destroyed. To create more key caches, the [key\\_buffer\\_size](#) server system variable.

The associations between tables indexes and key caches are lost on server restart. To recreate them automatically, it is necessary to configure caches in a [configuration file](#) and include some

```
CACHE INDEX  
(and optionally
```

```
LOAD INDEX
```

) statements in the init file.

## Examples

The following statement assigns indexes from the tables t1, t2, and t3 to the key cache named hot\_cache:

```
CACHE INDEX t1, t2, t3 IN hot_cache;  
+-----+-----+-----+  
| Table | Op          | Msg_type | Msg_text |  
+-----+-----+-----+  
| test.t1 | assign_to_keycache | status    | OK        |  
| test.t2 | assign_to_keycache | status    | OK        |  
| test.t3 | assign_to_keycache | status    | OK        |  
+-----+-----+-----+
```

## Implementation (for MyISAM)

Normally CACHE INDEX should not take a long time to execute. Internally it's implemented the following way:

- Find the right key cache (under LOCK\_global\_system\_variables)
- Open the table with a TL\_READ\_NO\_INSERT lock.
- Flush the original key cache for the given file (under key cache lock)
- Flush the new key cache for the given file (safety)
- Move the file to the new key cache (under file share lock)

The only possible long operations are getting the locks for the table and flushing the original key cache, if there were many key blocks for the file in it.

We plan to also add CACHE INDEX for Aria tables if there is a need for this.

### 1.1.2.13 DESCRIBE

## Syntax

```
{DESCRIBE | DESC} tbl_name [col_name | wild]
```

## Contents

1. [Syntax](#)
2. [Description](#)
3. [See Also](#)

## Description

DESCRIBE provides information about the columns in a table. It is a shortcut for

```
SHOW COLUMNS FROM
```

. These statements also display information for [views](#).

col\_name can be a column name, or a string containing the SQL "%

" and "

— wildcard characters to obtain output only for the columns with names matching the string. There is no need to enclose the string within quotes unless it contains spaces or other special characters.

```
DESCRIBE city;
+-----+-----+-----+-----+
| Field | Type   | Null | Key  | Default | Extra      |
+-----+-----+-----+-----+
| Id    | int(11) | NO   | PRI   | NULL    | auto_increment |
| Name  | char(35) | YES  |       | NULL    |             |
| Country | char(3) | NO   | UNI   |          |             |
| District | char(20) | YES  | MUL   |          |             |
| Population | int(11) | YES  |       | NULL    |             |
+-----+-----+-----+-----+
```

The description for

```
SHOW COLUMNS
```

provides more information about the output columns.

## See Also

- [SHOW COLUMNS](#)
- [INFORMATION\\_SCHEMA.COLUMNS Table](#)
- [mysqlshow](#)

## 1.1.2.14 EXECUTE Statement

### Syntax

```
EXECUTE stmt_name
      [USING expression[, expression] ...]
```

### Contents

1. [Syntax](#)
2. [Description](#)
3. [Example](#)
4. [See Also](#)

MariaDB starting with 10.2.3

EXECUTE  
with expression as parameters was introduced in [MariaDB 10.2.3](#). Before that one could only use variables (@var\_name) as parameters.

## Description

After preparing a statement with

```
PREPARE
```

, you execute it with an  
EXECUTE  
statement that refers to the prepared statement name. If the prepared statement contains any parameter markers, you must supply a  
USING  
clause that lists user variables containing the values to be bound to the parameters. Parameter values can be supplied only by user variables,  
and the  
USING  
clause must name exactly as many variables as the number of parameter markers in the statement.

You can execute a given prepared statement multiple times, passing different variables to it or setting the variables to different values before each execution.

If the specified statement has not been PREPARED, an error similar to the following is produced:

ERROR 1243 (HY000): Unknown prepared statement handler (stmt\_name) given to EXECUTE

## Example

See [example in PREPARE](#).

## See Also

- [EXECUTE IMMEDIATE](#)

## 1.1.2.15 HELP Command

### Syntax

```
HELP search_string
```

### Description

The

HELP

command can be used in any MariaDB client, such as the [mysql](#) command-line client, to get basic syntax help and a short description for most commands and functions.

If you provide an argument to the

HELP

command, the [mysql](#) client uses it as a search string to access server-side help. The proper operation of this command requires that the help tables in the

mysql

database be initialized with help topic information.

If there is no match for the search string, the search fails. Use

HELP contents

to see a list of the help categories:

```
HELP contents
You asked for help about help category: "Contents"
For more information, type 'help <item>', where <item> is one of the following
categories:
  Account Management
  Administration
  Compound Statements
  Data Definition
  Data Manipulation
  Data Types
  Functions
  Functions and Modifiers for Use with GROUP BY
  Geographic Features
  Help Metadata
  Language Structure
  Plugins
  Procedures
  Sequences
  Table Maintenance
  Transactions
  User-Defined Functions
  Utility
```

If a search string matches multiple items, MariaDB shows a list of matching topics:

```
HELP drop
Many help items for your request exist.
To make a more specific request, please type 'help <item>',
where <item> is one of the following
topics:
ALTER TABLE
DROP DATABASE
DROP EVENT
DROP FUNCTION
DROP FUNCTION UDF
DROP INDEX
DROP PACKAGE
DROP PACKAGE BODY
DROP PROCEDURE
DROP ROLE
DROP SEQUENCE
DROP SERVER
DROP TABLE
DROP TRIGGER
DROP USER
DROP VIEW
```

Then you can enter a topic as the search string to see the help entry for that topic.

The help is provided with the MariaDB server and makes use of four help tables found in the

```
mysql
database: help\_relation , help\_topic , help\_category and help\_keyword . These tables are populated by the
mysql_install_db
or
fill\_help\_table.sql
scripts which, until MariaDB 10.4.7 , contain data generated from an old version of MySQL.
```

## 1.1.2.16 KILL [CONNECTION | QUERY]

### Syntax

```
KILL [HARD | SOFT] [CONNECTION | QUERY [ID] ] [thread_id | USER user_name | query_id]
```

### Contents

1. [Syntax](#)
2. [Description](#)
3. [See Also](#)

### Description

Each connection to mysqld runs in a separate thread. You can see which threads are running with the

```
SHOW PROCESSLIST
statement and kill a thread with the
KILL thread_id
statement.
KILL
allows the optional
CONNECTION
or
QUERY
modifier:
•
    KILL CONNECTION
    is the same as
    KILL
    with no modifier: It terminates the connection associated with the given thread or query id.
•
    KILL QUERY
    terminates the statement that the connection thread_id is currently executing, but leaves the connection itself intact.
•
    KILL QUERY ID
    (introduced in MariaDB 10.0.5 ) terminates the query by query_id, leaving the connection intact.
```

If a connection is terminated that has an active transaction, the transaction will be rolled back. If only a query is killed, the current transaction will stay

active. See also [idle\\_transaction\\_timeout](#).

If you have the [PROCESS](#) privilege, you can see all threads. If you have the [SUPER](#) privilege, or, from [MariaDB 10.5.2](#), the [CONNECTION ADMIN](#) privilege, you can kill all threads and statements. Otherwise, you can see and kill only your own threads and statements.

Killing queries that repair or create indexes on MyISAM and Aria tables may result in corrupted tables. Use the [SOFT](#) option to avoid this!

The

HARD  
option (default) kills a command as soon as possible. If you use SOFT, then critical operations that may leave a table in an inconsistent state will not be interrupted. Such operations include REPAIR and INDEX creation for MyISAM and Aria tables ([REPAIR TABLE](#), [OPTIMIZE TABLE](#)).

KILL ... USER username  
will kill all connections/queries for a given user.  
USER  
can be specified one of the following ways:

- username (Kill without regard to hostname)
- username@hostname
- 

[CURRENT\\_USER](#)

or

[CURRENT\\_USER\(\)](#)

If you specify a thread id and that thread does not exist, you get the following error:

ERROR 1094 (HY000): Unknown thread id: <thread\_id>

If you specify a query id that doesn't exist, you get the following error:

ERROR 1957 (HY000): Unknown query id: <query\_id>

However, if you specify a user name, no error is issued for non-connected (or even non-existing) users. To check if the connection/query has been killed, you can use the [ROW\\_COUNT\(\)](#) function.

A client whose connection is killed receives the following error:

ERROR 1317 (70100): Query execution was interrupted

To obtain a list of existing sessions, use the

[SHOW PROCESSLIST](#)

statement or query the [Information Schema](#)

[PROCESSLIST](#)

table.

**Note:** You cannot use

[KILL](#)

with the Embedded MySQL Server library because the embedded server merely runs inside the threads of the host application. It does not create any connection threads of its own.

**Note:** You can also use

[mysqladmin kill thread\\_id \[,thread\\_id...\]](#)

to kill connections. To get a list of running queries, use

[mysqladmin processlist](#)

. See [mysqladmin](#).

Percona Toolkit contains a program, [pt-kill](#) that can be used to automatically kill connections that match certain criteria. For example, it can be used to terminate idle connections, or connections that have been busy for more than 60 seconds.

- [idle\\_transaction\\_timeout](#)

## 1.1.2.17 LOAD INDEX

### Syntax

```
LOAD INDEX INTO CACHE
tbl_index_list [, tbl_index_list] ...

tbl_index_list:
tbl_name
[[INDEX|KEY] (index_name[, index_name] ...)]
[IGNORE LEAVES]
```

### Description

The

```
LOAD INDEX INTO CACHE
statement preloads a table index into the key cache to which it has been assigned by an explicit
CACHE INDEX
statement, or into the default key cache otherwise.
LOAD INDEX INTO CACHE
is used only for MyISAM or Aria tables. Until MariaDB 5.3, it was not supported for tables having user-defined partitioning, but this limitation was
removed in MariaDB 5.5.
```

The

```
IGNORE LEAVES
modifier causes only blocks for the nonleaf nodes of the index to be preloaded.
```

## 1.1.2.18 RESET

### Syntax

```
RESET reset_option [, reset_option] ...
```

### Description

The

```
RESET
statement is used to clear the state of various server operations. You must have the
```

```
RELOAD privilege
```

```
to execute
```

```
RESET
```

```
.
```

```
RESET
acts as a stronger version of the FLUSH statement.
```

The different

```
RESET
```

```
options are:
```

Option	Description
SLAVE ["connection_name"] [ALL]	Deletes all <a href="#">relay logs</a> from the slave and reset the replication position in the master <a href="#">binary log</a> .

MASTER	Deletes all old binary logs, makes the binary index file ( <a href="#">--log-bin-index</a> ) empty and creates a new binary log file. This is useful when you want to reset the master to an initial state. If you want to just delete old, not used binary logs, you should use the <a href="#">PURGE BINARY LOGS</a> command.
QUERY CACHE	Removes all queries from <a href="#">the query cache</a> . See also <a href="#">FLUSH QUERY CACHE</a> .

## 1.1.2.19 SHUTDOWN

### Contents

1. [Syntax](#)
2. [Description](#)
3. [WAIT FOR ALL SLAVES](#)
4. [Required Permissions](#)
5. [Shutdown for Upgrades](#)
6. [Example](#)
7. [Other Ways to Stop mysqld](#)
8. [See Also](#)

### Syntax

```
SHUTDOWN [WAIT FOR ALL { SLAVES | REPLICAS } ]
```

### Description

The

`SHUTDOWN`

command shuts the server down.

### WAIT FOR ALL SLAVES

MariaDB starting with [10.4.4](#)

The

`WAIT FOR ALL SLAVES`

option was first added in [MariaDB 10.4.4](#).

`WAIT FOR ALL REPLICAS`

has been a synonym since [MariaDB 10.5.1](#).

When a master server is shutdown and it goes through the normal shutdown process, the master kills client threads in random order. By default, the master also considers its binary log dump threads to be regular client threads. As a consequence, the binary log dump threads can be killed while client threads still exist, and this means that data can be written on the master during a normal shutdown that won't be replicated. This is true even if [semi-synchronous replication](#) is being used.

In [MariaDB 10.4](#) and later, this problem can be solved by shutting down the server with the `SHUTDOWN` command and by providing the

`WAIT FOR ALL SLAVES`

option to the command. For example:

```
SHUTDOWN WAIT FOR ALL SLAVES;
```

When the

`WAIT FOR ALL SLAVES`

option is provided, the server only kills its binary log dump threads after all client threads have been killed, and it only completes the shutdown after the last `binary log` has been sent to all connected replicas.

See [Replication Threads: Binary Log Dump Threads and the Shutdown Process](#) for more information.

### Required Permissions

One must have a

`SHUTDOWN`

privilege (see [GRANT](#)) to use this command. It is the same privilege one needs to use the `mariadb-admin/mysqladmin shutdown` command.

### Shutdown for Upgrades

If you are doing a shutdown to [migrate to another major version of MariaDB](#), please ensure that the `innodb_fast_shutdown` variable is not 2 (fast crash shutdown). The default of this variable is 1.

## Example

The following example shows how to create an [event](#) which turns off the server at a certain time:

```
CREATE EVENT `test`.`shutd`
  ON SCHEDULE
    EVERY 1 DAY
    STARTS '2014-01-01 20:00:00'
    COMMENT 'Shutdown Maria when the office is closed'
DO BEGIN
  SHUTDOWN;
END;
```

## Other Ways to Stop mysqld

You can use the [mariadb-admin/mysqladmin shutdown](#) command to take down mysqld cleanly.

You can also use the system kill command on Unix with signal SIGTERM (15)

```
kill -SIGTERM pid-of-mysqld-process
```

You can find the process number of the server process in the file that ends with

.pid  
in your data directory.

The above is identical to

```
mysqladmin shutdown
```

On windows you should use:

```
NET STOP MySQL
```

## See Also

- [mariadb-admin/mysqladmin shutdown](#) .
- [InnoDB fast shutdown option](#)

## 1.1.2.20 USE

### Syntax

```
USE db_name
```

### Description

The

'USE db\_name'  
statement tells MariaDB to use the  
db\_name  
database as the default (current) database for subsequent statements. The database remains the default until the end of the session or another  
USE  
statement is issued:

```
USE db1;
SELECT COUNT(*) FROM mytable;  # selects from db1.mytable
USE db2;
SELECT COUNT(*) FROM mytable;  # selects from db2.mytable
```

The [DATABASE\(\)](#) function ( [SCHEMA\(\)](#) is a synonym) returns the default database.

Another way to set the default database is specifying its name at [mysql](#) command line client startup.

## See Also

- [Identifier Qualifiers](#)

## 1.1.3 Data Definition

### 1.1.3.1 CREATE

#### 1.1.3.1.1 CREATE DATABASE

##### Syntax

```
CREATE [OR REPLACE] {DATABASE | SCHEMA} [IF NOT EXISTS] db_name  
[create_specification] ...  
  
create_specification:  
  [DEFAULT] CHARACTER SET [=] charset_name  
  | [DEFAULT] COLLATE [=] collation_name  
  | COMMENT [=] 'comment'
```

##### Contents

1. [Syntax](#)
2. [Description](#)
  1. [OR REPLACE](#)
  2. [IF NOT EXISTS](#)
  3. [COMMENT](#)
3. [Examples](#)
4. [See Also](#)

##### Description

CREATE DATABASE  
creates a database with the given name. To use this statement, you need the [CREATE privilege](#) for the database.  
CREATE SCHEMA  
is a synonym for  
CREATE DATABASE

For valid identifiers to use as database names, see [Identifier Names](#).

##### OR REPLACE

MariaDB starting with [10.1.3](#)

The

OR REPLACE  
clause was added in [MariaDB 10.1.3](#)

If the optional

OR REPLACE  
clause is used, it acts as a shortcut for:

```
DROP DATABASE IF EXISTS db_name;  
CREATE DATABASE db_name ...;
```

##### IF NOT EXISTS

When the

IF NOT EXISTS  
clause is used, MariaDB will return a warning instead of an error if the specified database already exists.

##### COMMENT

MariaDB starting with [10.5.0](#)

From [MariaDB 10.5.0](#), it is possible to add a comment of a maximum of 1024 bytes. If the comment length exceeds this length, an error/warning code 4144 is thrown. The database comment is also added to the db.opt file, as well as to the [information\\_schema.schemata](#) table.

## Examples

```
CREATE DATABASE db1;
Query OK, 1 row affected (0.18 sec)

CREATE DATABASE db1;
ERROR 1007 (HY000): Can't create database 'db1'; database exists

CREATE OR REPLACE DATABASE db1;
Query OK, 2 rows affected (0.00 sec)

CREATE DATABASE IF NOT EXISTS db1;
Query OK, 1 row affected, 1 warning (0.01 sec)

SHOW WARNINGS;
+-----+-----+
| Level | Code | Message |
+-----+-----+
| Note  | 1007 | Can't create database 'db1'; database exists |
+-----+-----+
```

Setting the [character sets and collation](#). See [Setting Character Sets and Collations](#) for more details.

```
CREATE DATABASE czech_slovak_names
  CHARACTER SET = 'keybcs2'
  COLLATE = 'keybcs2_bin';
```

Comments, from [MariaDB 10.5.0](#):

```
CREATE DATABASE presentations COMMENT 'Presentations for conferences';
```

## See Also

### 1.1.3.1.2 CREATE EVENT

## Syntax

```
CREATE [OR REPLACE]
  [DEFINER = { user | CURRENT_USER | role | CURRENT_ROLE }]
  EVENT
  [IF NOT EXISTS]
  event_name
  ON SCHEDULE schedule
  [ON COMPLETION [NOT] PRESERVE]
  [ENABLE | DISABLE | DISABLE ON SLAVE]
  [COMMENT 'comment']
  DO sql_statement;

schedule:
  AT timestamp [+ INTERVAL interval] ...
  | EVERY interval
  [STARTS timestamp [+ INTERVAL interval] ...]
  [ENDS timestamp [+ INTERVAL interval] ...]

interval:
  quantity {YEAR | QUARTER | MONTH | DAY | HOUR | MINUTE |
            WEEK | SECOND | YEAR_MONTH | DAY_HOUR | DAY_MINUTE |
            DAY_SECOND | HOUR_MINUTE | HOUR_SECOND | MINUTE_SECOND}
```

## Contents

1. [Syntax](#)
2. [Description](#)
  1. [OR REPLACE](#)
  2. [IF NOT EXISTS](#)
  3. [ON SCHEDULE](#)
  4. [AT](#)
  5. [ON COMPLETION \[NOT\] PRESERVE](#)
  6. [ENABLE/DISABLE/DISABLE ON SLAVE](#)
  7. [COMMENT](#)
3. [Examples](#)
4. [See Also](#)

## Description

This statement creates and schedules a new [event](#). It requires the

`EVENT`

privilege for the schema in which the event is to be created.

The minimum requirements for a valid CREATE EVENT statement are as follows:

- The keywords

`CREATE EVENT`

plus an event name, which uniquely identifies the event in the current schema. (Prior to MySQL 5.1.12, the event name needed to be unique only among events created by the same user on a given database.)

- An

`ON SCHEDULE`

clause, which determines when and how often the event executes.

- A

`DO`

clause, which contains the SQL statement to be executed by an event.

Here is an example of a minimal

`CREATE EVENT`  
statement:

```
CREATE EVENT myevent
  ON SCHEDULE AT CURRENT_TIMESTAMP + INTERVAL 1 HOUR
  DO
    UPDATE myschema.mytable SET mycol = mycol + 1;
```

The previous statement creates an event named `myevent`. This event executes once — one hour following its creation — by running an SQL statement that increments the value of the `myschema.mytable` table's `mycol` column by 1.

The `event_name` must be a valid MariaDB identifier with a maximum length of 64 characters. It may be delimited using back ticks, and may be qualified with the name of a database schema. An event is associated with both a MariaDB user (the definer) and a schema, and its name must be unique among names of events within that schema. In general, the rules governing event names are the same as those for names of stored routines. See [Identifier Names](#).

If no schema is indicated as part of `event_name`, the default (current) schema is assumed.

For valid identifiers to use as event names, see [Identifier Names](#).

### OR REPLACE

The

`OR REPLACE`

clause was included in [MariaDB 10.1.4](#). If used and the event already exists, instead of an error being returned, the existing event will be dropped and replaced by the newly defined event.

### IF NOT EXISTS

If the

`IF NOT EXISTS`

clause is used, MariaDB will return a warning instead of an error if the event already exists. Cannot be used together with OR REPLACE.

### ON SCHEDULE

The

`ON SCHEDULE`

clause can be used to specify when the event must be triggered.

## AT

If you want to execute the event only once (one time event), you can use the

AT

keyword, followed by a timestamp. If you use

CURRENT\_TIMESTAMP

, the event acts as soon as it is created. As a convenience, you can add one or more intervals to that timestamp. You can also specify a timestamp in the past, so that the event is stored but not triggered, until you modify it via [ALTER EVENT](#).

The following example shows how to create an event that will be triggered tomorrow at a certain time:

```
CREATE EVENT example
ON SCHEDULE AT CURRENT_TIMESTAMP + INTERVAL 1 DAY + INTERVAL 3 HOUR
DO something;
```

You can also specify that an event must be triggered at a regular interval (recurring event). In such cases, use the

EVERY

clause followed by the interval.

If an event is recurring, you can specify when the first execution must happen via the

STARTS

clause and a maximum time for the last execution via the

ENDS

clause.

STARTS

and

ENDS

clauses are followed by a timestamp and, optionally, one or more intervals. The

ENDS

clause can specify a timestamp in the past, so that the event is stored but not executed until you modify it via [ALTER EVENT](#).

In the following example, next month a recurring event will be triggered hourly for a week:

```
CREATE EVENT example
ON SCHEDULE EVERY 1 HOUR
STARTS CURRENT_TIMESTAMP + INTERVAL 1 MONTH
ENDS CURRENT_TIMESTAMP + INTERVAL 1 MONTH + INTERVAL 1 WEEK
DO some_task;
```

Intervals consist of a quantity and a time unit. The time units are the same used for other statements and time functions, except that you can't use microseconds for events. For simple time units, like

HOUR

or

MINUTE

, the quantity is an integer number, for example '10 MINUTE'. For composite time units, like

HOUR\_MINUTE

or

HOUR\_SECOND

, the quantity must be a string with all involved simple values and their separators, for example '2:30' or '2:30:30'.

## ON COMPLETION [NOT] PRESERVE

The

ON COMPLETION

clause can be used to specify if the event must be deleted after its last execution (that is, after its

AT

or

ENDS

timestamp is past). By default, events are dropped when they are expired. To explicitly state that this is the desired behaviour, you can use

ON COMPLETION NOT PRESERVE

. Instead, if you want the event to be preserved, you can use

ON COMPLETION PRESERVE

In you specify

ON COMPLETION NOT PRESERVE

, and you specify a timestamp in the past for

AT

```
or
ENDS
clause, the event will be immediately dropped. In such cases, you will get a Note 1558: "Event execution time is in the past and ON COMPLETION NOT PRESERVE is set. The event was dropped immediately after creation".
```

## ENABLE/DISABLE/DISABLE ON SLAVE

Events are

```
ENABLE
d by default. If you want to stop MariaDB from executing an event, you may specify
DISABLE
. When it is ready to be activated, you may enable it using
```

```
ALTER EVENT
```

```
. Another option is
DISABLE ON SLAVE
, which indicates that an event was created on a master and has been replicated to the slave, which is prevented from executing the event. If
DISABLE ON SLAVE
is specifically set, the event will not be executed.
```

## COMMENT

The

```
COMMENT
```

clause may be used to set a comment for the event. Maximum length for comments is 64 characters. The comment is a string, so it must be quoted. To see events comments, you can query the [INFORMATION\\_SCHEMA.EVENTS](#) table (the column is named `EVENT_COMMENT`).

## Examples

Minimal

```
CREATE EVENT
statement:
```

```
CREATE EVENT myevent
ON SCHEDULE AT CURRENT_TIMESTAMP + INTERVAL 1 HOUR
DO
    UPDATE myschema.mytable SET mycol = mycol + 1;
```

An event that will be triggered tomorrow at a certain time:

```
CREATE EVENT example
ON SCHEDULE AT CURRENT_TIMESTAMP + INTERVAL 1 DAY + INTERVAL 3 HOUR
DO something;
```

Next month a recurring event will be triggered hourly for a week:

```
CREATE EVENT example
ON SCHEDULE EVERY 1 HOUR
STARTS CURRENT_TIMESTAMP + INTERVAL 1 MONTH
ENDS CURRENT_TIMESTAMP + INTERVAL 1 MONTH + INTERVAL 1 WEEK
DO some_task;
```

OR REPLACE and IF NOT EXISTS:

```

CREATE EVENT myevent
  ON SCHEDULE AT CURRENT_TIMESTAMP + INTERVAL 1 HOUR
  DO
    UPDATE myschema.mytable SET mycol = mycol + 1;
ERROR 1537 (HY000): Event 'myevent' already exists

CREATE OR REPLACE EVENT myevent
  ON SCHEDULE AT CURRENT_TIMESTAMP + INTERVAL 1 HOUR
  DO
    UPDATE myschema.mytable SET mycol = mycol + 1;
Query OK, 0 rows affected (0.00 sec)

CREATE EVENT IF NOT EXISTS myevent
  ON SCHEDULE AT CURRENT_TIMESTAMP + INTERVAL 1 HOUR
  DO
    UPDATE myschema.mytable SET mycol = mycol + 1;
Query OK, 0 rows affected, 1 warning (0.00 sec)

SHOW WARNINGS;
+-----+-----+
| Level | Code | Message |
+-----+-----+
| Note  | 1537 | Event 'myevent' already exists |
+-----+-----+

```

## See Also

### 1.1.3.1.3 CREATE FUNCTION

#### Syntax

```

CREATE [OR REPLACE]
  [DEFINER = {user | CURRENT_USER | role | CURRENT_ROLE}]
  [AGGREGATE] FUNCTION [IF NOT EXISTS] func_name ([func_parameter[,...]])
  RETURNS type
  [characteristic ...]
  RETURN func_body

func_parameter:
  [ IN | OUT | INOUT | IN OUT ] param_name type

type:
  Any valid MariaDB data type

characteristic:
  LANGUAGE SQL
  | [NOT] DETERMINISTIC
  | { CONTAINS SQL | NO SQL | READS SQL DATA | MODIFIES SQL DATA }
  | SQL SECURITY { DEFINER | INVOKER }
  | COMMENT 'string'

func_body:
  Valid SQL procedure statement

```

## Contents

- 1. [Syntax](#)
  - 2. [Description](#)
    - 1. [IN | OUT | INOUT | IN OUT](#)
    - 2. [AGGREGATE](#)
    - 3. [RETURNS](#)
    - 4. [LANGUAGE SQL](#)
    - 5. [OR REPLACE](#)
    - 6. [IF NOT EXISTS](#)
    - 7. [\[NOT\] DETERMINISTIC](#)
    - 8. [MODIFIES SQL DATA](#)
    - 9. [READS SQL DATA](#)
  - 10. [CONTAINS SQL](#)
  - 11. [NO SQL](#)
  - 12. [Oracle Mode](#)
- 3. [Security](#)
  - 4. [Character sets and collations](#)
  - 5. [Examples](#)
  - 6. [See Also](#)

## Description

Use the

```
CREATE FUNCTION
```

statement to create a new [stored function](#). You must have the [CREATE ROUTINE](#) database privilege to use

```
CREATE FUNCTION
```

. A function takes any number of arguments and returns a value from the function body. The function body can be any valid SQL expression as you would use, for example, in any select expression. If you have the appropriate privileges, you can call the function exactly as you would any built-in function. See [Security](#) below for details on privileges.

You can also use a variant of the

```
CREATE FUNCTION
```

statement to install a user-defined function (UDF) defined by a plugin. See [CREATE FUNCTION \(UDF\)](#) for details.

You can use a [SELECT](#) statement for the function body by enclosing it in parentheses, exactly as you would to use a subselect for any other expression.

The

```
SELECT
```

statement must return a single value. If more than one column is returned when the function is called, error 1241 results. If more than one row is returned when the function is called, error 1242 results. Use a

```
LIMIT
```

clause to ensure only one row is returned.

You can also replace the

```
RETURN
```

clause with a [BEGIN...END](#) compound statement. The compound statement must contain a

```
RETURN
```

statement. When the function is called, the

```
RETURN
```

statement immediately returns its result, and any statements after

```
RETURN
```

are effectively ignored.

By default, a function is associated with the current database. To associate the function explicitly with a given database, specify the fully-qualified name as

```
db_name
```

```
.
```

```
func_name
```

when you create it. If the function name is the same as the name of a built-in function, you must use the fully qualified name when you call it.

The parameter list enclosed within parentheses must always be present. If there are no parameters, an empty parameter list of () should be used. Parameter names are not case sensitive.

Each parameter can be declared to use any valid data type, except that the COLLATE attribute cannot be used.

For valid identifiers to use as function names, see [Identifier Names](#).

[IN | OUT | INOUT | IN OUT](#)

The function parameter qualifiers for

```
IN  
,  
OUT  
,  
INOUT  
, and  
IN OUT
```

were added in a 10.8.0 preview release. Prior to 10.8.0 quantifiers were supported only in procedures.

```
OUT  
,  
INOUT  
and its equivalent  
IN OUT  
, are only valid if called from  
SET  
and not  
SELECT
```

. These quantifiers are especially useful for creating functions with more than one return value. This allows functions to be more complex and nested.

```
DELIMITER $$  
CREATE FUNCTION add_func3(IN a INT, IN b INT, OUT c INT) RETURNS INT  
BEGIN  
    SET c = 100;  
    RETURN a + b;  
END;  
$$  
DELIMITER ;  
  
SET @a = 2;  
SET @b = 3;  
SET @c = 0;  
SET @res= add_func3(@a, @b, @c);  
  
SELECT add_func3(@a, @b, @c);  
ERROR 4186 (HY000): OUT or INOUT argument 3 for function add_func3 is not allowed here  
  
DELIMITER $$  
CREATE FUNCTION add_func4(IN a INT, IN b INT, d INT) RETURNS INT  
BEGIN  
    DECLARE c, res INT;  
    SET res = add_func3(a, b, c) + d;  
    if (c > 99) then  
        return 3;  
    else  
        return res;  
    end if;  
END;  
$$  
  
DELIMITER ;  
  
SELECT add_func4(1,2,3);  
+-----+  
| add_func4(1,2,3) |  
+-----+  
|            3 |  
+-----+
```

## AGGREGATE

MariaDB starting with 10.3.3

From [MariaDB 10.3.3](#), it is possible to create stored aggregate functions as well. See [Stored Aggregate Functions](#) for details.

## RETURNS

The

```
RETURNS
```

clause specifies the return type of the function.

NULL

values are permitted with all return types.

What happens if the

RETURN

clause returns a value of a different type? It depends on the `SQL_MODE` in effect at the moment of the function creation.

If the `SQL_MODE` is strict (`STRICT_ALL_TABLES` or `STRICT_TRANS_TABLES` flags are specified), a 1366 error will be produced.

Otherwise, the value is coerced to the proper type. For example, if a function specifies an

ENUM

or

SET

value in the

RETURNS

clause, but the

RETURN

clause returns an integer, the value returned from the function is the string for the corresponding

ENUM

member of set of

SET

members.

MariaDB stores the `SQL_MODE` system variable setting that is in effect at the time a routine is created, and always executes the routine with this setting in force, regardless of the server SQL mode in effect when the routine is invoked.

## LANGUAGE SQL

LANGUAGE SQL

is a standard SQL clause, and it can be used in MariaDB for portability. However that clause has no meaning, because SQL is the only supported language for stored functions.

A function is deterministic if it can produce only one result for a given list of parameters. If the result may be affected by stored data, server variables, random numbers or any value that is not explicitly passed, then the function is not deterministic. Also, a function is non-deterministic if it uses non-deterministic functions like `NOW()` or `CURRENT_TIMESTAMP()`. The optimizer may choose a faster execution plan if it known that the function is deterministic. In such cases, you should declare the routine using the

DETERMINISTIC

keyword. If you want to explicitly state that the function is not deterministic (which is the default) you can use the

NOT DETERMINISTIC

keywords.

If you declare a non-deterministic function as

DETERMINISTIC

, you may get incorrect results. If you declare a deterministic function as

NOT DETERMINISTIC

, in some cases the queries will be slower.

## OR REPLACE

MariaDB starting with 10.1.3

If the optional

OR REPLACE

clause is used, it acts as a shortcut for:

```
DROP FUNCTION IF EXISTS function_name;  
CREATE FUNCTION function_name ...;
```

with the exception that any existing privileges for the function are not dropped.

## IF NOT EXISTS

MariaDB starting with 10.1.3

If the IF NOT EXISTS clause is used, MariaDB will return a warning instead of an error if the function already exists. Cannot be used together with OR REPLACE.

## [NOT] DETERMINISTIC

The

[NOT] DETERMINISTIC  
clause also affects [binary logging](#), because the  
STATEMENT  
format can not be used to store or replicate non-deterministic statements.

CONTAINS SQL  
,  
NO SQL  
,  
READS SQL DATA  
, and  
MODIFIES SQL DATA  
are informative clauses that tell the server what the function does. MariaDB does not check in any way whether the specified clause is correct. If none of these clauses are specified,  
CONTAINS SQL  
is used by default.

## MODIFIES SQL DATA

MODIFIES SQL DATA  
means that the function contains statements that may modify data stored in databases. This happens if the function contains statements like [DELETE](#), [UPDATE](#), [INSERT](#), [REPLACE](#) or DDL.

## READS SQL DATA

READS SQL DATA  
means that the function reads data stored in databases, but does not modify any data. This happens if [SELECT](#) statements are used, but there no write operations are executed.

## CONTAINS SQL

CONTAINS SQL  
means that the function contains at least one SQL statement, but it does not read or write any data stored in a database. Examples include [SET](#) or [DO](#).

## NO SQL

NO SQL  
means nothing, because MariaDB does not currently support any language other than SQL.

## Oracle Mode

MariaDB starting with 10.3

From [MariaDB 10.3](#), a subset of Oracle's PL/SQL language has been supported in addition to the traditional SQL/PSM-based MariaDB syntax. See [Oracle mode from MariaDB 10.3](#) for details on changes when running Oracle mode.

# Security

You must have the [EXECUTE](#) privilege on a function to call it. MariaDB automatically grants the

EXECUTE  
and  
ALTER ROUTINE  
privileges to the account that called  
CREATE FUNCTION  
, even if the  
DEFINER  
clause was used.

Each function has an account associated as the definer. By default, the definer is the account that created the function. Use the  
DEFINER  
clause to specify a different account as the definer. You must have the [SUPER](#) privilege, or, from [MariaDB 10.5.2](#), the [SET USER](#) privilege, to  
use the  
DEFINER  
clause. See [Account Names](#) for details on specifying accounts.

The

```
SQL SECURITY
clause specifies what privileges are used when a function is called. If
SQL SECURITY
is
INVOKER
, the function body will be evaluated using the privileges of the user calling the function. If
SQL SECURITY
is
DEFINER
, the function body is always evaluated using the privileges of the definer account.
DEFINER
is the default.
```

This allows you to create functions that grant limited access to certain data. For example, say you have a table that stores some employee information, and that you've granted

```
SELECT
privileges only on certain columns to the user account
roger
.
```

```
CREATE TABLE employees (name TINYTEXT, dept TINYTEXT, salary INT);
GRANT SELECT (name, dept) ON employees TO roger;
```

To allow the user to get the maximum salary for a department, define a function and grant the

```
EXECUTE
privilege:
```

```
CREATE FUNCTION max_salary (dept TINYTEXT) RETURNS INT RETURN
(SELECT MAX(salary) FROM employees WHERE employees.dept = dept);
GRANT EXECUTE ON FUNCTION max_salary TO roger;
```

Since

```
SQL SECURITY
defaults to
DEFINER
, whenever the user
roger
```

calls this function, the subselect will execute with your privileges. As long as you have privileges to select the salary of each employee, the caller of the function will be able to get the maximum salary for each department without being able to see individual salaries.

## Character sets and collations

Function return types can be declared to use any valid [character set and collation](#). If used, the COLLATE attribute needs to be preceded by a CHARACTER SET attribute.

If the character set and collation are not specifically set in the statement, the database defaults at the time of creation will be used. If the database defaults change at a later stage, the stored function character set/collation will not be changed at the same time; the stored function needs to be dropped and recreated to ensure the same character set/collation as the database is used.

## Examples

The following example function takes a parameter, performs an operation using an SQL function, and returns the result.

```
CREATE FUNCTION hello (s CHAR(20))
RETURNS CHAR(50) DETERMINISTIC
RETURN CONCAT('Hello, ',s,'!');

SELECT hello('world');
+-----+
| hello('world') |
+-----+
| Hello, world! |
+-----+
```

You can use a compound statement in a function to manipulate data with statements like

```
INSERT
and
UPDATE
.
The following example creates a counter function that uses a temporary table to store the current value. Because the compound statement
```

contains statements terminated with semicolons, you have to first change the statement delimiter with the `DELIMITER` statement to allow the semicolon to be used in the function body. See [Delimiters in the mysql client](#) for more.

```
CREATE TEMPORARY TABLE counter (c INT);
INSERT INTO counter VALUES (0);
DELIMITER //
CREATE FUNCTION counter () RETURNS INT
BEGIN
    UPDATE counter SET c = c + 1;
    RETURN (SELECT c FROM counter LIMIT 1);
END //
DELIMITER ;
```

Character set and collation:

```
CREATE FUNCTION hello2 (s CHAR(20))
RETURNS CHAR(50) CHARACTER SET 'utf8' COLLATE 'utf8_bin' DETERMINISTIC
RETURN CONCAT('Hello, ',s,'!');
```

### 1.1.3.1.4 CREATE FUNCTION UDF

## Syntax

```
CREATE [OR REPLACE] [AGGREGATE] FUNCTION [IF NOT EXISTS] function_name
RETURNS {STRING|INTEGER|REAL|DECIMAL}
SONAME shared_library_name
```

## Contents

1. [Syntax](#)
2. [Description](#)
  1. [RETURNS](#)
  2. [shared\\_library\\_name](#)
  3. [AGGREGATE](#)
  4. [OR REPLACE](#)
  5. [IF NOT EXISTS](#)
  6. [Upgrading a UDF](#)
  7. [Examples](#)
3. [See Also](#)

## Description

A user-defined function (UDF) is a way to extend MariaDB with a new function that works like a native (built-in) MariaDB function such as `ABS()` or `CONCAT()`.

`function_name`  
is the name that should be used in SQL statements to invoke the function.

To create a function, you must have the `INSERT` privilege for the `mysql` database. This is necessary because

```
CREATE FUNCTION
adds a row to the mysql.func system table that records the function's name, type, and shared library name. If you do not have this table, you
should run the mysql_upgrade command to create it.
```

UDFs need to be written in C, C++ or another language that uses C calling conventions, MariaDB needs to have been dynamically compiled, and your operating system must support dynamic loading.

For an example, see

Statements making use of user-defined functions are not [safe for replication](#).

For creating a stored function as opposed to a user-defined function, see [CREATE FUNCTION](#).

For valid identifiers to use as function names, see [Identifier Names](#).

## RETURNS

The

```
RETURNS
clause indicates the type of the function's return value, and can be one of STRING , INTEGER , REAL or DECIMAL .
DECIMAL
functions currently return string values and should be written like STRING functions.
```

## shared\_library\_name

```
shared_library_name
```

is the basename of the shared object file that contains the code that implements the function. The file must be located in the plugin directory. This directory is given by the value of the [plugin\\_dir](#) system variable. Note that before MariaDB/MySQL 5.1, the shared object could be located in any directory that was searched by your system's dynamic linker.

## AGGREGATE

Aggregate functions are summary functions such as [SUM\(\)](#) and [AVG\(\)](#).

MariaDB starting with [10.4](#)

Aggregate UDF functions can be used as [window functions](#).

## OR REPLACE

MariaDB starting with [10.1.3](#)

The

```
OR REPLACE
clause was added in MariaDB 10.1.3
```

If the optional

```
OR REPLACE
clause is used, it acts as a shortcut for:
```

```
DROP FUNCTION IF EXISTS function_name;
CREATE FUNCTION name ...;
```

## IF NOT EXISTS

MariaDB starting with [10.1.3](#)

The

```
IF NOT EXISTS
clause was added in MariaDB 10.1.3
```

When the IF NOT EXISTS clause is used, MariaDB will return a warning instead of an error if the specified function already exists. Cannot be used together with OR REPLACE.

## Upgrading a UDF

To upgrade the UDF's shared library, first run a [DROP FUNCTION](#) statement, then upgrade the shared library and finally run the [CREATE FUNCTION](#) statement. If you upgrade without following this process, you may crash the server.

## Examples

```
CREATE FUNCTION jsoncontains_path RETURNS integer SONAME 'ha_connect.so';
Query OK, 0 rows affected (0.00 sec)
```

OR REPLACE and IF NOT EXISTS:

```
CREATE FUNCTION jsoncontains_path RETURNS integer SONAME 'ha_connect.so';
ERROR 1125 (HY000): Function 'jsoncontains_path' already exists

CREATE OR REPLACE FUNCTION jsoncontains_path RETURNS integer SONAME 'ha_connect.so';
Query OK, 0 rows affected (0.00 sec)

CREATE FUNCTION IF NOT EXISTS jsoncontains_path RETURNS integer SONAME 'ha_connect.so';
Query OK, 0 rows affected, 1 warning (0.00 sec)

SHOW WARNINGS;
+-----+-----+
| Level | Code | Message |
+-----+-----+
| Note  | 1125 | Function 'jsoncontains_path' already exists |
+-----+-----+
```

- CREATE FUNCTION

### 1.1.3.1.5 CREATE INDEX

#### Syntax

```
CREATE [OR REPLACE] [UNIQUE|FULLTEXT|SPATIAL] INDEX
[IF NOT EXISTS] index_name
[index_type]
ON tbl_name (index_col_name,...)
[WAIT n | NOWAIT]
[index_option]
[algorithm_option | lock_option] ...

index_col_name:
    col_name [(length)] [ASC | DESC]

index_type:
    USING {BTREE | HASH | RTREE}

index_option:
    [ KEY_BLOCK_SIZE [=] value
    | index_type
    | WITH PARSER parser_name
    | COMMENT 'string'
    | CLUSTERING={YES| NO} ]
    [ IGNORED | NOT IGNORED ]

algorithm_option:
    ALGORITHM [=] {DEFAULT|INPLACE|COPY|NOCOPY|INSTANT}

lock_option:
    LOCK [=] {DEFAULT|NONE|SHARED|EXCLUSIVE}
```

## Contents

1. [Syntax](#)
2. [Description](#)
3. [Privileges](#)
4. [Online DDL](#)
5. [CREATE OR REPLACE INDEX](#)
6. [CREATE INDEX IF NOT EXISTS](#)
7. [Index Definitions](#)
8. [WAIT/NOWAIT](#)
9. [ALGORITHM](#)
10. [LOCK](#)
11. [Progress Reporting](#)
12. [WITHOUT OVERLAPS](#)
13. [Examples](#)
14. [See Also](#)

## Description

CREATE INDEX is mapped to an ALTER TABLE statement to create indexes . See [ALTER TABLE](#) . CREATE INDEX cannot be used to create a PRIMARY KEY; use ALTER TABLE instead.

If another connection is using the table, a [metadata lock](#) is active, and this statement will wait until the lock is released. This is also true for non-transactional tables.

Another shortcut, [DROP INDEX](#) , allows the removal of an index.

For valid identifiers to use as index names, see [Identifier Names](#) .

Note that `KEY_BLOCK_SIZE` is currently ignored in CREATE INDEX, although it is included in the output of [SHOW CREATE TABLE](#) .

## Privileges

Executing the

`CREATE INDEX`  
statement requires the

`INDEX`

privilege for the table or the database.

## Online DDL

Online DDL is supported with the [ALGORITHM](#) and [LOCK](#) clauses.

See [InnoDB Online DDL Overview](#) for more information on online DDL with InnoDB .

## CREATE OR REPLACE INDEX

MariaDB starting with [10.1.4](#)

The

`OR REPLACE`  
clause was added in [MariaDB 10.1.4](#) .

If the

`OR REPLACE`  
clause is used and if the index already exists, then instead of returning an error, the server will drop the existing index and replace it with the newly defined index.

## CREATE INDEX IF NOT EXISTS

If the

`IF NOT EXISTS`  
clause is used, then the index will only be created if an index with the same name does not already exist. If the index already exists, then a warning will be triggered by default.

## Index Definitions

See [CREATE TABLE: Index Definitions](#) for information about index definitions.

## WAIT/NOWAIT

MariaDB starting with [10.3.0](#)

Set the lock wait timeout. See [WAIT](#) and [NOWAIT](#).

## ALGORITHM

See [ALTER TABLE: ALGORITHM](#) for more information.

## LOCK

See [ALTER TABLE: LOCK](#) for more information.

## Progress Reporting

MariaDB provides progress reporting for

`CREATE INDEX` statement for clients that support the new progress reporting protocol. For example, if you were using the

`mysql`

client, then the progress report might look like this::

```
CREATE INDEX ON tab (num);;
Stage: 1 of 2 'copy to tmp table'    46% of stage
```

The progress report is also shown in the output of the

`SHOW PROCESSLIST`

statement and in the contents of the

`information_schema.PROCESSLIST`

table.

See [Progress Reporting](#) for more information.

## WITHOUT OVERLAPS

MariaDB starting with [10.5.3](#)

The `WITHOUT OVERLAPS` clause allows one to constrain a primary or unique index such that [application-time periods](#) cannot overlap.

## Examples

Creating a unique index:

```
CREATE UNIQUE INDEX HomePhone ON Employees(Home_Phone);
```

OR REPLACE and IF NOT EXISTS:

```
CREATE INDEX xi ON xx5 (x);
Query OK, 0 rows affected (0.03 sec)

CREATE INDEX xi ON xx5 (x);
ERROR 1061 (42000): Duplicate key name 'xi'

CREATE OR REPLACE INDEX xi ON xx5 (x);
Query OK, 0 rows affected (0.03 sec)

CREATE INDEX IF NOT EXISTS xi ON xx5 (x);
Query OK, 0 rows affected, 1 warning (0.00 sec)

SHOW WARNINGS;
+-----+-----+
| Level | Code | Message           |
+-----+-----+
| Note  | 1061 | Duplicate key name 'xi' |
+-----+-----+
```

From MariaDB 10.5.3 , creating a unique index for an application-time period table with a WITHOUT OVERLAPS constraint:

```
CREATE UNIQUE INDEX u ON rooms (room_number, p WITHOUT OVERLAPS);
```

### 1.1.3.1.6 CREATE LOGFILE GROUP

The

CREATE LOGFILE GROUP

statement is not supported by MariaDB. It was originally inherited from MySQL NDB Cluster. See [MDEV-19295](#) for more information.

### 1.1.3.1.7 CREATE PACKAGE

MariaDB starting with 10.3.5

Oracle-style packages were introduced in [MariaDB 10.3.5](#).

## Syntax

```

CREATE
  [ OR REPLACE]
  [DEFINER = { user | CURRENT_USER | role | CURRENT_ROLE }]
PACKAGE [ IF NOT EXISTS ]
[ db_name . ] package_name
[ package_characteristic ... ]
{ AS | IS }
[ package_specification_element ... ]
END [ package_name ]

package_characteristic:
  COMMENT 'string'
| SQL SECURITY { DEFINER | INVOKER }

package_specification_element:
  FUNCTION_SYM package_specification_function ;
| PROCEDURE_SYM package_specification_procedure ;

package_specification_function:
  func_name [ ( func_param [, func_param]... ) ]
RETURNS func_return_type
[ package_routine_characteristic... ]

package_specification_procedure:
  proc_name [ ( proc_param [, proc_param]... ) ]
[ package_routine_characteristic... ]

func_return_type:
  type

func_param:
  param_name [ IN | OUT | INOUT | IN OUT ] type

proc_param:
  param_name [ IN | OUT | INOUT | IN OUT ] type

type:
  Any valid MariaDB explicit or anchored data type

package_routine_characteristic:
  COMMENT 'string'
| LANGUAGE SQL
| { CONTAINS SQL | NO SQL | READS SQL DATA | MODIFIES SQL DATA }
| SQL SECURITY { DEFINER | INVOKER }

```

## Contents

1. [Syntax](#)
2. [Description](#)
3. [Function parameter quantifiers IN | OUT |  
INOUT | IN OUT](#)
4. [Examples](#)
5. [See Also](#)

## Description

The

```
CREATE PACKAGE
```

statement can be used when [Oracle SQL\\_MODE](#) is set.

The

```
CREATE PACKAGE
```

creates the specification for a stored package (a collection of logically related stored objects). A stored package specification declares public routines (procedures and functions) of the package, but does not implement these routines.

A package whose specification was created by the

```
CREATE PACKAGE
```

statement, should later be implemented using the [CREATE PACKAGE BODY](#) statement.

## Function parameter quantifiers IN | OUT | INOUT | IN OUT

MariaDB starting with 10.8.0

The function parameter quantifiers for

```
IN  
,  
OUT  
,  
INOUT  
, and  
IN OUT
```

where added in a 10.8.0 preview release. Prior to 10.8.0 quantifiers were supported only in procedures.

```
OUT  
,  
INOUT  
and its equivalent  
IN OUT  
, are only valid if called from  
SET  
and not  
SELECT
```

. These quantifiers are especially useful for creating functions and procedures with more than one return value. This allows functions and procedures to be more complex and nested.

## Examples

```
SET sql_mode=ORACLE;  
DELIMITER $$  
CREATE OR REPLACE PACKAGE employee_tools AS  
    FUNCTION getSalary(eid INT) RETURN DECIMAL(10,2);  
    PROCEDURE raiseSalary(eid INT, amount DECIMAL(10,2));  
    PROCEDURE raiseSalaryStd(eid INT);  
    PROCEDURE hire(ename TEXT, esalary DECIMAL(10,2));  
END;  
$$  
DELIMITER ;
```

## Contents

1. [Syntax](#)
2. [Description](#)
3. [Examples](#)
4. [See Also](#)

# Description

The

```
CREATE PACKAGE BODY  
statement can be used when Oracle SQL_MODE is set.
```

The

```
CREATE PACKAGE BODY  
statement creates the package body for a stored package. The package specification must be previously created using the CREATE PACKAGE statement.
```

A package body provides implementations of the package public routines and can optionally have:

- package-wide private variables
- package private routines
- forward declarations for private routines
- an executable initialization section

## Examples

```

SET sql_mode=ORACLE;
DELIMITER $$

CREATE OR REPLACE PACKAGE employee_tools AS
  FUNCTION getSalary(eid INT) RETURN DECIMAL(10,2);
  PROCEDURE raiseSalary(eid INT, amount DECIMAL(10,2));
  PROCEDURE raiseSalaryStd(eid INT);
  PROCEDURE hire(ename TEXT, esalary DECIMAL(10,2));
END;
$$

CREATE PACKAGE BODY employee_tools AS
  -- package body variables
  stdRaiseAmount DECIMAL(10,2):=500;

  -- private routines
  PROCEDURE log (eid INT, ecmnt TEXT) AS
  BEGIN
    INSERT INTO employee_log (id, cmnt) VALUES (eid, ecmnt);
  END;

  -- public routines
  PROCEDURE hire(ename TEXT, esalary DECIMAL(10,2)) AS
    eid INT;
  BEGIN
    INSERT INTO employee (name, salary) VALUES (ename, esalary);
    eid:= last_insert_id();
    log(eid, 'hire ' || ename);
  END;

  FUNCTION getSalary(eid INT) RETURN DECIMAL(10,2) AS
    nSalary DECIMAL(10,2);
  BEGIN
    SELECT salary INTO nSalary FROM employee WHERE id=eid;
    log(eid, 'getSalary id=' || eid || ' salary=' || nSalary);
    RETURN nSalary;
  END;

  PROCEDURE raiseSalary(eid INT, amount DECIMAL(10,2)) AS
  BEGIN
    UPDATE employee SET salary=salary+amount WHERE id=eid;
    log(eid, 'raiseSalary id=' || eid || ' amount=' || amount);
  END;

  PROCEDURE raiseSalaryStd(eid INT) AS
  BEGIN
    raiseSalary(eid, stdRaiseAmount);
    log(eid, 'raiseSalaryStd id=' || eid);
  END;

BEGIN
  -- This code is executed when the current session
  -- accesses any of the package routines for the first time
  log(0, 'Session ' || connection_id() || ' ' || current_user || ' started');
END;
$$

DELIMITER ;

```

  6. [sql\\_mode](#)
  7. [Character Sets and Collations](#)
  8. [Oracle Mode](#)
3. [Examples](#)
4. [See Also](#)

## Description

Creates a [stored procedure](#). By default, a routine is associated with the default database. To associate the routine explicitly with a given database, specify the name as db\_name.sp\_name when you create it.

When the routine is invoked, an implicit USE db\_name is performed (and undone when the routine terminates). This causes the routine to have the given default database while it executes. USE statements within stored routines are disallowed.

When a stored procedure has been created, you invoke it by using the

```
CALL
statement (see CALL ).
```

To execute the

```
CREATE PROCEDURE
statement, it is necessary to have the
CREATE ROUTINE
privilege. By default, MariaDB automatically grants the
ALTER ROUTINE
and
EXECUTE
privileges to the routine creator. See also Stored Routine Privileges.
```

The

```
DEFINER
```

and SQL SECURITY clauses specify the security context to be used when checking access privileges at routine execution time, as described later. Requires the [SUPER](#) privilege, or, from [MariaDB 10.5.2](#), the [SET USER](#) privilege.

If the routine name is the same as the name of a built-in SQL function, you must use a space between the name and the following parenthesis when defining the routine, or a syntax error occurs. This is also true when you invoke the routine later. For this reason, we suggest that it is better to avoid re-using the names of existing SQL functions for your own stored routines.

The IGNORE\_SPACE SQL mode applies to built-in functions, not to stored routines. It is always allowable to have spaces after a routine name, regardless of whether IGNORE\_SPACE is enabled.

The parameter list enclosed within parentheses must always be present. If there are no parameters, an empty parameter list of () should be used.

Parameter names are not case sensitive.

Each parameter can be declared to use any valid data type, except that the COLLATE attribute cannot be used.

For valid identifiers to use as procedure names, see [Identifier Names](#).

## IN/OUT/INOUT

Each parameter is an

IN  
parameter by default. To specify otherwise for a parameter, use the keyword  
OUT  
or  
INOUT  
before the parameter name.

An

IN  
parameter passes a value into a procedure. The procedure might modify the value, but the modification is not visible to the caller when the procedure returns. An  
OUT  
parameter passes a value from the procedure back to the caller. Its initial value is NULL within the procedure, and its value is visible to the caller when the procedure returns. An  
INOUT  
parameter is initialized by the caller, can be modified by the procedure, and any change made by the procedure is visible to the caller when the procedure returns.

For each

OUT  
or  
INOUT  
parameter, pass a user-defined variable in the  
CALL  
statement that invokes the procedure so that you can obtain its value when the procedure returns. If you are calling the procedure from within another stored procedure or function, you can also pass a routine parameter or local routine variable as an  
IN  
or  
INOUT  
parameter.

## DETERMINISTIC/NOT DETERMINISTIC

DETERMINISTIC  
and  
NOT DETERMINISTIC  
apply only to [functions](#). Specifying  
DETERMINISTIC  
or  
NON-DETERMINISTIC  
in procedures has no effect. The default value is  
NOT DETERMINISTIC  
. Functions are  
DETERMINISTIC  
when they always return the same value for the same input. For example, a truncate or substring function. Any function involving data, therefore, is always  
NOT DETERMINISTIC

## CONTAINS SQL/NO SQL/READS SQL DATA/MODIFIES SQL DATA

CONTAINS SQL  
,  
NO SQL  
,  
READS SQL DATA  
, and  
MODIFIES SQL DATA  
are informative clauses that tell the server what the function does. MariaDB does not check in any way whether the specified clause is correct. If none of these clauses are specified,

`CONTAINS SQL`  
is used by default.

`MODIFIES SQL DATA`  
means that the function contains statements that may modify data stored in databases. This happens if the function contains statements like `DELETE`, `UPDATE`, `INSERT`, `REPLACE` or DDL.

`READS SQL DATA`  
means that the function reads data stored in databases, but does not modify any data. This happens if `SELECT` statements are used, but there no write operations are executed.

`CONTAINS SQL`  
means that the function contains at least one SQL statement, but it does not read or write any data stored in a database. Examples include `SET` or `DO`.

`NO SQL`  
means nothing, because MariaDB does not currently support any language other than SQL.

The routine \_body consists of a valid SQL procedure statement. This can be a simple statement such as `SELECT` or `INSERT`, or it can be a compound statement written using `BEGIN` and `END`. Compound statements can contain declarations, loops, and other control structure statements. See [Programmatic and Compound Statements](#) for syntax details.

MariaDB allows routines to contain DDL statements, such as

`CREATE`  
and `DROP`. MariaDB also allows `stored procedures` (but not `stored functions`) to contain SQL transaction statements such as  
`COMMIT`

For additional information about statements that are not allowed in stored routines, see [Stored Routine Limitations](#).

## Invoking stored procedure from within programs

For information about invoking `stored procedures` from within programs written in a language that has a MariaDB/MySQL interface, see [CALL](#).

## OR REPLACE

MariaDB starting with 10.1.3

If the optional

`OR REPLACE`

clause is used, it acts as a shortcut for:

```
DROP PROCEDURE IF EXISTS name;
CREATE PROCEDURE name ...;
```

with the exception that any existing `privileges` for the procedure are not dropped.

## sql\_mode

MariaDB stores the `sql_mode` system variable setting that is in effect at the time a routine is created, and always executes the routine with this setting in force, regardless of the server `SQL mode` in effect when the routine is invoked.

## Character Sets and Collations

Procedure parameters can be declared with any character set/collation. If the character set and collation are not specifically set, the database defaults at the time of creation will be used. If the database defaults change at a later stage, the stored procedure character set/collation will not be changed at the same time; the stored procedure needs to be dropped and recreated to ensure the same character set/collation as the database is used.

## Oracle Mode

MariaDB starting with 10.3

From [MariaDB 10.3](#), a subset of Oracle's PL/SQL language has been supported in addition to the traditional SQL/PSM-based MariaDB syntax. See [Oracle mode from MariaDB 10.3](#) for details on changes when running Oracle mode.

## Examples

The following example shows a simple stored procedure that uses an

OUT

parameter. It uses the DELIMITER command to set a new delimiter for the duration of the process — see [Delimiters in the mysql client](#).

```
DELIMITER //  
  
CREATE PROCEDURE simpleproc (OUT param1 INT)  
BEGIN  
    SELECT COUNT(*) INTO param1 FROM t;  
END;  
//  
  
DELIMITER ;  
  
CALL simpleproc(@a);  
  
SELECT @a;  
+-----+  
| @a   |  
+-----+  
|     1 |  
+-----+
```

Character set and collation:

```
DELIMITER //  
  
CREATE PROCEDURE simpleproc2 (  
    OUT param1 CHAR(10) CHARACTER SET 'utf8' COLLATE 'utf8_bin'  
)  
BEGIN  
    SELECT CONCAT('a'),f1 INTO param1 FROM t;  
END;  
//  
  
DELIMITER ;
```

CREATE OR REPLACE:

```
DELIMITER //  
  
CREATE PROCEDURE simpleproc2 (  
    OUT param1 CHAR(10) CHARACTER SET 'utf8' COLLATE 'utf8_bin'  
)  
BEGIN  
    SELECT CONCAT('a'),f1 INTO param1 FROM t;  
END;  
//  
ERROR 1304 (42000): PROCEDURE simpleproc2 already exists  
  
DELIMITER ;  
  
DELIMITER //  
  
CREATE OR REPLACE PROCEDURE simpleproc2 (  
    OUT param1 CHAR(10) CHARACTER SET 'utf8' COLLATE 'utf8_bin'  
)  
BEGIN  
    SELECT CONCAT('a'),f1 INTO param1 FROM t;  
END;  
//  
ERROR 1304 (42000): PROCEDURE simpleproc2 already exists  
  
DELIMITER ;  
Query OK, 0 rows affected (0.03 sec)
```

## 1.1.3.1.10 CREATE ROLE

## 1.1.3.1.11 CREATE SEQUENCE

MariaDB starting with 10.3

CREATE SEQUENCE was introduced in MariaDB 10.3 .

### Syntax

```
CREATE [OR REPLACE] [TEMPORARY] SEQUENCE [IF NOT EXISTS] sequence_name
[ INCREMENT [ BY | = ] increment ]
[ MINVALUE [=] minvalue | NO MINVALUE | NOMINVALUE ]
[ MAXVALUE [=] maxvalue | NO MAXVALUE | NOMAXVALUE ]
[ START [ WITH | = ] start ]
[ CACHE [=] cache | NOCACHE ] [ CYCLE | NOCYCLE]
[table_options]
```

### Contents

1. [Syntax](#)
2. [Description](#)
  1. [Arguments to Create](#)
  2. [Constraints on Create Arguments](#)
  3. [Atomic DDL](#)
3. [Examples](#)
4. [See Also](#)

The options for

`CREATE SEQUENCE`  
can be given in any order, optionally followed by  
`table_options`

`table_options` can be any of the normal table options in [CREATE TABLE](#) but the most usable ones are

`ENGINE=...`  
and  
`COMMENT=`

`NOMAXVALUE`  
and  
`NOMINVALUE`  
are there to allow one to create SEQUENCES using the Oracle syntax.

### Description

`CREATE SEQUENCE` will create a sequence that generates new values when called with

`NEXT VALUE FOR sequence_name`

. It's an alternative to [AUTO INCREMENT](#) when one wants to have more control of how the numbers are generated. As the SEQUENCE caches values (up to

`CACHE`

) it can in some cases be much faster than [AUTO INCREMENT](#) . Another benefit is that one can access the last value generated by all used sequences, which solves one of the limitations with [LAST\\_INSERT\\_ID\(\)](#) .

`CREATE SEQUENCE` requires the [CREATE privilege](#) .

`DROP SEQUENCE` can be used to drop a sequence, and `ALTER SEQUENCE` to change it.

### Arguments to Create

The following options may be used:

Option	Default value	Description
INCREMENT	1	Increment to use for values. May be negative. Setting an increment of 0 causes the sequence to use the value of the <a href="#">auto_increment_increment</a> system variable at the time of creation, which is always a positive number. (see <a href="#">MDEV-16035</a> ).
MINVALUE	1 if INCREMENT > 0 and -9223372036854775807 if INCREMENT < 0	Minimum value for the sequence
MAXVALUE	9223372036854775806 if INCREMENT > 0 and -1 if INCREMENT < 0	Max value for sequence
START	MINVALUE if INCREMENT > 0 and MAX_VALUE if INCREMENT < 0	First value that the sequence will generate
CACHE	1000	Number of values that should be cached. 0 if no CACHE. The underlying table will be updated first time a new sequence number is generated and each time the cache runs out.

If

CYCLE

is used then the sequence should start again from

MINVALUE

after it has run out of values. Default value is

NOCYCLE

## Constraints on Create Arguments

To be able to create a legal sequence, the following must hold:

- MAXVALUE >= start
- MAXVALUE > MINVALUE
- START >= MINVALUE
- MAXVALUE <= 9223372036854775806 (LONGLONG\_MAX-1)
- MINVALUE >= -9223372036854775807 (LONGLONG\_MIN+1)

Note that sequences can't generate the maximum/minimum 64 bit number because of the constraint of

MINVALUE

and

MAXVALUE

## Atomic DDL

MariaDB starting with [10.6.1](#)

MariaDB [10.6.1](#) supports Atomic DDL and

```
CREATE SEQUENCE
    is atomic.
```

## Examples

```
CREATE SEQUENCE s START WITH 100 INCREMENT BY 10;
CREATE SEQUENCE s2 START WITH -100 INCREMENT BY -10;
```

The following statement fails, as the increment conflicts with the defaults

```
CREATE SEQUENCE s3 START WITH -100 INCREMENT BY 10;
ERROR 4082 (HY000): Sequence 'test.s3' values are conflicting
```

The sequence can be created by specifying workable minimum and maximum values:

```
CREATE SEQUENCE s3 START WITH -100 INCREMENT BY 10 MINVALUE=-100 MAXVALUE=1000;
```

## 1.1.3.1.12 CREATE SERVER

### Syntax

```
CREATE [OR REPLACE] SERVER [IF NOT EXISTS] server_name
    FOREIGN DATA WRAPPER wrapper_name
    OPTIONS (option [, option] ...)

option:
{ HOST character-literal
| DATABASE character-literal
| USER character-literal
| PASSWORD character-literal
| SOCKET character-literal
| OWNER character-literal
| PORT numeric-literal }
```

### Contents

1. [Syntax](#)
2. [Description](#)
  1. [OR REPLACE](#)
  2. [IF NOT EXISTS](#)
3. [Examples](#)
4. [See Also](#)

### Description

This statement creates the definition of a server for use with the [Spider](#) , [Connect](#) , [FEDERATED](#) or [FederatedX](#) storage engine. The CREATE SERVER statement creates a new row within the `servers` table within the `mysql` database. This statement requires the [SUPER](#) privilege or, from [MariaDB 10.5.2](#) , the [FEDERATED ADMIN](#) privilege.

The `server_name` should be a unique reference to the server. Server definitions are global within the scope of the server, it is not possible to qualify the server definition to a specific database. `server_name` has a maximum length of 64 characters (names longer than 64 characters are silently truncated), and is case insensitive. You may specify the name as a quoted string.

The `wrapper_name` may be quoted with single quotes. Supported values are:

- mysql
- mariadb  
(in [MariaDB 10.3](#) and later)

For each option you must specify either a character literal or numeric literal. Character literals are UTF-8, support a maximum length of 64 characters and default to a blank (empty) string. String literals are silently truncated to 64 characters. Numeric literals must be a number between 0 and 9999, default value is 0.

**Note :** The

OWNER  
option is currently not applied, and has no effect on the ownership or operation of the server connection that is created.

The CREATE SERVER statement creates an entry in the `mysql.servers` table that can later be used with the CREATE TABLE statement when creating a [Spider](#) , [Connect](#) , [FederatedX](#) or [FEDERATED](#) table. The options that you specify will be used to populate the columns in the `mysql.servers` table. The table columns are `Server_name`, `Host`, `Db`, `Username`, `Password`, `Port` and `Socket`.

[DROP SERVER](#) removes a previously created server definition.

CREATE SERVER is not written to the [binary log](#) , irrespective of the [binary log format](#) being used. From [MariaDB 10.1.13](#) , [Galera](#) replicates the CREATE SERVER, [ALTER SERVER](#) and [DROP SERVER](#) statements.

For valid identifiers to use as server names, see [Identifier Names](#) .

### OR REPLACE

If the optional  
OR REPLACE  
clause is used, it acts as a shortcut for:

```
DROP SERVER IF EXISTS name;  
CREATE SERVER server_name ...;
```

## IF NOT EXISTS

If the IF NOT EXISTS clause is used, MariaDB will return a warning instead of an error if the server already exists. Cannot be used together with OR REPLACE.

## Examples

```
CREATE SERVER s  
FOREIGN DATA WRAPPER mysql  
OPTIONS (USER 'Remote', HOST '192.168.1.106', DATABASE 'test');
```

OR REPLACE and IF NOT EXISTS:

```
CREATE SERVER s  
FOREIGN DATA WRAPPER mysql  
OPTIONS (USER 'Remote', HOST '192.168.1.106', DATABASE 'test');  
ERROR 1476 (HY000): The foreign server, s, you are trying to create already exists  
  
CREATE OR REPLACE SERVER s  
FOREIGN DATA WRAPPER mysql  
OPTIONS (USER 'Remote', HOST '192.168.1.106', DATABASE 'test');  
Query OK, 0 rows affected (0.00 sec)  
  
CREATE SERVER IF NOT EXISTS s  
FOREIGN DATA WRAPPER mysql  
OPTIONS (USER 'Remote', HOST '192.168.1.106', DATABASE 'test');  
Query OK, 0 rows affected, 1 warning (0.00 sec)  
  
SHOW WARNINGS;  
+-----+-----+  
| Level | Code | Message |  
+-----+-----+  
| Note  | 1476 | The foreign server, s, you are trying to create already exists |  
+-----+-----+
```

## 1.1.3.1.13 CREATE TABLE

## 1.1.3.1.14 CREATE TABLESPACE

The

```
CREATE TABLESPACE
```

statement is not supported by MariaDB. It was originally inherited from MySQL NDB Cluster. In MySQL 5.7 and later, the statement is also supported for InnoDB. However, MariaDB has chosen not to include that specific feature. See [MDEV-19294](#) for more information.

## 1.1.3.1.15 CREATE TRIGGER

## Syntax

```
CREATE [OR REPLACE]
[DEFINER = { user | CURRENT_USER | role | CURRENT_ROLE }]
TRIGGER [IF NOT EXISTS] trigger_name trigger_time trigger_event
ON tbl_name FOR EACH ROW
[ { FOLLOWES | PRECEDES } other_trigger_name ]
trigger_stmt;
```

## Contents

1. [Syntax](#)
2. [Description](#)
  1. [OR REPLACE](#)
  2. [DEFINER](#)
  3. [IF NOT EXISTS](#)
  4. [trigger\\_time](#)
  5. [trigger\\_event](#)
    1. [FOLLOWES/PRECEDES](#)  
[other\\_trigger\\_name](#)
  6. [Atomic DDL](#)
3. [Examples](#)
4. [See Also](#)

## Description

This statement creates a new [trigger](#). A trigger is a named database object that is associated with a table, and that activates when a particular event occurs for the table. The trigger becomes associated with the table named

tbl\_name  
, which must refer to a permanent table. You cannot associate a trigger with a TEMPORARY table or a view.

CREATE TRIGGER  
requires the [TRIGGER](#) privilege for the table associated with the trigger.

MariaDB starting with [10.2.3](#)

You can have multiple triggers for the same

trigger\_time  
and  
trigger\_event

For valid identifiers to use as trigger names, see [Identifier Names](#).

## OR REPLACE

MariaDB starting with [10.1.4](#)

If used and the trigger already exists, instead of an error being returned, the existing trigger will be dropped and replaced by the newly defined trigger.

## DEFINER

The

DEFINER  
clause determines the security context to be used when checking access privileges at trigger activation time. Usage requires the [SUPER](#) privilege, or, from [MariaDB 10.5.2](#), the [SET USER](#) privilege.

## IF NOT EXISTS

MariaDB starting with [10.1.4](#)

If the

IF NOT EXISTS  
clause is used, the trigger will only be created if a trigger of the same name does not exist. If the trigger already exists, by default a warning will be returned.

## trigger\_time

`trigger_time`  
is the trigger action time. It can be  
`BEFORE`  
or  
`AFTER`  
to indicate that the trigger activates before or after each row to be modified.

## trigger\_event

`trigger_event`  
indicates the kind of statement that activates the trigger. The  
`trigger_event`  
can be one of the following:

- `INSERT`  
: The trigger is activated whenever a new row is inserted into the table; for example, through `INSERT`, `LOAD DATA`, and `REPLACE` statements.
- `UPDATE`  
: The trigger is activated whenever a row is modified; for example, through `UPDATE` statements.
- `DELETE`  
: The trigger is activated whenever a row is deleted from the table; for example, through `DELETE` and `REPLACE` statements. However,  
`DROP TABLE`  
and  
`TRUNCATE`  
statements on the table do not activate this trigger, because they do not use  
`DELETE`  
. Dropping a partition does not activate  
`DELETE`  
triggers, either.

## FOLLOWNS/PRECEDES other\_trigger\_name

MariaDB starting with [10.2.3](#)

The

`FOLLOWNS other_trigger_name`  
and  
`PRECEDES other_trigger_name`  
options were added in [MariaDB 10.2.3](#) as part of supporting multiple triggers per action time. This is the same syntax used by MySQL 5.7, although MySQL 5.7 does not have multi-trigger support.

`FOLLOWNS`  
adds the new trigger after another trigger while  
`PRECEDES`  
adds the new trigger before another trigger. If neither option is used, the new trigger is added last for the given action and time.

`FOLLOWNS`  
and  
`PRECEDES`  
are not stored in the trigger definition. However the trigger order is guaranteed to not change over time. `mariadb-dump/mysqldump` and other backup methods will not change trigger order. You can verify the trigger order from the  
`ACTION_ORDER`  
column in `INFORMATION_SCHEMA.TRIGGERS` table.

```
SELECT trigger_name, action_order FROM information_schema.triggers
WHERE event_object_table='t1';
```

## Atomic DDL

MariaDB starting with [10.6.1](#)

[MariaDB 10.6.1](#) supports **Atomic DDL** and  
`CREATE TRIGGER`

is atomic.

## Examples

```
CREATE DEFINER=`root`@`localhost` TRIGGER increment_animal
AFTER INSERT ON animals FOR EACH ROW
UPDATE animal_count SET animal_count.animals = animal_count.animals+1;
```

OR REPLACE and IF NOT EXISTS

```
CREATE DEFINER=`root`@`localhost` TRIGGER increment_animal
AFTER INSERT ON animals FOR EACH ROW
UPDATE animal_count SET animal_count.animals = animal_count.animals+1;
ERROR 1359 (HY000): Trigger already exists

CREATE OR REPLACE DEFINER=`root`@`localhost` TRIGGER increment_animal
AFTER INSERT ON animals FOR EACH ROW
UPDATE animal_count SET animal_count.animals = animal_count.animals+1;
Query OK, 0 rows affected (0.12 sec)

CREATE DEFINER=`root`@`localhost` TRIGGER IF NOT EXISTS increment_animal
AFTER INSERT ON animals FOR EACH ROW
UPDATE animal_count SET animal_count.animals = animal_count.animals+1;
Query OK, 0 rows affected, 1 warning (0.00 sec)

SHOW WARNINGS;
+-----+-----+
| Level | Code | Message      |
+-----+-----+
| Note  | 1359 | Trigger already exists |
+-----+-----+
1 row in set (0.00 sec)
```

### 1.1.3.1.16 CREATE USER

### 1.1.3.1.17 CREATE VIEW

## Syntax

```
CREATE
[OR REPLACE]
[ALGORITHM = {UNDEFINED | MERGE | TEMPTABLE}]
[DEFINER = { user | CURRENT_USER | role | CURRENT_ROLE }]
[SQL SECURITY { DEFINER | INVOKER }]
VIEW [IF NOT EXISTS] view_name [(column_list)]
AS select_statement
[WITH [CASCADED | LOCAL] CHECK OPTION]
```

## Contents

- 1. [Syntax](#)
- 2. [Description](#)
  - 1. [WITH CHECK OPTION](#)
  - 2. [IF NOT EXISTS](#)
  - 3. [Atomic DDL](#)
- 3. [Examples](#)
- 4. [See Also](#)

## Description

The CREATE VIEW statement creates a new [view](#), or replaces an existing one if the OR REPLACE clause is given. If the view does not exist, CREATE OR REPLACE VIEW is the same as CREATE VIEW. If the view does exist, CREATE OR REPLACE VIEW is the same as [ALTER VIEW](#).

The select\_statement is a [SELECT](#) statement that provides the definition of the view. (When you select from the view, you select in effect using the SELECT statement.) select\_statement can select from base tables or other views.

The view definition is "frozen" at creation time, so changes to the underlying tables afterwards do not affect the view definition. For example, if a view is defined as SELECT \* on a table, new columns added to the table later do not become part of the view. A [SHOW CREATE VIEW](#) shows that such queries are rewritten and column names are included in the view definition.

The view definition must be a query that does not return errors at view creation times. However, the base tables used by the views might be altered later and the query may not be valid anymore. In this case, querying the view will result in an error. [CHECK TABLE](#) helps in finding this kind of problems.

The [ALGORITHM clause](#) affects how MariaDB processes the view. The DEFINER and SQL SECURITY clauses specify the security context to be used when checking access privileges at view invocation time. The WITH CHECK OPTION clause can be given to constrain inserts or updates to rows in tables referenced by the view. These clauses are described later in this section.

The CREATE VIEW statement requires the CREATE VIEW privilege for the view, and some privilege for each column selected by the SELECT statement. For columns used elsewhere in the SELECT statement you must have the SELECT privilege. If the OR REPLACE clause is present, you must also have the DROP privilege for the view.

A view belongs to a database. By default, a new view is created in the default database. To create the view explicitly in a given database, specify the name as db\_name.view\_name when you create it.

```
CREATE VIEW test.v AS SELECT * FROM t;
```

Base tables and views share the same namespace within a database, so a database cannot contain a base table and a view that have the same name.

Views must have unique column names with no duplicates, just like base tables. By default, the names of the columns retrieved by the SELECT statement are used for the view column names. To define explicit names for the view columns, the optional column\_list clause can be given as a list of comma-separated identifiers. The number of names in column\_list must be the same as the number of columns retrieved by the SELECT statement.

### MySQL until 5.1.28

Prior to MySQL 5.1.29, When you modify an existing view, the current view definition is backed up and saved. It is stored in that table's database directory, in a subdirectory named arc. The backup file for a view v is named v.frm-00001. If you alter the view again, the next backup is named v.frm-00002. The three latest view backup definitions are stored. Backed up view definitions are not preserved by [mysqldump](#), or any other such programs, but you can retain them using a file copy operation. However, they are not needed for anything but to provide you with a backup of your previous view definition. It is safe to remove these backup definitions, but only while mysqld is not running. If you delete the arc subdirectory or its files while mysqld is running, you will receive an error the next time you try to alter the view:

```
MariaDB [test]> ALTER VIEW v AS SELECT * FROM t;
ERROR 6 (HY000): Error on delete of '.\test\arc\v.frm-0004' (Errcode: 2)
```

Columns retrieved by the SELECT statement can be simple references to table columns. They can also be expressions that use functions, constant values, operators, and so forth.

Unqualified table or view names in the SELECT statement are interpreted with respect to the default database. A view can refer to tables or views in other databases by qualifying the table or view name with the proper database name.

A view can be created from many kinds of SELECT statements. It can refer to base tables or other views. It can use joins, UNION, and subqueries. The SELECT need not even refer to any tables. The following example defines a view that selects two columns from another table, as well as an expression calculated from those columns:

```

CREATE TABLE t (qty INT, price INT);

INSERT INTO t VALUES(3, 50);

CREATE VIEW v AS SELECT qty, price, qty*price AS value FROM t;

SELECT * FROM v;
+-----+-----+
| qty | price | value |
+-----+-----+
|    3 |     50 |    150 |
+-----+-----+

```

A view definition is subject to the following restrictions:

- The SELECT statement cannot contain a subquery in the FROM clause.
- The SELECT statement cannot refer to system or user variables.
- Within a stored program, the definition cannot refer to program parameters or local variables.
- The SELECT statement cannot refer to prepared statement parameters.
- Any table or view referred to in the definition must exist. However, after a view has been created, it is possible to drop a table or view that the definition refers to. In this case, use of the view results in an error. To check a view definition for problems of this kind, use the CHECK TABLE statement.
- The definition cannot refer to a TEMPORARY table, and you cannot create a TEMPORARY view.
- Any tables named in the view definition must exist at definition time.
- You cannot associate a trigger with a view.
- For valid identifiers to use as view names, see [Identifier Names](#).

ORDER BY is allowed in a view definition, but it is ignored if you select from a view using a statement that has its own ORDER BY.

For other options or clauses in the definition, they are added to the options or clauses of the statement that references the view, but the effect is undefined. For example, if a view definition includes a LIMIT clause, and you select from the view using a statement that has its own LIMIT clause, it is undefined which limit applies. This same principle applies to options such as ALL, DISTINCT, or SQL\_SMALL\_RESULT that follow the SELECT keyword, and to clauses such as INTO, FOR UPDATE, and LOCK IN SHARE MODE.

The PROCEDURE clause cannot be used in a view definition, and it cannot be used if a view is referenced in the FROM clause.

If you create a view and then change the query processing environment by changing system variables, that may affect the results that you get from the view:

```

CREATE VIEW v (mycol) AS SELECT 'abc';

SET sql_mode = '';

SELECT "mycol" FROM v;
+-----+
| mycol |
+-----+
| mycol |
+-----+

SET sql_mode = 'ANSI_QUOTES';

SELECT "mycol" FROM v;
+-----+
| mycol |
+-----+
| abc   |
+-----+

```

The DEFINER and SQL SECURITY clauses determine which MariaDB account to use when checking access privileges for the view when a statement is executed that references the view. They were added in MySQL 5.1.2. The legal SQL SECURITY characteristic values are DEFINER and INVOKER. These indicate that the required privileges must be held by the user who defined or invoked the view, respectively. The default SQL SECURITY value is DEFINER.

If a user value is given for the DEFINER clause, it should be a MariaDB account in 'user\_name'@'host\_name' format (the same format used in the GRANT statement). The user\_name and host\_name values both are required. The definer can also be given as CURRENT\_USER or CURRENT\_USER(). The default DEFINER value is the user who executes the CREATE VIEW statement. This is the same as specifying DEFINER = CURRENT\_USER explicitly.

If you specify the DEFINER clause, these rules determine the legal DEFINER user values:

- If you do not have the [SUPER](#) privilege, or, from [MariaDB 10.5.2](#), the [SET USER](#) privilege, the only legal user value is your own account, either specified literally or by using CURRENT\_USER. You cannot set the definer to some other account.
- If you have the [SUPER](#) privilege, or, from [MariaDB 10.5.2](#), the [SET USER](#) privilege, you can specify any syntactically legal account name. If the account does not actually exist, a warning is generated.
- If the SQL SECURITY value is DEFINER but the definer account does not exist when the view is referenced, an error occurs.

Within a view definition, CURRENT\_USER returns the view's DEFINER value by default. For views defined with the SQL SECURITY INVOKER characteristic, CURRENT\_USER returns the account for the view's invoker. For information about user auditing within views, see <http://dev.mysql.com/doc/refman/5.1/en/account-activity-auditing.html>.

Within a stored routine that is defined with the SQL SECURITY DEFINER characteristic, CURRENT\_USER returns the routine's DEFINER value. This also affects a view defined within such a program, if the view definition contains a DEFINER value of CURRENT\_USER.

View privileges are checked like this:

- At view definition time, the view creator must have the privileges needed to use the top-level objects accessed by the view. For example, if the view definition refers to table columns, the creator must have privileges for the columns, as described previously. If the definition refers to a stored function, only the privileges needed to invoke the function can be checked. The privileges required when the function runs can be checked only as it executes: For different invocations of the function, different execution paths within the function might be taken.
- When a view is referenced, privileges for objects accessed by the view are checked against the privileges held by the view creator or invoker, depending on whether the SQL SECURITY characteristic is DEFINER or INVOKER, respectively.
- If reference to a view causes execution of a stored function, privilege checking for statements executed within the function depend on whether the function is defined with a SQL SECURITY characteristic of DEFINER or INVOKER. If the security characteristic is DEFINER, the function runs with the privileges of its creator. If the characteristic is INVOKER, the function runs with the privileges determined by the view's SQL SECURITY characteristic.

Example: A view might depend on a stored function, and that function might invoke other stored routines. For example, the following view invokes a stored function f():

```
CREATE VIEW v AS SELECT * FROM t WHERE t.id = f(t.name);
```

Suppose that f() contains a statement such as this:

```
IF name IS NULL then
  CALL p1();
ELSE
  CALL p2();
END IF;
```

The privileges required for executing statements within f() need to be checked when f() executes. This might mean that privileges are needed for p1() or p2(), depending on the execution path within f(). Those privileges must be checked at runtime, and the user who must possess the privileges is determined by the SQL SECURITY values of the view v and the function f().

The DEFINER and SQL SECURITY clauses for views are extensions to standard SQL. In standard SQL, views are handled using the rules for SQL SECURITY INVOKER.

If you invoke a view that was created before MySQL 5.1.2, it is treated as though it was created with a SQL SECURITY DEFINER clause and with a DEFINER value that is the same as your account. However, because the actual definer is unknown, MySQL issues a warning. To make the warning go away, it is sufficient to re-create the view so that the view definition includes a DEFINER clause.

The optional ALGORITHM clause is an extension to standard SQL. It affects how MariaDB processes the view. ALGORITHM takes three values: MERGE, TEMPTABLE, or UNDEFINED. The default algorithm is UNDEFINED if no ALGORITHM clause is present. See [View Algorithms](#) for more information.

Some views are updatable. That is, you can use them in statements such as UPDATE, DELETE, or INSERT to update the contents of the underlying table. For a view to be updatable, there must be a one-to-one relationship between the rows in the view and the rows in the underlying table. There are also certain other constructs that make a view non-updatable. See [Inserting and Updating with Views](#).

## WITH CHECK OPTION

The WITH CHECK OPTION clause can be given for an updatable view to prevent inserts or updates to rows except those for which the WHERE clause in the select\_statement is true.

In a WITH CHECK OPTION clause for an updatable view, the LOCAL and CASCDED keywords determine the scope of check testing when the view is defined in terms of another view. The LOCAL keyword restricts the CHECK OPTION only to the view being defined. CASCDED causes the checks for underlying views to be evaluated as well. When neither keyword is given, the default is CASCDED.

For more information about updatable views and the WITH CHECK OPTION clause, see [Inserting and Updating with Views](#).

## IF NOT EXISTS

MariaDB starting with 10.1.3

The

```
IF NOT EXISTS
clause was added in MariaDB 10.1.3
```

When the IF NOT EXISTS clause is used, MariaDB will return a warning instead of an error if the specified view already exists. Cannot be used together with the

```
OR REPLACE
clause.
```

## Atomic DDL

MariaDB starting with 10.6.1

MariaDB 10.6.1 supports Atomic DDL and  
CREATE VIEW  
is atomic.

## Examples

```
CREATE TABLE t (a INT, b INT) ENGINE = InnoDB;  
  
INSERT INTO t VALUES (1,1), (2,2), (3,3);  
  
CREATE VIEW v AS SELECT a, a*2 AS a2 FROM t;  
  
SELECT * FROM v;  
+-----+-----+  
| a    | a2   |  
+-----+-----+  
| 1    | 2    |  
| 2    | 4    |  
| 3    | 6    |  
+-----+-----+
```

OR REPLACE and IF NOT EXISTS:

```
CREATE VIEW v AS SELECT a, a*2 AS a2 FROM t;  
ERROR 1050 (42S01): Table 'v' already exists  
  
CREATE OR REPLACE VIEW v AS SELECT a, a*2 AS a2 FROM t;  
Query OK, 0 rows affected (0.04 sec)  
  
CREATE VIEW IF NOT EXISTS v AS SELECT a, a*2 AS a2 FROM t;  
Query OK, 0 rows affected, 1 warning (0.01 sec)  
  
SHOW WARNINGS;  
+-----+-----+  
| Level | Code | Message          |  
+-----+-----+  
| Note  | 1050 | Table 'v' already exists |  
+-----+-----+
```

- [DROP VIEW](#)
- [SHOW CREATE VIEWS](#)
- [INFORMATION SCHEMA VIEWS Table](#)

### 1.1.3.1.18 Silent Column Changes

When a [CREATE TABLE](#) or [ALTER TABLE](#) command is issued, MariaDB will silently change a column specification in the following cases:

- [PRIMARY KEY](#) columns are always NOT NULL.
- Any trailing spaces from [SET](#) and [ENUM](#) values are discarded.
- [TIMESTAMP](#) columns are always NOT NULL, and display sizes are discarded
- A row-size limit of 65535 bytes applies
- If [strict SQL mode](#) is not enabled (it is enabled by default from [MariaDB 10.2](#)), a [VARCHAR](#) column longer than 65535 becomes [TEXT](#), and a [VARBINARY](#) columns longer than 65535 becomes a [BLOB](#). If strict mode is enabled the silent changes will not be made, and an error will occur.
- If a [USING](#) clause specifies an index that's not permitted by the storage engine, the engine will instead use another available index type that can be applied without affecting results.
- If the CHARACTER SET binary attribute is specified, the column is created as the matching binary data type. A [TEXT](#) becomes a [BLOB](#), [CHAR](#) a [BINARY](#) and [VARCHAR](#) a [VARBINARY](#). [ENUMs](#) and [SETs](#) are created as defined.

To ease imports from other RDBMSs, MariaDB will also silently map the following data types:

Other Vendor Type	MariaDB Type
BOOL	TINYINT

BOOLEAN	TINYINT
CHARACTER VARYING(M)	VARCHAR (M)
FIXED	DECIMAL
FLOAT4	FLOAT
FLOAT8	DOUBLE
INT1	TINYINT
INT2	SMALLINT
INT3	MEDIUMINT
INT4	INT
INT8	BIGINT
LONG VARBINARY	MEDIUMBLOB
LONG VARCHAR	MEDIUMTEXT
LONG	MEDIUMTEXT
MIDDLEINT	MEDIUMINT
NUMERIC	DECIMAL

Currently, all MySQL types are supported in MariaDB.

For type mapping between Cassandra and MariaDB, see [Cassandra storage engine](#).

## Example

Silent changes in action:

```
CREATE TABLE SilenceIsGolden
(
  f1 TEXT CHARACTER SET binary,
  f2 VARCHAR(15) CHARACTER SET binary,
  f3 CHAR CHARACTER SET binary,
  f4 ENUM('x','y','z') CHARACTER SET binary,
  f5 VARCHAR (65536),
  f6 VARBINARY (65536),
  f7 INT1
);
Query OK, 0 rows affected, 2 warnings (0.31 sec)

SHOW WARNINGS;
+-----+-----+
| Level | Code | Message |
+-----+-----+
| Note  | 1246 | Converting column 'f5' from VARCHAR to TEXT |
| Note  | 1246 | Converting column 'f6' from VARBINARY to BLOB |
+-----+-----+

DESCRIBE SilenceIsGolden;
+-----+-----+-----+-----+-----+
| Field | Type          | Null | Key | Default | Extra |
+-----+-----+-----+-----+-----+
| f1    | blob          | YES  |     | NULL    |       |
| f2    | varbinary(15) | YES  |     | NULL    |       |
| f3    | binary(1)     | YES  |     | NULL    |       |
| f4    | enum('x','y','z') | YES  |     | NULL    |       |
| f5    | mediumtext    | YES  |     | NULL    |       |
| f6    | mediumblob   | YES  |     | NULL    |       |
| f7    | tinyint(4)    | YES  |     | NULL    |       |
+-----+-----+-----+-----+-----+
```

### 1.1.3.1.19 Generated (Virtual and Persistent/Stored) Columns

#### Syntax

```
<type> [GENERATED ALWAYS] AS ( <expression> )
[VIRTUAL | PERSISTENT | STORED] [UNIQUE] [UNIQUE KEY] [COMMENT <text>]
```

## Contents

- 7. [See Also](#)

MariaDB's generated columns syntax is designed to be similar to the syntax for [Microsoft SQL Server's computed columns](#) and [Oracle Database's virtual columns](#). In [MariaDB 10.2](#) and later, the syntax is also compatible with the syntax for [MySQL's generated columns](#).

## Description

A generated column is a column in a table that cannot explicitly be set to a specific value in a [DML query](#). Instead, its value is automatically generated based on an expression. This expression might generate the value based on the values of other columns in the table, or it might generate the value by calling [built-in functions](#) or [user-defined functions \(UDFs\)](#).

There are two types of generated columns:

- - PERSISTENT
    - (a.k.a.
    - STORED
  - ): This type's value is actually stored in the table.
- - VIRTUAL
    - : This type's value is not stored at all. Instead, the value is generated dynamically when the table is queried. This type is the default.

Generated columns are also sometimes called computed columns or virtual columns.

## Supported Features

### Storage Engine Support

- Generated columns can only be used with storage engines which support them. If you try to use a storage engine that does not support them, then you will see an error similar to the following:

```
ERROR 1910 (HY000): TokuDB storage engine does not support computed columns
```

- [InnoDB](#), [Aria](#), [MyISAM](#) and [CONNECT](#) support generated columns.
- A column in a [MERGE](#) table can be built on a
  - PERSISTENT
    - generated column.
  - However, a column in a MERGE table can **not** be defined as a
    - VIRTUAL
    - and
    - PERSISTENT
    - generated column.

### Data Type Support

- All data types are supported when defining generated columns.
- Using the

[ZEROFILL](#)

column option is supported when defining generated columns.

#### MariaDB starting with 10.2.6

In MariaDB 10.2.6 and later, the following statements apply to data types for generated columns:

- Using the

AUTO\_INCREMENT

column option is **not** supported when defining generated columns. Previously, it was supported, but this support was removed, because it would not work correctly. See [MDEV-11117](#).

## Index Support

- Using a generated column as a table's primary key is **not** supported. See [MDEV-5590](#) for more information. If you try to use one as a primary key, then you will see an error similar to the following:

ERROR 1903 (HY000): Primary key cannot be defined upon a computed column

- Using

PERSISTENT

generated columns as part of a [foreign key](#) is supported.

- Referencing

PERSISTENT

generated columns as part of a [foreign key](#) is also supported.

- However, using the

ON UPDATE CASCADE

,

ON UPDATE SET NULL

, or

ON DELETE SET NULL

clauses is **not** supported. If you try to use an unsupported clause, then you will see an error similar to the following:

ERROR 1905 (HY000): Cannot define foreign key with ON UPDATE SET NULL clause on a computed column

#### MariaDB starting with 10.2.3

In MariaDB 10.2.3 and later, the following statements apply to indexes for generated columns:

- Defining indexes on both

VIRTUAL

and

PERSISTENT

generated columns is supported.

- If an index is defined on a generated column, then the optimizer considers using it in the same way as indexes based on "real" columns.

#### MariaDB until 10.2.2

In MariaDB 10.2.2 and before, the following statements apply to indexes for generated columns:

- Defining indexes on

VIRTUAL

generated columns is **not** supported.

- Defining indexes on

PERSISTENT

generated columns is supported.

- If an index is defined on a generated column, then the optimizer considers using it in the same way as indexes based on "real" columns.

## Statement Support

- Generated columns are used in [DML queries](#) just as if they were "real" columns.

- However,

VIRTUAL

and

PERSISTENT

generated columns differ in how their data is stored.

- Values for

PERSISTENT

generated columns are generated whenever a [DML queries](#) inserts or updates the row with the special

DEFAULT

value. This generates the columns value, and it is stored in the table like the other "real" columns. This value can be read by other [DML queries](#) just like the other "real" columns.

▪ Values for

VIRTUAL

generated columns are not stored in the table. Instead, the value is generated dynamically whenever the column is queried. If other columns in a row are queried, but the

VIRTUAL

generated column is not one of the queried columns, then the column's value is not generated.

- The

[SELECT](#)

statement supports generated columns.

- Generated columns can be referenced in the

[INSERT](#)

,

[UPDATE](#)

, and

[DELETE](#)

statements.

- However,

VIRTUAL

or

PERSISTENT

generated columns cannot be explicitly set to any other values than

NULL

or

[DEFAULT](#)

. If a generated column is explicitly set to any other value, then the outcome depends on whether [strict mode](#) is enabled in

[sql\\_mode](#)

. If it is not enabled, then a warning will be raised and the default generated value will be used instead. If it is enabled, then an error will be raised instead.

- The

[CREATE TABLE](#)

statement has limited support for generated columns.

- It supports defining generated columns in a new table.
- It supports using generated columns to [partition tables](#).
- It does **not** support using the [versioning clauses](#) with generated columns.

- The

[ALTER TABLE](#)

statement has limited support for generated columns.

- It supports the

MODIFY

and

CHANGE

clauses for

PERSISTENT

generated columns.

- It does **not** support the

MODIFY

clause for

VIRTUAL

generated columns if

#### ALGORITHM

is not set to  
COPY  
. See [MDEV-15476](#) for more information.

- It does **not** support the  
CHANGE  
clause for  
VIRTUAL  
generated columns if

#### ALGORITHM

is not set to  
COPY  
. See [MDEV-17035](#) for more information.

- It does **not** support altering a table if

#### ALGORITHM

is not set to  
COPY  
if the table has a  
VIRTUAL  
generated column that is indexed. See [MDEV-14046](#) for more information.

- It does **not** support adding a  
VIRTUAL  
generated column with the  
ADD  
clause if the same statement is also adding other columns if

#### ALGORITHM

is not set to  
COPY  
. See [MDEV-17468](#) for more information.

- It also does **not** support altering an existing column into a  
VIRTUAL  
generated column.
- It supports using generated columns to [partition tables](#) .
- It does **not** support using the [versioning clauses](#) with generated columns.

- The

#### SHOW CREATE TABLE

statement supports generated columns.

- The

#### DESCRIBE

statement can be used to check whether a table has generated columns.

- You can tell which columns are generated by looking for the ones where the  
Extra  
column is set to either  
VIRTUAL  
or  
PERSISTENT  
. For example:

```
DESCRIBE table1;
+-----+-----+-----+-----+
| Field | Type      | Null | Key | Default | Extra      |
+-----+-----+-----+-----+
| a     | int(11)   | NO   |     | NULL    |            |
| b     | varchar(32)| YES  |     | NULL    |            |
| c     | int(11)   | YES  |     | NULL    | VIRTUAL    |
| d     | varchar(5) | YES  |     | NULL    | PERSISTENT |
+-----+-----+-----+-----+
```

- Generated columns can be properly referenced in the

NEW  
and  
OLD  
rows in triggers .

- Stored procedures support generated columns.
- The

HANDLER

statement supports generated columns.

## Expression Support

- Most legal, deterministic expressions which can be calculated are supported in expressions for generated columns.
- Most [built-in functions](#) are supported in expressions for generated columns.
  - However, some [built-in functions](#) can't be supported for technical reasons. For example, If you try to use an unsupported function in an expression, an error is generated similar to the following:

```
ERROR 1901 (HY000): Function or expression 'dayname()' cannot be used in the GENERATED ALWAYS AS clause of `v`
```

- [Subqueries](#) are **not** supported in expressions for generated columns because the underlying data can change.
- Using anything that depends on data outside the row is **not** supported in expressions for generated columns.
- [Stored functions](#) are **not** supported in expressions for generated columns. See [MDEV-17587](#) for more information.

### MariaDB starting with 10.2.1

In MariaDB 10.2.1 and later, the following statements apply to expressions for generated columns:

- Non-deterministic [built-in functions](#) are supported in expressions for not indexed  
VIRTUAL  
generated columns.
- Non-deterministic [built-in functions](#) are **not** supported in expressions for  
PERSISTENT  
or indexed  
VIRTUAL  
generated columns.
- [User-defined functions \(UDFs\)](#) are supported in expressions for generated columns.
  - However, MariaDB can't check whether a UDF is deterministic, so it is up to the user to be sure that they do not use non-deterministic UDFs with  
VIRTUAL  
generated columns.
- Defining a generated column based on other generated columns defined before it in the table definition is supported. For example:

```
CREATE TABLE t1 (a int as (1), b int as (a));
```

- However, defining a generated column based on other generated columns defined after in the table definition is **not** supported in expressions for generation columns because generated columns are calculated in the order they are defined.
- Using an expression that exceeds 255 characters in length is supported in expressions for generated columns. The new limit for the entire table definition, including all expressions for generated columns, is 65,535 bytes.
- Using constant expressions is supported in expressions for generated columns. For example:

```
CREATE TABLE t1 (a int as (1));
```

### MariaDB until 10.2.0

In MariaDB 10.2.0 and before, the following statements apply to expressions for generated columns:

- Non-deterministic [built-in functions](#) are **not** supported in expressions for generated columns.
- [User-defined functions \(UDFs\)](#) are **not** supported in expressions for generated columns.
- Defining a generated column based on other generated columns defined in the table is **not** supported. Otherwise, it would generate errors like this:

```
ERROR 1900 (HY000): A computed column cannot be based on a computed column
```

- Using an expression that exceeds 255 characters in length is **not** supported in expressions for generated columns.
- Using constant expressions is **not** supported in expressions for generated columns. Otherwise, it would generate errors like this:

```
ERROR 1908 (HY000): Constant expression in computed column function is not allowed
```

## Making Stored Values Consistent

When a generated column is

PERSISTENT

or indexed, the value of the expression needs to be consistent regardless of the

[SQL Mode](#)

flags in the current session. If it is not, then the table will be seen as corrupted when the value that should actually be returned by the computed expression and the value that was previously stored and/or indexed using a different

[sql\\_mode](#)

setting disagree.

There are currently two affected classes of inconsistencies: character padding and unsigned subtraction:

- For a

VARCHAR

or

TEXT

generated column the length of the value returned can vary depending on the PAD\_CHAR\_TO\_FULL\_LENGTH

[sql\\_mode](#)

flag. To make the value consistent, create the generated column using an RTRIM() or RPAD() function. Alternately, create the generated column as a

CHAR

column so that its data is always fully padded.

- If a

SIGNED

generated column is based on the subtraction of an

UNSIGNED

value, the resulting value can vary depending on how large the value is and the NO\_UNSIGNED\_SUBTRACTION

[sql\\_mode](#)

flag. To make the value consistent, use

[CAST\(\)](#)

to ensure that each

UNSIGNED

operand is

SIGNED

before the subtraction.

MariaDB starting with [10.5](#)

Beginning in [MariaDB 10.5](#), there is a fatal error generated when trying to create a generated column whose value can change depending on the

[SQL Mode](#)

when its data is

PERSISTENT

or indexed.

For an existing generated column that has a potentially inconsistent value, a warning about a bad expression is generated the first time it is used (if warnings are enabled).

Beginning in [MariaDB 10.4.8](#), [MariaDB 10.3.18](#), and [MariaDB 10.2.27](#) a potentially inconsistent generated column outputs a warning when created or first used (without restricting their creation).

Here is an example of two tables that would be rejected in [MariaDB 10.5](#) and warned about in the other listed versions:

```

CREATE TABLE bad_pad (
    txt CHAR(5),
    -- CHAR -> VARCHAR or CHAR -> TEXT can't be persistent or indexed:
    vtxt VARCHAR(5) AS (txt) PERSISTENT
);

CREATE TABLE bad_sub (
    num1 BIGINT UNSIGNED,
    num2 BIGINT UNSIGNED,
    -- The resulting value can vary for some large values
    vnum BIGINT AS (num1 - num2) VIRTUAL,
    KEY(vnum)
);

```

The warnings for the above tables look like this:

```

Warning (Code 1901): Function or expression ``txt`` cannot be used in the GENERATED ALWAYS AS clause of `vtxt`
Warning (Code 1105): Expression depends on the @@sql_mode value PAD_CHAR_TO_FULL_LENGTH

Warning (Code 1901): Function or expression ``num1`` - ``num2`` cannot be used in the GENERATED ALWAYS AS clause of `vnum`
Warning (Code 1105): Expression depends on the @@sql_mode value NO_UNSIGNED_SUBTRACTION

```

To work around the issue, force the padding or type to make the generated column's expression return a consistent value. For example:

```

CREATE TABLE good_pad (
    txt CHAR(5),
    -- Using RTRIM() or RPAD() makes the value consistent:
    vtxt VARCHAR(5) AS (RTRIM(txt)) PERSISTENT,
    -- When not persistent or indexed, it is OK for the value to vary by mode:
    vtxt2 VARCHAR(5) AS (txt) VIRTUAL,
    -- CHAR -> CHAR is always OK:
    txt2 CHAR(5) AS (txt) PERSISTENT
);

CREATE TABLE good_sub (
    num1 BIGINT UNSIGNED,
    num2 BIGINT UNSIGNED,
    -- The indexed value will always be consistent in this expression:
    vnum BIGINT AS (CAST(num1 AS SIGNED) - CAST(num2 AS SIGNED)) VIRTUAL,
    KEY(vnum)
);

```

## MySQL Compatibility Support

MariaDB starting with 10.2.1

In MariaDB 10.2.1 and later, the following statements apply to MySQL compatibility for generated columns:

- The **STORED**  
keyword is supported as an alias for the  
**PERSISTENT**  
keyword.
- Tables created with MySQL 5.7 or later that contain [MySQL's generated columns](#) can be imported into MariaDB without a dump and restore.

MariaDB until 10.2.0

In MariaDB 10.2.0 and before, the following statements apply to MySQL compatibility for generated columns:

- The **STORED**  
keyword is **not** supported as an alias for the  
**PERSISTENT**  
keyword.
- Tables created with MySQL 5.7 or later that contain [MySQL's generated columns](#) can **not** be imported into MariaDB without a dump and restore.

## Implementation Differences

Generated columns are subject to various constraints in other DBMSs that are not present in MariaDB's implementation. Generated columns may also be called computed columns or virtual columns in different implementations. The various details for a specific implementation can be found in the

documentation for each specific DBMS.

## Implementation Differences Compared to Microsoft SQL Server

MariaDB's generated columns implementation does not enforce the following restrictions that are present in Microsoft SQL Server's computed columns implementation:

- MariaDB allows [server variables](#) in generated column expressions, including those that change dynamically, such as

`warning_count`

- MariaDB allows the

`CONVERT_TZ()`

function to be called with a named [time zone](#) as an argument, even though time zone names and time offsets are configurable.

- MariaDB allows the

`CAST()`

function to be used with non-unicode [character sets](#), even though character sets are configurable and differ between binaries/versions.

- MariaDB allows

`FLOAT`

expressions to be used in generated columns. Microsoft SQL Server considers these expressions to be "imprecise" due to potential cross-platform differences in floating-point implementations and precision.

- Microsoft SQL Server requires the

`ARITHABORT`

mode to be set, so that division by zero returns an error, and not a NULL.

- Microsoft SQL Server requires

`QUOTED_IDENTIFIER`

to be set in

`sql_mode`

. In MariaDB, if data is inserted without

`ANSI_QUOTES`

set in

`sql_mode`

, then it will be processed and stored differently in a generated column that contains quoted identifiers.

- In [MariaDB 10.2.0](#) and before, it does not allow [user-defined functions \(UDFs\)](#) to be used in expressions for generated columns.

Microsoft SQL Server enforces the above restrictions by doing one of the following things:

- Refusing to create computed columns.
- Refusing to allow updates to a table containing them.
- Refusing to use an index over such a column if it can not be guaranteed that the expression is fully deterministic.

In MariaDB, as long as the

`sql_mode`

, language, and other settings that were in effect during the CREATE TABLE remain unchanged, the generated column expression will always be evaluated the same. If any of these things change, then please be aware that the generated column expression might not be evaluated the same way as it previously was.

In [MariaDB 5.2](#) , you will get a warning if you try to update a virtual column. In [MariaDB 5.3](#) and later, this warning will be converted to an error if [strict mode](#) is enabled in

`sql_mode`

## Development History

Generated columns was originally developed by Andrey Zhakov. It was then modified by Sanja Byelkin and Igor Babaev at Monty Program for inclusion in MariaDB. Monty did the work on [MariaDB 10.2](#) to lift a some of the old limitations.

# Examples

Here is an example table that uses both

VIRTUAL  
and  
PERSISTENT  
virtual columns:

```
USE TEST;

CREATE TABLE table1 (
    a INT NOT NULL,
    b VARCHAR(32),
    c INT AS (a mod 10) VIRTUAL,
    d VARCHAR(5) AS (left(b,5)) PERSISTENT);
```

If you describe the table, you can easily see which columns are virtual by looking in the "Extra" column:

```
DESCRIBE table1;
+-----+-----+-----+-----+
| Field | Type      | Null | Key | Default | Extra       |
+-----+-----+-----+-----+
| a     | int(11)   | NO   |     | NULL    |             |
| b     | varchar(32) | YES  |     | NULL    |             |
| c     | int(11)   | YES  |     | NULL    | VIRTUAL     |
| d     | varchar(5) | YES  |     | NULL    | PERSISTENT |
+-----+-----+-----+-----+
```

To find out what function(s) generate the value of the virtual column you can use

```
SHOW CREATE TABLE
:
```

```
SHOW CREATE TABLE table1;

| table1 | CREATE TABLE `table1` (
  `a` int(11) NOT NULL,
  `b` varchar(32) DEFAULT NULL,
  `c` int(11) AS (a mod 10) VIRTUAL,
  `d` varchar(5) AS (left(b,5)) PERSISTENT
) ENGINE=MyISAM DEFAULT CHARSET=latin1 |
```

If you try to insert non-default values into a virtual column, you will receive a warning and what you tried to insert will be ignored and the derived value inserted instead:

```
WARNINGS;
Show warnings enabled.

INSERT INTO table1 VALUES (1, 'some text', default, default);
Query OK, 1 row affected (0.00 sec)

INSERT INTO table1 VALUES (2, 'more text', 5, default);
Query OK, 1 row affected, 1 warning (0.00 sec)

Warning (Code 1645): The value specified for computed column 'c' in table 'table1' has been ignored.

INSERT INTO table1 VALUES (123, 'even more text', default, 'something');
Query OK, 1 row affected, 2 warnings (0.00 sec)

Warning (Code 1645): The value specified for computed column 'd' in table 'table1' has been ignored.
Warning (Code 1265): Data truncated for column 'd' at row 1

SELECT * FROM table1;
+-----+-----+-----+
| a   | b       | c     | d     |
+-----+-----+-----+
| 1   | some text | 1   | some  |
| 2   | more text  | 2   | more  |
| 123 | even more text | 3   | even  |
+-----+-----+-----+
3 rows in set (0.00 sec)
```

If the

ZEROFILL

clause is specified, it should be placed directly after the type definition, before the  
AS (<expression>  
:  
:

```
CREATE TABLE table2 (a INT, b INT ZEROFILL AS (a*2) VIRTUAL);
INSERT INTO table2 (a) VALUES (1);

SELECT * FROM table2;
+-----+
| a    | b   |
+-----+
| 1   | 000000002 |
+-----+
1 row in set (0.00 sec)
```

You can also use virtual columns to implement a "poor man's partial index". See example at the end of [Unique Index](#).

## See Also

- [Putting Virtual Columns to good use](#) on the mariadb.com blog.

### 1.1.3.1.20 Invisible Columns

MariaDB starting with [10.3.3](#)

Invisible columns (sometimes also called hidden columns) first appeared in [MariaDB 10.3.3](#).

Columns can be given an

INVISIBLE

attribute in a [CREATE TABLE](#) or [ALTER TABLE](#) statement. These columns will then not be listed in the results of a [SELECT \\*](#) statement, nor do they need to be assigned a value in an [INSERT](#) statement, unless INSERT explicitly mentions them by name.

Since

[SELECT \\*](#)

does not return the invisible columns, new tables or views created in this manner will have no trace of the invisible columns. If specifically referenced in the [SELECT](#) statement, the columns will be brought into the view/new table, but the INVISIBLE attribute will not.

Invisible columns can be declared as

[NOT NULL](#)

, but then require a

[DEFAULT](#)

value.

It is not possible for all columns in a table to be invisible.

## Examples

```

CREATE TABLE t (x INT INVISIBLE);
ERROR 1113 (42000): A table must have at least 1 column

CREATE TABLE t (x INT, y INT INVISIBLE, z INT INVISIBLE NOT NULL);
ERROR 4106 (HY000): Invisible column `z` must have a default value

CREATE TABLE t (x INT, y INT INVISIBLE, z INT INVISIBLE NOT NULL DEFAULT 4);

INSERT INTO t VALUES (1),(2);

INSERT INTO t (x,y) VALUES (3,33);

SELECT * FROM t;
+---+
| x |
+---+
| 1 |
| 2 |
| 3 |
+---+

SELECT x,y,z FROM t;
+---+---+---+
| x | y | z |
+---+---+---+
| 1 | NULL | 4 |
| 2 | NULL | 4 |
| 3 | 33 | 4 |
+---+---+---+

DESC t;
+-----+-----+-----+-----+-----+
| Field | Type | Null | Key | Default | Extra |
+-----+-----+-----+-----+-----+
| x | int(11) | YES | | NULL | |
| y | int(11) | YES | | NULL | INVISIBLE |
| z | int(11) | NO | | 4 | INVISIBLE |
+-----+-----+-----+-----+-----+

ALTER TABLE t MODIFY x INT INVISIBLE, MODIFY y INT, MODIFY z INT NOT NULL DEFAULT 4;

DESC t;
+-----+-----+-----+-----+-----+
| Field | Type | Null | Key | Default | Extra |
+-----+-----+-----+-----+-----+
| x | int(11) | YES | | NULL | INVISIBLE |
| y | int(11) | YES | | NULL | |
| z | int(11) | NO | | 4 | |
+-----+-----+-----+-----+-----+

```

Creating a view from a table with hidden columns:

```

CREATE VIEW v1 AS SELECT * FROM t;

DESC v1;
+-----+-----+-----+-----+-----+
| Field | Type | Null | Key | Default | Extra |
+-----+-----+-----+-----+-----+
| y | int(11) | YES | | NULL | |
| z | int(11) | NO | | 4 | |
+-----+-----+-----+-----+-----+

CREATE VIEW v2 AS SELECT x,y,z FROM t;

DESC v2;
+-----+-----+-----+-----+-----+
| Field | Type | Null | Key | Default | Extra |
+-----+-----+-----+-----+-----+
| x | int(11) | YES | | NULL | |
| y | int(11) | YES | | NULL | |
| z | int(11) | NO | | 4 | |
+-----+-----+-----+-----+-----+

```

## 1.1.3.2 ALTER

## 1.1.3.2.1 ALTER TABLE

## 1.1.3.2.2 ALTER DATABASE

## 1.1.3.2.3 ALTER EVENT

## 1.1.3.2.4 ALTER FUNCTION

## 1.1.3.2.5 ALTER LOGFILE GROUP

## 1.1.3.2.6 ALTER PROCEDURE

## 1.1.3.2.7 ALTER SEQUENCE

## 1.1.3.2.8 ALTER SERVER

## 1.1.3.2.9 ALTER TABLESPACE

## 1.1.3.2.10 ALTER USER

## 1.1.3.2.11 ALTER VIEW

## 1.1.3.3 DROP

### 1.1.3.3.1 DROP DATABASE

## Syntax

```
DROP {DATABASE | SCHEMA} [IF EXISTS] db_name
```

## Contents

- 1. [Syntax](#)
- 2. [Description](#)
  - 1. [IF EXISTS](#)
  - 2. [Atomic DDL](#)
- 3. [Examples](#)
- 4. [See Also](#)

## Description

`DROP DATABASE`

drops all tables in the database and deletes the database. Be very careful with this statement! To use `DROP DATABASE`, you need the [DROP privilege](#) on the database.

`DROP SCHEMA`

is a synonym for

`DROP DATABASE`

**Important:** When a database is dropped, user privileges on the database are not automatically dropped. See [GRANT](#).

### IF EXISTS

Use

`IF EXISTS`

to prevent an error from occurring for databases that do not exist. A

`NOTE`

is generated for each non-existent database when using  
IF EXISTS  
. See [SHOW WARNINGS](#).

## Atomic DDL

MariaDB starting with [10.6.1](#)

MariaDB [10.6.1](#) supports [Atomic DDL](#).

DROP DATABASE  
is implemented as

```
loop over all tables
DROP TABLE table
```

Each individual [DROP TABLE](#) is atomic while

DROP DATABASE  
as a whole is crash-safe.

## Examples

```
DROP DATABASE bufg;
Query OK, 0 rows affected (0.39 sec)

DROP DATABASE bufg;
ERROR 1008 (HY000): Can't drop database 'bufg'; database doesn't exist

\W
Show warnings enabled.

DROP DATABASE IF EXISTS bufg;
Query OK, 0 rows affected, 1 warning (0.00 sec)
Note (Code 1008): Can't drop database 'bufg'; database doesn't exist
```

## See Also

- [CREATE DATABASE](#)
- [ALTER DATABASE](#)
- [SHOW DATABASES](#)
- [Information Schema SCHEMATA Table](#)
- [SHOW CREATE DATABASE](#)

### 1.1.3.3.2 DROP EVENT

#### Syntax

```
DROP EVENT [IF EXISTS] event_name
```

#### Description

This statement drops the [event](#) named

[event\\_name](#)  
. The event immediately ceases being active, and is deleted completely from the server.

If the event does not exist, the error

ERROR 1517 (HY000): Unknown event 'event\_name'  
results. You can override this and cause the statement to generate a  
NOTE  
for non-existent events instead by using  
IF EXISTS  
. See

[SHOW WARNINGS](#)

This statement requires the

EVENT

privilege. In MySQL 5.1.11 and earlier, an event could be dropped only by its definer, or by a user having the

SUPER

privilege.

## Examples

```
DROP EVENT myevent3;
```

Using the IF EXISTS clause:

```
DROP EVENT IF EXISTS myevent3;
Query OK, 0 rows affected, 1 warning (0.01 sec)

SHOW WARNINGS;
+-----+-----+
| Level | Code | Message |
+-----+-----+
| Note  | 1305 | Event myevent3 does not exist |
+-----+-----+
```

## See also

- [Events Overview](#)
- [CREATE EVENT](#)
- [SHOW CREATE EVENT](#)
- [ALTER EVENT](#)

### 1.1.3.3.3 DROP FUNCTION

## Syntax

```
DROP FUNCTION [IF EXISTS] f_name
```

### Contents

1. [Syntax](#)
2. [Description](#)
  - 1. [IF EXISTS](#)
3. [Examples](#)
4. [See Also](#)

## Description

The DROP FUNCTION statement is used to drop a [stored function](#) or a user-defined function (UDF). That is, the specified routine is removed from the server, along with all privileges specific to the function. You must have the

ALTER ROUTINE  
privilege for the routine in order to drop it. If the [automatic\\_sp\\_privileges](#) server system variable is set, both the  
ALTER ROUTINE  
and  
EXECUTE  
privileges are granted automatically to the routine creator - see [Stored Routine Privileges](#).

### IF EXISTS

The

IF EXISTS  
clause is a MySQL/MariaDB extension. It prevents an error from occurring if the function does not exist. A  
NOTE  
is produced that can be viewed with [SHOW WARNINGS](#).

For dropping a [user-defined functions](#) (UDF), see [DROP FUNCTION UDF](#).

## Examples

```
DROP FUNCTION hello;
Query OK, 0 rows affected (0.042 sec)

DROP FUNCTION hello;
ERROR 1305 (42000): FUNCTION test.hello does not exist

DROP FUNCTION IF EXISTS hello;
Query OK, 0 rows affected, 1 warning (0.000 sec)

SHOW WARNINGS;
+-----+-----+
| Level | Code | Message           |
+-----+-----+
| Note  | 1305 | FUNCTION test.hello does not exist |
+-----+-----+
```

## See Also

- [DROP PROCEDURE](#)
- [Stored Function Overview](#)
- [CREATE FUNCTION](#)
- [CREATE FUNCTION UDF](#)
- [ALTER FUNCTION](#)
- [SHOW CREATE FUNCTION](#)
- [SHOW FUNCTION STATUS](#)
- [Stored Routine Privileges](#)
- [INFORMATION\\_SCHEMA ROUTINES Table](#)

### 1.1.3.3.4 DROP FUNCTION UDF

## Syntax

```
DROP FUNCTION [IF EXISTS] function_name
```

## Contents

1. [Syntax](#)
2. [Description](#)
  1. [Upgrading a UDF](#)
3. [Examples](#)

## Description

This statement drops the user-defined function (UDF) named  
function\_name

To drop a function, you must have the

```
DELETE privilege
```

for the mysql database. This is because

```
DROP FUNCTION
```

removes the row from the `mysql.func` system table that records the function's name, type and shared library name.

For dropping a stored function, see [DROP FUNCTION](#).

## Upgrading a UDF

To upgrade the UDF's shared library, first run a [DROP FUNCTION](#) statement, then upgrade the shared library and finally run the [CREATE FUNCTION](#) statement. If you upgrade without following this process, you may crash the server.

## Examples

```
DROP FUNCTION jsoncontains_path;
```

IF EXISTS:

```
DROP FUNCTION jsoncontains_path;
ERROR 1305 (42000): FUNCTION test.jsoncontains_path does not exist

DROP FUNCTION IF EXISTS jsoncontains_path;
Query OK, 0 rows affected, 1 warning (0.00 sec)

SHOW WARNINGS;
+-----+-----+
| Level | Code | Message |
+-----+-----+
| Note  | 1305 | FUNCTION test.jsoncontains_path does not exist |
+-----+-----+
```

## 1.1.3.3.5 DROP INDEX

### Syntax

```
DROP INDEX [IF EXISTS] index_name ON tbl_name
    [WAIT n | NOWAIT]
```

### Contents

1. [Syntax](#)
2. [Description](#)
3. [Privileges](#)
4. [Online DDL](#)
5. [DROP INDEX IF EXISTS ...](#)
6. [WAIT/NOWAIT](#)
7. [Progress Reporting](#)
8. [See Also](#)

### Description

```
DROP INDEX
drops the index named
index_name
from the table
tbl_name
. This statement is mapped to an
ALTER TABLE
statement to drop the index.
```

If another connection is using the table, a [metadata lock](#) is active, and this statement will wait until the lock is released. This is also true for non-transactional tables.

See

[ALTER TABLE](#)

Another shortcut,

[CREATE INDEX](#)

, allows the creation of an index.

To remove the primary key,

`PRIMARY`  
must be specified as index\_name. Note that [the quotes](#) are necessary, because  
PRIMARY  
is a keyword.

### Privileges

Executing the

[DROP INDEX](#)

statement requires the

#### INDEX

privilege for the table or the database.

## Online DDL

Online DDL is used by default with InnoDB, when the drop index operation supports it.

See [InnoDB Online DDL Overview](#) for more information on online DDL with InnoDB .

### DROP INDEX IF EXISTS ...

If the

IF EXISTS

clause is used, then MariaDB will return a warning instead of an error if the index does not exist.

### WAIT/NOWAIT

MariaDB starting with 10.3.0

Set the lock wait timeout. See [WAIT](#) and [NOWAIT](#) .

## Progress Reporting

MariaDB provides progress reporting for

DROP INDEX

statement for clients that support the new progress reporting protocol. For example, if you were using the

mysql

client, then the progress report might look like this::

## See Also

- [Getting Started with Indexes](#)
- [CREATE INDEX](#)
- [ALTER TABLE](#)

### 1.1.3.3.6 DROP LOGFILE GROUP

The

DROP LOGFILE GROUP

statement is not supported by MariaDB. It was originally inherited from MySQL NDB Cluster. See [MDEV-19295](#) for more information.

### 1.1.3.3.7 DROP PACKAGE

MariaDB starting with 10.3.5

Oracle-style packages were introduced in [MariaDB 10.3.5](#) .

## Syntax

```
DROP PACKAGE [IF EXISTS] [ db_name . ] package_name
```

## Contents

1. [Syntax](#)
2. [Description](#)
3. [See Also](#)

## Description

The

```
DROP PACKAGE  
statement can be used when Oracle SQL_MODE is set.
```

The

```
DROP PACKAGE  
statement drops a stored package entirely.
```

- Drops the package specification (earlier created using the [CREATE PACKAGE](#) statement).
- Drops the package implementation, if the implementation was already created using the [CREATE PACKAGE BODY](#) statement.

## See Also

- [SHOW CREATE PACKAGE](#)
- [CREATE PACKAGE](#)
- [CREATE PACKAGE BODY](#)
- [DROP PACKAGE BODY](#)
- [Oracle SQL\\_MODE](#)

## 1.1.3.3.8 DROP PACKAGE BODY

MariaDB starting with [10.3.5](#)

Oracle-style packages were introduced in [MariaDB 10.3.5](#).

## Syntax

```
DROP PACKAGE BODY [IF EXISTS] [ db_name . ] package_name
```

## Contents

1. [Syntax](#)
2. [Description](#)
3. [See also](#)

## Description

The

```
DROP PACKAGE BODY  
statement can be used when Oracle SQL_MODE is set.
```

The

```
DROP PACKAGE BODY  
statement drops the package body (i.e the implementation), previously created using the CREATE PACKAGE BODY statement.
```

Note,

```
DROP PACKAGE BODY  
drops only the package implementation, but does not drop the package specification. Use DROP PACKAGE to drop the package entirely (i.e. both implementation and specification).
```

## See also

- [CREATE PACKAGE](#)
- [SHOW CREATE PACKAGE](#)
- [DROP PACKAGE](#)
- [CREATE PACKAGE BODY](#)
- [SHOW CREATE PACKAGE BODY](#)
- [Oracle SQL\\_MODE](#)

## 1.1.3.3.9 DROP PROCEDURE

# Syntax

```
DROP PROCEDURE [IF EXISTS] sp_name
```

## Contents

1. [Syntax](#)
2. [Description](#)
3. [Examples](#)
4. [See Also](#)

## Description

This statement is used to drop a [stored procedure](#). That is, the specified routine is removed from the server along with all privileges specific to the [procedure](#). You must have the

ALTER ROUTINE  
privilege for the routine. If the

`automatic_sp_privileges`

server system variable is set, that privilege and  
`EXECUTE`  
are granted automatically to the routine creator - see [Stored Routine Privileges](#).

The

`IF EXISTS`  
clause is a MySQL/MariaDB extension. It prevents an error from occurring if the procedure or function does not exist. A  
`NOTE`  
is produced that can be viewed with

`SHOW WARNINGS`

While this statement takes effect immediately, threads which are executing a procedure can continue execution.

## Examples

```
DROP PROCEDURE simpleproc;
```

IF EXISTS:

```
DROP PROCEDURE simpleproc;
ERROR 1305 (42000): PROCEDURE test.simpleproc does not exist

DROP PROCEDURE IF EXISTS simpleproc;
Query OK, 0 rows affected, 1 warning (0.00 sec)

SHOW WARNINGS;
+-----+-----+
| Level | Code | Message |
+-----+-----+
| Note  | 1305 | PROCEDURE test.simpleproc does not exist |
+-----+-----+
```

## See Also

- [DROP FUNCTION](#)
- [Stored Procedure Overview](#)
- [CREATE PROCEDURE](#)
- [ALTER PROCEDURE](#)
- [SHOW CREATE PROCEDURE](#)
- [SHOW PROCEDURE STATUS](#)
- [Information Schema ROUTINES Table](#)

## 1.1.3.3.10 DROP ROLE

## 1.1.3.3.11 DROP SEQUENCE

MariaDB starting with [10.3](#)

DROP SEQUENCE was introduced in [MariaDB 10.3](#).

### Syntax

```
DROP [TEMPORARY] SEQUENCE [IF EXISTS] /*COMMENT TO SAVE*/
sequence_name [, sequence_name] ...
```

### Contents

1. [Syntax](#)
2. [Description](#)
3. [Notes](#)
4. [See Also](#)

### Description

`DROP SEQUENCE`

removes one or more sequences created with [CREATE SEQUENCE](#). You must have the

`DROP`

privilege for each sequence. MariaDB returns an error indicating by name which non-existing tables it was unable to drop, but it also drops all of the tables in the list that do exist.

Important: When a table is dropped, user privileges on the table are not automatically dropped. See [GRANT](#).

If another connection is using the sequence, a metadata lock is active, and this statement will wait until the lock is released. This is also true for non-transactional tables.

For each referenced sequence, `DROP SEQUENCE` drops a temporary sequence with that name, if it exists. If it does not exist, and the

`TEMPORARY`

keyword is not used, it drops a non-temporary sequence with the same name, if it exists. The

`TEMPORARY`

keyword ensures that a non-temporary sequence will not accidentally be dropped.

Use

`IF EXISTS`

to prevent an error from occurring for sequences that do not exist. A NOTE is generated for each non-existent sequence when using

`IF EXISTS`

. See [SHOW WARNINGS](#).

`DROP SEQUENCE` requires the [DROP privilege](#).

### Notes

`DROP SEQUENCE` only removes sequences, not tables. However, [DROP TABLE](#) can remove both sequences and tables.

### See Also

- [Sequence Overview](#)
- [CREATE SEQUENCE](#)
- [ALTER SEQUENCE](#)
- [DROP TABLE](#)

## 1.1.3.3.12 DROP SERVER

### Syntax

```
DROP SERVER [ IF EXISTS ] server_name
```

## Contents

1. [Syntax](#)
2. [Description](#)
  - 1. [IF EXISTS](#)
3. [Examples](#)
4. [See Also](#)

## Description

Drops the server definition for the server named `server_name`. The corresponding row within the [mysql.servers table](#) will be deleted. This statement requires the [SUPER](#) privilege or, from MariaDB 10.5.2, the [FEDERATED ADMIN](#) privilege.

Dropping a server for a table does not affect any [FederatedX](#), [FEDERATED](#), [Connect](#) or [Spider](#) tables that used this connection information when they were created.

`DROP SERVER` is not written to the [binary log](#), irrespective of the [binary log format](#) being used. From MariaDB 10.1.13, Galera replicates the [CREATE SERVER](#), [ALTER SERVER](#) and `DROP SERVER` statements.

### IF EXISTS

If the IF EXISTS clause is used, MariaDB will not return an error if the server does not exist. Unlike all other statements, `DROP SERVER` IF EXISTS does not issue a note if the server does not exist. See [MDEV-9400](#).

## Examples

```
DROP SERVER s;
```

IF EXISTS:

```
DROP SERVER s;
ERROR 1477 (HY000): The foreign server name you are trying to reference
does not exist. Data source error: s
```

```
DROP SERVER IF EXISTS s;
Query OK, 0 rows affected (0.00 sec)
```

## See Also

- [CREATE SERVER](#)
- [ALTER SERVER](#)
- [Spider Storage Engine](#)
- [FederatedX Storage Engine](#)
- [Connect Storage Engine](#)

### 1.1.3.3.13 DROP TABLE

### 1.1.3.3.14 DROP TABLESPACE

The

```
DROP TABLESPACE
```

statement is not supported by MariaDB. It was originally inherited from MySQL NDB Cluster. In MySQL 5.7 and later, the statement is also supported for InnoDB. However, MariaDB has chosen not to include that specific feature. See [MDEV-19294](#) for more information.

### 1.1.3.3.15 DROP TRIGGER

## Syntax

```
DROP TRIGGER [IF EXISTS] [schema_name.]trigger_name
```

## Contents

1. [Syntax](#)
2. [Description](#)
  - 1. [Atomic DDL](#)
3. [Examples](#)
4. [See Also](#)

## Description

This statement drops a [trigger](#). The schema (database) name is optional. If the schema is omitted, the trigger is dropped from the default schema. Its use requires the

TRIGGER  
privilege for the table associated with the trigger.

Use

IF EXISTS  
to prevent an error from occurring for a trigger that does not exist. A  
NOTE  
is generated for a non-existent trigger when using  
IF EXISTS  
. See [SHOW WARNINGS](#).

**Note:** Triggers for a table are also dropped if you drop the table.

## Atomic DDL

MariaDB starting with 10.6.1

MariaDB 10.6.1 supports [Atomic DDL](#) and

DROP TRIGGER  
is atomic.

## Examples

```
DROP TRIGGER test.example_trigger;
```

Using the IF EXISTS clause:

```
DROP TRIGGER IF EXISTS test.example_trigger;  
Query OK, 0 rows affected, 1 warning (0.01 sec)  
  
SHOW WARNINGS;  
+-----+-----+  
| Level | Code | Message           |  
+-----+-----+  
| Note  | 1360 | Trigger does not exist |  
+-----+-----+
```

## See Also

- [Trigger Overview](#)
- [CREATE TRIGGER](#)
- [Information Schema TRIGGERS Table](#)
- [SHOW TRIGGERS](#)
- [SHOW CREATE TRIGGER](#)
- [Trigger Limitations](#)

### 1.1.3.3.16 DROP USER

### 1.1.3.3.17 DROP VIEW

## Syntax

```
DROP VIEW [IF EXISTS]
view_name [, view_name] ...
[RESTRICT | CASCADE]
```

## Contents

1. [Syntax](#)
2. [Description](#)
3. [Atomic DDL](#)
4. [Examples](#)
5. [See Also](#)

## Description

DROP VIEW

removes one or more [views](#). You must have the DROP privilege for each view. If any of the views named in the argument list do not exist, MariaDB returns an error indicating by name which non-existing views it was unable to drop, but it also drops all of the views in the list that do exist.

The

IF EXISTS

clause prevents an error from occurring for views that don't exist. When this clause is given, a

NOTE

is generated for each non-existent view. See [SHOW WARNINGS](#).

RESTRICT

and

CASCADE

, if given, are parsed and ignored.

It is possible to specify view names as

db\_name

.

view\_name

. This is useful to delete views from multiple databases with one statement. See [Identifier Qualifiers](#) for details.

The [DROP privilege](#) is required to use

DROP TABLE

on non-temporary tables. For temporary tables, no privilege is required, because such tables are only visible for the current session.

If a view references another view, it will be possible to drop the referenced view. However, the other view will reference a view which does not exist any more. Thus, querying it will produce an error similar to the following:

```
ERROR 1356 (HY000): View 'db_name.view_name' references invalid table(s) or
column(s) or function(s) or definer/invoker of view lack rights to use them
```

This problem is reported in the output of [CHECK TABLE](#).

Note that it is not necessary to use

DROP VIEW

to replace an existing view, because

[CREATE VIEW](#)

has an

OR REPLACE

clause.

## Atomic DDL

MariaDB starting with [10.6.1](#)

[MariaDB 10.6.1](#) supports [Atomic DDL](#) and

DROP VIEW

for a singular view is atomic. Dropping multiple views is crash-safe.

## Examples

```
DROP VIEW v,v2;
```

Given views

v  
and  
v2  
, but no view  
v3

```
DROP VIEW v,v2,v3;  
ERROR 1051 (42S02): Unknown table 'v3'
```

```
DROP VIEW IF EXISTS v,v2,v3;  
Query OK, 0 rows affected, 1 warning (0.01 sec)
```

```
SHOW WARNINGS;  
+-----+-----+  
| Level | Code | Message |  
+-----+-----+  
| Note | 1051 | Unknown table 'test.v3' |  
+-----+-----+
```

## See Also

- [CREATE VIEW](#)
- [ALTER VIEW](#)
- [SHOW CREATE VIEWS](#)
- [INFORMATION SCHEMA VIEWS Table](#)

### 1.1.3.4

### 1.1.3.5 CONSTRAINT

MariaDB supports the implementation of constraints at the table-level using either [CREATE TABLE](#) or [ALTER TABLE](#) statements. A table constraint restricts the data you can add to the table. If you attempt to insert invalid data on a column, MariaDB throws an error.

## Syntax

```
[CONSTRAINT [symbol]] constraint_expression  
  
constraint_expression:  
| PRIMARY KEY [index_type] (index_col_name, ...) [index_option] ...  
| FOREIGN KEY [index_name] (index_col_name, ...) REFERENCES tbl_name (index_col_name, ...)  
  [ON DELETE reference_option]  
  [ON UPDATE reference_option]  
| UNIQUE [INDEX|KEY] [index_name] [index_type] (index_col_name, ...) [index_option] ...  
| CHECK (check_constraints)  
  
index_type:  
  USING {BTREE | HASH | RTREE}  
  
index_col_name:  
  col_name [(length)] [ASC | DESC]  
  
index_option:  
  | KEY_BLOCK_SIZE [=] value  
  | index_type  
  | WITH PARSER parser_name  
  | COMMENT 'string'  
  | CLUSTERING={YES|NO}  
  
reference_option:  
  RESTRICT | CASCADE | SET NULL | NO ACTION | SET DEFAULT
```

## Contents

1. [Syntax](#)
2. [Description](#)
  1. [FOREIGN KEY Constraints](#)
  2. [CHECK Constraints](#)
  3. [Replication](#)
  4. [Auto\\_increment](#)
3. [Examples](#)
4. [See Also](#)

## Description

Constraints provide restrictions on the data you can add to a table. This allows you to enforce data integrity from MariaDB, rather than through application logic. When a statement violates a constraint, MariaDB throws an error.

There are four types of table constraints:

Constraint	Description
PRIMARY KEY	Sets the column for referencing rows. Values must be unique and not null.
FOREIGN KEY	Sets the column to reference the primary key on another table.
UNIQUE	Requires values in column or columns only occur once in the table.
CHECK	Checks whether the data meets the given condition.

The [Information Schema TABLE\\_CONSTRAINTS Table](#) contains information about tables that have constraints.

## FOREIGN KEY Constraints

InnoDB supports [foreign key](#) constraints. The syntax for a foreign key constraint definition in InnoDB looks like this:

```
[CONSTRAINT [symbol]] FOREIGN KEY  
    [index_name] (index_col_name, ...)  
    REFERENCES tbl_name (index_col_name,...)  
    [ON DELETE reference_option]  
    [ON UPDATE reference_option]  
  
reference_option:  
    RESTRICT | CASCADE | SET NULL | NO ACTION
```

The [Information Schema REFERENTIAL\\_CONSTRAINTS](#) table has more information about foreign keys.

## CHECK Constraints

MariaDB starting with [10.2.1](#)

From [MariaDB 10.2.1](#), constraints are enforced. Before [MariaDB 10.2.1](#) constraint expressions were accepted in the syntax but ignored.

In [MariaDB 10.2.1](#) you can define constraints in 2 different ways:

- - ```
CHECK(expression)
```

given as part of a column definition.
- ```
CONSTRAINT [constraint_name] CHECK (expression)
```

Before a row is inserted or updated, all constraints are evaluated in the order they are defined. If any constraint expression returns false, then the row will not be inserted or updated. One can use most deterministic functions in a constraint, including [UDFs](#).

```
CREATE TABLE t1 (a INT CHECK (a>2), b INT CHECK (b>2), CONSTRAINT a_greater CHECK (a>b));
```

If you use the second format and you don't give a name to the constraint, then the constraint will get an automatically generated name. This is done so

that you can later delete the constraint with `ALTER TABLE DROP constraint_name`.

One can disable all constraint expression checks by setting the `check_constraint_checks` variable to

`OFF`

. This is useful for example when loading a table that violates some constraints that you want to later find and fix in SQL.

## Replication

In [row-based replication](#), only the master checks constraints, and failed statements will not be replicated. In [statement-based replication](#), the slaves will also check constraints. Constraints should therefore be identical, as well as deterministic, in a replication environment.

## Auto\_increment

MariaDB starting with 10.2.6

- From MariaDB 10.2.6, `auto_increment` columns are no longer permitted in check constraints. Previously they were permitted, but would not work correctly. See [MDEV-11117](#).

## Examples

```
CREATE TABLE product (category INT NOT NULL, id INT NOT NULL,
                      price DECIMAL,
                      PRIMARY KEY(category, id)) ENGINE=INNODB;
CREATE TABLE customer (id INT NOT NULL,
                      PRIMARY KEY (id)) ENGINE=INNODB;
CREATE TABLE product_order (no INT NOT NULL AUTO_INCREMENT,
                           product_category INT NOT NULL,
                           product_id INT NOT NULL,
                           customer_id INT NOT NULL,
                           PRIMARY KEY(no),
                           INDEX (product_category, product_id),
                           FOREIGN KEY (product_category, product_id)
                             REFERENCES product(category, id)
                             ON UPDATE CASCADE ON DELETE RESTRICT,
                           INDEX (customer_id),
                           FOREIGN KEY (customer_id)
                             REFERENCES customer(id)) ENGINE=INNODB;
```

MariaDB starting with 10.2.1

The following examples will work from MariaDB 10.2.1 onwards.

Numeric constraints and comparisons:

```
CREATE TABLE t1 (a INT CHECK (a>2), b INT CHECK (b>2), CONSTRAINT a_greater CHECK (a>b));

INSERT INTO t1(a) VALUES (1);
ERROR 4022 (23000): CONSTRAINT `a` failed for `test`.`t1`

INSERT INTO t1(a,b) VALUES (3,4);
ERROR 4022 (23000): CONSTRAINT `a_greater` failed for `test`.`t1`

INSERT INTO t1(a,b) VALUES (4,3);
Query OK, 1 row affected (0.04 sec)
```

Dropping a constraint:

```
ALTER TABLE t1 DROP CONSTRAINT a_greater;
```

Adding a constraint:

```
ALTER TABLE t1 ADD CONSTRAINT a_greater CHECK (a>b);
```

Date comparisons and character length:

```

CREATE TABLE t2 (name VARCHAR(30) CHECK (CHAR_LENGTH(name)>2), start_date DATE,
end_date DATE CHECK (start_date IS NULL OR end_date IS NULL OR start_date<end_date));

INSERT INTO t2(name, start_date, end_date) VALUES('Ione', '2003-12-15', '2014-11-09');
Query OK, 1 row affected (0.04 sec)

INSERT INTO t2(name, start_date, end_date) VALUES('Io', '2003-12-15', '2014-11-09');
ERROR 4222 (23000): CONSTRAINT `name` failed for `test`.`t2`

INSERT INTO t2(name, start_date, end_date) VALUES('Ione', NULL, '2014-11-09');
Query OK, 1 row affected (0.04 sec)

INSERT INTO t2(name, start_date, end_date) VALUES('Ione', '2015-12-15', '2014-11-09');
ERROR 4222 (23000): CONSTRAINT `end_date` failed for `test`.`t2`

```

A misplaced parenthesis:

```

CREATE TABLE t3 (name VARCHAR(30) CHECK (CHAR_LENGTH(name)>2), start_date DATE,
end_date DATE CHECK (start_date IS NULL OR end_date IS NULL OR start_date<end_date));
Query OK, 0 rows affected (0.32 sec)

INSERT INTO t3(name, start_date, end_date) VALUES('Io', '2003-12-15', '2014-11-09');
Query OK, 1 row affected, 1 warning (0.04 sec)

SHOW WARNINGS;
+-----+-----+
| Level | Code | Message           |
+-----+-----+
| Warning | 1292 | Truncated incorrect DOUBLE value: 'Io' |
+-----+-----+

```

Compare the definition of table *t2* to table *t3*.

CHAR\_LENGTH(name)>2

is very different to

CHAR\_LENGTH(name)>2)

as the latter mistakenly performs a numeric comparison on the *name* field, leading to unexpected results.

### 1.1.3.6 MERGE

#### Contents

1. [Description](#)
2. [Examples](#)

## Description

The MERGE storage engine, also known as the MRG\_MyISAM engine, is a collection of identical MyISAM tables that can be used as one. "Identical" means that all tables have identical column and index information. You cannot merge MyISAM tables in which the columns are listed in a different order, do not have exactly the same columns, or have the indexes in different order. However, any or all of the MyISAM tables can be compressed with `myisampack`. Columns names and indexes names can be different, as long as data types and NULL/NOT NULL clauses are the same. Differences in table options such as AVG\_ROW\_LENGTH, MAX\_ROWS, or PACK\_KEYS do not matter.

Each index in a MERGE table must match an index in underlying MyISAM tables, but the opposite is not true. Also, a MERGE table cannot have a PRIMARY KEY or UNIQUE indexes, because it cannot enforce uniqueness over all underlying tables.

The following options are meaningful for MERGE tables:

- - UNION
    - . This option specifies the list of the underlying MyISAM tables. The list is enclosed between parentheses and separated with commas.
- - INSERT\_METHOD
    - . This option specifies whether, and how, INSERTs are allowed for the table. Allowed values are:
      - NO
      - (INSERTs are not allowed),
      - FIRST
      - (new rows will be written into the first table specified in the
      - UNION
      - list),

```

LAST
(new rows will be written into the last table specified in the
UNION
list). The default value is
NO
.

```

If you define a MERGE table with a definition which is different from the underlying MyISAM tables, or one of the underlying tables is not MyISAM, the CREATE TABLE statement will not return any error. But any statement which involves the table will produce an error like the following:

```
ERROR 1168 (HY000): Unable to open underlying table which is differently defined
or of non-MyISAM type or doesn't exist
```

A

[CHECK TABLE](#)

will show more information about the problem.

The error is also produced if the table is properly define, but an underlying table's definition changes at some point in time.

If you try to insert a new row into a MERGE table with INSERT\_METHOD=NO, you will get an error like the following:

```
ERROR 1036 (HY000): Table 'tbl_name' is read only
```

It is possible to build a MERGE table on MyISAM tables which have one or more [virtual columns](#). MERGE itself does not support virtual columns, thus such columns will be seen as regular columns. The data types and sizes will still need to be identical, and they cannot be NOT NULL.

## Examples

```

CREATE TABLE t1 (
    a INT NOT NULL AUTO_INCREMENT PRIMARY KEY,
    message CHAR(20) ENGINE=MyISAM;

CREATE TABLE t2 (
    a INT NOT NULL AUTO_INCREMENT PRIMARY KEY,
    message CHAR(20) ENGINE=MyISAM;

INSERT INTO t1 (message) VALUES ('Testing'),('table'),('t1');

INSERT INTO t2 (message) VALUES ('Testing'),('table'),('t2');

CREATE TABLE total (
    a INT NOT NULL AUTO_INCREMENT,
    message CHAR(20), INDEX(a))
ENGINE=MERGE UNION=(t1,t2) INSERT_METHOD=LAST;

SELECT * FROM total;
+-----+
| a | message |
+-----+
| 1 | Testing |
| 2 | table   |
| 3 | t1      |
| 1 | Testing |
| 2 | table   |
| 3 | t2      |
+-----+

```

In the following example, we'll create three MyISAM tables, and then a MERGE table on them. However, one of them uses a different data type for the column b, so a SELECT will produce an error:

```

CREATE TABLE t1 (
  a INT,
  b INT
) ENGINE = MyISAM;

CREATE TABLE t2 (
  a INT,
  b INT
) ENGINE = MyISAM;

CREATE TABLE t3 (
  a INT,
  b TINYINT
) ENGINE = MyISAM;

CREATE TABLE t_mrg (
  a INT,
  b INT
) ENGINE = MERGE,UNION=(t1,t2,t3);

SELECT * FROM t_mrg;
ERROR 1168 (HY000): Unable to open underlying table which is differently defined
or of non-MyISAM type or doesn't exist

```

To find out what's wrong, we'll use a CHECK TABLE:

Table	Op	Msg_type	Msg_text
test.t_mrg	check	Error	Table 'test.t3' is differently defined or of non-MyISAM type or doesn't exist
test.t_mrg	check	Error	Unable to open underlying table which is differently defined or of non-MyISAM type or doesn't
test.t_mrg	check	error	Corrupt

Now, we know that the problem is in

t3  
's definition.

## Description

`SELECT` is used to retrieve rows selected from one or more tables, and can include [UNION](#) statements and [subqueries](#).

- Each `select_expr` expression indicates a column or data that you want to retrieve. You must have at least one select expression. See [Select Expressions](#) below.
- The
 

```
FROM
clause indicates the table or tables from which to retrieve rows. Use either a single table name or a
JOIN
expression. See JOIN for details. If no table is involved, FROM DUAL can be specified.
```
- Each table can also be specified as
 

```
db_name
```

```

tbl_name
. Each column can also be specified as
tbl_name

.
col_name
or even
db_name

.
tbl_name

.
col_name
. This allows one to write queries which involve multiple databases. See Identifier Qualifiers for syntax details.

```

- The

WHERE

clause, if given, indicates the condition or conditions that rows must satisfy to be selected.

where\_condition

is an expression that evaluates to true for each row to be selected. The statement selects all rows if there is no WHERE clause.

- In the

WHERE

clause, you can use any of the functions and operators that MariaDB supports, except for aggregate (summary) functions. See [Functions and Operators](#) and [Functions and Modifiers for use with GROUP BY](#) (aggregate).

- Use the [ORDER BY](#) clause to order the results.

- Use the [LIMIT](#) clause allows you to restrict the results to only a certain number of rows, optionally with an offset.

- Use the [GROUP BY](#) and

HAVING

clauses to group rows together when they have columns or computed values in common.

SELECT can also be used to retrieve rows computed without reference to any table.

## Select Expressions

A

SELECT

statement must contain one or more select expressions, separated by commas. Each select expression can be one of the following:

- The name of a column.
- Any expression using [functions and operators](#).
- 

\*

to select all columns from all tables in the

FROM

clause.

- 

tbl\_name.\*

to select all columns from just the table *tbl\_name*.

When specifying a column, you can either use just the column name or qualify the column name with the name of the table using

tbl\_name.col\_name

. The qualified form is useful if you are joining multiple tables in the

FROM

clause. If you do not qualify the column names when selecting from multiple tables, MariaDB will try to find the column in each table. It is an error if that column name exists in multiple tables.

You can quote column names using backticks. If you are qualifying column names with table names, quote each part separately as

`tbl\_name`.`col\_name`

If you use any [grouping functions](#) in any of the select expressions, all rows in your results will be implicitly grouped, as if you had used

GROUP BY NULL

## DISTINCT

A query may produce some identical rows. By default, all rows are retrieved, even when their values are the same. To explicitly specify that you want to retrieve identical rows, use the

ALL

option. If you want duplicates to be removed from the resultset, use the

DISTINCT

option.

DISTINCTROW

is a synonym for

DISTINCT  
. See also [COUNT DISTINCT](#) and [SELECT UNIQUE](#) in Oracle mode .

## INTO

The

INTO  
clause is used to specify that the query results should be written to a file or variable.

- [SELECT INTO OUTFILE](#) - formatting and writing the result to an external file.
- [SELECT INTO DUMPFILE](#) - binary-safe writing of the unformatted results to an external file.
- [SELECT INTO Variable](#) - selecting and setting variables.

The reverse of

SELECT INTO OUTFILE  
is [LOAD DATA](#) .

## LIMIT

Restricts the number of returned rows. See [LIMIT](#) and [LIMIT ROWS EXAMINED](#) for details.

## LOCK IN SHARE MODE/FOR UPDATE

See [LOCK IN SHARE MODE](#) and [FOR UPDATE](#) for details on the respective locking clauses.

## OFFSET ... FETCH

MariaDB starting with 10.6

See [SELECT ... OFFSET ... FETCH](#) .

## ORDER BY

Order a resultset. See [ORDER BY](#) for details.

## PARTITION

Specifies to the optimizer which partitions are relevant for the query. Other partitions will not be read. See [Partition Pruning and Selection](#) for details.

## PROCEDURE

Passes the whole result set to a C Procedure. See [PROCEDURE](#) and [PROCEDURE ANALYSE](#) (the only built-in procedure not requiring the server to be recompiled).

## SKIP LOCKED

MariaDB starting with 10.6

The SKIP LOCKED clause was introduced in [MariaDB 10.6.0](#) .

This causes those rows that couldn't be locked ( [LOCK IN SHARE MODE](#) or [FOR UPDATE](#) ) to be excluded from the result set. An explicit  
NOWAIT  
is implied here. This is only implemented on [InnoDB](#) tables and ignored otherwise.

## SQL\_CALC\_FOUND\_ROWS

When

`SQL_CALC_FOUND_ROWS`

is used, then MariaDB will calculate how many rows would have been in the result, if there would be no [LIMIT](#) clause. The result can be found by calling the function [FOUND\\_ROWS\(\)](#) in your next sql statement.

## max\_statement\_time clause

By using [max\\_statement\\_time](#) in conjunction with [SET STATEMENT](#) , it is possible to limit the execution time of individual queries. For example:

```
SET STATEMENT max_statement_time=100 FOR
SELECT field1 FROM table_name ORDER BY field1;
```

## WAIT/NOWAIT

Set the lock wait timeout. See [WAIT](#) and [NOWAIT](#).

## Examples

```
SELECT f1,f2 FROM t1 WHERE (f3<=10) AND (f4='y');
```

See [Getting Data from MariaDB](#) (Beginner tutorial), or the various sub-articles, for more examples.

### 1.1.4.1.2 Joins and Subqueries

#### 1.1.4.1.2.1 Joins

##### 1.1.4.1.2.1.1 Joining Tables with JOIN Clauses

In the absence of a more tutorial-level document, here is a simple example of three basic JOIN types, which you can experiment with in order to see what the different joins accomplish:

```
CREATE TABLE t1 ( a INT );
CREATE TABLE t2 ( b INT );
INSERT INTO t1 VALUES (1), (2), (3);
INSERT INTO t2 VALUES (2), (4);
SELECT * FROM t1 INNER JOIN t2 ON t1.a = t2.b;
SELECT * FROM t1 CROSS JOIN t2;
SELECT * FROM t1 LEFT JOIN t2 ON t1.a = t2.b;
SELECT * FROM t2 LEFT JOIN t1 ON t1.a = t2.b;
```

The first two SELECTs are (unfortunately) commonly written with an older form:

```
SELECT * FROM t1, t2 WHERE t1.a = t2.b;
SELECT * FROM t1, t2;
```

What you can see from this is that an **INNER JOIN** produces a result set containing only rows that have a match, in both tables (t1 and t2), for the specified join condition(s).

A **CROSS JOIN** produces a result set in which every row in each table is joined to every row in the other table; this is also called a **cartesian product**. In MariaDB the CROSS keyword can be omitted, as it does nothing. Any JOIN without an ON clause is a CROSS JOIN.

The **LEFT JOIN** is an **outer join**, which produces a result set with all rows from the table on the "left" (t1); the values for the columns in the other table (t2) depend on whether or not a match was found. If no match is found, all columns from that table are set to NULL for that row.

The **RIGHT JOIN** is similar to the LEFT JOIN, though its resultset contains all rows from the right table, and the left table's columns will be filled with NULLS when needed.

JOINS can be concatenated to read results from three or more tables.

Here is the output of the various SELECT statements listed above:

```
SELECT * FROM t1 INNER JOIN t2 ON t1.a = t2.b;
-----
| a      | b      |
-----
| 2      | 2      |
-----
1 row in set (0.00 sec)
```

```
SELECT * FROM t1 CROSS JOIN t2;
-----
| a      | b      |
-----
| 1      | 2      |
| 2      | 2      |
| 3      | 2      |
| 1      | 4      |
| 2      | 4      |
| 3      | 4      |
-----
6 rows in set (0.00 sec)
```

```
SELECT * FROM t1 LEFT JOIN t2 ON t1.a = t2.b;
-----
| a      | b      |
-----
| 1      | NULL  |
| 2      | 2      |
| 3      | NULL  |
-----
3 rows in set (0.00 sec)
```

```
SELECT * FROM t2 LEFT JOIN t1 ON t1.a = t2.b;
-----
| b      | a      |
-----
| 2      | 2      |
| 4      | NULL  |
-----
2 rows in set (0.00 sec)
```

That should give you a bit more understanding of how JOINS work!

This article is a follow up to the [Introduction to JOINS](#) page. If you're just getting started with JOINS, go through that page first and then come back here.

## The Employee Database

Let us begin by using an example employee database of a fairly small family business, which does not anticipate expanding in the future.

First, we create the table that will hold all of the employees and their contact information:

```
CREATE TABLE `Employees` (
  `ID` TINYINT(3) UNSIGNED NOT NULL AUTO_INCREMENT,
  `First_Name` VARCHAR(25) NOT NULL,
  `Last_Name` VARCHAR(25) NOT NULL,
  `Position` VARCHAR(25) NOT NULL,
  `Home_Address` VARCHAR(50) NOT NULL,
  `Home_Phone` VARCHAR(12) NOT NULL,
  PRIMARY KEY (`ID`)
) ENGINE=MyISAM;
```

Next, we add a few employees to the table:

```
INSERT INTO `Employees` (`First_Name`, `Last_Name`, `Position`, `Home_Address`, `Home_Phone`)
VALUES
('Mustapha', 'Mond', 'Chief Executive Officer', '692 Promiscuous Plaza', '326-555-3492'),
('Henry', 'Foster', 'Store Manager', '314 Savage Circle', '326-555-3847'),
('Bernard', 'Marx', 'Cashier', '1240 Ambient Avenue', '326-555-8456'),
('Lenina', 'Crowne', 'Cashier', '281 Bumblepuppy Boulevard', '328-555-2349'),
('Fanny', 'Crowne', 'Restocker', '1023 Bokanovsky Lane', '326-555-6329'),
('Helmholtz', 'Watson', 'Janitor', '944 Soma Court', '329-555-2478');
```

Now, we create a second table, containing the hours which each employee clocked in and out during the week:

```
CREATE TABLE `Hours` (
  `ID` TINYINT(3) UNSIGNED NOT NULL,
  `Clock_In` DATETIME NOT NULL,
  `Clock_Out` DATETIME NOT NULL
) ENGINE=MyISAM;
```

Finally, although it is a lot of information, we add a full week of hours for each of the employees into the second table that we created:

```
INSERT INTO `Hours`
VALUES
('1', '2005-08-08 07:00:42', '2005-08-08 17:01:36'),
('1', '2005-08-09 07:01:34', '2005-08-09 17:10:11'),
('1', '2005-08-10 06:59:56', '2005-08-10 17:09:29'),
('1', '2005-08-11 07:00:17', '2005-08-11 17:00:47'),
('1', '2005-08-12 07:02:29', '2005-08-12 16:59:12'),
('2', '2005-08-08 07:00:25', '2005-08-08 17:03:13'),
('2', '2005-08-09 07:00:57', '2005-08-09 17:05:09'),
('2', '2005-08-10 06:58:43', '2005-08-10 16:58:24'),
('2', '2005-08-11 07:01:58', '2005-08-11 17:00:45'),
('2', '2005-08-12 07:02:12', '2005-08-12 16:58:57'),
('3', '2005-08-08 07:00:12', '2005-08-08 17:01:32'),
('3', '2005-08-09 07:01:10', '2005-08-09 17:00:26'),
('3', '2005-08-10 06:59:53', '2005-08-10 17:02:53'),
('3', '2005-08-11 07:01:15', '2005-08-11 17:04:23'),
('3', '2005-08-12 07:00:51', '2005-08-12 16:57:52'),
('4', '2005-08-08 06:54:37', '2005-08-08 17:01:23'),
('4', '2005-08-09 06:58:23', '2005-08-09 17:00:54'),
('4', '2005-08-10 06:59:14', '2005-08-10 17:00:12'),
('4', '2005-08-11 07:00:49', '2005-08-11 17:00:34'),
('4', '2005-08-12 07:01:09', '2005-08-12 16:58:29'),
('5', '2005-08-08 07:00:04', '2005-08-08 17:01:43'),

```

## Working with the Employee Database

Now that we have a cleanly structured database to work with, let us begin this tutorial by stepping up one notch from the last tutorial and filtering our information a little.

## Filtering by Name

Earlier in the week, an anonymous employee reported that Helmholtz came into work almost four minutes late; to verify this, we will begin our investigation by filtering out employees whose first names are "Helmholtz".

```
SELECT
`Employees`.`First_Name`,
`Employees`.`Last_Name`,
`Hours`.`Clock_In`,
`Hours`.`Clock_Out`
FROM `Employees`
INNER JOIN `Hours` ON `Employees`.`ID` = `Hours`.`ID`
WHERE `Employees`.`First_Name` = 'Helmholtz';
```

The result:

First_Name	Last_Name	Clock_In	Clock_Out
Helmholtz	Watson	2005-08-08 07:00:12	2005-08-08 17:01:02
Helmholtz	Watson	2005-08-09 07:03:44	2005-08-09 17:00:00
Helmholtz	Watson	2005-08-10 06:54:19	2005-08-10 17:03:31
Helmholtz	Watson	2005-08-11 07:00:05	2005-08-11 17:02:57
Helmholtz	Watson	2005-08-12 07:02:07	2005-08-12 16:58:23

5 rows in set (0.00 sec)

This is obviously more information than we care to trudge through, considering we only care about when he arrived past 7:00:59 on any given day within this week; thus, we need to add a couple more conditions to our WHERE clause.

## Filtering by Name, Date and Time

In the following example, we will filter out all of the times which Helmholtz clocked in that were before 7:01:00 and during the work week that lasted from the 8th to the 12th of August:

```
SELECT
`Employees`.`First_Name`,
`Employees`.`Last_Name`,
`Hours`.`Clock_In`,
`Hours`.`Clock_Out`
FROM `Employees`
INNER JOIN `Hours` ON `Employees`.`ID` = `Hours`.`ID`
WHERE `Employees`.`First_Name` = 'Helmholtz'
AND DATE_FORMAT(`Hours`.`Clock_In`, '%Y-%m-%d') >= '2005-08-08'
AND DATE_FORMAT(`Hours`.`Clock_In`, '%Y-%m-%d') <= '2005-08-12'
AND DATE_FORMAT(`Hours`.`Clock_In`, '%H:%i:%S') > '07:00:59';
```

The result:

First_Name	Last_Name	Clock_In	Clock_Out
Helmholtz	Watson	2005-08-09 07:03:44	2005-08-09 17:00:00
Helmholtz	Watson	2005-08-12 07:02:07	2005-08-12 16:58:23

2 rows in set (0.00 sec)

We have now, by merely adding a few more conditions, eliminated all of the irrelevant information; Helmholtz was late to work on the 9th and the 12th of August.

## Displaying Total Work Hours per Day

Suppose you would like to based on the information stored in both of our tables in the employee database develop a quick list of the total hours each employee has worked for each day recorded; a simple way to estimate the time each employee worked per day is exemplified below:

```

SELECT
`Employees`.`ID`,
`Employees`.`First_Name`,
`Employees`.`Last_Name`,
`Hours`.`Clock_In`,
`Hours`.`Clock_Out`,
DATE_FORMAT(`Hours`.`Clock_Out`, '%T')-DATE_FORMAT(`Hours`.`Clock_In`, '%T') AS 'Total_Hours'
FROM `Employees` INNER JOIN `Hours` ON `Employees`.`ID` = `Hours`.`ID`;

```

The result (limited by 10):

ID	First_Name	Last_Name	Clock_In	Clock_Out	Total_Hours
1	Mustapha	Mond	2005-08-08 07:00:42	2005-08-08 17:01:36	10
1	Mustapha	Mond	2005-08-09 07:01:34	2005-08-09 17:10:11	10
1	Mustapha	Mond	2005-08-10 06:59:56	2005-08-10 17:09:29	11
1	Mustapha	Mond	2005-08-11 07:00:17	2005-08-11 17:00:47	10
1	Mustapha	Mond	2005-08-12 07:02:29	2005-08-12 16:59:12	9
2	Henry	Foster	2005-08-08 07:00:25	2005-08-08 17:03:13	10
2	Henry	Foster	2005-08-09 07:00:57	2005-08-09 17:05:09	10
2	Henry	Foster	2005-08-10 06:58:43	2005-08-10 16:58:24	10
2	Henry	Foster	2005-08-11 07:01:58	2005-08-11 17:00:45	10
2	Henry	Foster	2005-08-12 07:02:12	2005-08-12 16:58:57	9

10 rows in set (0.00 sec)

### 1.1.4.1.2.1.3 JOIN Syntax

#### Description

MariaDB supports the following

JOIN  
syntaxes for the  
table\_references  
part of

[SELECT](#)

statements and multiple-table

[DELETE](#)

and

[UPDATE](#)

statements:

```

table_references:
  table_reference [, table_reference] ...

table_reference:
  table_factor
  | join_table

table_factor:
  tbl_name [PARTITION (partition_list)]
    [query_system_time_period_specification] [[AS] alias] [index_hint_list]
  | table_subquery [query_system_time_period_specification] [AS] alias
  | ( table_references )
  | { ON table_reference LEFT OUTER JOIN table_reference
      ON conditional_expr }

join_table:
  table_reference [INNER | CROSS] JOIN table_factor [join_condition]
  | table_reference STRAIGHT_JOIN table_factor
  | table_reference STRAIGHT_JOIN table_factor ON conditional_expr
  | table_reference {LEFT|RIGHT} [OUTER] JOIN table_reference join_condition
  | table_reference NATURAL [{LEFT|RIGHT} [OUTER]] JOIN table_factor

join_condition:
  ON conditional_expr
  | USING (column_list)

query_system_time_period_specification:
  FOR SYSTEM_TIME AS OF point_in_time
  | FOR SYSTEM_TIME BETWEEN point_in_time AND point_in_time
  | FOR SYSTEM_TIME FROM point_in_time TO point_in_time
  | FOR SYSTEM_TIME ALL

point_in_time:
  [TIMESTAMP] expression
  | TRANSACTION expression

index_hint_list:
  index_hint [, index_hint] ...

index_hint:
  USE {INDEX|KEY}
    [{FOR {JOIN|ORDER BY|GROUP BY}] ([index_list])
  | IGNORE {INDEX|KEY}
    [{FOR {JOIN|ORDER BY|GROUP BY}] (index_list)
  | FORCE {INDEX|KEY}
    [{FOR {JOIN|ORDER BY|GROUP BY}] (index_list)

index_list:
  index_name [, index_name] ...

```

A table reference is also known as a join expression.

Each table can also be specified as

```

db_name
.
tbl_name
. This allows to write queries which involve multiple databases. See Identifier Qualifiers for syntax details.

```

The syntax of

```

table_factor
is extended in comparison with the SQL Standard. The latter accepts only
table_reference
, not a list of them inside a pair of parentheses.

```

This is a conservative extension if we consider each comma in a list of table\_reference items as equivalent to an inner join. For example:

```

SELECT * FROM t1 LEFT JOIN (t2, t3, t4)
  ON (t2.a=t1.a AND t3.b=t1.b AND t4.c=t1.c)

```

is equivalent to:

```

SELECT * FROM t1 LEFT JOIN (t2 CROSS JOIN t3 CROSS JOIN t4)
  ON (t2.a=t1.a AND t3.b=t1.b AND t4.c=t1.c)

```

In MariaDB,

CROSS JOIN  
is a syntactic equivalent to  
INNER JOIN  
(theys can replace each other). In standard SQL, they are not equivalent.  
INNER JOIN  
is used with an  
ON  
clause,  
CROSS JOIN  
is used otherwise.

In general, parentheses can be ignored in join expressions containing only inner join operations. MariaDB also supports nested joins (see <http://dev.mysql.com/doc/refman/5.1/en/nested-join-optimization.html> ).

See [System-versioned tables](#) for more information about

FOR SYSTEM\_TIME  
syntax.

Index hints can be specified to affect how the MariaDB optimizer makes use of indexes. For more information, see [How to force query plans](#).

## Examples

```
SELECT left_tbl.*  

  FROM left_tbl LEFT JOIN right_tbl ON left_tbl.id = right_tbl.id  

 WHERE right_tbl.id IS NULL;
```

### 1.1.4.1.2.1.4 Comma vs JOIN

A query to grab the list of phone numbers for clients who ordered in the last two weeks might be written in a couple of ways. Here are two:

```
SELECT *  

  FROM  

  clients,  

  orders,  

  phoneNumbers  

 WHERE  

  clients.id = orders.clientId  

 AND clients.id = phoneNumbers.clientId  

 AND orderPlaced >= NOW() - INTERVAL 2 WEEK;
```

```
SELECT *  

  FROM  

  clients  

 INNER JOIN orders ON clients.id = orders.clientId  

 INNER JOIN phoneNumbers ON clients.id = phoneNumbers.clientId  

 WHERE  

 orderPlaced >= NOW() - INTERVAL 2 WEEK;
```

Does it make a difference? Not much as written. But you should use the second form. Why?

- **Readability.** Once the WHERE clause contains more than two conditions, it becomes tedious to pick out the difference between business logic (only dates in the last two weeks) and relational logic (which fields relate clients to orders). Using the JOIN syntax with an ON clause makes the WHERE list shorter, and makes it very easy to see how tables relate to each other.

- **Flexibility.** Let's say we need to see all clients even if they don't have a phone number in the system. With the second version, it's easy; just change

```
    INNER JOIN phoneNumbers  

      to
```

```
    LEFT JOIN phoneNumbers
```

. Try that with the first version, and MySQL version 5.0.12+ will issue a syntax error because of the change in precedence between the comma operator and the JOIN keyword. The solution is to rearrange the FROM clause or add parentheses to override the precedence, and that quickly becomes frustrating.

- **Portability.** The changes in 5.0.12 were made to align with SQL:2003. If your queries use standard syntax, you will have an easier time switching to a different database should the need ever arise.

## 1.1.4.1.2.2 Subqueries

### 1.1.4.1.2.2.1 Subqueries

A subquery is a query nested in another query.

#### Scalar Subqueries

*Subquery returning a single value.*

#### Row Subqueries

*Subquery returning a row.*

#### Subqueries and ALL

*Return true if the comparison returns true for each row, or the subquery returns no rows.*

#### Subqueries and ANY

*Return true if the comparison returns true for at least one row returned by the subquery.*

#### Subqueries and EXISTS

*Returns true if the subquery returns any rows.*

#### Subqueries in a FROM Clause

*Subqueries are more commonly placed in a WHERE clause, but can also form part of the FROM clause.*

#### Subquery Optimizations

*Articles about subquery optimizations in MariaDB.*

#### Subqueries and JOINS

*Rewriting subqueries as JOINs, and using subqueries instead of JOINs.*

#### Subquery Limitations

*There are a number of limitations regarding subqueries.*

There are 1 related questions .

## 1.1.4.1.2.2.2 Scalar Subqueries

A scalar subquery is a [subquery](#) that returns a single value. This is the simplest form of a subquery, and can be used in most places a literal or single column value is valid.

The data type, length and [character set and collation](#) are all taken from the result returned by the subquery. The result of a subquery can always be NULL, that is, no result returned. Even if the original value is defined as NOT NULL, this is disregarded.

A subquery cannot be used where only a literal is expected, for example [LOAD DATA INFILE](#) expects a literal string containing the file name, and LIMIT requires a literal integer.

## Examples

```
CREATE TABLE sq1 (num TINYINT);

CREATE TABLE sq2 (num TINYINT);

INSERT INTO sq1 VALUES (1);

INSERT INTO sq2 VALUES (10* (SELECT num FROM sq1));

SELECT * FROM sq2;
+----+
| num |
+----+
| 10 |
+----+
```

Inserting a second row means the subquery is no longer a scalar, and this particular query is not valid:

```

INSERT INTO sq1 VALUES (2);

INSERT INTO sq2 VALUES (10* (SELECT num FROM sq1));
ERROR 1242 (21000): Subquery returns more than 1 row

```

No rows in the subquery, so the scalar is NULL:

```

INSERT INTO sq2 VALUES (10* (SELECT num FROM sq3 WHERE num='3'));

SELECT * FROM sq2;
+-----+
| num |
+-----+
|   10 |
|  NULL |
+-----+

```

A more traditional scalar subquery, as part of a WHERE clause:

```

SELECT * FROM sq1 WHERE num = (SELECT MAX(num)/10 FROM sq2);
+-----+
| num |
+-----+
|   1 |
+-----+

```

## 1.1.4.1.2.2.3 Row Subqueries

A row subquery is a [subquery](#) returning a single row, as opposed to a [scalar subquery](#), which returns a single column from a row, or a literal.

### Examples

```

CREATE TABLE staff (name VARCHAR(10), age TINYINT);

CREATE TABLE customer (name VARCHAR(10), age TINYINT);

INSERT INTO staff VALUES ('Bilhah',37), ('Valerius',61), ('Maia',25);

INSERT INTO customer VALUES ('Thanasis',48), ('Valerius',61), ('Brion',51);

SELECT * FROM staff WHERE (name,age) = (SELECT name,age FROM customer WHERE name='Valerius');
+-----+-----+
| name | age |
+-----+-----+
| Valerius | 61 |
+-----+-----+

```

Finding all rows in one table also in another:

```

SELECT name,age FROM staff WHERE (name,age) IN (SELECT name,age FROM customer);
+-----+-----+
| name | age |
+-----+-----+
| Valerius | 61 |
+-----+-----+

```

## 1.1.4.1.2.2.4 Subqueries and ALL

### Contents

1. [Syntax](#)
2. [Examples](#)

[Subqueries](#) using the ALL keyword will return

true  
if the comparison returns  
true  
for each row returned by the subquery, or the subquery returns no rows.

# Syntax

```
scalar_expression comparison_operator ALL <Table subquery>
```

- scalar\_expression  
may be any expression that evaluates to a single value
- comparison\_operator  
may be any one of:  
=,  
,  
>  
,  
<  
,  
>=  
,  
<=  
,  
<>  
or  
!=

ALL

returns:

- NULL  
if the comparison operator returns  
NULL  
for at least one row returned by the Table subquery or scalar\_expression returns  
NULL
- FALSE  
if the comparison operator returns  
FALSE  
for at least one row returned by the Table subquery.
- TRUE  
if the comparison operator returns  
TRUE  
for all rows returned by the Table subquery, or if Table subquery returns no rows.

NOT IN

is an alias for

<> ALL

## Examples

```
CREATE TABLE sq1 (num TINYINT);
CREATE TABLE sq2 (num2 TINYINT);
INSERT INTO sq1 VALUES(100);
INSERT INTO sq2 VALUES(40),(50),(60);
SELECT * FROM sq1 WHERE num > ALL (SELECT * FROM sq2);
+-----+
| num |
+-----+
| 100 |
+-----+
```

Since

```
100
> all of
40
,
50
and
60
, the evaluation is true and the row is returned
```

Adding a second row to sq1, where the evaluation for that record is false:

```
INSERT INTO sq1 VALUES(30);

SELECT * FROM sq1 WHERE num > ALL (SELECT * FROM sq2);
+-----+
| num |
+-----+
| 100 |
+-----+
```

Adding a new row to sq2, causing all evaluations to be false:

```
INSERT INTO sq2 VALUES(120);

SELECT * FROM sq1 WHERE num > ALL (SELECT * FROM sq2);
Empty set (0.00 sec)
```

When the subquery returns no results, the evaluation is still true:

```
SELECT * FROM sq1 WHERE num > ALL (SELECT * FROM sq2 WHERE num2 > 300);
+-----+
| num |
+-----+
| 100 |
| 30 |
+-----+
```

Evaluating against a NULL will cause the result to be unknown, or not true, and therefore return no rows:

```
INSERT INTO sq2 VALUES (NULL);

SELECT * FROM sq1 WHERE num > ALL (SELECT * FROM sq2);
```

## 1.1.4.1.2.2.5 Subqueries and ANY

### Contents

1. [Syntax](#)
2. [Examples](#)

[Subqueries](#) using the ANY keyword will return

true  
if the comparison returns  
true  
for at least one row returned by the subquery.

## Syntax

The required syntax for an

ANY  
or  
SOME  
quantified comparison is:

```
scalar_expression comparison_operator ANY <Table subquery>
```

Or:

```
scalar_expression comparison_operator SOME <Table subquery>
```

- scalar\_expression  
may be any expression that evaluates to a single value.

- comparison\_operator  
may be any one of  
=,  
,  
>  
,  
<  
,  
>=  
,  
<=  
,  
<>  
or  
!=  
.

ANY  
returns:

- TRUE  
if the comparison operator returns  
TRUE  
for at least one row returned by the Table subquery.
- FALSE  
if the comparison operator returns  
FALSE  
for all rows returned by the Table subquery, or Table subquery has zero rows.
- NULL  
if the comparison operator returns  
NULL  
for at least one row returned by the Table subquery and doesn't return  
TRUE  
for any of them, or if scalar\_expression returns  
NULL  
.

SOME  
is a synonym for  
ANY  
, and  
IN  
is a synonym for  
= ANY

## Examples

```
CREATE TABLE sq1 (num TINYINT);

CREATE TABLE sq2 (num2 TINYINT);

INSERT INTO sq1 VALUES(100);

INSERT INTO sq2 VALUES(40),(50),(120);

SELECT * FROM sq1 WHERE num > ANY (SELECT * FROM sq2);
+-----+
| num |
+-----+
| 100 |
+-----+
```

```
100  
is greater than two of the three values, and so the expression evaluates as true.
```

SOME is a synonym for ANY:

```
SELECT * FROM sq1 WHERE num < SOME (SELECT * FROM sq2);  
+-----+  
| num |  
+-----+  
| 100 |  
+-----+
```

IN  
is a synonym for  
= ANY  
, and here there are no matches, so no results are returned:

```
SELECT * FROM sq1 WHERE num IN (SELECT * FROM sq2);  
Empty set (0.00 sec)
```

```
INSERT INTO sq2 VALUES(100);  
Query OK, 1 row affected (0.05 sec)
```

```
SELECT * FROM sq1 WHERE num <> ANY (SELECT * FROM sq2);  
+-----+  
| num |  
+-----+  
| 100 |  
+-----+
```

Reading this query, the results may be counter-intuitive. It may seem to read as "SELECT \* FROM sq1 WHERE num does not match any results in sq2. Since it does match 100, it could seem that the results are incorrect. However, the query returns a result if the match does not match any of sq2. Since

100  
already does not match  
40  
, the expression evaluates to true immediately, regardless of the 100's matching. It may be more easily readable to use SOME in a case such as this:

```
SELECT * FROM sq1 WHERE num <> SOME (SELECT * FROM sq2);  
+-----+  
| num |  
+-----+  
| 100 |  
+-----+
```

## 1.1.4.1.2.2.6 Subqueries and EXISTS

### Syntax

```
SELECT ... WHERE EXISTS <Table subquery>
```

### Description

Subqueries using the

EXISTS  
keyword will return  
true  
if the subquery returns any rows. Conversely, subqueries using  
NOT EXISTS  
will return  
true  
only if the subquery returns no rows from the table.

EXISTS subqueries ignore the columns specified by the **SELECT** of the subquery, since they're not relevant. For example,

```
SELECT col1 FROM t1 WHERE EXISTS (SELECT * FROM t2);
```

and

```
SELECT col1 FROM t1 WHERE EXISTS (SELECT col2 FROM t2);
```

produce identical results.

## Examples

```
CREATE TABLE sq1 (num TINYINT);
CREATE TABLE sq2 (num2 TINYINT);
INSERT INTO sq1 VALUES(100);
INSERT INTO sq2 VALUES(40),(50),(60);
SELECT * FROM sq1 WHERE EXISTS (SELECT * FROM sq2 WHERE num2>50);
+-----+
| num |
+-----+
| 100 |
+-----+
SELECT * FROM sq1 WHERE NOT EXISTS (SELECT * FROM sq2 GROUP BY num2 HAVING MIN(num2)=40);
Empty set (0.00 sec)
```

### 1.1.4.1.2.2.7 Subqueries in a FROM Clause

Although [subqueries](#) are more commonly placed in a WHERE clause, they can also form part of the FROM clause. Such subqueries are commonly called derived tables.

If a subquery is used in this way, you must also use an AS clause to name the result of the subquery.

#### ORACLE mode

MariaDB starting with [10.6.0](#)

From [MariaDB 10.6.0 , anonymous subqueries in a FROM clause](#) (no AS clause) are permitted in [ORACLE mode](#) .

## Examples

```
CREATE TABLE student (name CHAR(10), test CHAR(10), score TINYINT);

INSERT INTO student VALUES
    ('Chun', 'SQL', 75), ('Chun', 'Tuning', 73),
    ('Esben', 'SQL', 43), ('Esben', 'Tuning', 31),
    ('Kaolin', 'SQL', 56), ('Kaolin', 'Tuning', 88),
    ('Tatiana', 'SQL', 87), ('Tatiana', 'Tuning', 83);
```

Assume that, given the data above, you want to return the average total for all students. In other words, the average of Chun's 148 (75+73), Esben's 74 (43+31), etc.

You cannot do the following:

```
SELECT AVG(SUM(score)) FROM student GROUP BY name;
ERROR 1111 (HY000): Invalid use of group function
```

A subquery in the FROM clause is however permitted:

```
SELECT AVG(sq_sum) FROM (SELECT SUM(score) AS sq_sum FROM student GROUP BY name) AS t;
+-----+
| AVG(sq_sum) |
+-----+
| 134.0000 |
+-----+
```

From MariaDB 10.6 in ORACLE mode , the following is permitted:

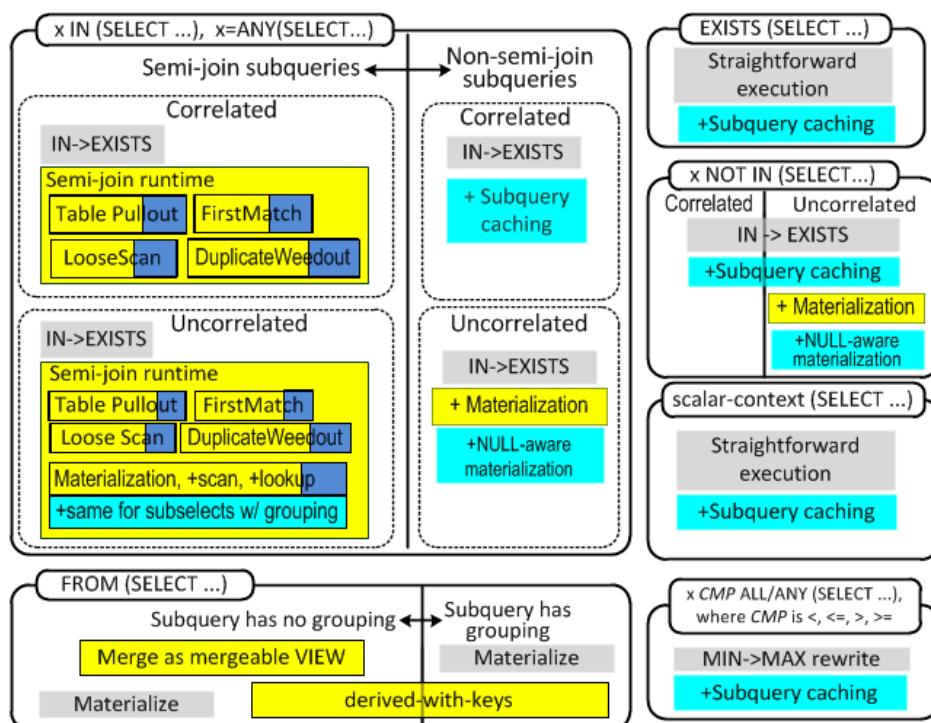

```
SELECT * FROM (SELECT 1 FROM DUAL), (SELECT 2 FROM DUAL);
```

## 1.1.4.1.2.2.8 Subquery Optimizations

### 1.1.4.1.2.2.8.1 Subquery Optimizations Map

Below is a map showing all types of subqueries allowed in the SQL language, and the optimizer strategies available to handle them.

- Uncolored areas represent different kinds of subqueries, for example:
  - Subqueries that have form $x \text{ IN } (\text{SELECT } ...)$
  - Subqueries that are in the  $\text{FROM }$  clause
  - ... and so forth
- The size of each uncolored area roughly corresponds to how important (i.e. frequently used) that kind of subquery is. For example,
  - $x \text{ IN } (\text{SELECT } ...)$  queries are the most important, and
  - $\text{EXISTS } (\text{SELECT } ...)$  are relatively unimportant.
- Colored areas represent optimizations/execution strategies that are applied to handle various kinds of subqueries.
- The color of optimization indicates which version of MySQL/MariaDB it was available in (see legend below)

MySQL 5.1

MariaDB 5.5, MySQL 5.6

MariaDB 5.5 only

MySQL 5.6 only

Some things are not on the map:

- MariaDB doesn't evaluate expensive subqueries when doing optimization (this means, EXPLAIN is always fast). MySQL 5.6 has made a progress in this regard but its optimizer will still evaluate certain kinds of subqueries (for example, scalar-context subqueries used in range predicates)

### Links to pages about individual optimizations:

### 1.1.4.1.2.2.8.2 Semi-join Subquery Optimizations

#### Contents

1. What is a semi-join subquery
  1. Difference from inner joins
2. Semi-join optimizations in MariaDB
3. See Also

MariaDB has a set of optimizations specifically targeted at *semi-join subqueries*.

## What is a semi-join subquery

A semi-join subquery has a form of

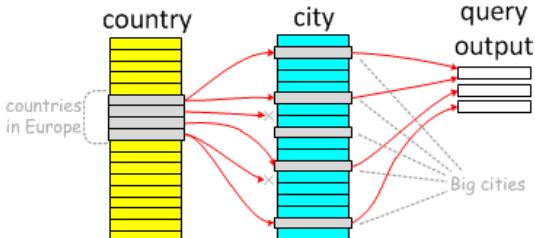

```
SELECT ... FROM outer_tables WHERE expr IN (SELECT ... FROM inner_tables ...)
```

that is, the subquery is an IN-subquery and it is located in the WHERE clause. The most important part here is *with semi-join subquery, we're only interested in records of outer\_tables that have matches in the subquery*

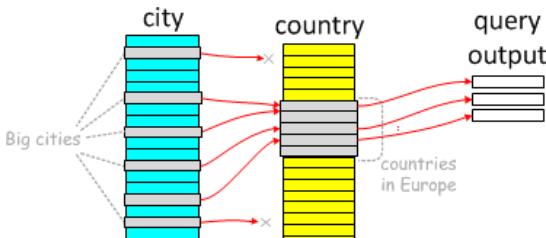

Let's see why this is important. Consider a semi-join subquery:

```
select * from Country
where
  Continent='Europe' and
  Country.Code in (select City.country
                    from City
                    where City.Population>1*1000*1000);
```

One can execute it "naturally", by starting from countries in Europe and checking if they have populous Cities:

The semi-join property also allows "backwards" execution: we can start from big cities, and check which countries they are in:

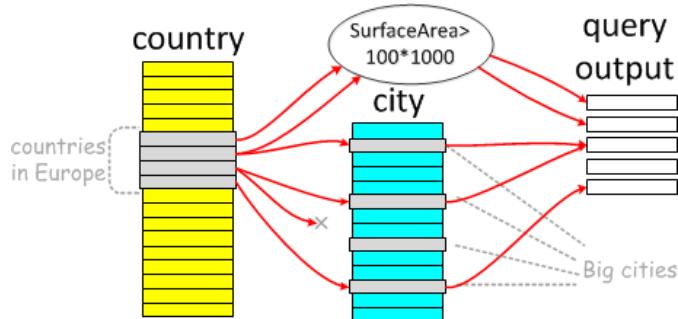

To contrast, let's change the subquery to be non-semi-join:

```
select * from Country
where
  Country.Continent='Europe' and
  (Country.Code in (select City.country
                    from City where City.Population>1*1000*1000)
   or Country.SurfaceArea > 100*1000 -- Added this part
);
```

It is still possible to start from countries, and then check

- if a country has any big cities

- if it has a large surface area:

The opposite, city-to-country way is not possible. This is not a semi-join.

## Difference from inner joins

Semi-join operations are similar to regular relational joins. There is a difference though: with semi-joins, you don't care how many matches an inner table has for an outer row. In the above countries-with-big-cities example, Germany will be returned once, even if it has three cities with populations of more than one million each.

## Semi-join optimizations in MariaDB

MariaDB uses semi-join optimizations to run IN subqueries starting from [MariaDB 5.3](#). Starting in [MariaDB 5.3.3](#), Semi-join subquery optimizations are enabled by default. You can disable them by turning off their `optimizer_switch` like so:

```
SET optimizer_switch='semijoin=off'
```

MariaDB has five different semi-join execution strategies:

- [Table pullout optimization](#)
- [FirstMatch execution strategy](#)
- [Semi-join Materialization execution strategy](#)
- [LooseScan execution strategy](#)
- [DuplicateWeedout execution strategy](#)

## 1.1.4.1.2.2.8.3 Table Pullout Optimization

### Contents

1. [The idea of Table Pullout](#)
2. [Table pullout in action](#)
3. [Table pullout fact sheet](#)
4. [Controlling table pullout](#)

Table pullout is an optimization for [Semi-join subqueries](#).

## The idea of Table Pullout

Sometimes, a subquery can be re-written as a join. For example:

```
select *
from City
where City.Country in (select Country.Code
                      from Country
                      where Country.Population < 100*1000);
```

If we know that there can be, at most, one country with with a given value of

`Country.Code`

(we can tell that if we see that table `Country` has a primary key or unique index over that column), we can re-write this query as:

```

select City.*
from
  City, Country
where
  City.Country=Country.Code AND Country.Population < 100*1000;

```

## Table pullout in action

If one runs

`EXPLAIN`

for the above query in MySQL 5.1-5.6 or MariaDB 5.1 -5.2, they'll get this plan:

```

MySQL [world]> explain select * from City where City.Country in (select Country.Code from Country where Country.Population < 100
+-----+-----+-----+-----+-----+-----+-----+-----+
| id | select_type | table | type | possible_keys | key | key_len | ref | rows | Extra |
+-----+-----+-----+-----+-----+-----+-----+-----+
| 1 | PRIMARY | City | ALL | NULL | NULL | NULL | NULL | 4079 | Using where |
| 2 | DEPENDENT SUBQUERY | Country | unique_subquery | PRIMARY,Population | PRIMARY | 3 | func | 1 | Using where |
+-----+-----+-----+-----+-----+-----+-----+-----+
2 rows in set (0.00 sec)

```

It shows that the optimizer is going to do a full scan on table

`City`

, and for each city it will do a lookup in table

`Country`

If one runs the same query in MariaDB 5.3 , they will get this plan:

```

MariaDB [world]> explain select * from City where City.Country in (select Country.Code from Country where Country.Population < 1
+-----+-----+-----+-----+-----+-----+-----+-----+
| id | select_type | table | type | possible_keys | key | key_len | ref | rows | Extra |
+-----+-----+-----+-----+-----+-----+-----+-----+
| 1 | PRIMARY | Country | range | PRIMARY,Population | Population | 4 | NULL | 37 | Using index condit
| 1 | PRIMARY | City | ref | Country | Country | 3 | world.Country.Code | 18 |
+-----+-----+-----+-----+-----+-----+-----+-----+
2 rows in set (0.00 sec)

```

The interesting parts are:

- Both tables have
  - `select_type=PRIMARY`
  - , and
  - `id=1`
  - as if they were in one join.
- The `Country` table is first, followed by the `City` table.

Indeed, if one runs EXPLAIN EXTENDED; SHOW WARNINGS, they will see that the subquery is gone and it was replaced with a join:

```

MariaDB [world]> show warnings
***** 1. row *****
Level: Note
Code: 1003
Message: select `world`.`City`.`ID` AS `ID`,`world`.`City`.`Name` AS
`Name`, `world`.`City`.`Country` AS `Country`, `world`.`City`.`Population` AS
`Population`

from `world`.`City` join `world`.`Country` where

(`world`.`City`.`Country` = `world`.`Country`.`Code`) and (`world`.`Country` .
`Population` < (100 * 1000))
1 row in set (0.00 sec)

```

Changing the subquery into a join allows feeding the join to the join optimizer, which can make a choice between two possible join orders:

1. City -> Country
2. Country -> City

as opposed to the single choice of

## 1. City->Country

which we had before the optimization.

In the above example, the choice produces a better query plan. Without pullout, the query plan with a subquery would read

$$(4079 + 1 * 4079) = 8158$$

table records. With table pullout, the join plan would read

$$(37 + 37 * 18) = 703$$

rows. Not all row reads are equal, but generally, reading

10

times fewer table records is faster.

## Table pullout fact sheet

- Table pullout is possible only in semi-join subqueries.

- Table pullout is based on

UNIQUE

/

PRIMARY

key definitions.

- Doing table pullout does not cut off any possible query plans, so MariaDB will always try to pull out as much as possible.

- Table pullout is able to pull individual tables out of subqueries to their parent selects. If all tables in a subquery have been pulled out, the subquery (i.e. its semi-join) is removed completely.

- One common bit of advice for optimizing MySQL has been "If possible, rewrite your subqueries as joins". Table pullout does exactly that, so manual rewrites are no longer necessary.

## Controlling table pullout

There is no separate @@optimizer\_switch flag for table pullout. Table pullout can be disabled by switching off all semi-join optimizations with

```
SET @@optimizer_switch='semijoin=off'  
command.
```

## 1.1.4.1.2.2.8.4 Non-semi-join Subquery Optimizations

### Contents

- 1. Applicability

- 3. The IN-TO-EXISTS transformation
- 4. Performance discussion
  - 1. Example speedup over MySQL 5.x and MariaDB 5.1/5.2
  - 2. Performance guidelines
- 5. Optimizer control

Certain kinds of IN-subqueries cannot be flattened into [semi-joins](#). These subqueries can be both correlated or non-correlated. In order to provide consistent performance in all cases, MariaDB provides several alternative strategies for these types of subqueries. Whenever several strategies are possible, the optimizer chooses the optimal one based on cost estimates.

The two primary non-semi-join strategies are materialization (also called outside-in materialization), and in-to-exists transformation. Materialization is applicable only for non-correlated subqueries, while in-to-exist can be used both for correlated and non-correlated subqueries.

## Applicability

An IN subquery cannot be flattened into a semi-join in the following cases. The examples below use the *World* database from the MariaDB regression test suite.

### Subquery in a disjunction (OR)

The subquery is located directly or indirectly under an OR operation in the WHERE clause of the outer query.

Query pattern:

```
SELECT ... FROM ... WHERE (expr1, ..., exprN) [NOT] IN (SELECT ... ) OR expr;
```

Example:

```
SELECT Name FROM Country
WHERE (Code IN (select Country from City where City.Population > 100000) OR
      Name LIKE 'L%') AND
      surfacearea > 1000000;
```

## Negated subquery predicate (NOT IN)

The subquery predicate itself is negated.

Query pattern:

```
SELECT ... FROM ... WHERE ... (expr1, ..., exprN) NOT IN (SELECT ... ) ...;
```

Example:

```
SELECT Country.Name
FROM Country, CountryLanguage
WHERE Code NOT IN (SELECT Country FROM CountryLanguage WHERE Language = 'English')
      AND CountryLanguage.Language = 'French'
      AND Code = Country;
```

## Subquery in the SELECT or HAVING clause

The subquery is located in the SELECT or HAVING clauses of the outer query.

Query pattern:

```
SELECT field1, ..., (SELECT ...) WHERE ...;
SELECT ... WHERE ... HAVING (SELECT ...);
```

Example:

```
select Name, City.id in (select capital from Country where capital is not null) as is_capital
from City
where City.population > 1000000;
```

## Subquery with a UNION

The subquery itself is a UNION, while the IN predicate may be anywhere in the query where IN is allowed.

Query pattern:

```
... [NOT] IN (SELECT ... UNION SELECT ...)
```

Example:

```
SELECT * from City where (Name, 91) IN
(SELECT Name, round(Population/1000) FROM City WHERE Country = "IND" AND Population > 2500000
UNION
SELECT Name, round(Population/1000) FROM City WHERE Country = "IND" AND Population < 100000);
```

## Materialization for non-correlated IN-subqueries

### Materialization basics

The basic idea of subquery materialization is to execute the subquery and store its result in an internal temporary table indexed on all its columns. Naturally, this is possible only when the subquery is non-correlated. The IN predicate tests whether its left operand is present in the subquery result. Therefore it is not necessary to store duplicate subquery result rows in the temporary table. Storing only unique subquery rows provides two benefits - the size of the temporary table is smaller, and the index on all its columns can be unique.

If the size of the temporary table is less than the tmp\_table\_size system variable, the table is a hash-indexed in-memory HEAP table. In the rare cases when the subquery result exceeds this limit, the temporary table is stored on disk in an ARIA or MyISAM B-tree indexed table (ARIA is the default).

Subquery materialization happens on demand during the first execution of the IN predicate. Once the subquery is materialized, the IN predicate is evaluated very efficiently by index lookups of the outer expression into the unique index of the materialized temporary table. If there is a match, IN is

TRUE, otherwise IN is FALSE.

## NULL-aware efficient execution

An IN predicate may produce a NULL result if there is a NULL value in either of its arguments. Depending on its location in a query, a NULL predicate value is equivalent to FALSE. These are the cases when substituting NULL with FALSE would reject exactly the same result rows. A NULL result of IN is indistinguishable from a FALSE if the IN predicate is:

- not negated,
- not a function argument,
- inside a WHERE or ON clause.

In all these cases the evaluation of IN is performed as described in the previous paragraph via index lookups into the materialized subquery. In all remaining cases when NULL cannot be substituted with FALSE, it is not possible to use index lookups. This is not a limitation in the server, but a consequence of the NULL semantics in the ANSI SQL standard.

Suppose an IN predicate is evaluated as

```
NULL IN (select  
not_null_col from t1)
```

, that is, the left operand of IN is a NULL value, and there are no NULLs in the subquery. In this case the value of IN is neither FALSE, nor TRUE. Instead it is NULL. If we were to perform an index lookup with the NULL as a key, such a value would not be found in not\_null\_col, and the IN predicate would incorrectly produce a FALSE.

In general, an NULL value on either side of an IN acts as a "wildcard" that matches any value, and if a match exists, the result of IN is NULL. Consider the following example:

If the left argument of IN is the row:

```
(
```

```
7
```

```
,
```

```
NULL
```

```
,
```

```
9
```

```
)
```

, and the result of the right subquery operand of IN is the table:

```
(7, 8, 10)  
(6, NULL, NULL)  
(7, 11, 9)
```

The the IN predicate matches the row

```
(
```

```
7
```

```
,
```

```
11
```

```
,
```

)

, and the result of IN is NULL. Matches where the differing values on either side of the IN arguments are matched by a NULL in the other IN argument, are called *partial matches*.

In order to efficiently compute the result of an IN predicate in the presence of NULLs, MariaDB implements two special algorithms for [partial matching](#), described here in detail .

- Rowid-merge partial matching

This technique is used when the number of rows in the subquery result is above a certain limit. The technique creates special indexes on some of the columns of the temporary table, and merges them by alternative scanning of each index thus performing an operation similar to set-intersection.

- Table scan partial matching

This algorithm is used for very small tables when the overhead of the rowid-merge algorithm is not justifiable. Then the server simply scans the materialized subquery, and checks for partial matches. Since this strategy doesn't need any in-memory buffers, it is also used when there is not enough memory to hold the indexes of the rowid-merge strategy.

## Limitations

In principle the subquery materialization strategy is universal, however, due to some technical limitations in the MariaDB server, there are few cases when the server cannot apply this optimization.

- BLOB fields

Either the left operand of an IN predicate refers to a BLOB field, or the subquery selects one or more BLOBS.

- Incomparable fields

TODO

In the above cases, the server reverts to the [IN-TO-EXISTS](#) transformation.

## The IN-TO-EXISTS transformation

This optimization is the only subquery execution strategy that existed in older versions of MariaDB and MySQL prior to [MariaDB 5.3](#) . We have made various changes and fixed a number of bugs in this code as well, but in essence it remains the same.

## Performance discussion

### Example speedup over MySQL 5.x and [MariaDB 5.1 /5.2](#)

Depending on the query and data, either of the two strategies described here may result in orders of magnitude better/worse plan than the other strategy.

Older versions of MariaDB and any current MySQL version (including MySQL 5.5, and MySQL 5.6 DMR as of July 2011) implement only the IN-TO-EXISTS transformation. As illustrated below, this strategy is inferior in many common cases to subquery materialization.

Consider the following query over the data of the DBT3 benchmark scale 10. Find customers with top balance in their nations:

```
SELECT * FROM part
WHERE p_partkey IN
    (SELECT l_partkey FROM lineitem
     WHERE l_shipdate between '1997-01-01' and '1997-02-01')
ORDER BY p_retailprice DESC LIMIT 10;
```

The times to run this query is as follows:

- Execution time in [MariaDB 5.2 /MySQL 5.x \(any MySQL\)](#): > 1 h

The query takes more than one hour (we didn't wait longer), which makes it impractical to use subqueries in such cases. The EXPLAIN below shows that the subquery was transformed into a correlated one, which indicates an IN-TO-EXISTS transformation.

id   select_type   table   type   key   ref   rows   Extra
1   PRIMARY   part   ALL   NULL   NULL   199755   Using where; Using filesort
2   DEPENDENT SUBQUERY   lineitem   index_subquery   i_l_suppkey_partkey   func   14   Using where

- Execution time in [MariaDB 5.3](#) : 43 sec

In [MariaDB 5.3](#) it takes less than a minute to run the same query. The EXPLAIN shows that the subquery remains uncorrelated, which is an indication that it is being executed via subquery materialization.

id	select_type	table	type	key	ref	rows	Extra
1	PRIMARY	part	ALL	NULL	NULL	199755	Using temporary; Using filesort
1	PRIMARY	<subquery2>	eq_ref	distinct_key	func	1	
2	MATERIALIZED	lineitem	range	l_shipdate_partkey	NULL	160060	Using where; Using index

The speedup here is practically infinite, because both MySQL and older MariaDB versions cannot complete the query in any reasonable time.

In order to show the benefits of partial matching we extended the *customer* table from the DBT3 benchmark with two extra columns:

- c\_pref\_nationkey - preferred nation to buy from,
- c\_pref\_brand - preferred brand.

Both columns are prefixed with the percent NULL values in the column, that is, c\_pref\_nationkey\_05 contains 5% NULL values.

Consider the query "Find all customers that didn't buy from a preferred country, and from a preferred brand withing some date ranges":

```
SELECT count(*)
FROM customer
WHERE (c_custkey, c_pref_nationkey_05, c_pref_brand_05) NOT IN
  (SELECT o_custkey, s_nationkey, p_brand
   FROM orders, supplier, part, lineitem
   WHERE l_orderkey = o_orderkey AND
     l_suppkey = s_suppkey AND
     l_partkey = p_partkey AND
     p_retailprice < 1200 AND
     l_shipdate >= '1996-04-01' AND l_shipdate < '1996-04-05' AND
     o_orderdate >= '1996-04-01' AND o_orderdate < '1996-04-05');
```

- Execution time in [MariaDB 5.2](#) /MySQL 5.x (any MySQL): **40 sec**
- Execution time in [MariaDB 5.3](#) : **2 sec**

The speedup for this query is 20 times.

## Performance guidelines

TODO

## Optimizer control

In certain cases it may be necessary to override the choice of the optimizer. Typically this is needed for benchmarking or testing purposes, or to mimic the behavior of an older version of the server, or if the optimizer made a poor choice.

All the above strategies can be controlled via the following switches in `optimizer_switch` system variable.

- materialization=on/off

In some very special cases, even if materialization was forced, the optimizer may still revert to the IN-TO-EXISTS strategy if materialization is not applicable. In the cases when materialization requires partial matching (because of the presence of NULL values), there are two subordinate switches that control the two partial matching strategies:

- partial\_match\_rowid\_merge=on/off

This switch controls the Rowid-merge strategy. In addition to this switch, the system variable `rowid_merge_buff_size` controls the maximum memory available to the Rowid-merge strategy.

- partial\_match\_table\_scan=on/off

Controls the alternative partial match strategy that performs matching via a table scan.

- in\_to\_exists=on/off

This switch controls the IN-TO-EXISTS transformation.

- tmp\_table\_size and max\_heap\_table\_size system variables

The `tmp_table_size` system variable sets the upper limit for internal MEMORY temporary tables. If an internal temporary table exceeds this size, it is converted automatically into a Aria or MyISAM table on disk with a B-tree index. Notice however, that a MEMORY table cannot be larger than `max_heap_table_size`.

The two main optimizer switches - `materialization` and `in_to_exists` cannot be simultaneously off. If both are set to off, the server will issue an error.

## 1.1.4.1.2.2.8.5 Subquery Cache

## Contents

1. Administration
2. Visibility
3. Implementation
4. Performance Impact
  1. Example 1
  2. Example 2
  3. Example 3
  4. Example 4
5. See Also

The goal of the subquery cache is to optimize the evaluation of correlated subqueries by storing results together with correlation parameters in a cache and avoiding re-execution of the subquery in cases where the result is already in the cache.

## Administration

The cache is on by default. One can switch it off using the [optimizer\\_switch](#)

```
subquery_cache  
setting, like so:
```

```
SET optimizer_switch='subquery_cache=off';
```

The efficiency of the subquery cache is visible in 2 statistical variables:

- [Subquery\\_cache\\_hit](#) - Global counter for all subquery cache hits.
- [Subquery\\_cache\\_miss](#) - Global counter for all subquery cache misses.

The session variables [tmp\\_table\\_size](#) and [max\\_heap\\_table\\_size](#) influence the size of in-memory temporary tables in the table used for caching. It cannot grow more than the minimum of the above variables values (see the [Implementation](#) section for details).

## Visibility

Your usage of the cache is visible in

```
EXTENDED EXPLAIN  
output (warnings) as  
<expr_cache></list of parameters//>(</cached expression//>  
. For example:
```

```
EXPLAIN EXTENDED SELECT * FROM t1 WHERE a IN (SELECT b FROM t2);  
+-----+-----+-----+-----+-----+-----+-----+-----+-----+-----+  
| id | select_type | table | type | possible_keys | key | key_len | ref | rows | filtered | Extra |  
+-----+-----+-----+-----+-----+-----+-----+-----+-----+-----+  
| 1 | PRIMARY | t1 | ALL | NULL | NULL | NULL | NULL | 2 | 100.00 | Using where |  
| 2 | DEPENDENT SUBQUERY | t2 | ALL | NULL | NULL | NULL | NULL | 2 | 100.00 | Using where |  
+-----+-----+-----+-----+-----+-----+-----+-----+-----+-----+  
2 rows in set, 1 warning (0.00 sec)  
  
SHOW WARNINGS;  
+-----+-----+  
| Level | Code | Message |  
+-----+-----+  
| Note | 1003 | SELECT `test`.`t1`.`a` AS `a` FROM `test`.`t1` WHERE <expr_cache><`test`.`t1`.`a`>(<in_optimizer>(`test`.`t1`.`  
+-----+-----+  
1 row in set (0.00 sec)
```

In the example above the presence of

```
"<expr_cache><`test`.`t1`.`a`>(...)"
```

is how you know you are using the subquery cache.

## Implementation

Every subquery cache creates a temporary table where the results and all parameters are stored. It has a unique index over all parameters. First the cache is created in a [MEMORY](#) table (if doing this is impossible the cache becomes disabled for that expression). When the table grows up to the minimum of

```
tmp_table_size  
and  
max_heap_table_size  
, the hit rate will be checked:
```

- if the hit rate is really small (<0.2) the cache will be disabled.

- if the hit rate is moderate (<0.7) the table will be cleaned (all records deleted) to keep the table in memory
- if the hit rate is high the table will be converted to a disk table (for 5.3.0 it can only be converted to a disk table).

```
hit rate = hit / (hit + miss)
```

## Performance Impact

Here are some examples that show the performance impact of the subquery cache (these tests were made on a 2.53 GHz Intel Core 2 Duo MacBook Pro with dbt-3 scale 1 data set).

example	cache on	cache off	gain	hit	miss	hit rate
1	1.01sec	1 hour 31 min 43.33sec	5445x	149975	25	99.98%
2	0.21sec	1.41sec	6.71x	6285	220	96.6%
3	2.54sec	2.55sec	1.00044x	151	461	24.67%
4	1.87sec	1.95sec	0.96x	0	23026	0%

## Example 1

Dataset from DBT-3 benchmark, a query to find customers with balance near top in their nation:

```
select count(*) from customer
where
    c_acctbal > 0.8 * (select max(c_acctbal)
                          from customer C
                          where C.c_nationkey=customer.c_nationkey
                          group by c_nationkey);
```

## Example 2

DBT-3 benchmark, Query #17

```
select sum(l_extendedprice) / 7.0 as avg_yearly
from lineitem, part
where
    p_partkey = l_partkey and
    p_brand = 'Brand#42' and p_container = 'JUMBO BAG' and
    l_quantity < (select 0.2 * avg(l_quantity) from lineitem
                  where l_partkey = p_partkey);
```

## Example 3

DBT-3 benchmark, Query #2

```
select
    s_acctbal, s_name, n_name, p_partkey, p_mfgr, s_address, s_phone, s_comment
from
    part, supplier, partsupp, nation, region
where
    p_partkey = ps_partkey and s_suppkey = ps_suppkey and p_size = 33
    and p_type like '%STEEL' and s_nationkey = n_nationkey
    and n_regionkey = r_regionkey and r_name = 'MIDDLE EAST'
    and ps_supplycost =
        select
            min(ps_supplycost)
        from
            partsupp, supplier, nation, region
        where
            p_partkey = ps_partkey and s_suppkey = ps_suppkey
            and s_nationkey = n_nationkey and n_regionkey = r_regionkey
            and r_name = 'MIDDLE EAST'
)
order by
    s_acctbal desc, n_name, s_name, p_partkey;
```

## Example 4

DBT-3 benchmark, Query #20

```

select
    s_name, s_address
from
    supplier, nation
where
    s_suppkey in (
        select
            distinct (ps_suppkey)
        from
            partsupp, part
        where
            ps_partkey=p_partkey
            and p_name like 'indian%'
            and ps_availqty > (
                select
                    0.5 * sum(l_quantity)
                from
                    lineitem
                where
                    l_partkey = ps_partkey
                    and l_suppkey = ps_suppkey
                    and l_shipdate >= '1995-01-01'
                    and l_shipdate < date_ADD('1995-01-01',interval 1 year)
            )
        )
        and s_nationkey = n_nationkey and n_name = 'JAPAN'
order by
    s_name;

```

## 1.1.4.1.2.2.8.6 Condition Pushdown Into IN subqueries

This article describes Condition Pushdown into IN subqueries as implemented in [MDEV-12387](#).

`optimizer_switch` flag name:

```
condition_pushdown_for_subquery
```

## 1.1.4.1.2.2.8.7 Conversion of Big IN Predicates Into Subqueries

Starting from [MariaDB 10.3](#), the optimizer converts certain big IN predicates into IN subqueries.

That is, an IN predicate in the form

```
column [NOT] IN (const1, const2, .... )
```

is converted into an equivalent IN-subquery:

```
column [NOT] IN (select ... from temporary_table)
```

which opens new opportunities for the query optimizer.

The conversion happens if the following conditions are met:

- the IN list has more than 1000 elements (One can control it through the `in_predicate_conversion_threshold` parameter).
- the [NOT] IN condition is at the top level of the WHERE/ON clause.

## Controlling the Optimization

- The optimization is on by default. [MariaDB 10.3.18](#) (and debug builds prior to that) introduced the `in_predicate_conversion_threshold` variable. Set to

```
0
```

to disable the optimization.

# Benefits of the Optimization

If

column  
is a key-prefix, MariaDB optimizer will process the condition

```
column [NOT] IN (const1, const2, .... )
```

by trying to construct a range access. If the list is large, the analysis may take a lot of memory and CPU time. The problem gets worse when column is a part of a multi-column index and the query has conditions on other parts of the index.

Conversion of IN predicates into a subqueries bypass the range analysis, which means the query optimization phase will use less CPU and memory.

Possible disadvantages of the conversion are:

- The optimization may convert 'IN LIST elements' key accesses to a table scan (if there is no other usable index for the table)
- The estimates for the number of rows matching the  
IN (...)  
are less precise.

## 1.1.4.1.2.2.8.8 EXISTS-to-IN Optimization

### Contents

1. [Trivially-correlated EXISTS subqueries](#)
2. [Semi-join EXISTS subqueries](#)
3. [Handling of NULL values](#)
4. [Control](#)
5. [Limitations](#)

MySQL (including MySQL 5.6) has only one execution strategy for EXISTS subqueries. The strategy is essentially the straightforward, "naive" execution, without any rewrites.

MariaDB 5.3 introduced a rich set of optimizations for IN subqueries. Since then, it makes sense to convert an EXISTS subquery into an IN so that the new optimizations can be used.

EXISTS  
will be converted into  
IN  
in two cases:

1. Trivially correlated EXISTS subqueries
2. Semi-join EXISTS

We will now describe these two cases in detail

### Trivially-correlated EXISTS subqueries

Often, EXISTS subquery is correlated, but the correlation is trivial. The subquery has form

```
EXISTS (SELECT ... FROM ... WHERE outer_col= inner_col AND inner_where)
```

and "outer\_col" is the only place where the subquery refers to outside fields. In this case, the subquery can be re-written into uncorrelated IN:

```
outer_col IN (SELECT inner_col FROM ... WHERE inner_where)
```

(

NULL  
values require some special handling, see below). For uncorrelated IN subqueries, MariaDB is able a cost-based choice between two execution strategies:

- [IN-to-EXISTS](#) (basically, convert back into EXISTS)

- Materialization

That is, converting trivially-correlated

```
EXISTS
into uncorrelated
IN
gives query optimizer an option to use Materialization strategy for the subquery.
```

Currently, EXISTS->IN conversion works only for subqueries that are at top level of the WHERE clause, or are under NOT operation which is directly at top level of the WHERE clause.

## Semi-join EXISTS subqueries

If

```
EXISTS
subquery is an AND-part of the
WHERE
clause:
```

```
SELECT ... FROM outer_tables WHERE EXISTS (SELECT ...) AND ...
```

then it satisfies the main property of [semi-join subqueries](#) :

*with semi-join subquery, we're only interested in records of outer\_tables that have matches in the subquery*

Semi-join optimizer offers a rich set of execution strategies for both correlated and uncorrelated subqueries. The set includes FirstMatch strategy which is an equivalent of how EXISTS subqueries are executed, so we do not lose any opportunities when converting an EXISTS subquery into a semi-join.

In theory, it makes sense to convert all kinds of EXISTS subqueries: convert both correlated and uncorrelated ones, convert irrespectively of whether the subquery has inner=outer equality.

In practice, the subquery will be converted only if it has inner=outer equality. Both correlated and uncorrelated subqueries are converted.

## Handling of NULL values

TODO: rephrase this:

- IN has complicated NULL-semantics. NOT EXISTS doesn't.
- EXISTS-to-IN adds IS NOT NULL before the subquery predicate, when required

## Control

The optimization is controlled by the

```
exists_to_in
flag in optimizer_switch . Before MariaDB 10.0.12 , the optimization was OFF by default. Since MariaDB 10.0.12 , it has been ON by default.
```

## Limitations

EXISTS-to-IN doesn't handle

- subqueries that have GROUP BY, aggregate functions, or HAVING clause
- subqueries are UNIONs
- a number of degenerate edge cases

## 1.1.4.1.2.2.8.9 Optimizing GROUP BY and DISTINCT Clauses in Subqueries

A DISTINCT clause and a GROUP BY without a corresponding HAVING clause have no meaning in IN/ALL/ANY/SOME/EXISTS subqueries. The reason is that IN/ALL/ANY/SOME/EXISTS only check if an outer row satisfies some condition with respect to all or any row in the subquery result. Therefore it doesn't matter if the subquery has duplicate result rows or not - if some condition is true for some row of the subquery, this condition will be true for all duplicates of this row. Notice that GROUP BY without a corresponding HAVING clause is equivalent to a DISTINCT.

MariaDB 5.3 and later versions automatically remove DISTINCT and GROUP BY without HAVING if these clauses appear in an IN/ALL/ANY/SOME/EXISTS subquery. For instance:

```
select * from t1
where t1.a > ALL(select distinct b from t2 where t2.c > 100)
```

is transformed to:

```
select * from t1
where t1.a > ALL(select b from t2 where t2.c > 100)
```

Removing these unnecessary clauses allows the optimizer to find more efficient query plans because it doesn't need to take care of post-processing the subquery result to satisfy DISTINCT / GROUP BY.

## 1.1.4.1.2.2.9 Subqueries and JOINS

A [subquery](#) can quite often, but not in all cases, be rewritten as a [JOIN](#).

### Contents

1. [Rewriting Subqueries as JOINS](#)
2. [Using Subqueries instead of JOINS](#)

## Rewriting Subqueries as JOINS

A subquery using

IN  
can be rewritten with the  
DISTINCT  
keyword, for example:

```
SELECT * FROM table1 WHERE col1 IN (SELECT col1 FROM table2);
```

can be rewritten as:

```
SELECT DISTINCT table1.* FROM table1, table2 WHERE table1.col1=table2.col1;
```

NOT IN  
or  
NOT EXISTS

queries can also be rewritten. For example, these two queries returns the same result:

```
SELECT * FROM table1 WHERE col1 NOT IN (SELECT col1 FROM table2);
SELECT * FROM table1 WHERE NOT EXISTS (SELECT col1 FROM table2 WHERE table1.col1=table2.col1);
```

and both can be rewritten as:

```
SELECT table1.* FROM table1 LEFT JOIN table2 ON table1.id=table2.id WHERE table2.id IS NULL;
```

Subqueries that can be rewritten as a LEFT JOIN are sometimes more efficient.

## Using Subqueries instead of JOINS

There are some scenarios, though, which call for subqueries rather than joins:

- When you want duplicates, but not false duplicates. Suppose

```
Table_1
has three rows —{
1
,
1
,
2
} — and
Table_2
has two rows —{
1
,
2
,
2
}. If you need to list the rows in
Table_1
which are also in
Table_2
, only this subquery-based
```

```
SELECT
statement will give the right answer (
1
,
1
,
2
):
```

```
SELECT Table_1.column_1
FROM Table_1
WHERE Table_1.column_1 IN
(SELECT Table_2.column_1
FROM Table_2);
```

This SQL statement won't work:

```
SELECT Table_1.column_1
FROM Table_1,Table_2
WHERE Table_1.column_1 = Table_2.column_1;
```

because the result will be {

```
1
,
1
,
2
,
2
```

} — and the duplication of 2 is an error. This SQL statement won't work either:

```
SELECT DISTINCT Table_1.column_1
FROM Table_1,Table_2
WHERE Table_1.column_1 = Table_2.column_1;
```

because the result will be {

```
1
,
2
```

} — and the removal of the duplicated 1 is an error too.

- When the outermost statement is not a query. The SQL statement:

```
UPDATE Table_1 SET column_1 = (SELECT column_1 FROM Table_2);
```

can't be expressed using a join unless some rare SQL3 features are used.

- When the join is over an expression. The SQL statement:

```
SELECT * FROM Table_1
WHERE column_1 + 5 =
(SELECT MAX(column_1) FROM Table_2);
```

is hard to express with a join. In fact, the only way we can think of is this SQL statement:

```
SELECT Table_1.*
FROM Table_1,
(SELECT MAX(column_1) AS max_column_1 FROM Table_2) AS Table_2
WHERE Table_1.column_1 + 5 = Table_2.max_column_1;
```

which still involves a parenthesized query, so nothing is gained from the transformation.

- When you want to see the exception. For example, suppose the question is: what books are longer than Das Kapital? These two queries are effectively almost the same:

```

SELECT DISTINCT Bookcolumn_1.*
FROM Books AS Bookcolumn_1 JOIN Books AS Bookcolumn_2 USING(page_count)
WHERE title = 'Das Kapital';

SELECT DISTINCT Bookcolumn_1.*
FROM Books AS Bookcolumn_1
WHERE Bookcolumn_1.page_count >
(SELECT DISTINCT page_count
FROM Books AS Bookcolumn_2
WHERE title = 'Das Kapital');

```

The difference is between these two SQL statements is, if there are two editions of *Das Kapital* (with different page counts), then the self-join example will return the books which are longer than the shortest edition of *Das Kapital*. That might be the wrong answer, since the original question didn't ask for "... longer than

ANY  
book named *Das Kapital*" (it seems to contain a false assumption that there's only one edition).

## 1.1.4.1.2.2.10 Subquery Limitations

### Contents

1. ORDER BY and LIMIT
2. Modifying and Selecting from the Same Table
3. Row Comparison Operations
4. Correlated Subqueries
5. Stored Functions

There are a number of limitations regarding **subqueries**, which are discussed below.

The following tables and data will be used in the examples that follow:

```

CREATE TABLE staff(name VARCHAR(10),age TINYINT);

CREATE TABLE customer(name VARCHAR(10),age TINYINT);

```

```

INSERT INTO staff VALUES
('Bilhah',37), ('Valerius',61), ('Maia',25);

INSERT INTO customer VALUES
('Thanasis',48), ('Valerius',61), ('Brion',51);

```

### ORDER BY and LIMIT

To use **ORDER BY** or limit **LIMIT** in **subqueries** both must be used.. For example:

```

SELECT * FROM staff WHERE name IN (SELECT name FROM customer ORDER BY name);
+-----+-----+
| name | age |
+-----+-----+
| Valerius | 61 |
+-----+-----+

```

is valid, but

```

SELECT * FROM staff WHERE name IN (SELECT NAME FROM customer ORDER BY name LIMIT 1);
ERROR 1235 (42000): This version of MariaDB doesn't
yet support 'LIMIT & IN/ALL/ANY/SOME subquery'

```

is not.

### Modifying and Selecting from the Same Table

It's not possible to both modify and select from the same table in a subquery. For example:

```
DELETE FROM staff WHERE name = (SELECT name FROM staff WHERE age=61);
ERROR 1093 (HY000): Table 'staff' is specified twice, both
as a target for 'DELETE' and as a separate source for data
```

## Row Comparison Operations

There is only partial support for row comparison operations. The expression in

```
expr op {ALL|ANY|SOME} subquery,
```

must be scalar and the subquery can only return a single column.

However, because of the way

```
IN  
is implemented (it is rewritten as a sequence of  
=  
comparisons and  
AND  
, the expression in
```

```
expression [NOT] IN subquery
```

is permitted to be an n-tuple and the subquery can return rows of n-tuples.

For example:

```
SELECT * FROM staff WHERE (name,age) NOT IN (
    SELECT name,age FROM customer WHERE age >=51]
);
+-----+-----+
| name | age |
+-----+-----+
| Bilhah | 37 |
| Maia | 25 |
+-----+-----+
```

is permitted, but

```
SELECT * FROM staff WHERE (name,age) = ALL (
    SELECT name,age FROM customer WHERE age >=51
);
ERROR 1241 (21000): Operand should contain 1 column(s)
```

is not.

## Correlated Subqueries

Subqueries in the FROM clause cannot be correlated subqueries. They cannot be evaluated for each row of the outer query since they are evaluated to produce a result set during when the query is executed.

## Stored Functions

A subquery can refer to a [stored function](#) which modifies data. This is an extension to the SQL standard, but can result in indeterminate outcomes. For example, take:

```
SELECT ... WHERE x IN (SELECT f() ...);
```

where *f()* inserts rows. The function *f()* could be executed a different number of times depending on how the optimizer chooses to handle the query.

This sort of construct is therefore not safe to use in replication that is not [row-based](#), as there could be different results on the master and the slave.

## 1.1.4.1.2.3 UNION

UNION

is used to combine the results from multiple [SELECT](#) statements into a single result set.

## Syntax

```
SELECT ...
UNION [ALL | DISTINCT] SELECT ...
[UNION [ALL | DISTINCT] SELECT ...]
[ORDER BY [column [, column ...]]]
[LIMIT {[offset,] row_count | row_count OFFSET offset}]
```

## Contents

1. [Syntax](#)
2. [Description](#)
  1. [ALL/DISTINCT](#)
  2. [ORDER BY and LIMIT](#)
  3. [HIGH\\_PRIORITY](#)
  4. [SELECT ... INTO ...](#)
  5. [Parentheses](#)
3. [Examples](#)
4. [See Also](#)

## Description

### UNION

is used to combine the results from multiple [SELECT](#) statements into a single result set.

The column names from the first

`SELECT`

statement are used as the column names for the results returned. Selected columns listed in corresponding positions of each `SELECT` statement should have the same data type. (For example, the first column selected by the first statement should have the same type as the first column selected by the other statements.)

If they don't, the type and length of the columns in the result take into account the values returned by all of the `SELECT`s, so there is no need for explicit casting. Note that currently this is not the case for [recursive CTEs](#) - see [MDEV-12325](#).

Table names can be specified as

`db_name`

`tbl_name`

. This permits writing

`UNION`

s which involve multiple databases. See [Identifier Qualifiers](#) for syntax details.

`UNION` queries cannot be used with [aggregate functions](#).

`EXCEPT`

and

`UNION`

have the same operation precedence and

`INTERSECT`

has a higher precedence, unless [running in Oracle mode](#), in which case all three have the same precedence.

## ALL/DISTINCT

The

`ALL`

keyword causes duplicate rows to be preserved. The

`DISTINCT`

keyword (the default if the keyword is omitted) causes duplicate rows to be removed by the results.

`UNION ALL` and `UNION DISTINCT` can both be present in a query. In this case, `UNION DISTINCT` will override any `UNION ALLs` to its left.

MariaDB starting with [10.1.1](#)

Until [MariaDB 10.1.1](#), all

`UNION ALL`

statements required the server to create a temporary table. Since [MariaDB 10.1.1](#), the server can in most cases execute

`UNION ALL`

without creating a temporary table, improving performance (see [MDEV-334](#)).

## ORDER BY and LIMIT

Individual `SELECT`s can contain their own `ORDER BY` and `LIMIT` clauses. In this case, the individual queries need to be wrapped between parentheses.

However, this does not affect the order of the UNION, so they only are useful to limit the record read by one SELECT.

The UNION can have global ORDER BY and LIMIT clauses, which affect the whole resultset. If the columns retrieved by individual SELECT statements have an alias (AS), the ORDER BY must use that alias, not the real column names.

## HIGH\_PRIORITY

Specifying a query as HIGH\_PRIORITY will not work inside a UNION. If applied to the first SELECT, it will be ignored. Applying to a later SELECT results in a syntax error:

```
ERROR 1234 (42000): Incorrect usage/placement of 'HIGH_PRIORITY'
```

## SELECT ... INTO ...

Individual SELECTs cannot be written INTO DUMPFILE or INTO OUTFILE . If the last SELECT statement specifies INTO DUMPFILE or INTO OUTFILE, the entire result of the UNION will be written. Placing the clause after any other SELECT will result in a syntax error.

If the result is a single row, SELECT ... INTO @var\_name can also be used.

MariaDB starting with 10.4.0

## Parentheses

From MariaDB 10.4.0 , parentheses can be used to specify precedence. Before this, a syntax error would be returned.

## Examples

UNION  
between tables having different column names:

```
(SELECT e_name AS name, email FROM employees)
UNION
(SELECT c_name AS name, email FROM customers);
```

Specifying the

UNION

's global order and limiting total rows:

```
(SELECT name, email FROM employees)
UNION
(SELECT name, email FROM customers)
ORDER BY name LIMIT 10;
```

Adding a constant row:

```
(SELECT 'John Doe' AS name, 'john.doe@example.net' AS email)
UNION
(SELECT name, email FROM customers);
```

Differing types:

```
SELECT CAST('x' AS CHAR(1)) UNION SELECT REPEAT('y',4);
+-----+
| CAST('x' AS CHAR(1)) |
+-----+
| x
| yyyy
+-----+
```

Returning the results in order of each individual SELECT by use of a sort column:

```
(SELECT 1 AS sort_column, e_name AS name, email FROM employees)
UNION
(SELECT 2, c_name AS name, email FROM customers) ORDER BY sort_column;
```

Difference between UNION, EXCEPT and INTERSECT .

INTERSECT ALL

and  
EXCEPT ALL  
are available from [MariaDB 10.5.0](#).

```
CREATE TABLE seqs (i INT);
INSERT INTO seqs VALUES (1),(2),(3),(3),(4),(5),(6);

SELECT i FROM seqs WHERE i <= 3 UNION SELECT i FROM seqs WHERE i>=3;
+---+
| i |
+---+
| 1 |
| 2 |
| 3 |
| 3 |
| 4 |
| 5 |
| 6 |
+---+

SELECT i FROM seqs WHERE i <= 3 UNION ALL SELECT i FROM seqs WHERE i>=3;
+---+
| i |
+---+
| 1 |
| 2 |
| 2 |
| 3 |
| 3 |
| 3 |
| 3 |
| 4 |
| 5 |
| 6 |
+---+

SELECT i FROM seqs WHERE i <= 3 EXCEPT SELECT i FROM seqs WHERE i>=3;
+---+
| i |
+---+
| 1 |
| 2 |
+---+

SELECT i FROM seqs WHERE i <= 3 EXCEPT ALL SELECT i FROM seqs WHERE i>=3;
+---+
| i |
+---+
| 1 |
| 2 |
| 2 |
+---+

SELECT i FROM seqs WHERE i <= 3 INTERSECT SELECT i FROM seqs WHERE i>=3;
+---+
| i |
+---+
| 3 |
+---+

SELECT i FROM seqs WHERE i <= 3 INTERSECT ALL SELECT i FROM seqs WHERE i>=3;
+---+
| i |
+---+
| 3 |
| 3 |
+---+
```

Parentheses for specifying precedence, from [MariaDB 10.4.0](#)

```

CREATE OR REPLACE TABLE t1 (a INT);
CREATE OR REPLACE TABLE t2 (b INT);
CREATE OR REPLACE TABLE t3 (c INT);

INSERT INTO t1 VALUES (1),(2),(3),(4);
INSERT INTO t2 VALUES (5),(6);
INSERT INTO t3 VALUES (1),(6);

((SELECT a FROM t1) UNION (SELECT b FROM t2)) INTERSECT (SELECT c FROM t3);
+-----+
| a   |
+-----+
| 1   |
| 6   |
+-----+

(SELECT a FROM t1) UNION ((SELECT b FROM t2) INTERSECT (SELECT c FROM t3));
+-----+
| a   |
+-----+
| 1   |
| 2   |
| 3   |
| 4   |
| 6   |
+-----+

```

- [Recursive Common Table Expressions Overview](#)
- [Get Set for Set Theory: UNION, INTERSECT and EXCEPT in SQL](#) (video tutorial)

## 1.1.4.1.2.4 EXCEPT

MariaDB starting with [10.3.0](#)

EXCEPT was introduced in [MariaDB 10.3.0](#).

The result of

```

EXCEPT
is all records of the left
SELECT
result set except records which are in right
SELECT
result set, i.e. it is subtraction of two result sets. From MariaDB 10.6.1,
MINUS
is a synonym.

```

## Syntax

```

SELECT ...
  (INTERSECT [ALL | DISTINCT] | EXCEPT [ALL | DISTINCT] | UNION [ALL | DISTINCT]) SELECT ...
  [(INTERSECT [ALL | DISTINCT] | EXCEPT [ALL | DISTINCT] | UNION [ALL | DISTINCT]) SELECT ...]
  [ORDER BY [column [, column ...]]]
  [LIMIT {[offset,] row_count | row_count OFFSET offset}]

```

## Contents

1. [Syntax](#)
  1. [Description](#)
  2. [Parentheses](#)
  3. [ALL/DISTINCT](#)
2. [Examples](#)
3. [See Also](#)

Please note:

- Brackets for explicit operation precedence are not supported; use a subquery in the `FROM` clause as a workaround).

## Description

MariaDB has supported

`EXCEPT`  
and `INTERSECT` in addition to `UNION` since [MariaDB 10.3](#).

All behavior for naming columns,

`ORDER BY`  
and  
`LIMIT`  
is the same as for  
`UNION`

`EXCEPT`  
implicitly supposes a  
`DISTINCT`  
operation.

The result of

`EXCEPT`  
is all records of the left  
`SELECT`  
result except records which are in right  
`SELECT`  
result set, i.e. it is subtraction of two result sets.

`EXCEPT`  
and  
`UNION`  
have the same operation precedence and  
`INTERSECT`  
has a higher precedence, unless [running in Oracle mode](#), in which case all three have the same precedence.

MariaDB starting with [10.4.0](#)

### Parentheses

From [MariaDB 10.4.0](#), parentheses can be used to specify precedence. Before this, a syntax error would be returned.

MariaDB starting with [10.5.0](#)

### ALL/DISTINCT

`EXCEPT ALL`  
and  
`EXCEPT DISTINCT`  
were introduced in [MariaDB 10.5.0](#). The  
`ALL`  
operator leaves duplicates intact, while the  
`DISTINCT`  
operator removes duplicates.  
`DISTINCT`  
is the default behavior if neither operator is supplied, and the only behavior prior to [MariaDB 10.5](#).

## Examples

Show customers which are not employees:

```
(SELECT e_name AS name, email FROM customers)
EXCEPT
(SELECT c_name AS name, email FROM employees);
```

Difference between **UNION**, **EXCEPT** and **INTERSECT**.

INTERSECT ALL  
and  
EXCEPT ALL  
are available from [MariaDB 10.5.0](#).

```
CREATE TABLE seqs (i INT);
INSERT INTO seqs VALUES (1),(2),(3),(4),(5),(6);

SELECT i FROM seqs WHERE i <= 3 UNION SELECT i FROM seqs WHERE i>=3;
```

```
+----+
| i |
+----+

## 1.1.4.1.2.5 INTERSECT

MariaDB starting with [10.3.0](#)

INTERSECT was introduced in [MariaDB 10.3.0](#).

The result of an intersect is the intersection of right and left

```

SELECT ...
results, i.e. only records that are present in both result sets will be included in the result of the operation.
```

## Syntax

```

SELECT ...
(INTERSECT [ALL | DISTINCT] | EXCEPT [ALL | DISTINCT] | UNION [ALL | DISTINCT]) SELECT ...
[(INTERSECT [ALL | DISTINCT] | EXCEPT [ALL | DISTINCT] | UNION [ALL | DISTINCT]) SELECT ...]
[ORDER BY [column [, column ...]]]
[LIMIT {[offset,] row_count | row_count OFFSET offset}]
```

## Contents

1. [Syntax](#)
  1. [Description](#)
    1. [Parentheses](#)
    2. [ALL/DISTINCT](#)
  2. [Examples](#)
  3. [See Also](#)

## Description

MariaDB has supported

`INTERSECT`  
(as well as `EXCEPT`) in addition to `UNION` since [MariaDB 10.3](#).

All behavior for naming columns,

`ORDER BY`

and  
LIMIT  
is the same as for [UNION](#) .

INTERSECT  
implicitly supposes a  
DISTINCT  
operation.

The result of an intersect is the intersection of right and left

SELECT  
results, i.e. only records that are present in both result sets will be included in the result of the operation.

INTERSECT  
has higher precedence than  
UNION  
and  
EXCEPT  
(unless running [running in Oracle mode](#), in which case all three have the same precedence). If possible it will be executed linearly but if not it will be translated to a subquery in the  
FROM  
clause:

```
(select a,b from t1)
union
(select c,d from t2)
intersect
(select e,f from t3)
union
(select 4,4);
```

will be translated to:

```
(select a,b from t1)
union
select c,d from
((select c,d from t2)
 intersect
 (select e,f from t3)) dummy_subselect
union
(select 4,4)
```

MariaDB starting with [10.4.0](#)

## Parentheses

From [MariaDB 10.4.0](#), parentheses can be used to specify precedence. Before this, a syntax error would be returned.

MariaDB starting with [10.5.0](#)

## ALL/DISTINCT

INTERSECT ALL  
and  
INTERSECT DISTINCT  
were introduced in [MariaDB 10.5.0](#). The  
ALL  
operator leaves duplicates intact, while the  
DISTINCT  
operator removes duplicates.  
DISTINCT  
is the default behavior if neither operator is supplied, and the only behavior prior to [MariaDB 10.5](#).

## Examples

Show customers which are employees:

```
(SELECT e_name AS name, email FROM employees)
INTERSECT
(SELECT c_name AS name, email FROM customers);
```

Difference between UNION , EXCEPT and INTERSECT.

INTERSECT ALL

and

EXCEPT ALL

are available from MariaDB 10.5.0 .

```
CREATE TABLE seqs (i INT);
INSERT INTO seqs VALUES (1),(2),(2),(3),(3),(4),(5),(6);

SELECT i FROM seqs WHERE i <= 3 UNION SELECT i FROM seqs WHERE i>=3;
+----+
| i |
+----+
| 1 |
| 2 |
| 3 |
| 4 |
| 5 |
| 6 |
+----+

SELECT i FROM seqs WHERE i <= 3 UNION ALL SELECT i FROM seqs WHERE i>=3;
+----+
| i |
+----+
| 1 |
| 2 |
| 2 |
| 3 |
| 3 |
| 3 |
| 3 |
| 4 |

## 1.1.4.1.2.6 Precedence Control in Table Operations

MariaDB starting with [10.4.0](#)

Beginning in [MariaDB 10.4](#), you can control the ordering of execution on table operations using parentheses.

## Syntax

```
( expression )
[ORDER BY [column[, column...]]]
[LIMIT {[offset,] row_count | row_count OFFSET offset}]
```

### Contents

1. [Syntax](#)
2. [Description](#)
3. [Example](#)

## Description

Using parentheses in your SQL allows you to control the order of execution for

`SELECT`

statements and [Table Value Constructor](#), including

`UNION`

,

`EXCEPT`

, and

## INTERSECT

operations. MariaDB executes the parenthetical expression before the rest of the statement. You can then use

## ORDER BY

and

## LIMIT

clauses to further organize the result-set.

**Note :** In practice, the Optimizer may rearrange the exact order in which MariaDB executes different parts of the statement. When it calculates the result-set, however, it returns values as though the parenthetical expression were executed first.

## Example

```
CREATE TABLE test.t1 (num INT);

INSERT INTO test.t1 VALUES (1),(2),(3);

(SELECT * FROM test.t1
UNION
VALUES (10))
INTERSECT
VALUES (1),(3),(10),(11);
+-----+
| num |
+-----+
|   1 |
|   3 |
|  10 |
+-----+

((SELECT * FROM test.t1
UNION
VALUES (10))
INTERSECT
VALUES (1),(3),(10),(11))
ORDER BY 1 DESC;
+-----+
| num |
+-----+
|  10 |
|   3 |
|    1 |
+-----+
```

## 1.1.4.1.2.7 MINUS

MariaDB starting with 10.6.1

### MINUS

was introduced as a synonym for EXCEPT from MariaDB 10.6.1 .

## 1.1.4.1.3 LIMIT

### Contents

1. [Description](#)
  1. [Multi-Table Updates](#)
  2. [GROUP\\_CONCAT](#)
2. [Examples](#)
3. [See Also](#)

## Description

Use the

```
LIMIT
clause to restrict the number of returned rows. When you use a single integer n with
LIMIT
, the first n rows will be returned. Use the ORDER BY clause to control which rows come first. You can also select a number of rows after an offset using either of the following:
```

```
LIMIT offset, row_count
LIMIT row_count OFFSET offset
```

When you provide an offset *m* with a limit *n* , the first *m* rows will be ignored, and the following *n* rows will be returned.

Executing an UPDATE with the

```
LIMIT
clause is not safe for replication.
LIMIT 0
is an exception to this rule (see MDEV-6170 ).
```

There is a LIMIT ROWS EXAMINED optimization which provides the means to terminate the execution of SELECT statements which examine too many rows, and thus use too many resources. See LIMIT ROWS EXAMINED .

## Multi-Table Updates

MariaDB starting with 10.3.2

Until MariaDB 10.3.1 , it was not possible to use

```
LIMIT
(or ORDER BY ) in a multi-table UPDATE statement. This restriction was lifted in MariaDB 10.3.2 .
```

## GROUP\_CONCAT

MariaDB starting with 10.3.2

Starting from MariaDB 10.3.3 , it is possible to use

```
LIMIT
with GROUP_CONCAT() .
```

## Examples

```
CREATE TABLE members (name VARCHAR(20));
INSERT INTO members VALUES('Jagdish'),('Kenny'),('Rokurou'),('Immaculada');

SELECT * FROM members;
+-----+
| name   |
+-----+
| Jagdish |
| Kenny  |
| Rokurou|
| Immaculada |
+-----+
```

Select the first two names (no ordering specified):

```
SELECT * FROM members LIMIT 2;
+-----+
| name   |
+-----+
| Jagdish |
| Kenny  |
+-----+
```

All the names in alphabetical order:

```
SELECT * FROM members ORDER BY name;
```

```
+-----+
| name      |
+-----+
| Immaculada |
| Jagdish    |
| Kenny      |
| Rokurou    |
+-----+
```

The first two names, ordered alphabetically:

```
SELECT * FROM members ORDER BY name LIMIT 2;
```

```
+-----+
| name      |
+-----+
| Immaculada |
| Jagdish    |
+-----+
```

The third name, ordered alphabetically (the first name would be offset zero, so the third is offset two):

```
SELECT * FROM members ORDER BY name LIMIT 2,1;
```

```
+-----+
| name      |
+-----+
| Kenny     |
+-----+
```

From MariaDB 10.3.2 ,

LIMIT

can be used in a multi-table update:

```
CREATE TABLE warehouse (product_id INT, qty INT);
INSERT INTO warehouse VALUES (1,100),(2,100),(3,100),(4,100);

CREATE TABLE store (product_id INT, qty INT);
INSERT INTO store VALUES (1,5),(2,5),(3,5),(4,5);

UPDATE warehouse,store SET warehouse.qty = warehouse.qty-2, store.qty = store.qty+2
WHERE (warehouse.product_id = store.product_id AND store.product_id  >= 1)
ORDER BY store.product_id DESC LIMIT 2;
```

```
SELECT * FROM warehouse;
```

```
+-----+
| product_id | qty   |
+-----+
|          1 |  100 |
|          2 |  100 |
|          3 |   98 |
|          4 |   98 |
+-----+
```

```
SELECT * FROM store;
```

```
+-----+
| product_id | qty   |
+-----+
|          1 |    5 |
|          2 |    5 |
|          3 |    7 |
|          4 |    7 |
+-----+
```

From MariaDB 10.3.3 ,

LIMIT

can be used with GROUP\_CONCAT , so, for example, given the following table:

```
CREATE TABLE d (dd DATE, cc INT);
```

```
INSERT INTO d VALUES ('2017-01-01',1);
INSERT INTO d VALUES ('2017-01-02',2);
INSERT INTO d VALUES ('2017-01-04',3);
```

the following query:

```
SELECT SUBSTRING_INDEX(GROUP_CONCAT(CONCAT_WS(":",dd,cc) ORDER BY cc DESC),",",1) FROM d;
+-----+
| SUBSTRING_INDEX(GROUP_CONCAT(CONCAT_WS(":",dd,cc) ORDER BY cc DESC),",",1) |
+-----+
| 2017-01-04:3 |
+-----+
```

can be more simply rewritten as:

```
SELECT GROUP_CONCAT(CONCAT_WS(":",dd,cc) ORDER BY cc DESC LIMIT 1) FROM d;
+-----+
| GROUP_CONCAT(CONCAT_WS(":",dd,cc) ORDER BY cc DESC LIMIT 1) |
+-----+
| 2017-01-04:3 |
+-----+
```

## 1.1.4.1.4 ORDER BY

### Contents

1. [Description](#)
2. [Examples](#)
3. [See Also](#)

## Description

Use the

ORDER BY

clause to order a resultset, such as that are returned from a [SELECT](#) statement. You can specify just a column or use any expression with functions. If you are using the

GROUP BY

clause, you can use grouping functions in

ORDER BY

. Ordering is done after grouping.

You can use multiple ordering expressions, separated by commas. Rows will be sorted by the first expression, then by the second expression if they have the same value for the first, and so on.

You can use the keywords

ASC

and

DESC

after each ordering expression to force that ordering to be ascending or descending, respectively. Ordering is ascending by default.

You can also use a single integer as the ordering expression. If you use an integer  $n$ , the results will be ordered by the  $n$ th column in the select expression.

When string values are compared, they are compared as if by the [STRCMP](#) function.

STRCMP

ignores trailing whitespace and may normalize characters and ignore case, depending on the [collation](#) in use.

Duplicated entries in the

ORDER BY

clause are removed.

ORDER BY

can also be used to order the activities of a [DELETE](#) or [UPDATE](#) statement (usually with the [LIMIT](#) clause).

MariaDB starting with [10.3.2](#)

Until [MariaDB 10.3.1](#), it was not possible to use

ORDER BY

(or [LIMIT](#)) in a multi-table [UPDATE](#) statement. This restriction was lifted in [MariaDB 10.3.2](#).

MariaDB starting with [10.5](#)

From [MariaDB 10.5](#), MariaDB allows packed sort keys and values of non-sorted fields in the sort buffer. This can make filesort temporary files much smaller when VARCHAR, CHAR or BLOBS are used, notably speeding up some ORDER BY sorts.

## Examples

```
CREATE TABLE seq (i INT, x VARCHAR(1));
INSERT INTO seq VALUES (1,'a'), (2,'b'), (3,'b'), (4,'f'), (5,'e');

SELECT * FROM seq ORDER BY i;
+---+---+
| i | x |
+---+---+
| 1 | a |
| 2 | b |
| 3 | b |
| 4 | f |
| 5 | e |
+---+---+

SELECT * FROM seq ORDER BY i DESC;
+---+---+
| i | x |
+---+---+
| 5 | e |
| 4 | f |
| 3 | b |
| 2 | b |
| 1 | a |
+---+---+

SELECT * FROM seq ORDER BY x,i;
+---+---+
| i | x |
+---+---+
| 1 | a |
| 2 | b |
| 3 | b |
| 5 | e |
| 4 | f |
+---+---+
```

ORDER BY in an [UPDATE](#) statement, in conjunction with [LIMIT](#):

```
UPDATE seq SET x='z' WHERE x='b' ORDER BY i DESC LIMIT 1;

SELECT * FROM seq;
+---+---+
| i | x |
+---+---+
| 1 | a |
| 2 | b |
| 3 | z |
| 4 | f |
| 5 | e |
+---+---+
```

From [MariaDB 10.3.2](#),

ORDER BY

can be used in a multi-table update:

```
CREATE TABLE warehouse (product_id INT, qty INT);
INSERT INTO warehouse VALUES (1,100),(2,100),(3,100),(4,100);

CREATE TABLE store (product_id INT, qty INT);
INSERT INTO store VALUES (1,5),(2,5),(3,5),(4,5);

UPDATE warehouse,store SET warehouse.qty = warehouse.qty-2, store.qty = store.qty+2
WHERE (warehouse.product_id = store.product_id AND store.product_id >= 1)
ORDER BY store.product_id DESC LIMIT 2;

SELECT * FROM warehouse;
+-----+-----+
| product_id | qty |
+-----+-----+
| 1 | 100 |
| 2 | 100 |
| 3 | 98 |
| 4 | 98 |
+-----+-----+

SELECT * FROM store;
+-----+-----+
| product_id | qty |
+-----+-----+
| 1 | 5 |
| 2 | 5 |
| 3 | 7 |
| 4 | 7 |
+-----+-----+
```

## 1.1.4.1.5 GROUP BY

### Contents

1. WITH ROLLUP
2. GROUP BY Examples
3. See Also

Use the

GROUP BY

clause in a **SELECT** statement to group rows together that have the same value in one or more column, or the same computed value using expressions with any **functions and operators** except **grouping functions**. When you use a

GROUP BY

clause, you will get a single result row for each group of rows that have the same value for the expression given in

GROUP BY

When grouping rows, grouping values are compared as if by the

=

operator. For string values, the

=

operator ignores trailing whitespace and may normalize characters and ignore case, depending on the [collation](#) in use.

You can use any of the grouping functions in your select expression. Their values will be calculated based on all the rows that have been grouped together for each result row. If you select a non-grouped column or a value computed from a non-grouped column, it is undefined which row the returned value is taken from. This is not permitted if the

`ONLY_FULL_GROUP_BY`  
`SQL_MODE` is used.

You can use multiple expressions in the

`GROUP BY`  
clause, separated by commas. Rows are grouped together if they match on each of the expressions.

You can also use a single integer as the grouping expression. If you use an integer  $n$ , the results will be grouped by the  $n$ th column in the select expression.

The

`WHERE`  
clause is applied before the  
`GROUP BY`  
clause. It filters non-aggregated rows before the rows are grouped together. To filter grouped rows based on aggregate values, use the  
`HAVING`  
clause. The  
`HAVING`  
clause takes any expression and evaluates it as a boolean, just like the  
`WHERE`  
clause. You can use grouping functions in the  
`HAVING`  
clause. As with the select expression, if you reference non-grouped columns in the  
`HAVING`  
clause, the behavior is undefined.

By default, if a

`GROUP BY`  
clause is present, the rows in the output will be sorted by the expressions used in the  
`GROUP BY`  
. You can also specify  
`ASC`  
or  
`DESC`  
(ascending, descending) after those expressions, like in [ORDER BY](#). The default is  
`ASC`  
.

If you want the rows to be sorted by another field, you can add an explicit [ORDER BY](#). If you don't want the result to be ordered, you can add [ORDER BY NULL](#).

## WITH ROLLUP

The

`WITH ROLLUP`  
modifier adds extra rows to the resultset that represent super-aggregate summaries. For a full description with examples, see [SELECT WITH ROLLUP](#).

## GROUP BY Examples

Consider the following table that records how many times each user has played and won a game:

```
CREATE TABLE plays (name VARCHAR(16), plays INT, wins INT);
INSERT INTO plays VALUES
("John", 20, 5),
("Robert", 22, 8),
("Wanda", 32, 8),
("Susan", 17, 3);
```

Get a list of win counts along with a count:

```

SELECT wins, COUNT(*) FROM plays GROUP BY wins;
+-----+
| wins | COUNT(*) |
+-----+
|   3 |      1 |
|   5 |      1 |
|   8 |      2 |
+-----+
3 rows in set (0.00 sec)

```

The

GROUP BY  
expression can be a computed value, and can refer back to an identifier specified with  
AS  
. Get a list of win averages along with a count:

```

SELECT (wins / plays) AS winavg, COUNT(*) FROM plays GROUP BY winavg;
+-----+
| winavg | COUNT(*) |
+-----+
| 0.1765 |      1 |
| 0.2500 |      2 |
| 0.3636 |      1 |
+-----+
3 rows in set (0.00 sec)

```

You can use any [grouping function](#) in the select expression. For each win average as above, get a list of the average play count taken to get that average:

```

SELECT (wins / plays) AS winavg, AVG(plays) FROM plays
  GROUP BY winavg;
+-----+
| winavg | AVG(plays) |
+-----+
| 0.1765 |    17.0000 |
| 0.2500 |    26.0000 |
| 0.3636 |    22.0000 |
+-----+
3 rows in set (0.00 sec)

```

You can filter on aggregate information using the

HAVING  
clause. The  
HAVING  
clause is applied after  
GROUP BY  
and allows you to filter on aggregate data that is not available to the  
WHERE  
clause. Restrict the above example to results that involve an average number of plays over 20:

```

SELECT (wins / plays) AS winavg, AVG(plays) FROM plays
  GROUP BY winavg HAVING AVG(plays) > 20;
+-----+
| winavg | AVG(plays) |
+-----+
| 0.2500 |    26.0000 |
| 0.3636 |    22.0000 |
+-----+
2 rows in set (0.00 sec)

```

## 1.1.4.1.6 Common Table Expressions

### 1.1.4.1.6.1 WITH

MariaDB starting with [10.2.1](#)

Common Table Expressions were introduced in [MariaDB 10.2.1](#).

#### Syntax

```
WITH [RECURSIVE] table_reference [(columns_list)] AS (
    SELECT ...
)
[CYCLE cycle_column_list RESTRICT]
SELECT ...
```

#### Contents

1. [Syntax](#)
2. [Description](#)
  1. [CYCLE ... RESTRICT](#)
3. [Examples](#)
4. [See Also](#)

#### Description

The

`WITH`

keyword signifies a [Common Table Expression](#) (CTE). It allows you to refer to a subquery expression many times in a query, as if having a temporary table that only exists for the duration of a query.

There are two kinds of CTEs:

- [Non-Recursive](#)
- [Recursive](#) (signified by the  
`RECURSIVE`  
keyword, supported since [MariaDB 10.2.2](#))

You can use

```
table_reference
as any normal table in the external
SELECT
part. You can also use
WITH
in subqueries, as well as with EXPLAIN and SELECT.
```

Poorly-formed recursive CTEs can in theory cause infinite loops. The `max_recursive_iterations` system variable limits the number of recursions.

#### CYCLE ... RESTRICT

MariaDB starting with [10.5.2](#)

The CYCLE clause enables CTE cycle detection, avoiding excessive or infinite loops, MariaDB supports a relaxed, non-standard grammar.

The SQL Standard permits a CYCLE clause, as follows:

```
WITH RECURSIVE ... (
...
)
CYCLE <cycle column list>
SET <cycle mark column> TO <cycle mark value> DEFAULT <non-cycle mark value>
USING <path column>
```

where all clauses are mandatory.

MariaDB does not support this, but from 10.5.2 permits a non-standard relaxed grammar, as follows:

```
WITH RECURSIVE ... (
...
)
CYCLE <cycle column list> RESTRICT
```

With the use of  
 CYCLE ... RESTRICT  
 it makes no difference whether the CTE uses  
 UNION ALL  
 or  
 UNION DISTINCT  
 anymore.  
 UNION ALL  
 means "all rows, but without cycles", which is exactly what the  
 CYCLE  
 clause enables. And  
 UNION DISTINCT  
 means all rows should be different, which, again, is what will happen — as uniqueness is enforced over a subset of columns, complete rows  
 will automatically all be different.

## Examples

Below is an example with the

WITH

at the top level:

```
WITH t AS (SELECT a FROM t1 WHERE b >= 'c')
SELECT * FROM t2, t WHERE t2.c = t.a;
```

The example below uses

WITH

in a subquery:

```
SELECT t1.a, t1.b FROM t1, t2
WHERE t1.a > t2.c
AND t2.c IN(WITH t AS (SELECT * FROM t1 WHERE t1.a < 5)
            SELECT t2.c FROM t2, t WHERE t2.c = t.a);
```

Below is an example of a Recursive CTE:

```
WITH RECURSIVE ancestors AS
( SELECT * FROM folks
  WHERE name='Alex'
UNION
  SELECT f./*
    FROM folks AS f, ancestors AS a
   WHERE f.id = a.father OR f.id = a.mother )
SELECT * FROM ancestors;
```

Take the following structure, and data,

```
CREATE TABLE t1 (from_ int, to_ int);
INSERT INTO t1 VALUES (1,2), (1,100), (2,3), (3,4), (4,1);
SELECT * FROM t1;
+-----+-----+
| from_ | to_  |
+-----+-----+
|     1 |     2 |
|     1 |    100|
|     2 |     3 |
|     3 |     4 |
|     4 |     1 |
+-----+-----+
```

Given the above, the following query would theoretically result in an infinite loop due to the last record in t1 (note that `max_recursive_iterations` is set to 10 for the purposes of this example, to avoid the excessive number of cycles):

```

SET max_recursive_iterations=10;

WITH RECURSIVE cte (depth, from_, to_) AS (
  SELECT 0,1,1 UNION DISTINCT SELECT depth+1, t1.from_, t1.to_
    FROM t1, cte WHERE t1.from_ = cte.to_
)
SELECT * FROM cte;
+-----+-----+-----+
| depth | from_ | to_ |
+-----+-----+-----+
|    0 |     1 |    1 |
|    1 |     1 |    2 |
|    1 |     1 |   100 |
|    2 |     2 |    3 |
|    3 |     3 |    4 |
|    4 |     4 |    1 |
|    5 |     1 |    2 |
|    5 |     1 |   100 |
|    6 |     2 |    3 |
|    7 |     3 |    4 |
|    8 |     4 |    1 |
|    9 |     1 |    2 |
|    9 |     1 |   100 |
|   10 |     2 |    3 |
+-----+-----+-----+

```

However, the CYCLE ... RESTRICT clause (from [MariaDB 10.5.2](#) ) can overcome this:

```

WITH RECURSIVE cte (depth, from_, to_) AS (
  SELECT 0,1,1 UNION SELECT depth+1, t1.from_, t1.to_
    FROM t1, cte WHERE t1.from_ = cte.to_
)
CYCLE from_, to_ RESTRICT
SELECT * FROM cte;
+-----+-----+-----+
| depth | from_ | to_ |
+-----+-----+-----+
|    0 |     1 |    1 |
|    1 |     1 |    2 |
|    1 |     1 |   100 |
|    2 |     2 |    3 |
|    3 |     3 |    4 |
|    4 |     4 |    1 |
+-----+-----+-----+

```

## 1.1.4.1.6.2 Non-Recursive Common Table Expressions Overview

### Contents

1. [Non-Recursive CTEs](#)
  1. [A CTE referencing Another CTE](#)
  2. [Multiple Uses of a CTE](#)

Common Table Expressions (CTEs) are a standard SQL feature, and are essentially temporary named result sets. There are two kinds of CTEs: Non-Recursive, which this article covers; and [Recursive](#) .

MariaDB starting with [10.2.1](#)

Common table expressions were introduced in [MariaDB 10.2.1](#) .

## Non-Recursive CTEs

The `WITH` keyword signifies a CTE. It is given a name, followed by a body (the main query) as follows:

```

WITH          CTE name
with engineers as (
    select *
    from employees
    where dept='Engineering'
)
select *
from engineers      ← CTE Usage
where ...

```

CTEs are similar to derived tables. For example

```

WITH engineers AS
( SELECT * FROM employees
  WHERE dept = 'Engineering' )

SELECT * FROM engineers
WHERE ...

```

```

SELECT * FROM
( SELECT * FROM employees
  WHERE dept = 'Engineering' ) AS engineers
WHERE
...

```

A non-recursive CTE is basically a query-local [VIEW](#). There are several advantages and caveats to them. The syntax is more readable than nested  
`FROM (SELECT ...)`  
. A CTE can refer to another and it can be referenced from multiple places.

## A CTE referencing Another CTE

Using this format makes for a more readable SQL than a nested

`FROM(SELECT ...)`

clause. Below is an example of this:

```

WITH engineers AS (
  SELECT * FROM employees
  WHERE dept IN('Development','Support') ),
eu_engineers AS ( SELECT * FROM engineers WHERE country IN('NL',...) )
SELECT
...
FROM eu_engineers;

```

## Multiple Uses of a CTE

This can be an 'anti-self join', for example:

```

WITH engineers AS (
  SELECT * FROM employees
  WHERE dept IN('Development','Support') )

SELECT * FROM engineers E1
WHERE NOT EXISTS
  (SELECT 1 FROM engineers E2
   WHERE E2.country=E1.country
   AND E2.name <> E1.name );

```

Or, for year-over-year comparisons, for example:

```

WITH sales_product_year AS (
SELECT product, YEAR(ship_date) AS year,
SUM(price) AS total_amt
FROM item_sales
GROUP BY product, year )

SELECT *
FROM sales_product_year CUR,
sales_product_year PREV,
WHERE CUR.product=PREV.product
AND CUR.year=PREV.year + 1
AND CUR.total_amt > PREV.total_amt

```

Another use is to compare individuals against their group. Below is an example of how this might be executed:

```

WITH sales_product_year AS (
SELECT product,
YEAR(ship_date) AS year,
SUM(price) AS total_amt
FROM item_sales
GROUP BY product, year
)

SELECT *
FROM sales_product_year S1
WHERE
total_amt >
(SELECT 0.1 * SUM(total_amt)
FROM sales_product_year S2
WHERE S2.year = S1.year)

```

## 1.1.4.1.6.3 Recursive Common Table Expressions Overview

MariaDB starting with 10.2.2

Recursive Common Table Expressions have been supported since MariaDB 10.2.2 .

### Contents

1. Syntax example
2. Computation
3. Summary so far
4. CAST to avoid truncating data
5. Examples
  1. Transitive closure - determining bus destinations
  2. Computing paths - determining bus routes
  3. CAST to avoid data truncation

Common Table Expressions (CTEs) are a standard SQL feature, and are essentially temporary named result sets. CTEs first appeared in the SQL standard in 1999, and the first implementations began appearing in 2007.

There are two kinds of CTEs:

- Non-recursive
- Recursive, which this article covers.

SQL is generally poor at recursive structures.

CTEs permit a query to reference itself. A recursive CTE will repeatedly execute subsets of the data until it obtains the complete result set. This makes it particularly useful for handling hierarchical or tree-structured data. `max_recursive_iterations` avoids infinite loops.

## Syntax example

WITH RECURSIVE signifies a recursive CTE. It is given a name, followed by a body (the main query) as follows:

```
with recursive ancestors as (
    select * from folks
    where name = 'Alex' ← Anchor part
    union [all]
    select f.*
    from folks as f, ancestors AS a
    where
        f.id = a.father or f.id = a.mother ← Recursive use of CTE
)
select * from ancestors; ← Recursive part
```

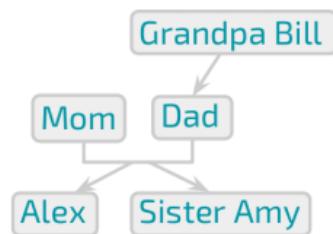

```
WITH ← WITH
with engineers as ( ← CTE name
    select *
    from employees
    where dept='Engineering' ← CTE Body
)
select *
from engineers ← CTE Usage
where ...
```

## Computation

### Recursive CTE computation

Given the following structure:

id	name	father	mother
100	Alex	20	30
20	Dad	10	NULL
30	Mom	NULL	NULL
10	Grandpa Bill	NULL	NULL
98	Sister Amy	20	30

### Computation

First execute the anchor part of the query:

```
with recursive ancestors as (
    select * from folks
    where name = 'Alex'
    union
    select f.*
    from folks as f, ancestors AS a
    where
        f.id = a.father or f.id = a.mother
)
select * from ancestors;
```

### Result table

id	name	father	mother
100	Alex	20	30

Step #1:  
execution of the anchor part

## Computation

## Result table

```
with recursive ancestors as (
  select * from folks
  where name = 'Alex'
  union
  select f.*
  from folks as f, ancestors AS a
  where
    f.id = a.father or f.id = a.mother
)
select * from ancestors;
```

id	name	father	mother
100	Alex	20	30

Next, execute the recursive part of the query:

### Step #2: execution of the recursive part

## Computation

## Result table

```
with recursive ancestors as (
  select * from folks
  where name = 'Alex'
  union
  select f.*
  from folks as f, ancestors AS a
  where
    f.id = a.father or f.id = a.mother
)
select * from ancestors;
```

id	name	father	mother
100	Alex	20	30
20	Dad	10	NULL
30	Mom	NULL	NULL

## Computation

## Result table

```
with recursive ancestors as (
  select * from folks
  where name = 'Alex'
  union
  select f.*
  from folks as f, ancestors AS a
  where
    f.id = a.father or f.id = a.mother
)
select * from ancestors;
```

id	name	father	mother
100	Alex	20	30
20	Dad	10	NULL
30	Mom	NULL	NULL
10	Grandpa Bill	NULL	NULL
98	Sister Amy	20	30

## Computation

## Result table

```
with recursive ancestors as (
  select * from folks
  where name = 'Alex'
  union
  select f.*
  from folks as f, ancestors AS a
  where
    f.id = a.father or f.id = a.mother
)
select * from ancestors;
```

id	name	father	mother
100	Alex	20	30
20	Dad	10	NULL
30	Mom	NULL	NULL
10	Grandpa Bill	NULL	NULL
98	Sister Amy	20	30

## Computation

## Result table

```
with recursive ancestors as (
  select * from folks
  where name = 'Alex'
  union
  select f.*
  from folks as f, ancestors AS a
  where
    f.id = a.father or f.id = a.mother
)
select * from ancestors;
```

id	name	father	mother
100	Alex	20	30
20	Dad	10	NULL
30	Mom	NULL	NULL
10	Grandpa Bill	NULL	NULL
98	Sister Amy	20	30

No results!

## Summary so far

```
with recursive R as (
  select anchor_data
  union [all]
  select recursive_part
  from R, ...
)
select ...
```

1. Compute anchor\_data
2. Compute recursive\_part to get the new data
3. if (new data is non-empty) goto 2;

## CAST to avoid truncating data

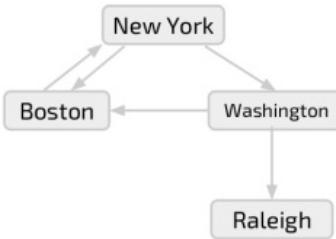

As currently implemented by MariaDB and by the SQL Standard, data may be truncated if not correctly cast. It is necessary to **CAST** the column to the correct width if the CTE's recursive part produces wider values for a column than the CTE's nonrecursive part. Some other DBMS give an error in this situation, and MariaDB's behavior may change in future - see [MDEV-12325](#). See the [examples below](#).

## Examples

Transitive closure - determining bus destinations

Sample data:

bus_routes	
origin	dst
New York	Boston
Boston	New York
New York	Washington
Washington	Boston
Washington	Raleigh

```
CREATE TABLE bus_routes (origin varchar(50), dst varchar(50));
INSERT INTO bus_routes VALUES
  ('New York', 'Boston'),
  ('Boston', 'New York'),
  ('New York', 'Washington'),
  ('Washington', 'Boston'),
  ('Washington', 'Raleigh');
```

Now, we want to return the bus destinations with New York as the origin:

```
WITH RECURSIVE bus_dst as (
  SELECT origin as dst FROM bus_routes WHERE origin='New York'
  UNION
  SELECT bus_routes.dst FROM bus_routes JOIN bus_dst ON bus_dst.dst= bus_routes.origin
)
SELECT * FROM bus_dst;
+-----+
| dst   |
+-----+
| New York |
| Boston   |
| Washington |
| Raleigh  |
+-----+
```

The above example is computed as follows:

First, the anchor data is calculated:

- Starting from New York
- Boston and Washington are added

Next, the recursive part:

- Starting from Boston and then Washington
- Raleigh is added
- UNION excludes nodes that are already present.

## Computing paths - determining bus routes

This time, we are trying to get bus routes such as “New York -> Washington -> Raleigh”.

Using the same sample data as the previous example:

```
WITH RECURSIVE paths (cur_path, cur_dest) AS (
    SELECT origin, origin FROM bus_routes WHERE origin='New York'
    UNION
    SELECT CONCAT(paths.cur_path, ',', bus_routes.dst), bus_routes.dst
    FROM paths
    JOIN bus_routes
    ON paths.cur_dest = bus_routes.origin AND
       NOT FIND_IN_SET(bus_routes.dst, paths.cur_path)
)
SELECT * FROM paths;
```

cur_path	cur_dest
New York	New York
New York,Boston	Boston
New York,Washington	Washington
New York,Washington,Boston	Boston
New York,Washington,Raleigh	Raleigh

## CAST to avoid data truncation

In the following example, data is truncated because the results are not specifically cast to a wide enough type:

```
WITH RECURSIVE tbl AS (
    SELECT NULL AS col
    UNION
    SELECT "THIS NEVER SHOWS UP" AS col FROM tbl
)
SELECT col FROM tbl
```

col
NULL

Explicitly use `CAST` to overcome this:

```
WITH RECURSIVE tbl AS (
    SELECT CAST(NULL AS CHAR(50)) AS col
    UNION SELECT "THIS NEVER SHOWS UP" AS col FROM tbl
)
SELECT * FROM tbl;
```

col
NULL
THIS NEVER SHOWS UP

## 1.1.4.1.7 SELECT WITH ROLLUP

### Contents

1. [Syntax](#)
2. [Description](#)
3. [Examples](#)
4. [See Also](#)

### Syntax

See [SELECT](#) for the full syntax.

### Description

The

WITH ROLLUP

modifier adds extra rows to the resultset that represent super-aggregate summaries. The super-aggregated column is represented by a NULL value. Multiple aggregates over different columns will be added if there are multiple GROUP BY columns.

The LIMIT clause can be used at the same time, and is applied after the

WITH ROLLUP

rows have been added.

WITH ROLLUP

cannot be used with ORDER BY . Some sorting is still possible by using

ASC

or

DESC

clauses with the

GROUP BY

column, although the super-aggregate rows will always be added last.

## Examples

These examples use the following sample table

```
CREATE TABLE booksales (
    country VARCHAR(35), genre ENUM('fiction','non-fiction'), year YEAR, sales INT);

INSERT INTO booksales VALUES
    ('Senegal','fiction',2014,12234), ('Senegal','fiction',2015,15647),
    ('Senegal','non-fiction',2014,64980), ('Senegal','non-fiction',2015,78901),
    ('Paraguay','fiction',2014,87970), ('Paraguay','fiction',2015,76940),
    ('Paraguay','non-fiction',2014,8760), ('Paraguay','non-fiction',2015,9030);
```

The addition of the

WITH ROLLUP

modifier in this example adds an extra row that aggregates both years:

```
SELECT year, SUM(sales) FROM booksales GROUP BY year;
+-----+
| year | SUM(sales) |
+-----+
| 2014 | 173944 |
| 2015 | 180518 |
+-----+
2 rows in set (0.08 sec)

SELECT year, SUM(sales) FROM booksales GROUP BY year WITH ROLLUP;
+-----+
| year | SUM(sales) |
+-----+
| 2014 | 173944 |
| 2015 | 180518 |
| NULL | 354462 |
+-----+
```

In the following example, each time the genre, the year or the country change, another super-aggregate row is added:

```

SELECT country, year, genre, SUM(sales)
  FROM booksales GROUP BY country, year, genre;
+-----+-----+-----+
| country | year | genre      | SUM(sales) |
+-----+-----+-----+
| Paraguay | 2014 | fiction    | 87970 |
| Paraguay | 2014 | non-fiction | 8760 |
| Paraguay | 2015 | fiction    | 76940 |
| Paraguay | 2015 | non-fiction | 9030 |
| Senegal  | 2014 | fiction    | 12234 |
| Senegal  | 2014 | non-fiction | 64980 |
| Senegal  | 2015 | fiction    | 15647 |
| Senegal  | 2015 | non-fiction | 78901 |
+-----+-----+-----+

SELECT country, year, genre, SUM(sales)
  FROM booksales GROUP BY country, year, genre WITH ROLLUP;
+-----+-----+-----+
| country | year | genre      | SUM(sales) |
+-----+-----+-----+
| Paraguay | 2014 | fiction    | 87970 |
| Paraguay | 2014 | non-fiction | 8760 |
| Paraguay | 2014 | NULL       | 96730 |
| Paraguay | 2015 | fiction    | 76940 |
| Paraguay | 2015 | non-fiction | 9030 |
| Paraguay | 2015 | NULL       | 85970 |
| Paraguay | NULL  | NULL       | 182700 |
| Senegal  | 2014 | fiction    | 12234 |
| Senegal  | 2014 | non-fiction | 64980 |
| Senegal  | 2014 | NULL       | 77214 |
| Senegal  | 2015 | fiction    | 15647 |
| Senegal  | 2015 | non-fiction | 78901 |
| Senegal  | 2015 | NULL       | 94548 |
| Senegal  | NULL  | NULL       | 171762 |
| NULL    | NULL  | NULL       | 354462 |
+-----+-----+-----+

```

The LIMIT clause, applied after WITH ROLLUP:

```

SELECT country, year, genre, SUM(sales)
  FROM booksales GROUP BY country, year, genre WITH ROLLUP LIMIT 4;
+-----+-----+-----+
| country | year | genre      | SUM(sales) |
+-----+-----+-----+
| Paraguay | 2014 | fiction    | 87970 |
| Paraguay | 2014 | non-fiction | 8760 |
| Paraguay | 2014 | NULL       | 96730 |
| Paraguay | 2015 | fiction    | 76940 |
+-----+-----+-----+

```

Sorting by year descending:

```

SELECT country, year, genre, SUM(sales)
  FROM booksales GROUP BY country, year DESC, genre WITH ROLLUP;
+-----+-----+-----+
| country | year | genre      | SUM(sales) |
+-----+-----+-----+
| Paraguay | 2015 | fiction    | 76940 |
| Paraguay | 2015 | non-fiction | 9030 |
| Paraguay | 2015 | NULL       | 85970 |
| Paraguay | 2014 | fiction    | 87970 |
| Paraguay | 2014 | non-fiction | 8760 |
| Paraguay | 2014 | NULL       | 96730 |
| Paraguay | NULL  | NULL       | 182700 |
| Senegal  | 2015 | fiction    | 15647 |
| Senegal  | 2015 | non-fiction | 78901 |
| Senegal  | 2015 | NULL       | 94548 |
| Senegal  | 2014 | fiction    | 12234 |
| Senegal  | 2014 | non-fiction | 64980 |
| Senegal  | 2014 | NULL       | 77214 |
| Senegal  | NULL  | NULL       | 171762 |
| NULL    | NULL  | NULL       | 354462 |
+-----+-----+-----+

```

## 1.1.4.1.8 SELECT INTO OUTFILE

### Syntax

```
SELECT ... INTO OUTFILE 'file_name'  
    [CHARACTER SET charset_name]  
    [export_options]  
  
export_options:  
    [{FIELDS | COLUMNS}  
        [TERMINATED BY 'string']  
        [[OPTIONALLY] ENCLOSED BY 'char']  
        [ESCAPED BY 'char']  
    ]  
    [LINES  
        [STARTING BY 'string']  
        [TERMINATED BY 'string']  
    ]
```

### Contents

1. [Syntax](#)
2. [Description](#)
  1. [Character-sets](#)
3. [Example](#)
4. [See Also](#)

### Description

```
SELECT INTO OUTFILE
```

writes the resulting rows to a file, and allows the use of column and row terminators to specify a particular output format. The default is to terminate fields with tabs (`\t`) and lines with newlines (`\n`).

The file must not exist. It cannot be overwritten. A user needs the `FILE` privilege to run this statement. Also, MariaDB needs permission to write files in the specified location. If the `secure_file_priv` system variable is set to a non-empty directory name, the file can only be written to that directory.

The

```
LOAD DATA INFILE
```

statement complements

```
SELECT INTO OUTFILE
```

### Character-sets

The

```
CHARACTER SET
```

clause specifies the `character set` in which the results are to be written. Without the clause, no conversion takes place (the binary character set). In this case, if there are multiple character sets, the output will contain these too, and may not easily be able to be reloaded.

In cases where you have two servers using different character-sets, using

```
SELECT INTO OUTFILE
to transfer data from one to the other can have unexpected results. To ensure that MariaDB correctly interprets the escape sequences, use the
CHARACTER SET
clause on both the
SELECT INTO OUTFILE
statement and the subsequent
```

```
LOAD DATA INFILE
```

statement.

## Example

The following example produces a file in the CSV format:

```
SELECT customer_id, firstname, surname INTO OUTFILE '/exportdata/customers.txt'
FIELDS TERMINATED BY ',' OPTIONALLY ENCLOSED BY ""
LINES TERMINATED BY '\n'
FROM customers;
```

## See Also

- [SELECT INTO DUMPFILE](#)

### 1.1.4.1.9 SELECT INTO DUMPFILE

#### Contents

1. [Syntax](#)
2. [Description](#)
3. [Example](#)
4. [See Also](#)

## Syntax

```
SELECT ... INTO DUMPFILE 'file_path'
```

## Description

```
SELECT ... INTO DUMPFILE
```

is a [SELECT](#) clause which writes the resultset into a single unformatted row, without any separators, in a file. The results will not be returned to the client.

*file\_path* can be an absolute path, or a relative path starting from the data directory. It can only be specified as a [string literal](#), not as a variable. However, the statement can be dynamically composed and executed as a prepared statement to work around this limitation.

This statement is binary-safe and so is particularly useful for writing [BLOB](#) values to file. It can be used, for example, to copy an image or an audio document from the database to a file. [SELECT ... INTO FILE](#) can be used to save a text file.

The file must not exist. It cannot be overwritten. A user needs the [FILE](#) privilege to run this statement. Also, MariaDB needs permission to write files in the specified location. If the [secure\\_file\\_priv](#) system variable is set to a non-empty directory name, the file can only be written to that directory.

Since [MariaDB 5.1](#), the [character\\_set\\_filesystem](#) system variable has controlled interpretation of file names that are given as literal strings.

## Example

```
SELECT _utf8'Hello world!' INTO DUMPFILE '/tmp/world';

SELECT LOAD_FILE('/tmp/world') AS world;
+-----+
| world      |
+-----+
| Hello world! |
+-----+
```

## See Also

- [LOAD\\_FILE\(\)](#)
- [SELECT INTO Variable](#)
- [SELECT INTO OUTFILE](#)

## 1.1.4.1.10 FOR UPDATE

InnoDB supports row-level locking. Selected rows can be locked using [LOCK IN SHARE MODE](#) or [FOR UPDATE](#). In both cases, a lock is acquired on the rows read by the query, and it will be released when the current transaction is committed.

The

FOR UPDATE  
clause of [SELECT](#) applies only when [autocommit](#) is set to 0 or the

SELECT  
is enclosed in a transaction. A lock is acquired on the rows, and other transactions are prevented from writing the rows, acquire locks, and from reading them (unless their isolation level is

[READ UNCOMMITTED](#)

).

If

autocommit  
is set to 1, the [LOCK IN SHARE MODE](#) and  
FOR UPDATE  
clauses have no effect.

If the isolation level is set to [SERIALIZABLE](#), all plain

SELECT  
statements are converted to  
SELECT ... LOCK IN SHARE MODE

## Example

```
SELECT * FROM trans WHERE period=2001 FOR UPDATE;
```

## See Also

- [SELECT](#)
- [LOCK IN SHARE MODE](#)
- [InnoDB Lock Modes](#)

## 1.1.4.1.11 LOCK IN SHARE MODE

InnoDB supports row-level locking. Selected rows can be locked using

[LOCK IN SHARE MODE](#)  
or [FOR UPDATE](#). In both cases, a lock is acquired on the rows read by the query, and it will be released when the current transaction is committed.

When

[LOCK IN SHARE MODE](#)  
is specified in a [SELECT](#) statement, MariaDB will wait until all transactions that have modified the rows are committed. Then, a write lock is acquired. All transactions can read the rows, but if they want to modify them, they have to wait until your transaction is committed.

If

autocommit  
is set to 1, the [LOCK IN SHARE MODE](#) and [FOR UPDATE](#) clauses have no effect.

## See Also

- [SELECT](#)
- [FOR UPDATE](#)
- [InnoDB Lock Modes](#)

## 1.1.4.1.12 Optimizer Hints

# Optimizer hints

There are some options available in `SELECT` to affect the execution plan. These are known as optimizer hints.

## HIGH\_PRIORITY

```
HIGH_PRIORITY
gives the statement a higher priority. If the table is locked, high priority
SELECT
s will be executed as soon as the lock is released, even if other statements are queued.
HIGH_PRIORITY
applies only if the storage engine only supports table-level locking (
MyISAM
,
MEMORY
,
MERGE
). See HIGH\_PRIORITY and LOW\_PRIORITY clauses for details.
```

## SQL\_CACHE / SQL\_NO\_CACHE

If the `query_cache_type` system variable is set to 2 or

```
DEMAND
, and the current statement is cacheable,
SQL_CACHE
causes the query to be cached and
SQL_NO_CACHE
causes the query not to be cached. For
UNION
S,
SQL_CACHE
or
SQL_NO_CACHE
should be specified for the first query. See also The Query Cache for more detail and a list of the types of statements that aren't cacheable.
```

## SQL\_BUFFER\_RESULT

```
SQL_BUFFER_RESULT
forces the optimizer to use a temporary table to process the result. This is useful to free locks as soon as possible.
```

## SQL\_SMALL\_RESULT / SQL\_BIG\_RESULT

```
SQL_SMALL_RESULT
and
SQL_BIG_RESULT
tell the optimizer whether the result is very big or not. Usually,
GROUP BY
and
DISTINCT
operations are performed using a temporary table. Only if the result is very big, using a temporary table is not convenient. The optimizer
automatically knows if the result is too big, but you can force the optimizer to use a temporary table with
SQL_SMALL_RESULT
, or avoid the temporary table using
SQL_BIG_RESULT
```

## STRAIGHT\_JOIN

```
STRAIGHT_JOIN
applies to the JOIN queries, and tells the optimizer that the tables must be read in the order they appear in the
SELECT
. For
const
and
system
```

table this option is sometimes ignored.

## SQL\_CALC\_FOUND\_ROWS

SQL\_CALC\_FOUND\_ROWS  
is only applied when using the  
LIMIT  
clause. If this option is used, MariaDB will count how many rows would match the query, without the  
LIMIT  
clause. That number can be retrieved in the next query, using [FOUND\\_ROWS\(\)](#).

## USE/FORCE/IGNORE INDEX

USE INDEX  
,  
FORCE INDEX  
and  
IGNORE INDEX  
constrain the query planning to a specific index.

For further information about some of these options, see [How to force query plans](#).

## 1.1.4.1.13 PROCEDURE

The

PROCEDURE  
clause of [SELECT](#) passes the whole result set to a Procedure which will process it. These Procedures are not [Stored Procedures](#), and can only be written in the C language, so it is necessary to recompile the server.

Currently, the only available procedure is [ANALYSE](#), which examines the resultset and suggests the optimal datatypes for each column. It is defined in the

sql/sql\_analyse.cc  
file, and can be used as an example to create more Procedures.

This clause cannot be used in a [view](#)'s definition.

## See Also

- [SELECT](#)
- [Stored Procedures](#)

## 1.1.4.1.14 HANDLER

### 1.1.4.1.14.1 HANDLER Commands

#### Syntax

```
HANDLER tbl_name OPEN [ [AS] alias]
HANDLER tbl_name READ index_name { = | >= | <= | < } (value1,value2,...)
    [ WHERE where_condition ] [LIMIT ... ]
HANDLER tbl_name READ index_name { FIRST | NEXT | PREV | LAST }
    [ WHERE where_condition ] [LIMIT ... ]
HANDLER tbl_name READ { FIRST | NEXT }
    [ WHERE where_condition ] [LIMIT ... ]
HANDLER tbl_name CLOSE
```

## Contents

1. [Syntax](#)
2. [Description](#)
3. [Key Lookup](#)
4. [Key Scans](#)
5. [Table Scans](#)
6. [Limitations](#)
  1. [Finding 'Old Rows'](#)
  2. [Invisible Columns](#)
  3. [System-Versioned Tables](#)
  4. [Other Limitations](#)
7. [Error Codes](#)
8. [See Also](#)

## Description

The

HANDLER

statement provides direct access to table storage engine interfaces for key lookups and key or table scans. It is available for at least [Aria](#), [Memory](#), [MyISAM](#) and [InnoDB](#) tables (and should work with most 'normal' storage engines, but not with system tables, [MERGE](#) or [views](#)).

HANDLER ... OPEN

opens a table, allowing it to be accessible to subsequent

HANDLER ... READ

statements. The table can either be opened using an alias (which must then be used by

HANDLER ... READ

, or a table name.

The table object is only closed when

HANDLER ... CLOSE

is called by the session, and is not shared by other sessions.

[Prepared statements](#) work with

HANDLER READ

, which gives a much higher performance (50% speedup) as there is no parsing and all data is transformed in binary (without conversions to text, as with the normal protocol).

The HANDLER command does not work with [partitioned tables](#).

## Key Lookup

A key lookup is started with:

```
HANDLER tbl_name READ index_name { = | >= | <= | < } (value,value) [LIMIT...]
```

The values stands for the value of each of the key columns. For most key types (except for HASH keys in MEMORY storage engine) you can use a prefix subset of it's columns.

If you are using LIMIT, then in case of >= or > then there is an implicit NEXT implied, while if you are using <= or < then there is an implicit PREV implied.

After the initial read, you can use

```
HANDLER tbl_name READ index_name NEXT [ LIMIT ... ]  
or  
HANDLER tbl_name READ index_name PREV [ LIMIT ... ]
```

to scan the rows in key order.

Note that the row order is not defined for keys with duplicated values and will vary from engine to engine.

## Key Scans

You can scan a table in key order by doing:

```
HANDLER tbl_name READ index_name FIRST [ LIMIT ... ]  
HANDLER tbl_name READ index_name NEXT [ LIMIT ... ]
```

or, if the handler supports backwards key scans (most do):

```
HANDLER tbl_name READ index_name LAST [ LIMIT ... ]
HANDLER tbl_name READ index_name PREV [ LIMIT ... ]
```

## Table Scans

You can scan a table in row order by doing:

```
HANDLER tbl_name READ FIRST [ LIMIT ... ]
HANDLER tbl_name READ NEXT [ LIMIT ... ]
```

## Limitations

As this is a direct interface to the storage engine, some limitations may apply for what you can do and what happens if the table changes. Here follows some of the common limitations:

### Finding 'Old Rows'

HANDLER READ is not transaction safe, consistent or atomic. It's ok for the storage engine to return rows that existed when you started the scan but that were later deleted. This can happen as the storage engine may cache rows as part of the scan from a previous read.

You may also find rows committed since the scan originally started.

### Invisible Columns

```
HANDLER ... READ
also reads the data of invisible-columns .
```

## System-Versioned Tables

```
HANDLER ... READ
reads everything from system-versioned tables , and so includes
row_start
and
row_end
fields, as well as all rows that have since been deleted or changed, including when history partitions are used.
```

## Other Limitations

- If you do an [ALTER TABLE](#) , all your HANDLER's for that table are automatically closed.
- If you do an ALTER TABLE for a table that is used by some other connection with HANDLER, the ALTER TABLE will wait for the HANDLER to be closed.
- For HASH keys, you must use all key parts when searching for a row.
- For HASH keys, you can't do a key scan of all values. You can only find all rows with the same key value.
- While each HANDLER READ command is atomic, if you do a scan in many steps, then some engines may give you error 1020 if the table changed between the commands. Please refer to the [specific engine handler page](#) if this happens.

## Error Codes

- Error 1031 (ER\_ILLEGAL\_HA) Table storage engine for 't1' doesn't have this option
  - If you get this for HANDLER OPEN it means the storage engine doesn't support HANDLER calls.
  - If you get this for HANDLER READ it means you are trying to use an incomplete HASH key.
- Error 1020 (ER\_CHECKREAD) Record has changed since last read in table '...'
  - This means that the table changed between two reads and the handler can't handle this case for the given scan.

## See Also

- [What is MariaDB 5.3](#)

## 1.1.4.1.14.2 HANDLER for MEMORY Tables

This article explains how to use [HANDLER commands](#) efficiently with [MEMORY/HEAP](#) tables.

If you want to scan a table for over different key values, not just search for exact key values, you should create your keys with 'USING BTREE':

```
CREATE TABLE t1 (a INT, b INT, KEY(a), KEY b USING BTREE (b)) engine=memory;
```

In the above table,

- a is a **HASH** key that only supports exact matches (=) while
- b is a **BTREE** key that you can use to scan the table in key order, starting from start or from a given key value.

The limitations for HANDLER READ with Memory|HEAP tables are:

## Limitations for HASH keys

- You must use all key parts when searching for a row.
- You can't do a key scan of all values. You can only find all rows with the same key value.
- READ NEXT gives error 1031 if the tables changed since last read.

## Limitations for BTREE keys

- READ NEXT gives error 1031 if the tables changed since last read. This limitation can be lifted in the future.

## Limitations for table scans

- READ NEXT gives error 1031 if the table was truncated since last READ call.

## See also

See also the the limitations listed in [HANDLER commands](#).

## 1.1.4.1.15 DUAL

### Description

You are allowed to specify

DUAL

as a dummy table name in situations where no tables are referenced, such as the following **SELECT** statement:

```
SELECT 1 + 1 FROM DUAL;
+-----+
| 1 + 1 |
+-----+
|      2 |
+-----+
```

DUAL

is purely for the convenience of people who require that all

SELECT

statements should have

FROM

and possibly other clauses. MariaDB ignores the clauses. MariaDB does not require

FROM DUAL

if no tables are referenced.

FROM DUAL could be used when you only SELECT computed values, but require a WHERE clause, perhaps to test that a script correctly handles empty resultsets:

```
SELECT 1 FROM DUAL WHERE FALSE;
Empty set (0.00 sec)
```

## See Also

- [SELECT](#)

## 1.1.4.1.16 SELECT ... OFFSET ... FETCH

MariaDB starting with [10.6.0](#)

```
SELECT ... OFFSET ... FETCH  
was introduced in MariaDB 10.6.
```

## Syntax

```
OFFSET start { ROW | ROWS }  
FETCH { FIRST | NEXT } [ count ] { ROW | ROWS } { ONLY | WITH TIES }
```

## Description

The

OFFSET clause allows one to return only those elements of a resultset that come after a specified offset. The FETCH clause specifies the number of rows to return, while ONLY or WITH TIES specifies whether or not to also return any further results that tie for last place according to the ordered resultset.

Either the singular

ROW or the plural  
ROWS can be used after the  
OFFSET and  
FETCH clauses; the choice has no impact on the results.

In the case of

WITH TIES, an ORDER BY clause is required, otherwise an ERROR will be returned.

```
SELECT i FROM t1 FETCH FIRST 2 ROWS WITH TIES;  
ERROR 4180 (HY000): FETCH ... WITH TIES requires ORDER BY clause to be present
```

## Examples

Given a table with 6 rows:

```
CREATE OR REPLACE TABLE t1 (i INT);  
INSERT INTO t1 VALUES (1),(2),(3),(4), (4), (5);  
SELECT i FROM t1 ORDER BY i ASC;  
+---+  
| i |  
+---+  
| 1 |  
| 2 |  
| 3 |  
| 4 |  
| 4 |  
| 5 |  
+---+
```

OFFSET 2 allows one to skip the first two results.

```
SELECT i FROM t1 ORDER BY i ASC OFFSET 2 ROWS;
+---+
| i |
+---+
| 3 |
| 4 |
| 4 |
| 5 |
+---+
```

FETCH FIRST 3 ROWS ONLY  
limits the results to three rows only

```
SELECT i FROM t1 ORDER BY i ASC OFFSET 1 ROWS FETCH FIRST 3 ROWS ONLY;
+---+
| i |
+---+
| 2 |
| 3 |
| 4 |
+---+
```

The same outcome can also be achieved with the [LIMIT](#) clause:

```
SELECT i FROM t1 ORDER BY i ASC LIMIT 3 OFFSET 1;
+---+
| i |
+---+
| 2 |
| 3 |
| 4 |
+---+
```

WITH TIES  
ensures the tied result  
4  
is also returned.

```
SELECT i FROM t1 ORDER BY i ASC OFFSET 1 ROWS FETCH FIRST 3 ROWS WITH TIES;
+---+
| i |
+---+
| 2 |
| 3 |
| 4 |
| 4 |
+---+
```

## See Also

- [SELECT](#)

### 1.1.4.2 Inserting and Loading Data

#### 1.1.4.2.1 INSERT

## Syntax

```
INSERT [LOW_PRIORITY | DELAYED | HIGH_PRIORITY] [IGNORE]
[INTO] tbl_name [PARTITION (partition_list)] [(col,...)]
{VALUES | VALUE} ({expr | DEFAULT},...),(...),...
[ ON DUPLICATE KEY UPDATE
  col=expr
  [, col=expr] ... ] [RETURNING select_expr
  [, select_expr ...]]
```

Or:

```
INSERT [LOW_PRIORITY | DELAYED | HIGH_PRIORITY] [IGNORE]
[INTO] tbl_name [PARTITION (partition_list)]
SET col={expr | DEFAULT}, ...
[ ON DUPLICATE KEY UPDATE
  col=expr
  [, col=expr] ... ] [RETURNING select_expr
  [, select_expr ...]]
```

Or:

```
INSERT [LOW_PRIORITY | HIGH_PRIORITY] [IGNORE]
[INTO] tbl_name [PARTITION (partition_list)] [(col,...)]
SELECT ...
[ ON DUPLICATE KEY UPDATE
  col=expr
  [, col=expr] ... ] [RETURNING select_expr
  [, select_expr ...]]
```

## Contents

1. [Syntax](#)
2. [INSERT DELAYED](#)
3. [HIGH PRIORITY and LOW PRIORITY](#)
4. [Defaults and Duplicate Values](#)
5. [INSERT IGNORE](#)
6. [INSERT ON DUPLICATE KEY UPDATE](#)
7. [Examples](#)
8. [INSERT ... RETURNING](#)
  1. [Examples](#)
9. [See Also](#)

The

`INSERT`  
statement is used to insert new rows into an existing table. The  
`INSERT ... VALUES`  
and  
`INSERT ... SET`  
forms of the statement insert rows based on explicitly specified values. The  
`INSERT ... SELECT`  
form inserts rows selected from another table or tables.  
`INSERT ... SELECT`  
is discussed further in the

[INSERT ... SELECT](#)

article.

The table name can be specified in the form

`db_name`  
. . .  
`tbl_name`  
or, if a default database is selected, in the form  
`tbl_name`  
(see [Identifier Qualifiers](#)). This allows to use `INSERT ... SELECT` to copy rows between different databases.

The PARTITION clause can be used in both the INSERT and the SELECT part. See [Partition Pruning and Selection](#) for details.

MariaDB starting with [10.5](#)

The RETURNING clause was introduced in [MariaDB 10.5](#).

The columns list is optional. It specifies which values are explicitly inserted, and in which order. If this clause is not specified, all values must be explicitly specified, in the same order they are listed in the table definition.

The list of value follow the

`VALUES`  
or  
`VALUE`

keyword (which are interchangeable, regardless how much values you want to insert), and is wrapped by parenthesis. The values must be listed in the same order as the columns list. It is possible to specify more than one list to insert more than one rows with a single statement. If many rows are inserted, this is a speed optimization.

For one-row statements, the

```
SET  
clause may be more simple, because you don't need to remember the columns order. All values are specified in the form  
col  
=  
expr
```

Values can also be specified in the form of a SQL expression or subquery. However, the subquery cannot access the same table that is named in the  
INTO  
clause.

If you use the

```
LOW_PRIORITY  
keyword, execution of the  
INSERT  
is delayed until no other clients are reading from the table. If you use the  
HIGH_PRIORITY  
keyword, the statement has the same priority as  
SELECT  
s. This affects only storage engines that use only table-level locking (MyISAM, MEMORY, MERGE). However, if one of these keywords is  
specified, concurrent inserts cannot be used. See HIGH\_PRIORITY and LOW\_PRIORITY clauses for details.
```

## INSERT DELAYED

For more details on the

```
DELAYED  
option, see INSERT DELAYED.
```

## HIGH PRIORITY and LOW PRIORITY

See [HIGH\\_PRIORITY and LOW\\_PRIORITY](#).

## Defaults and Duplicate Values

See [INSERT - Default & Duplicate Values](#) for details..

## INSERT IGNORE

See [INSERT IGNORE](#).

## INSERT ON DUPLICATE KEY UPDATE

See [INSERT ON DUPLICATE KEY UPDATE](#).

## Examples

Specifying the column names:

```
INSERT INTO person (first_name, last_name) VALUES ('John', 'Doe');
```

Inserting more than 1 row at a time:

```
INSERT INTO tbl_name VALUES (1, "row 1"), (2, "row 2");
```

Using the

```
SET  
clause:
```

```
INSERT INTO person SET first_name = 'John', last_name = 'Doe';
```

SELECTing from another table:

```
INSERT INTO contractor SELECT * FROM person WHERE status = 'c';
```

See [INSERT ON DUPLICATE KEY UPDATE](#) and [INSERT IGNORE](#) for further examples.

# INSERT ... RETURNING

INSERT ... RETURNING

returns a resultset of the inserted rows.

This returns the listed columns for all the rows that are inserted, or alternatively, the specified SELECT expression. Any SQL expressions which can be calculated can be used in the select expression for the RETURNING clause, including virtual columns and aliases, expressions which use various operators such as bitwise, logical and arithmetic operators, string functions, date-time functions, numeric functions, control flow functions, secondary functions and stored functions. Along with this, statements which have subqueries and prepared statements can also be used.

## Examples

Simple INSERT statement

```
INSERT INTO t2 VALUES (1,'Dog'),(2,'Lion'),(3,'Tiger'),(4,'Leopard')
RETURNING id2,id2+id2,id2&id2,id2||id2;
+-----+-----+-----+-----+
| id2 | id2+id2 | id2&id2 | id2||id2 |
+-----+-----+-----+
|  1  |      2  |      1  |      1  |
|  2  |      4  |      2  |      1  |
|  3  |      6  |      3  |      1  |
|  4  |      8  |      4  |      1  |
+-----+-----+-----+
```

Using stored functions in RETURNING

```
DELIMITER |
CREATE FUNCTION f(arg INT) RETURNS INT
BEGIN
    RETURN (SELECT arg+arg);
END|
DELIMITER ;

PREPARE stmt FROM "INSERT INTO t1 SET id1=1, animal1='Bear' RETURNING f(id1), UPPER(animal1)";

EXECUTE stmt;
+-----+-----+
| f(id1) | UPPER(animal1) |
+-----+-----+
|     2  | BEAR           |
+-----+-----+
```

Subqueries in the RETURNING clause that return more than one row or column cannot be used.

Aggregate functions cannot be used in the RETURNING clause. Since aggregate functions work on a set of values, and if the purpose is to get the row count, ROW\_COUNT() with SELECT can be used or it can be used in INSERT...SELECT...RETURNING if the table in the RETURNING clause is not the same as the INSERT table.

- [INSERT IGNORE](#)
- [INSERT ON DUPLICATE KEY UPDATE](#)
- [How to quickly insert data into MariaDB](#)

## 1.1.4.2.2 INSERT DELAYED

### Syntax

```
INSERT DELAYED ...
```

- INSERT DELAYED  
should be used only for  
INSERT  
statements that specify value lists. The server ignores  
DELAYED  
for  
INSERT ... SELECT  
or  
INSERT ... ON DUPLICATE KEY UPDATE  
statements.
- Because the  
`INSERT DELAYED`  
statement returns immediately, before the rows are inserted, you cannot use  
`LAST_INSERT_ID()`  
to get the  
`AUTO_INCREMENT`  
value that the statement might generate.
  - `DELAYED`  
rows are not visible to  
`SELECT`  
statements until they actually have been inserted.
  - After  
`INSERT DELAYED`  
`, ROW_COUNT()` returns the number of the rows you tried to insert, not the number of the successful writes.
  - `DELAYED`  
is ignored on slave replication servers, so that  
`INSERT DELAYED`  
is treated as a normal  
`INSERT`  
on slaves. This is because  
`DELAYED`  
could cause the slave to have different data than the master.  
`INSERT DELAYED`  
statements are not [safe for replication](#).
  - Pending  
`INSERT DELAYED`  
statements are lost if a table is write locked and `ALTER TABLE` is used to modify the table structure.
  - `INSERT DELAYED`  
is not supported for views. If you try, you will get an error like this:  
`ERROR 1347 (HY000): 'view_name' is not BASE TABLE`
  - `INSERT DELAYED`  
is not supported for [partitioned tables](#).
  - `INSERT DELAYED`  
is not supported within [stored programs](#).
  - `INSERT DELAYED`  
does not work with [triggers](#).
  - `INSERT DELAYED`  
does not work if there is a check constraint in place.
  - `INSERT DELAYED`  
does not work if [skip-new](#) mode is active.

## 1.1.4.2.3 INSERT SELECT

# Syntax

```
INSERT [LOW_PRIORITY | HIGH_PRIORITY] [IGNORE]
      [INTO] tbl_name [(col_name,...)]
      SELECT ...
      [ ON DUPLICATE KEY UPDATE col_name=expr, ... ]
```

## Contents

1. [Syntax](#)
2. [Description](#)
3. [See Also](#)

## Description

With

```
INSERT ... SELECT
, you can quickly insert many rows into a table from one or more other tables. For example:
```

```
INSERT INTO tbl_temp2 (fld_id)
SELECT tbl_temp1.fld_order_id
FROM tbl_temp1 WHERE tbl_temp1.fld_order_id > 100;
```

tbl\_name  
can also be specified in the form  
db\_name  
.  
tbl\_name  
(see [Identifier Qualifiers](#)). This allows to copy rows between different databases.

If the new table has a primary key or UNIQUE indexes, you can use [IGNORE](#) to handle duplicate key errors during the query. The newer values will not be inserted if an identical value already exists.

### REPLACE

can be used instead of  
INSERT  
to prevent duplicates on  
UNIQUE  
indexes by deleting old values. In that case,  
ON DUPLICATE KEY UPDATE  
cannot be used.

```
INSERT ... SELECT
works for tables which already exist. To create a table for a given resultset, you can use CREATE TABLE ... SELECT.
```

## 1.1.4.2.4 LOAD Data into Tables or Index

### 1.1.4.2.4.1 LOAD DATA INFILE

## Syntax

```

LOAD DATA [LOW_PRIORITY | CONCURRENT] [LOCAL] INFILE 'file_name'
[REPLACE | IGNORE]
INTO TABLE tbl_name
[CHARACTER SET charset_name]
[{{FIELDS | COLUMNS}
  [TERMINATED BY 'string']
  [[OPTIONALLY] ENCLOSED BY 'char']
  [ESCAPED BY 'char']]
]
[LINES
  [STARTING BY 'string']
  [TERMINATED BY 'string']]
]
[IGNORE number LINES]
[(col_name_or_user_var,...)]
[SET col_name = expr,...]

```

## Contents

1. [Syntax](#)
2. [Description](#)
  1. [LOAD DATA LOCAL INFILE](#)
  2. [REPLACE and IGNORE](#)
  3. [Character-sets](#)
  4. [Preprocessing Inputs](#)
  5. [Priority and Concurrency](#)
  6. [Progress Reporting](#)
  7. [Using mariadb-import/mysqlimport](#)
  8. [Indexing](#)
3. [Examples](#)
4. [See Also](#)

## Description

`LOAD DATA INFILE`  
is unsafe for statement-based replication.

Reads rows from a text file into the designated table on the database at a very high speed. The file name must be given as a literal string.

Files are written to disk using the `SELECT INTO OUTFILE` statement. You can then read the files back into a table using the

`LOAD DATA INFILE`  
statement. The  
`FIELDS`  
and  
`LINES`  
clauses are the same in both statements. These clauses are optional, but if both are specified then the  
`FIELDS`  
clause must precede  
`LINES`

Executing this statement activates

`INSERT`  
triggers.

One must have the `FILE` privilege to be able to execute `LOAD DATA`. This is to ensure normal users will not attempt to read system files.

Note that MariaDB's `systemd` unit file restricts access to

`/home`  
,

`/root`  
, and  
`/run/user`  
by default. See [Configuring access to home directories](#).

## LOAD DATA LOCAL INFILE

When you execute the

```
LOAD DATA INFILE  
statement, MariaDB Server attempts to read the input file from its own file system. In contrast, when you execute the  
LOAD DATA LOCAL INFILE  
statement, the client attempts to read the input file from its file system, and it sends the contents of the input file to the MariaDB Server. This  
allows you to load files from the client's local file system into the database.
```

In the event that you don't want to permit this operation (such as for security reasons), you can disable the

```
LOAD DATA LOCAL INFILE  
statement on either the server or the client.
```

- The

```
LOAD DATA LOCAL INFILE  
statement can be disabled on the server by setting the local\_infile system variable to  
0
```

- The

```
LOAD DATA LOCAL INFILE  
statement can be disabled on the client. If you are using MariaDB Connector/C, this can be done by unsetting the  
CLIENT_LOCAL_FILES  
capability flag with the mysql\_real\_connect function or by unsetting the  
MYSQL_OPT_LOCAL_INFILE  
option with mysql\_optionsv function. If you are using a different client or client library, then see the documentation for your specific client  
or client library to determine how it handles the
```

```
LOAD DATA LOCAL INFILE  
statement.
```

If the

```
LOAD DATA LOCAL INFILE  
statement is disabled by either the server or the client and if the user attempts to execute it, then the server will cause the statement to fail with  
the following error message:
```

```
The used command is not allowed with this MariaDB version
```

Note that it is not entirely accurate to say that the MariaDB version does not support the command. It would be more accurate to say that the MariaDB configuration does not support the command. See [MDEV-20500](#) for more information.

From [MariaDB 10.5.2](#), the error message is more accurate:

```
The used command is not allowed because the MariaDB server or client  
has disabled the local infile capability
```

## REPLACE and IGNORE

In cases where you load data from a file into a table that already contains data and has a [primary key](#), you may encounter issues where the statement attempts to insert a row with a primary key that already exists. When this happens, the statement fails with Error 1064, protecting the data already on the table. In cases where you want MariaDB to overwrite duplicates, use the

```
REPLACE  
keyword.
```

The

```
REPLACE  
keyword works like the REPLACE statement. Here, the statement attempts to load the data from the file. If the row does not exist, it adds it to the table. If the row contains an existing Primary Key, it replaces the table data. That is, in the event of a conflict, it assumes the file contains the desired row.
```

This operation can cause a degradation in load speed by a factor of 20 or more if the part that has already been loaded is larger than the capacity of the [InnoDB Buffer Pool](#). This happens because it causes a lot of turnaround in the buffer pool.

Use the

```
IGNORE  
keyword when you want to skip any rows that contain a conflicting primary key. Here, the statement attempts to load the data from the file. If the row does not exist, it adds it to the table. If the row contains an existing primary key, it ignores the addition request and moves on to the next. That is, in the event of a conflict, it assumes the table contains the desired row.
```

## Character-sets

When the statement opens the file, it attempts to read the contents using the default character-set, as defined by the [character\\_set\\_database](#) system variable.

In the cases where the file was written using a character-set other than the default, you can specify the character-set to use with the

CHARACTER SET clause in the statement. It ignores character-sets specified by the `SET NAMES` statement and by the `character_set_client` system variable.

Setting the

CHARACTER SET clause to a value of binary indicates "no conversion."

The statement interprets all fields in the file as having the same character-set, regardless of the column data type. To properly interpret file contents, you must ensure that it was written with the correct character-set. If you write a data file with `mysqldump -T` or with the `SELECT INTO OUTFILE` statement with the `mysql` client, be sure to use the

`--default-character-set` option, so that the output is written with the desired character-set.

When using mixed character sets, use the

CHARACTER SET clause in both `SELECT INTO OUTFILE` and `LOAD DATA INFILE` to ensure that MariaDB correctly interprets the escape sequences.

The `character_set_filesystem` system variable controls the interpretation of the filename.

It is currently not possible to load data files that use the

`ucs2` character set.

## Preprocessing Inputs

`col_name_or_user_var` can be a column name, or a user variable. In the case of a variable, the `SET` statement can be used to preprocess the value before loading into the table.

## Priority and Concurrency

In storage engines that perform table-level locking (`MyISAM`, `MEMORY` and `MERGE`), using the `LOW_PRIORITY` keyword, MariaDB delays insertions until no other clients are reading from the table. Alternatively, when using the `MyISAM` storage engine, you can use the `CONCURRENT` keyword to perform concurrent insertion.

The `LOW_PRIORITY` and `CONCURRENT` keywords are mutually exclusive. They cannot be used in the same statement.

## Progress Reporting

The

`LOAD DATA INFILE` statement supports `progress reporting`. You may find this useful when dealing with long-running operations. Using another client you can issue a `SHOW PROCESSLIST` query to check the progress of the data load.

## Using mariadb-import/mysqlimport

MariaDB ships with a separate utility for loading data from files: `mariadb-import` (or

`mysqlimport` before `MariaDB 10.5`). It operates by sending `LOAD DATA INFILE` statements to the server.

Using `mariadb-import/mysqlimport` you can compress the file using the

`--compress` option, to get better performance over slow networks, providing both the client and server support the compressed protocol. Use the `--local` option to load from the local file system.

## Indexing

In cases where the storage engine supports `ALTER TABLE... DISABLE KEYS` statements (`MyISAM` and `Aria`), the

`LOAD DATA INFILE` statement automatically disables indexes during the execution.

## Examples

You have a file with this content (note the the separator is ',', not tab, which is the default):

```
2,2  
3,3  
4,4  
5,5  
6,8
```

```
CREATE TABLE t1 (a int, b int, c int, d int);  
LOAD DATA LOCAL INFILE  
  '/tmp/loaddata7.dat' INTO TABLE t1 fields terminated by ',' (a,b) SET c=a+b;  
SELECT * FROM t1;  
+-----+-----+-----+  
| a    | b    | c    |  
+-----+-----+-----+  
| 2    | 2    | 4    |  
| 3    | 3    | 6    |  
| 4    | 4    | 8    |  
| 5    | 5    | 10   |  
| 6    | 8    | 14   |  
+-----+-----+-----+
```

Another example, given the following data (the separator is a tab):

```
1      a  
2      b
```

The value of the first column is doubled before loading:

```
LOAD DATA INFILE 'ld.txt' INTO TABLE ld (@i,v) SET i=@i*2;  
  
SELECT * FROM ld;  
+-----+-----+  
| i    | v    |  
+-----+-----+  
| 2    | a    |  
| 4    | b    |  
+-----+-----+
```

## 1.1.4.2.4.2 LOAD INDEX

## 1.1.4.2.4.3 LOAD XML

## Syntax

```
LOAD XML [LOW_PRIORITY | CONCURRENT] [LOCAL] INFILE 'file_name'  
  [REPLACE | IGNORE]  
  INTO TABLE [db_name.]tbl_name  
  [CHARACTER SET charset_name]  
  [ROWS IDENTIFIED BY '<tagname>']  
  [IGNORE number {LINES | ROWS}]  
  [(column_or_user_var,...)]  
  [SET col_name = expr,...]
```

## Description

The LOAD XML statement reads data from an XML file into a table. The

```
file_name  
must be given as a literal string. The  
tagname  
in the optional ROWS IDENTIFIED BY clause must also be given as a literal string, and must be surrounded by angle brackets (< and >).
```

LOAD XML acts as the complement of running the [mysql client](#) in XML output mode (that is, starting the client with the --xml option). To write data from a table to an XML file, use a command such as the following one from the system shell:

```
shell> mysql --xml -e 'SELECT * FROM mytable' > file.xml
```

To read the file back into a table, use LOAD XML INFILE. By default, the <row> element is considered to be the equivalent of a database table row; this can be changed using the ROWS IDENTIFIED BY clause.

This statement supports three different XML formats:

- Column names as attributes and column values as attribute values:

```
<row column1="value1" column2="value2" .../>
```

- Column names as tags and column values as the content of these tags:

```
<row>  
  <column1>value1</column1>  
  <column2>value2</column2>  
</row>
```

- Column names are the name attributes of <field> tags, and values are the contents of these tags:

```
<row>  
  <field name='column1'>value1</field>  
  <field name='column2'>value2</field>  
</row>
```

This is the format used by other tools, such as [mysqldump](#).

All 3 formats can be used in the same XML file; the import routine automatically detects the format for each row and interprets it correctly. Tags are matched based on the tag or attribute name and the column name.

The following clauses work essentially the same way for LOAD XML as they do for LOAD DATA:

- LOW\_PRIORITY or CONCURRENT
- LOCAL
- REPLACE or IGNORE
- CHARACTER SET
- (column\_or\_user\_var,...)
- SET

See [LOAD DATA](#) for more information about these clauses.

The IGNORE number LINES or IGNORE number ROWS clause causes the first number rows in the XML file to be skipped. It is analogous to the LOAD DATA statement's IGNORE ... LINES clause.

If the

[LOW\\_PRIORITY](#)

keyword is used, insertions are delayed until no other clients are reading from the table. The CONCURRENT keyword allows the use of [concurrent inserts](#). These clauses cannot be specified together.

This statement activates INSERT [triggers](#).

## See also

- The [CONNECT](#) storage engine has an [XML table type](#).

## 1.1.4.2.4.4 LOAD\_FILE

### Syntax

```
LOAD_FILE(file_name)
```

## Contents

1. [Syntax](#)
2. [Description](#)
3. [Examples](#)
4. [See Also](#)

## Description

Reads the file and returns the file contents as a string. To use this function, the file must be located on the server host, you must specify the full path name to the file, and you must have the FILE privilege. The file must be readable by all and it must be less than the size, in bytes, of the `max_allowed_packet` system variable. If the `secure_file_priv` system variable is set to a non-empty directory name, the file to be loaded must be located in that directory.

If the file does not exist or cannot be read because one of the preceding conditions is not satisfied, the function returns NULL.

Since MariaDB 5.1, the `character_set_filesystem` system variable has controlled interpretation of file names that are given as literal strings.

Statements using the `LOAD_FILE()` function are not [safe for statement based replication](#). This is because the slave will execute the `LOAD_FILE()` command itself. If the file doesn't exist on the slave, the function will return NULL.

## Examples

```
UPDATE t SET blob_col=LOAD_FILE('/tmp/picture') WHERE id=1;
```

## See Also

- [SELECT INTO DUMPFILE](#)

## 1.1.4.2.5 Concurrent Inserts

### Contents

1. [Notes](#)
2. [See Also](#)

The MyISAM storage engine supports concurrent inserts. This feature allows `SELECT` statements to be executed during `INSERT` operations, reducing contention.

Whether concurrent inserts can be used or not depends on the value of the `concurrent_insert` server system variable:

- NEVER  
(0) disables concurrent inserts.
- AUTO  
(1) allows concurrent inserts only when the target table has no free blocks (no data in the middle of the table has been deleted after the last `OPTIMIZE TABLE`). This is the default.
- ALWAYS  
(2) always enables concurrent inserts, in which case new rows are added at the end of a table if the table is being used by another thread.

If the `binary log` is used, `CREATE TABLE ... SELECT` and `INSERT ... SELECT` statements cannot use concurrent inserts. These statements acquire a read lock on the table, so concurrent inserts will need to wait. This way the log can be safely used to restore data.

Concurrent inserts are not used by replicas with the row based `replication` (see [binary log formats](#)).

If an `INSERT` statement contain the `HIGH_PRIORITY` clause, concurrent inserts cannot be used. `INSERT ... DELAYED` is usually unneeded if concurrent inserts are enabled.

`LOAD DATA INFILE` uses concurrent inserts if the

CONCURRENT  
keyword is specified and `concurrent_insert` is not  
NEVER  
. This makes the statement slower (even if no other sessions access the table) but reduces contention.

`LOCK TABLES` allows non-conflicting concurrent inserts if a

READ LOCAL  
lock is used. Concurrent inserts are not allowed if the  
LOCAL  
keyword is omitted.

## Notes

The decision to enable concurrent insert for a table is done when the table is opened. If you change the value of `concurrent_insert` it will only affect new opened tables. If you want it to work for also for tables in use or cached, you should do `FLUSH TABLES` after setting the variable.

- [INSERT IGNORE](#)
- [INSERT ON DUPLICATE KEY UPDATE](#)

## 1.1.4.2.6 HIGH\_PRIORITY and LOW\_PRIORITY

### Contents

1. [See Also](#)

The `InnoDB` storage engine uses row-level locking to ensure data integrity. However some storage engines (such as `MEMORY`, `MyISAM`, `Aria` and `MERGE`) lock the whole table to prevent conflicts. These storage engines use two separate queues to remember pending statements; one is for `SELECTs` and the other one is for write statements (`INSERT`, `DELETE`, `UPDATE`). By default, the latter has a higher priority.

To give write operations a lower priority, the `low_priority_updates` server system variable can be set to

`ON`

. The option is available on both the global and session levels, and it can be set at startup or via the `SET` statement.

When too many table locks have been set by write statements, some pending `SELECTs` are executed. The maximum number of write locks that can be acquired before this happens is determined by the `max_write_lock_count` server system variable, which is dynamic.

If write statements have a higher priority (default), the priority of individual write statements (`INSERT`, `REPLACE`, `UPDATE`, `DELETE`) can be changed via the

`LOW_PRIORITY`  
attribute, and the priority of a  
`SELECT`  
statement can be raised via the  
`HIGH_PRIORITY`  
attribute. Also, `LOCK TABLES` supports a  
`LOW_PRIORITY`  
attribute for  
`WRITE`  
locks.

If read statements have a higher priority, the priority of an

`INSERT`  
can be changed via the  
`HIGH_PRIORITY`  
attribute. However, the priority of other write statements cannot be raised individually.

The use of

`LOW_PRIORITY`  
or  
`HIGH_PRIORITY`  
for an  
`INSERT`  
prevents `Concurrent Inserts` from being used.

## 1.1.4.2.7 IGNORE

## 1.1.4.2.8 INSERT - Default & Duplicate Values

## Contents

1. Default Values
2. Duplicate Values
3. See Also

## Default Values

If the

```
SQL_MODE  
contains  
STRICT_TRANS_TABLES  
and you are inserting into a transactional table (like InnoDB), or if the SQL_MODE contains  
STRICT_ALL_TABLES  
, all  
NOT NULL  
columns which does not have a  
DEFAULT  
value (and is not AUTO_INCREMENT ) must be explicitly referenced in  
INSERT  
statements. If not, an error like this is produced:
```

```
ERROR 1364 (HY000): Field 'col' doesn't have a default value
```

In all other cases, if a

```
NOT NULL  
column without a  
DEFAULT  
value is not referenced, an empty value will be inserted (for example, 0 for  
INTEGER  
columns and " " for  
CHAR  
columns). See NULL Values in MariaDB:Inserting for examples.
```

If a

```
NOT NULL  
column having a  
DEFAULT  
value is not referenced,  
NULL  
will be inserted.
```

If a

```
NULL  
column having a  
DEFAULT  
value is not referenced, its default value will be inserted. It is also possible to explicitly assign the default value using the  
DEFAULT  
keyword or the
```

```
DEFAULT()
```

function.

If the

```
DEFAULT  
keyword is used but the column does not have a  
DEFAULT  
value, an error like this is produced:
```

```
ERROR 1364 (HY000): Field 'col' doesn't have a default value
```

## Duplicate Values

By default, if you try to insert a duplicate row and there is a

```
UNIQUE  
index,  
INSERT
```

stops and an error like this is produced:

```
ERROR 1062 (23000): Duplicate entry 'dup_value' for key 'col'
```

To handle duplicates you can use the [IGNORE](#) clause, [INSERT ON DUPLICATE KEY UPDATE](#) or the [REPLACE](#) statement. Note that the IGNORE and DELAYED options are ignored when you use [ON DUPLICATE KEY UPDATE](#).

## 1.1.4.2.9 INSERT IGNORE

### Contents

1. [Ignoring Errors](#)
2. [Examples](#)
3. [See Also](#)

## Ignoring Errors

Normally [INSERT](#) stops and rolls back when it encounters an error.

By using the [IGNORE](#) keyword all errors are converted to warnings, which will not stop inserts of additional rows.

The IGNORE and DELAYED options are ignored when you use [ON DUPLICATE KEY UPDATE](#).

Prior to MySQL and [MariaDB 5.5.28](#), no warnings were issued for duplicate key errors when using

```
IGNORE
. You can get the old behavior if you set OLD_MODE to
NO_DUP_KEY_WARNINGS_WITH_IGNORE
```

## Examples

```

CREATE TABLE t1 (x INT UNIQUE);

INSERT INTO t1 VALUES(1),(2);

INSERT INTO t1 VALUES(2),(3);
ERROR 1062 (23000): Duplicate entry '2' for key 'x'
SELECT * FROM t1;
+---+
| x |
+---+
| 1 |
| 2 |
+---+
2 rows in set (0.00 sec)

INSERT IGNORE INTO t1 VALUES(2),(3);
Query OK, 1 row affected, 1 warning (0.04 sec)

SHOW WARNINGS;
+-----+
| Level | Code | Message |
+-----+
| Warning | 1062 | Duplicate entry '2' for key 'x' |
+-----+

SELECT * FROM t1;
+---+
| x |
+---+
| 1 |
| 2 |
| 3 |
+---+

```

See [INSERT ON DUPLICATE KEY UPDATE](#) for further examples using that syntax.

## 1.1.4.2.10 INSERT ON DUPLICATE KEY UPDATE

### Syntax

```

INSERT [LOW_PRIORITY | DELAYED | HIGH_PRIORITY] [IGNORE]
[INTO] tbl_name [PARTITION (partition_list)] [(col,...)]
{VALUES | VALUE} ({expr | DEFAULT},...),(...),...
[ ON DUPLICATE KEY UPDATE
  col=expr
  [, col=expr] ... ]

```

Or:

```

INSERT [LOW_PRIORITY | DELAYED | HIGH_PRIORITY] [IGNORE]
[INTO] tbl_name [PARTITION (partition_list)]
SET col={expr | DEFAULT}, ...
[ ON DUPLICATE KEY UPDATE
  col=expr
  [, col=expr] ... ]

```

Or:

```

INSERT [LOW_PRIORITY | HIGH_PRIORITY] [IGNORE]
[INTO] tbl_name [PARTITION (partition_list)] [(col,...)]
SELECT ...
[ ON DUPLICATE KEY UPDATE
  col=expr
  [, col=expr] ... ]

```

## Contents

1. [Syntax](#)
2. [Description](#)
3. [Examples](#)
4. [See Also](#)

## Description

INSERT ... ON DUPLICATE KEY UPDATE is a MariaDB/MySQL extension to the [INSERT](#) statement that, if it finds a duplicate unique or primary key, will instead perform an [UPDATE](#).

The row/s affected value is reported as 1 if a row is inserted, and 2 if a row is updated, unless the API's

```
CLIENT_FOUND_ROWS
flag is set.
```

If more than one unique index is matched, only the first is updated. It is not recommended to use this statement on tables with more than one unique index.

If the table has an [AUTO\\_INCREMENT](#) primary key and the statement inserts or updates a row, the [LAST\\_INSERT\\_ID\(\)](#) function returns its AUTO\_INCREMENT value.

The [VALUES\(\)](#) function can only be used in a

```
ON DUPLICATE KEY UPDATE
clause and has no meaning in any other context. It returns the column values from the
INSERT
portion of the statement. This function is particularly useful for multi-rows inserts.
```

The [IGNORE](#) and [DELAYED](#) options are ignored when you use

```
ON DUPLICATE KEY UPDATE
```

See [Partition Pruning and Selection](#) for details on the PARTITION clause.

This statement activates INSERT and UPDATE triggers. See [Trigger Overview](#) for details.

See also a similar statement, [REPLACE](#).

## Examples

```

CREATE TABLE ins_duplicate (id INT PRIMARY KEY, animal VARCHAR(30));
INSERT INTO ins_duplicate VALUES (1,'Aardvark'), (2,'Cheetah'), (3,'Zebra');

```

If there is no existing key, the statement runs as a regular INSERT:

```

INSERT INTO ins_duplicate VALUES (4,'Gorilla')
  ON DUPLICATE KEY UPDATE animal='Gorilla';
Query OK, 1 row affected (0.07 sec)

```

```

SELECT * FROM ins_duplicate;
+----+-----+
| id | animal |
+----+-----+
| 1 | Aardvark |
| 2 | Cheetah |
| 3 | Zebra   |
| 4 | Gorilla |
+----+-----+

```

A regular INSERT with a primary key value of 1 will fail, due to the existing key:

```

INSERT INTO ins_duplicate VALUES (1,'Antelope');
ERROR 1062 (23000): Duplicate entry '1' for key 'PRIMARY'

```

However, we can use an INSERT ON DUPLICATE KEY UPDATE instead:

```
INSERT INTO ins_duplicate VALUES (1,'Antelope')
  ON DUPLICATE KEY UPDATE animal='Antelope';
Query OK, 2 rows affected (0.09 sec)
```

Note that there are two rows reported as affected, but this refers only to the UPDATE.

```
SELECT * FROM ins_duplicate;
+-----+
| id | animal |
+-----+
| 1 | Antelope |
| 2 | Cheetah |
| 3 | Zebra |
| 4 | Gorilla |
+-----+
```

Adding a second unique column:

```
ALTER TABLE ins_duplicate ADD id2 INT;
UPDATE ins_duplicate SET id2=id+10;
ALTER TABLE ins_duplicate ADD UNIQUE KEY(id2);
```

Where two rows match the unique keys match, only the first is updated. This can be unsafe and is not recommended unless you are certain what you are doing.

```
INSERT INTO ins_duplicate VALUES (2,'Lion',13)
  ON DUPLICATE KEY UPDATE animal='Lion';
Query OK, 2 rows affected (0.004 sec)

SELECT * FROM ins_duplicate;
+-----+
| id | animal | id2 |
+-----+
| 1 | Antelope | 11 |
| 2 | Lion | 12 |
| 3 | Zebra | 13 |
| 4 | Gorilla | 14 |
+-----+
```

Although the third row with an id of 3 has an id2 of 13, which also matched, it was not updated.

Changing id to an auto\_increment field. If a new row is added, the auto\_increment is moved forward. If the row is updated, it remains the same.

```

ALTER TABLE `ins_duplicate` CHANGE `id` `id` INT( 11 ) NOT NULL AUTO_INCREMENT;
ALTER TABLE ins_duplicate DROP id2;
SELECT Auto_increment FROM INFORMATION_SCHEMA.TABLES
  WHERE TABLE_NAME='ins_duplicate';
+-----+
| Auto_increment |
+-----+
|      5 |
+-----+

INSERT INTO ins_duplicate VALUES (2,'Leopard')
  ON DUPLICATE KEY UPDATE animal='Leopard';
Query OK, 2 rows affected (0.00 sec)

SELECT Auto_increment FROM INFORMATION_SCHEMA.TABLES
  WHERE TABLE_NAME='ins_duplicate';
+-----+
| Auto_increment |
+-----+
|      5 |
+-----+

INSERT INTO ins_duplicate VALUES (5,'Wild Dog')
  ON DUPLICATE KEY UPDATE animal='Wild Dog';
Query OK, 1 row affected (0.09 sec)

SELECT * FROM ins_duplicate;
+---+---+
| id | animal   |
+---+---+
| 1 | Antelope |
| 2 | Leopard   |
| 3 | Zebra     |
| 4 | Gorilla   |
| 5 | Wild Dog  |
+---+---+

SELECT Auto_increment FROM INFORMATION_SCHEMA.TABLES
  WHERE TABLE_NAME='ins_duplicate';
+-----+
| Auto_increment |
+-----+
|      6 |
+-----+

```

Referring to column values from the INSERT portion of the statement:

```

INSERT INTO table (a,b,c) VALUES (1,2,3),(4,5,6)
  ON DUPLICATE KEY UPDATE c=VALUES(a)+VALUES(b);

```

See the [VALUES\(\)](#) function for more.

## 1.1.4.2.11 INSERT...RETURNING

MariaDB starting with 10.5.0

INSERT ... RETURNING was added in [MariaDB 10.5.0](#), and returns a resultset of the inserted rows.

## Syntax

```

INSERT [LOW_PRIORITY | DELAYED | HIGH_PRIORITY] [IGNORE]
[INTO] tbl_name [PARTITION (partition_list)] [(col,...)]
{VALUES | VALUE} ({expr | DEFAULT},...),(...),...
[ ON DUPLICATE KEY UPDATE
  col=expr
  [, col=expr] ... ] [RETURNING select_expr
  [, select_expr ...]]

```

Or:

```

INSERT [LOW_PRIORITY | DELAYED | HIGH_PRIORITY] [IGNORE]
[INTO] tbl_name [PARTITION (partition_list)]
SET col={expr | DEFAULT}, ...
[ ON DUPLICATE KEY UPDATE
  col=expr
  [, col=expr] ... ] [RETURNING select_expr
  [, select_expr ...]]

```

Or:

```

INSERT [LOW_PRIORITY | HIGH_PRIORITY] [IGNORE]
[INTO] tbl_name [PARTITION (partition_list)] [(col,...)]
SELECT ...
[ ON DUPLICATE KEY UPDATE
  col=expr
  [, col=expr] ... ] [RETURNING select_expr
  [, select_expr ...]]

```

## Contents

1. [Syntax](#)
2. [Description](#)
3. [Examples](#)
4. [See Also](#)

## Description

```

INSERT ... RETURNING
returns a resultset of the inserted rows.

```

This returns the listed columns for all the rows that are inserted, or alternatively, the specified SELECT expression. Any SQL expressions which can be calculated can be used in the select expression for the RETURNING clause, including virtual columns and aliases, expressions which use various operators such as bitwise, logical and arithmetic operators, string functions, date-time functions, numeric functions, control flow functions, secondary functions and stored functions. Along with this, statements which have subqueries and prepared statements can also be used.

## Examples

Simple INSERT statements:

```

CREATE OR REPLACE TABLE t2 (id INT, animal VARCHAR(20), t TIMESTAMP);

INSERT INTO t2 (id) VALUES (2),(3) RETURNING id,t;
+-----+-----+
| id   | t      |
+-----+-----+
| 2    | 2021-04-28 00:59:32 |
| 3    | 2021-04-28 00:59:32 |
+-----+-----+

```

```

INSERT INTO t2(id,animal) VALUES (1,'Dog'),(2,'Lion'),(3,'Tiger'),(4,'Leopard')
  RETURNING id,id+id,id&id,id||id;
+-----+-----+-----+-----+
| id   | id+id | id&id | id||id |
+-----+-----+-----+-----+
| 1    | 2     | 1     | 1    |
| 2    | 4     | 2     | 1    |
| 3    | 6     | 3     | 1    |
| 4    | 8     | 4     | 1    |
+-----+-----+-----+-----+

```

```

DELIMITER |
CREATE FUNCTION f(arg INT) RETURNS INT
BEGIN
    RETURN (SELECT arg+arg);
END |

DELIMITER ;

PREPARE stmt FROM "INSERT INTO t1 SET id1=1, animal1='Bear' RETURNING f(id1), UPPER(animal1)";

EXECUTE stmt;
+-----+
| f(id1) | UPPER(animal1) |
+-----+
|     2   | BEAR           |
+-----+

```

Subqueries in the RETURNING clause that return more than one row or column cannot be used.

Aggregate functions cannot be used in the RETURNING clause. Since aggregate functions work on a set of values, and if the purpose is to get the row count, ROW\_COUNT() with SELECT can be used or it can be used in INSERT...SELECT...RETURNING if the table in the RETURNING clause is not the same as the INSERT table.

#### 1.1.4.3.1 DELETE

#### 1.1.4.3.2 HIGH\_PRIORITY and LOW\_PRIORITY

#### 1.1.4.3.3 IGNORE

#### 1.1.4.3.4 REPLACE

#### 1.1.4.3.5 REPLACE...RETURNING

MariaDB starting with [10.5.0](#)

REPLACE ... RETURNING was added in [MariaDB 10.5.0](#), and returns a resultset of the replaced rows.

## Syntax

```

REPLACE [LOW_PRIORITY | DELAYED]
[INTO] tbl_name [PARTITION (partition_list)] [(col,...)]
{VALUES | VALUE} ({expr | DEFAULT},...),(...),...
[RETURNING select_expr
[, select_expr ...]]

```

Or:

```

REPLACE [LOW_PRIORITY | DELAYED]
[INTO] tbl_name [PARTITION (partition_list)]
SET col={expr | DEFAULT}, ...
[RETURNING select_expr
[, select_expr ...]]

```

Or:

```

REPLACE [LOW_PRIORITY | DELAYED]
[INTO] tbl_name [PARTITION (partition_list)] [(col,...)]
SELECT ...
[RETURNING select_expr
[, select_expr ...]]

```

## Contents

1. [Syntax](#)
2. [Description](#)
3. [Examples](#)
4. [See Also](#)

## Description

```

REPLACE ... RETURNING
returns a resultset of the replaced rows.

```

This returns the listed columns for all the rows that are replaced, or alternatively, the specified SELECT expression. Any SQL expressions which can be calculated can be used in the select expression for the RETURNING clause, including virtual columns and aliases, expressions which use various operators such as bitwise, logical and arithmetic operators, string functions, date-time functions, numeric functions, control flow functions, secondary functions and stored functions. Along with this, statements which have subqueries and prepared statements can also be used.

## Examples

Simple REPLACE statement

```

REPLACE INTO t2 VALUES (1,'Leopard'),(2,'Dog') RETURNING id2, id2+id2
as Total ,id2|id2, id2&&id2;
+-----+-----+-----+
| id2 | Total | id2|id2 | id2&&id2 |
+-----+-----+-----+
|  1 |      2 |      1 |      1 |
|  2 |      4 |      2 |      1 |
+-----+-----+-----+

```

Using stored functions in RETURNING

```

DELIMITER |
CREATE FUNCTION f(arg INT) RETURNS INT
BEGIN
    RETURN (SELECT arg+arg);
END |

DELIMITER ;
PREPARE stmt FROM "REPLACE INTO t2 SET id2=3, animal2='Fox' RETURNING f2(id2),
UPPER(animal2)";

EXECUTE stmt;
+-----+
| f2(id2) | UPPER(animal2) |
+-----+
|      6 | FOX             |
+-----+

```

Subqueries in the statement

```

REPLACE INTO t1 SELECT * FROM t2 RETURNING (SELECT id2 FROM t2 WHERE
id2 IN (SELECT id2 FROM t2 WHERE id2=1)) AS new_id;
+-----+
| new_id |
+-----+
|      1 |
|      1 |
|      1 |
|      1 |
+-----+

```

Subqueries in the RETURNING clause that return more than one row or column cannot be used..

Aggregate functions cannot be used in the RETURNING clause. Since aggregate functions work on a set of values and if the purpose is to get the row

count, ROW\_COUNT() with SELECT can be used, or it can be used in REPLACE...SELECT...RETURNING if the table in the RETURNING clause is not the same as the REPLACE table.

## 1.1.4.3.6 TRUNCATE TABLE

## 1.1.4.3.7 UPDATE

## 1.1.5 Prepared Statements

### 1.1.5.1 PREPARE Statement

#### Syntax

```
PREPARE stmt_name FROM preparable_stmt
```

#### Contents

1. [Syntax](#)
2. [Description](#)
  - 1. Oracle Mode
3. [Permitted Statements](#)
4. [Example](#)
5. [See Also](#)

## Description

The

```
PREPARE  
statement prepares a statement and assigns it a name,  
stmt_name  
, by which to refer to the statement later. Statement names are not case sensitive.  
preparable_stmt
```

is either a string literal or a [user variable](#) (not a [local variable](#), an SQL expression or a subquery) that contains the text of the statement. The text must represent a single SQL statement, not multiple statements. Within the statement, "?" characters can be used as parameter markers to indicate where data values are to be bound to the query later when you execute it. The "?" characters should not be enclosed within quotes, even if you intend to bind them to string values. Parameter markers can be used only where expressions should appear, not for SQL keywords, identifiers, and so forth.

The scope of a prepared statement is the session within which it is created. Other sessions cannot see it.

If a prepared statement with the given name already exists, it is deallocated implicitly before the new statement is prepared. This means that if the new statement contains an error and cannot be prepared, an error is returned and no statement with the given name exists.

Prepared statements can be PREPARED and EXECUTED in a stored procedure, but not in a stored function or trigger. Also, even if the statement is PREPARED in a procedure, it will not be deallocated when the procedure execution ends.

A prepared statement can access [user-defined variables](#), but not [local variables](#) or procedure's parameters.

If the prepared statement contains a syntax error, PREPARE will fail. As a side effect, stored procedures can use it to check if a statement is valid. For example:

```
CREATE PROCEDURE `test_stmt` (IN sql_text TEXT)  
BEGIN  
    DECLARE EXIT HANDLER FOR SQLEXCEPTION  
    BEGIN  
        SELECT CONCAT(sql_text, ' is not valid');  
    END;  
    SET @SQL := sql_text;  
    PREPARE stmt FROM @SQL;  
    DEALLOCATE PREPARE stmt;  
END;
```

The [FOUND\\_ROWS\(\)](#) and [ROW\\_COUNT\(\)](#) functions, if called immediately after EXECUTE, return the number of rows read or affected by the prepared statements; however, if they are called after DEALLOCATE PREPARE, they provide information about this statement. If the prepared statement produces

errors or warnings, [GET DIAGNOSTICS](#) return information about them. DEALLOCATE PREPARE shouldn't clear the [diagnostics area](#), unless it produces an error.

A prepared statement is executed with

[EXECUTE](#)

and released with

[DEALLOCATE PREPARE](#)

The [max\\_prepared\\_stmt\\_count](#) server system variable determines the number of allowed prepared statements that can be prepared on the server. If it is set to 0, prepared statements are not allowed. If the limit is reached, an error similar to the following will be produced:

```
ERROR 1461 (42000): Can't create more than max_prepared_stmt_count statements  
(current value: 0)
```

## Oracle Mode

MariaDB starting with 10.3

In [Oracle mode from MariaDB 10.3](#),

```
PREPARE stmt FROM 'SELECT :1, :2'  
is used, instead of  
?
```

## Permitted Statements

Not all statements can be prepared. Only the following SQL commands are permitted:

- [ALTER TABLE](#)
- [ANALYZE TABLE](#)
- [BINLOG](#)
- [CACHE INDEX](#)
- [CALL](#)
- [CHANGE MASTER](#)
- [CHECKSUM {TABLE | TABLES}](#)
- [COMMIT](#)
- { [CREATE | DROP](#)  } [DATABASE](#)
- { [CREATE | DROP](#)  } [INDEX](#)
- { [CREATE | RENAME | DROP](#)  } [TABLE](#)
- { [CREATE | RENAME | DROP](#)  } [USER](#)
- { [CREATE | DROP](#)  } [VIEW](#)
- [DELETE](#)
- [DESCRIBE](#)
- [DO](#)
- [EXPLAIN](#)
- [FLUSH {TABLE | TABLES | TABLES WITH READ LOCK | HOSTS | PRIVILEGES | LOGS | STATUS | MASTER | SLAVE | DES\\_KEY\\_FILE | USER\\_RESOURCES | QUERY CACHE | TABLE\\_STATISTICS | INDEX\\_STATISTICS | USER\\_STATISTICS | CLIENT\\_STATISTICS}](#)
- [GRANT](#)
- [INSERT](#)
- [INSTALL { PLUGIN | SONAME }](#)
- [HANDLER READ](#)
- [KILL](#)
- [LOAD INDEX INTO CACHE](#)
- [OPTIMIZE TABLE](#)
- [REPAIR TABLE](#)
- [REPLACE](#)
- [RESET { MASTER | SLAVE | QUERY CACHE }](#)
- [REVOKE](#)
- [ROLLBACK](#)
- [SELECT](#)
- [SET](#)
- [SET GLOBAL SQL\\_SLAVE\\_SKIP\\_COUNTER](#)
- [SET ROLE](#)
- [SET SQL\\_LOG\\_BIN](#)
- [SET TRANSACTION ISOLATION LEVEL](#)
- [SHOW EXPLAIN](#)

- SHOW { DATABASES | TABLES | OPEN TABLES | TABLE STATUS | COLUMNS | INDEX | TRIGGERS | EVENTS | GRANTS | CHARACTER SET | COLLATION | ENGINES | PLUGINS [SONAME] | PRIVILEGES | PROCESSLIST | PROFILE | PROFILES | VARIABLES | STATUS | WARNINGS | ERRORS | TABLE\_STATISTICS | INDEX\_STATISTICS | USER\_STATISTICS | CLIENT\_STATISTICS | AUTHORS | CONTRIBUTORS }
- SHOW CREATE { DATABASE | TABLE | VIEW | PROCEDURE | FUNCTION | TRIGGER | EVENT }
- SHOW { FUNCTION | PROCEDURE } CODE
- SHOW BINLOG EVENTS
- SHOW SLAVE HOSTS
- SHOW {MASTER | BINARY} LOGS
- SHOW {MASTER | SLAVE | TABLES | INNODB | FUNCTION | PROCEDURE} STATUS
- SLAVE { START | STOP }
- TRUNCATE TABLE
- SHUTDOWN
- UNINSTALL {PLUGIN | SONAME}
- UPDATE

Synonyms are not listed here, but can be used. For example, DESC can be used instead of DESCRIBE.

MariaDB starting with 10.1.1

Compound statements can be prepared too.

Note that if a statement can be run in a stored routine, it will work even if it is called by a prepared statement. For example, SIGNAL can't be directly prepared. However, it is allowed in [stored routines](#). If the x() procedure contains SIGNAL, you can still prepare and execute the 'CALL x();' prepared statement.

MariaDB starting with 10.2.3

PREPARE now supports most kinds of expressions as well, for example:

```
PREPARE stmt FROM CONCAT('SELECT * FROM ', table_name);
```

MariaDB starting with 10.6.2

All statements can be prepared, except PREPARE , EXECUTE , and DEALLOCATE / DROP PREPARE .

When PREPARE is used with a statement which is not supported, the following error is produced:

```
ERROR 1295 (HY000): This command is not supported in the prepared statement protocol yet
```

## Example

```
create table t1 (a int,b char(10));
insert into t1 values (1,"one"),(2, "two"),(3,"three");
prepare test from "select * from t1 where a=?";
set @param=2;
execute test using @param;
+-----+
| a    | b    |
+-----+
|  2  | two |
+-----+
set @param=3;
execute test using @param;
+-----+
| a    | b    |
+-----+
|  3  | three |
+-----+
deallocate prepare test;
```

Since identifiers are not permitted as prepared statements parameters, sometimes it is necessary to dynamically compose an SQL statement. This technique is called *dynamic SQL* ). The following example shows how to use dynamic SQL:

```

CREATE PROCEDURE teststmt_test(IN tab_name VARCHAR(64))
BEGIN
    SET @sql = CONCAT('SELECT COUNT(*) FROM ', tab_name);
    PREPARE stmt FROM @sql;
    EXECUTE stmt;
    DEALLOCATE PREPARE stmt;
END;

CALL teststmt_test('mysql.user');
+-----+
| COUNT(*) |
+-----+
|      4   |
+-----+

```

Use of variables in prepared statements:

```

PREPARE stmt FROM 'SELECT @x;';

SET @x = 1;

EXECUTE stmt;
+-----+
| @x   |
+-----+
|    1  |
+-----+

SET @x = 0;

EXECUTE stmt;
+-----+
| @x   |
+-----+
|    0  |
+-----+

DEALLOCATE PREPARE stmt;

```

## See Also

## 1.1.5.2 Out Parameters in PREPARE

MariaDB 10.1.1

Out parameters in PREPARE were only available in [MariaDB 10.1.1](#)

One can use question mark placeholders for out-parameters in the PREPARE statement. Only SELECT ... INTO can be used this way:

```

prepare test from "select id into ? from t1 where val=?";
execute test using @out, @in;

```

This is particularly convenient when used with [compound statements](#) :

```

PREPARE stmt FROM "BEGIN NOT ATOMIC
DECLARE v_res INT;
SELECT COUNT(*) INTO v_res FROM t1;
SELECT 'Hello World', v_res INTO ?,?;
END" |

```

## 1.1.5.3 EXECUTE STATEMENT

## 1.1.5.4 DEALLOCATE / DROP PREPARE

### Syntax

```
{DEALLOCATE | DROP} PREPARE stmt_name
```

### Description

To deallocate a prepared statement produced with

PREPARE

, use a  
DEALLOCATE PREPARE  
statement that refers to the prepared statement name.

A prepared statement is implicitly deallocated when a new

PREPARE  
command is issued. In that case, there is no need to use  
DEALLOCATE

Attempting to execute a prepared statement after deallocating it results in an error, as if it was not prepared at all:

```
ERROR 1243 (HY000): Unknown prepared statement handler (stmt_name) given to EXECUTE
```

If the specified statement has not been PREPARED, an error similar to the following will be produced:

```
ERROR 1243 (HY000): Unknown prepared statement handler (stmt_name) given to DEALLOCATE PREPARE
```

### Example

See [example in PREPARE](#).

### See Also

- [PREPARE Statement](#)
- [EXECUTE Statement](#)
- [EXECUTE IMMEDIATE](#)

## 1.1.5.5 EXECUTE IMMEDIATE

MariaDB starting with [10.2.3](#)

EXECUTE IMMEDIATE was introduced in [MariaDB 10.2.3](#).

### Syntax

```
EXECUTE IMMEDIATE statement
```

### Description

EXECUTE IMMEDIATE  
executes a dynamic SQL statement created on the fly, which can reduce performance overhead.

For example:

```
EXECUTE IMMEDIATE 'SELECT 1'
```

which is shorthand for:

```
prepare stmt from "select 1";
execute stmt;
deallocate prepare stmt;
```

EXECUTE IMMEDIATE supports complex expressions as prepare source and parameters:

```
EXECUTE IMMEDIATE CONCAT('SELECT COUNT(*) FROM ', 't1', ' WHERE a=?') USING 5+5;
```

Limitations: subselects and stored function calls are not supported as a prepare source.

The following examples return an error:

```
CREATE OR REPLACE FUNCTION f1() RETURNS VARCHAR(64) RETURN 'SELECT * FROM t1';
EXECUTE IMMEDIATE f1();
ERROR 1970 (42000): EXECUTE IMMEDIATE does not support subqueries or stored functions

EXECUTE IMMEDIATE (SELECT 'SELECT * FROM t1');
ERROR 1064 (42000): You have an error in your SQL syntax; check the manual that
corresponds to your MariaDB server version for the right syntax to use near
'SELECT 'SELECT * FROM t1'' at line 1

CREATE OR REPLACE FUNCTION f1() RETURNS INT RETURN 10;
EXECUTE IMMEDIATE 'SELECT * FROM t1 WHERE a=?' USING f1();
ERROR 1970 (42000): EXECUTE..USING does not support subqueries or stored functions

EXECUTE IMMEDIATE 'SELECT * FROM t1 WHERE a=?' USING (SELECT 10);
ERROR 1064 (42000): You have an error in your SQL syntax; check the manual that
corresponds to your MariaDB server version for the right syntax to use near
'SELECT 10)' at line 1
```

One can use a user or an SP variable as a workaround:

```
CREATE OR REPLACE FUNCTION f1() RETURNS VARCHAR(64) RETURN 'SELECT * FROM t1';
SET @stmt=f1();
EXECUTE IMMEDIATE @stmt;

SET @stmt=(SELECT 'SELECT 1');
EXECUTE IMMEDIATE @stmt;

CREATE OR REPLACE FUNCTION f1() RETURNS INT RETURN 10;
SET @param=f1();
EXECUTE IMMEDIATE 'SELECT * FROM t1 WHERE a=?' USING @param;

SET @param=(SELECT 10);
EXECUTE IMMEDIATE 'SELECT * FROM t1 WHERE a=?' USING @param;
```

EXECUTE IMMEDIATE supports user variables and SP variables as OUT parameters

```
DELIMITER $$ 
CREATE OR REPLACE PROCEDURE p1(OUT a INT)
BEGIN
    SET a:= 10;
END;
$$
DELIMITER ;
SET @a=2;
EXECUTE IMMEDIATE 'CALL p1(?)' USING @a;
SELECT @a;
+----+
| @a |
+----+
| 10 |
+----+
```

Similar to PREPARE, EXECUTE IMMEDIATE is allowed in stored procedures but is not allowed in stored functions.

This example uses EXECUTE IMMEDIATE inside a stored procedure:

```

DELIMITER $$  

CREATE OR REPLACE PROCEDURE p1()  

BEGIN  

    EXECUTE IMMEDIATE 'SELECT 1';  

END;  

$$  

DELIMITER ;
CALL p1;
+---+
| 1 |
+---+
| 1 |
+---+

```

This script returns an error:

```

DELIMITER $$  

CREATE FUNCTION f1() RETURNS INT  

BEGIN  

    EXECUTE IMMEDIATE 'DO 1';  

    RETURN 1;  

END;  

$$  

ERROR 1336 (0A000): Dynamic SQL is not allowed in stored function or trigger

```

EXECUTE IMMEDIATE can use DEFAULT and IGNORE indicators as bind parameters:

```

CREATE OR REPLACE TABLE t1 (a INT DEFAULT 10);
EXECUTE IMMEDIATE 'INSERT INTO t1 VALUES (?)' USING DEFAULT;
SELECT * FROM t1;
+---+
| a |
+---+
| 10 |
+---+

```

EXECUTE IMMEDIATE increments the [Com\\_execute\\_immediate](#) status variable, as well as the [Com\\_stmt\\_prepare](#), [Com\\_stmt\\_execute](#) and [Com\\_stmt\\_close](#) status variables.

Note, EXECUTE IMMEDIATE does not increment the [Com\\_execute\\_sql](#) status variable. [Com\\_execute\\_sql](#) is used only for [PREPARE .. EXECUTE](#).

This session screenshot demonstrates how EXECUTE IMMEDIATE affects status variables:

```

SELECT * FROM INFORMATION_SCHEMA.SESSION_STATUS WHERE VARIABLE_NAMERLIKE
('COM_(EXECUTE|STMT_PREPARE|STMT_EXECUTE|STMT_CLOSE)');

+-----+-----+
| VARIABLE_NAME | VARIABLE_VALUE |  

+-----+-----+
| COM_EXECUTE_IMMEDIATE | 0 |  

| COM_EXECUTE_SQL | 0 |  

| COM_STMT_CLOSE | 0 |  

| COM_STMT_EXECUTE | 0 |  

| COM_STMT_PREPARE | 0 |  

+-----+-----+  
  

EXECUTE IMMEDIATE 'SELECT 1';
+---+
| 1 |
+---+
| 1 |
+---+  
  

SELECT * FROM INFORMATION_SCHEMA.SESSION_STATUS WHERE VARIABLE_NAMERLIKE
('COM_(EXECUTE|STMT_PREPARE|STMT_EXECUTE|STMT_CLOSE)');
+-----+-----+
| VARIABLE_NAME | VARIABLE_VALUE |  

+-----+-----+
| COM_EXECUTE_IMMEDIATE | 1 |  

| COM_EXECUTE_SQL | 0 |  

| COM_STMT_CLOSE | 1 |  

| COM_STMT_EXECUTE | 1 |  

| COM_STMT_PREPARE | 1 |  

+-----+-----+

```

## 1.1.6 Programmatic and Compound Statements

### 1.1.6.1 Using Compound Statements Outside of Stored Programs

MariaDB starting with 10.1.1

Starting from MariaDB 10.1.1 compound statements can also be used outside of stored programs .

```
delimiter |
IF @have_innodb THEN
CREATE TABLE IF NOT EXISTS innodb_index_stats (
    database_name      VARCHAR(64) NOT NULL,
    table_name         VARCHAR(64) NOT NULL,
    index_name         VARCHAR(64) NOT NULL,
    last_update        TIMESTAMP NOT NULL DEFAULT CURRENT_TIMESTAMP ON UPDATE CURRENT_TIMESTAMP,
    stat_name          VARCHAR(64) NOT NULL,
    stat_value         BIGINT UNSIGNED NOT NULL,
    sample_size        BIGINT UNSIGNED,
    stat_description   VARCHAR(1024) NOT NULL,
    PRIMARY KEY (database_name, table_name, index_name, stat_name)
) ENGINE=INNODB DEFAULT CHARSET=utf8 COLLATE=utf8_bin STATS_PERSISTENT=0;
END IF|
Query OK, 0 rows affected, 2 warnings (0.00 sec)
```

Note, that using compound statements this way is subject to following limitations:

- Only `BEGIN` , `IF` , `CASE` , `LOOP` , `WHILE` , `REPEAT` statements may start a compound statement outside of stored programs.
- `BEGIN` must use the  
`BEGIN NOT ATOMIC`  
syntax (otherwise it'll be confused with `BEGIN` that starts a transaction).
- A compound statement might not start with a label.
- A compound statement is parsed completely — note "2 warnings" in the above example, even if the condition was false (InnoDB was, indeed, disabled), and the `CREATE TABLE` statement was not executed, it was still parsed and the parser produced "Unknown storage engine" warning.

Inside a compound block first three limitations do not apply, one can use anything that can be used inside a stored program — including labels, condition handlers, variables, and so on:

```
BEGIN NOT ATOMIC
DECLARE foo CONDITION FOR 1146;
DECLARE x INT DEFAULT 0;
DECLARE CONTINUE HANDLER FOR SET x=1;
INSERT INTO test.t1 VALUES ("hdlr1", val, 2);
END|
```

Example how to use

```
IF
:
IF (1>0) THEN BEGIN NOT ATOMIC SELECT 1; END ; END IF;;
```

Example of how to use

```
WHILE
loop:
```

```
DELIMITER |
BEGIN NOT ATOMIC
DECLARE x INT DEFAULT 0;
WHILE x <= 10 DO
    SET x = x + 1;
    SELECT x;
END WHILE;
END|
DELIMITER ;
```

### 1.1.6.2 BEGIN END

# Syntax

```
[begin_label:] BEGIN [NOT ATOMIC]
[statement_list]
END [end_label]
```

## Contents

1. [Syntax](#)
2. [Description](#)
3. [See Also](#)

NOT ATOMIC

is required when used outside of a [stored procedure](#). Inside stored procedures or within an anonymous block,

BEGIN

alone starts a new anonymous block.

## Description

BEGIN ... END

syntax is used for writing compound statements. A compound statement can contain multiple statements, enclosed by the

BEGIN

and

END

keywords. statement\_list represents a list of one or more statements, each terminated by a semicolon (i.e.,

;

) statement delimiter. statement\_list is optional, which means that the empty compound statement (

BEGIN END

) is legal.

Note that

END

will perform a commit. If you are running in [autocommit](#) mode, every statement will be committed separately. If you are not running in autocommit

mode, you must execute a [COMMIT](#) or [ROLLBACK](#) after

END

to get the database up to date.

Use of multiple statements requires that a client is able to send statement strings containing the ; statement delimiter. This is handled in the [mysql](#) command-line client with the [DELIMITER](#) command. Changing the

```
;;
end-of-statement delimiter (for example, to
//)
) allows
;
to be used in a program body.
```

A compound statement within a [stored program](#) can be [labeled](#).

```
end_label
cannot be given unless
begin_label
also is present. If both are present, they must be the same.
```

BEGIN ... END

constructs can be nested. Each block can define its own variables, a

CONDITION

, a

HANDLER

and a [CURSOR](#), which don't exist in the outer blocks. The most local declarations override the outer objects which use the same name (see example below).

The declarations order is the following:

- DECLARE  
    local variables ;
- DECLARE CONDITION  
    s ;

- ```
DECLARE CURSOR
  S;
```
- ```
DECLARE HANDLER
  S;
```

Note that

```
DECLARE HANDLER
contains another
BEGIN ... END
construct.
```

Here is an example of a very simple, anonymous block:

```
BEGIN NOT ATOMIC
SET @a=1;
CREATE TABLE test.t1(a INT);
END |
```

Below is an example of nested blocks in a stored procedure:

```
CREATE PROCEDURE t()
BEGIN
  DECLARE x TINYINT UNSIGNED DEFAULT 1;
  BEGIN
    DECLARE x CHAR(2) DEFAULT '02';
    DECLARE y TINYINT UNSIGNED DEFAULT 10;
    SELECT x, y;
  END;
  SELECT x;
END;
```

In this example, a **TINYINT** variable,

x  
is declared in the outer block. But in the inner block  
x  
is re-declared as a **CHAR** and an  
y  
variable is declared. The inner **SELECT** shows the "new" value of  
x  
, and the value of  
y  
. But when x is selected in the outer block, the "old" value is returned. The final **SELECT** doesn't try to read  
y  
, because it doesn't exist in that context.

- [Changes in Oracle mode from MariaDB 10.3](#)

### 1.1.6.3 CASE Statement

#### Syntax

```
CASE case_value
  WHEN when_value THEN statement_list
  [WHEN when_value THEN statement_list] ...
  [ELSE statement_list]
END CASE
```

Or:

```
CASE
  WHEN search_condition THEN statement_list
  [WHEN search_condition THEN statement_list] ...
  [ELSE statement_list]
END CASE
```

# Description

The text on this page describes the

CASE  
statement for [stored programs](#). See the [CASE OPERATOR](#) for details on the CASE operator outside of stored programs.

The

CASE  
statement for [stored programs](#) implements a complex conditional construct. If a  
search\_condition  
evaluates to true, the corresponding SQL statement list is executed. If no search condition matches, the statement list in the  
ELSE  
clause is executed. Each  
statement\_list  
consists of one or more statements.

The

CASE  
statement cannot have an  
ELSE NULL  
clause, and it is terminated with  
END CASE  
instead of  
END  
. implements a complex conditional construct. If a  
search\_condition  
evaluates to true, the corresponding SQL statement list is executed. If no search condition matches, the statement list in the  
ELSE  
clause is executed. Each  
statement\_list  
consists of one or more statements.

If no when\_value or search\_condition matches the value tested and the

CASE  
statement contains no  
ELSE  
clause, a Case not found for  
CASE  
statement error results.

Each statement\_list consists of one or more statements; an empty

statement\_list  
is not allowed. To handle situations where no value is matched by any  
WHEN  
clause, use an  
ELSE  
containing an empty [BEGIN ... END](#) block, as shown in this example:

```
DELIMITER |
CREATE PROCEDURE p()
BEGIN
    DECLARE v INT DEFAULT 1;
    CASE v
        WHEN 2 THEN SELECT v;
        WHEN 3 THEN SELECT 0;
        ELSE BEGIN END;
    END CASE;
END;
|
```

The indentation used here in the

ELSE  
clause is for purposes of clarity only, and is not otherwise significant. See [Delimiters in the mysql client](#) for more on the use of the delimiter command.

**Note:** The syntax of the

CASE  
statement used inside stored programs differs slightly from that of the SQL CASE expression described in [CASE OPERATOR](#). The  
CASE  
statement cannot have an  
ELSE NULL  
clause, and it is terminated with  
END CASE

```
instead of  
END
```

## 1.1.6.4 DECLARE CONDITION

### Syntax

```
DECLARE condition_name CONDITION FOR condition_value  
  
condition_value:  
    SQLSTATE [VALUE] sqlstate_value  
    | mysql_error_code
```

### Description

The

```
DECLARE ... CONDITION
```

statement defines a named error condition. It specifies a condition that needs specific handling and associates a name with that condition. Later, the name can be used in a [DECLARE ... HANDLER](#), [SIGNAL](#) or [RESIGNAL](#) statement (as long as the statement is located in the same [BEGIN ... END](#) block).

Conditions must be declared after [local variables](#), but before [CURSORs](#) and [HANDLERS](#).

A condition\_value for

```
DECLARE ... CONDITION
```

can be an [SQLSTATE](#) value (a 5-character string literal) or a MySQL error code (a number). You should not use SQLSTATE value '00000' or MySQL error code 0, because those indicate success rather than an error condition. If you try, or if you specify an invalid SQLSTATE value, an error like this is produced:

```
ERROR 1407 (42000): Bad SQLSTATE: '00000'
```

For a list of SQLSTATE values and MariaDB error codes, see [MariaDB Error Codes](#).

## 1.1.6.5 DECLARE HANDLER

### Syntax

```
DECLARE handler_type HANDLER  
    FOR condition_value [, condition_value] ...  
    statement  
  
handler_type:  
    CONTINUE  
    | EXIT  
    | UNDO  
  
condition_value:  
    SQLSTATE [VALUE] sqlstate_value  
    | condition_name  
    | SQLWARNING  
    | NOT FOUND  
    | SQLEXCEPTION  
    | mariadb_error_code
```

### Description

The

```
DECLARE ... HANDLER
```

statement specifies handlers that each may deal with one or more conditions. If one of these conditions occurs, the specified statement is executed. statement can be a simple statement (for example,

```
SET var_name = value
```

), or it can be a compound statement written using [BEGIN](#) and [END](#).

Handlers must be declared after local variables, a

```
CONDITION
```

and a [CURSOR](#).

For a

CONTINUE

handler, execution of the current program continues after execution of the handler statement. For an EXIT handler, execution terminates for the BEGIN ... END compound statement in which the handler is declared. (This is true even if the condition occurs in an inner block.) The

UNDO

handler type statement is not supported.

If a condition occurs for which no handler has been declared, the default action is

EXIT

A condition\_value for

DECLARE ... HANDLER

can be any of the following values:

- An SQLSTATE value (a 5-character string literal) or a MariaDB error code (a number). You should not use SQLSTATE value '00000' or MariaDB error code 0, because those indicate success rather than an error condition. For a list of SQLSTATE values and MariaDB error codes, see [MariaDB Error Codes](#).
- A condition name previously specified with DECLARE ... CONDITION.
  - . It must be in the same stored program. See [DECLARE CONDITION](#).
- SQLWARNING is shorthand for the class of SQLSTATE values that begin with '01'.
- NOT FOUND is shorthand for the class of SQLSTATE values that begin with '02'. This is relevant only in the context of cursors and is used to control what happens when a cursor reaches the end of a data set. If no more rows are available, a No Data condition occurs with SQLSTATE value 02000. To detect this condition, you can set up a handler for it (or for a NOT FOUND condition). An example is shown in [Cursor Overview](#). This condition also occurs for SELECT ... INTO var\_list statements that retrieve no rows.
- SQLEXCEPTION is shorthand for the class of SQLSTATE values that do not begin with '00', '01', or '02'.

When an error raises, in some cases it could be handled by multiple

HANDLER

s. For example, there may be a handler for 1050 error, a separate handler for the 42S01 SQLSTATE, and another separate handler for the SQLEXCEPTION

class: in theory all occurrences of

HANDLER

may catch the 1050 error, but MariaDB chooses the

HANDLER

with the highest precedence. Here are the precedence rules:

- Handlers which refer to an error code have the highest precedence.
- Handlers which refer to a SQLSTATE come next.
- Handlers which refer to an error class have the lowest precedence.

In some cases, a statement could produce multiple errors. If this happens, in some cases multiple handlers could have the highest precedence. In such cases, the choice of the handler is indeterminate.

Note that if an error occurs within a

CONTINUE HANDLER

block, it can be handled by another

HANDLER

. However, a

HANDLER

which is already in the stack (that is, it has been called to handle an error and its execution didn't finish yet) cannot handle new errors — this prevents endless loops. For example, suppose that a stored procedure contains a

CONTINUE HANDLER

for

SQLWARNING

and another

CONTINUE HANDLER

for

NOT FOUND

. At some point, a NOT FOUND error occurs, and the execution enters the

NOT FOUND HANDLER

. But within that handler, a warning occurs, and the execution enters the

```

SQLWARNING HANDLER
. If another
NOT FOUND
error occurs, it cannot be handled again by the
NOT FOUND HANDLER
, because its execution is not finished.

```

When a

```

DECLARE HANDLER
block can handle more than one error condition, it may be useful to know which errors occurred. To do so, you can use the GET DIAGNOSTICS statement.

```

An error that is handled by a

```

DECLARE HANDLER
construct can be issued again using the RESIGNAL statement.

```

Below is an example using

```

DECLARE HANDLER
:
```

```

CREATE TABLE test.t (s1 INT, PRIMARY KEY (s1));

DELIMITER //

CREATE PROCEDURE handlerdemo ( )
BEGIN
    DECLARE CONTINUE HANDLER FOR SQLSTATE '23000' SET @x2 = 1;
    SET @x = 1;
    INSERT INTO test.t VALUES (1);
    SET @x = 2;
    INSERT INTO test.t VALUES (1);
    SET @x = 3;
END;
// 

DELIMITER ;

CALL handlerdemo();

SELECT @x;
+-----+
| @x   |
+-----+
|   3  |
+-----+

```

## 1.1.6.6 DECLARE Variable

### Syntax

```
DECLARE var_name [, var_name] ... [[ROW] TYPE OF]] type [DEFAULT value]
```

### Contents

1. [Syntax](#)
2. [Description](#)
  1. [TYPE OF / ROW TYPE OF](#)
3. [Examples](#)
4. [See Also](#)

### Description

This statement is used to declare local variables within [stored programs](#). To provide a default value for the variable, include a

```

DEFAULT
clause. The value can be specified as an expression (even subqueries are permitted); it need not be a constant. If the
DEFAULT
clause is missing, the initial value is
NULL

```

Local variables are treated like stored routine parameters with respect to data type and overflow checking. See [CREATE PROCEDURE](#).

Local variables must be declared before

CONDITION  
S, [CURSORS](#) and  
HANDLER  
S.

Local variable names are not case sensitive.

The scope of a local variable is within the

BEGIN ... END

block where it is declared. The variable can be referred to in blocks nested within the declaring block, except those blocks that declare a variable with the same name.

## TYPE OF / ROW TYPE OF

MariaDB starting with [10.3](#)

TYPE OF  
and  
ROW TYPE OF  
anchored data types for stored routines were introduced in [MariaDB 10.3](#).

Anchored data types allow a data type to be defined based on another object, such as a table row, rather than specifically set in the declaration. If the anchor object changes, so will the anchored data type. This can lead to routines being easier to maintain, so that if the data type in the table is changed, it will automatically be changed in the routine as well.

Variables declared with

ROW TYPE OF  
will have the same features as implicit [ROW](#) variables. It is not possible to use  
ROW TYPE OF  
variables in a [LIMIT](#) clause.

The real data type of

TYPE OF  
and  
ROW TYPE OF `table_name`

will become known at the very beginning of the stored routine call. [ALTER TABLE](#) or [DROP TABLE](#) statements performed inside the current routine on the tables that appear in anchors won't affect the data type of the anchored variables, even if the variable is declared after an [ALTER TABLE](#) or [DROP TABLE](#) statement.

The real data type of a

ROW TYPE OF `cursor_name`  
variable will become known when execution enters into the block where the variable is declared. Data type instantiation will happen only once. In a cursor  
ROW TYPE OF  
variable that is declared inside a loop, its data type will become known on the very first iteration and won't change on further loop iterations.

The tables referenced in

TYPE OF  
and  
ROW TYPE OF  
declarations will be checked for existence at the beginning of the stored routine call. [CREATE PROCEDURE](#) or [CREATE FUNCTION](#) will not check the referenced tables for existence.  
  
from MariaDB 10.3 :

```
DECLARE tmp TYPE OF t1.a; -- Get the data type from the column {{a}} in the table {{t1}}
DECLARE rec1 ROW TYPE OF t1; -- Get the row data type from the table {{t1}}
DECLARE rec2 ROW TYPE OF cur1; -- Get the row data type from the cursor {{cur1}}
```

## See Also

- [User-Defined variables](#)

## 1.1.6.7 FOR

MariaDB starting with [10.3](#)

FOR loops were introduced in [MariaDB 10.3](#).

### Syntax

Integer range FOR loop:

```
[begin_label:]  
FOR var_name IN [ REVERSE ] lower_bound .. upper_bound  
DO statement_list  
END FOR [ end_label ]
```

Explicit cursor FOR loop

```
[begin_label:]  
FOR record_name IN cursor_name [ ( cursor_actual_parameter_list )]  
DO statement_list  
END FOR [ end_label ]
```

Explicit cursor FOR loop ([Oracle mode](#))

```
[begin_label:]  
FOR record_name IN cursor_name [ ( cursor_actual_parameter_list )]  
LOOP  
    statement_list  
END LOOP [ end_label ]
```

Implicit cursor FOR loop

```
[begin_label:]  
FOR record_name IN ( select_statement )  
DO statement_list  
END FOR [ end_label ]
```

### Contents

1. [Syntax](#)
2. [Description](#)
3. [Examples](#)
4. [See Also](#)

### Description

FOR loops allow code to be executed a fixed number of times.

In an integer range FOR loop, MariaDB will compare the lower bound and upper bound values, and assign the lower bound value to a counter. If REVERSE is not specified, and the upper bound value is greater than or equal to the counter, the counter will be incremented and the statement will continue, after which the loop is entered again. If the upper bound value is greater than the counter, the loop will be exited.

If REVERSE is specified, the counter is decremented, and the upper bound value needs to be less than or equal for the loop to continue.

### Examples

Intger range FOR loop:

```

CREATE TABLE t1 (a INT);

DELIMITER //

FOR i IN 1..3
DO
    INSERT INTO t1 VALUES (i);
END FOR;
// 

DELIMITER ;

SELECT * FROM t1;
+---+
| a |
+---+
| 1 |
| 2 |
| 3 |
+---+

```

REVERSE integer range FOR loop:

```

CREATE OR REPLACE TABLE t1 (a INT);

DELIMITER //
FOR i IN REVERSE 4..12
DO
    INSERT INTO t1 VALUES (i);
END FOR;
// 
Query OK, 9 rows affected (0.422 sec)

DELIMITER ;

SELECT * FROM t1;
+---+
| a |
+---+
| 12 |
| 11 |
| 10 |
| 9 |
| 8 |
| 7 |
| 6 |
| 5 |
| 4 |
+---+

```

Explicit cursor in [Oracle mode](#) :

```

SET sql_mode=ORACLE;

CREATE OR REPLACE TABLE t1 (a INT, b VARCHAR(32));

INSERT INTO t1 VALUES (10, 'b0');
INSERT INTO t1 VALUES (11, 'b1');
INSERT INTO t1 VALUES (12, 'b2');

DELIMITER //

CREATE OR REPLACE PROCEDURE p1(pa INT) AS
  CURSOR cur(va INT) IS
    SELECT a, b FROM t1 WHERE a=va;
BEGIN
  FOR rec IN cur(pa)
  LOOP
    SELECT rec.a, rec.b;
  END LOOP;
END;
//

DELIMITER ;

CALL p1(10);
+-----+-----+
| rec.a | rec.b |
+-----+-----+
|     10 | b0      |
+-----+-----+

CALL p1(11);
+-----+-----+
| rec.a | rec.b |
+-----+-----+
|     11 | b1      |
+-----+-----+

CALL p1(12);
+-----+-----+
| rec.a | rec.b |
+-----+-----+
|     12 | b2      |
+-----+-----+

CALL p1(13);
Query OK, 0 rows affected (0.000 sec)

```

## See Also

- [LOOP](#)

## 1.1.6.8 GOTO

MariaDB starting with 10.3

The GOTO statement was introduced in [MariaDB 10.3](#) for Oracle compatibility.

## Syntax

```
GOTO label
```

### Contents

- [Syntax](#)
- [Description](#)
- [Example](#)

## Description

The

GOTO

statement causes the code to jump to the specified label, and continue operating from there. It is only accepted when in [Oracle mode](#) .

## Example

```
SET sql_mode=ORACLE;
DELIMITER //
CREATE OR REPLACE PROCEDURE p1 AS
BEGIN
  SELECT 1;
  GOTO label;
  SELECT 2;
  <<label>>
  SELECT 3;
END;
//
DELIMITER
call p1();
+---+
| 1 |
+---+
| 1 |
+---+
1 row in set (0.000 sec)

+---+
| 3 |
+---+
| 3 |
+---+
1 row in set (0.000 sec)
```

## 1.1.6.9 IF

### Syntax

```
IF search_condition THEN statement_list
  [ELSEIF search_condition THEN statement_list] ...
  [ELSE statement_list]
END IF;
```

### Description

The `IF` statement implements a basic conditional construct. If the `search_condition` evaluates to true, the corresponding SQL statement list is executed. If no `search_condition` matches, the statement list in the `ELSE` clause is executed. Each `statement_list` consists of one or more statements.

### See Also

- The [IF\(\) function](#) , which differs from the `IF` statement described above.
- [Changes in Oracle mode from MariaDB 10.3](#)

## 1.1.6.10 ITERATE

# Syntax

```
ITERATE label
```

ITERATE

can appear only within [LOOP](#), [REPEAT](#), and [WHILE](#) statements.

ITERATE

means "do the loop again", and uses the statement's [label](#) to determine which statements to repeat. The label must be in the same stored program, not in a caller procedure.

If you try to use

ITERATE

with a non-existing label, or if the label is associated to a construct which is not a loop, the following error will be produced:

```
ERROR 1308 (42000): ITERATE with no matching label: <label_name>
```

Below is an example of how

ITERATE

might be used:

```
CREATE PROCEDURE doiterate(p1 INT)
BEGIN
    label1: LOOP
        SET p1 = p1 + 1;
        IF p1 < 10 THEN ITERATE label1; END IF;
        LEAVE label1;
    END LOOP label1;
    SET @x = p1;
END
```

## See Also

- [LEAVE](#) - Exits a loop (or any labeled code block)

## 1.1.6.11 Labels

### Syntax

```
label: <construct>
[label]
```

Labels are MariaDB [identifiers](#) which can be used to identify a [BEGIN ... END](#) construct or a loop. They have a maximum length of 16 characters and can be quoted with backticks (i.e.,

).

Labels have a start part and an end part. The start part must precede the portion of code it refers to, must be followed by a colon (

:

) and can be on the same or different line. The end part is optional and adds nothing, but can make the code more readable. If used, the end part must precede the construct's delimiter (

;

). Constructs identified by a label can be nested. Each construct can be identified by only one label.

Labels need not be unique in the stored program they belong to. However, a label for an inner loop cannot be identical to a label for an outer loop. In this case, the following error would be produced:

```
ERROR 1309 (42000): Redefining label <label_name>
```

[LEAVE](#) and [ITERATE](#) statements can be used to exit or repeat a portion of code identified by a label. They must be in the same [Stored Routine](#), [Trigger](#) or [Event](#) which contains the target label.

Below is an example using a simple label that is used to exit a [LOOP](#):

```

CREATE PROCEDURE `test_sp`()
BEGIN
    `my_label`:
    LOOP
        SELECT 'looping';
        LEAVE `my_label`;
    END LOOP;
    SELECT 'out of loop';
END;

```

The following label is used to exit a procedure, and has an end part:

```

CREATE PROCEDURE `test_sp`()
`my_label`:
BEGIN
    IF @var = 1 THEN
        LEAVE `my_label`;
    END IF;
    DO something();
END `my_label`;

```

## 1.1.6.12 LEAVE

### Syntax

```
LEAVE label
```

This statement is used to exit the flow control construct that has the given `label`. The label must be in the same stored program, not in a caller procedure

`LEAVE`

can be used within `BEGIN ... END` or loop constructs (`LOOP`, `REPEAT`, `WHILE`). In [Stored Procedures](#), [Triggers](#) and [Events](#), `LEAVE` can refer to the outmost `BEGIN ... END` construct; in that case, the program exits the procedure. In [Stored Functions](#), `RETURN` can be used instead.

Note that `LEAVE` cannot be used to exit a [DECLARE HANDLER](#) block.

If you try to `LEAVE` a non-existing label, or if you try to `LEAVE` a `HANDLER` block, the following error will be produced:

```
ERROR 1308 (42000): LEAVE with no matching label: <label_name>
```

The following example uses

`LEAVE`

to exit the procedure if a condition is true:

```

CREATE PROCEDURE proc(IN p TINYINT)
CONTAINS SQL
`whole_proc`:
BEGIN
    SELECT 1;
    IF p < 1 THEN
        LEAVE `whole_proc`;
    END IF;
    SELECT 2;
END;

CALL proc(0);
+---+
| 1 |
+---+
| 1 |
+---+

```

### See Also

- [ITERATE](#) - Repeats a loop execution

## 1.1.6.13 LOOP

### Syntax

```
[begin_label:] LOOP  
    statement_list  
END LOOP [end_label]
```

## Contents

1. [Syntax](#)
2. [Description](#)
3. [See Also](#)

## Description

LOOP

implements a simple loop construct, enabling repeated execution of the statement list, which consists of one or more statements, each terminated by a semicolon (i.e.,

;

) statement delimiter. The statements within the loop are repeated until the loop is exited; usually this is accomplished with a [LEAVE](#) statement.

A

LOOP

statement can be [labeled](#).

end\_label

cannot be given unless

begin\_label

also is present. If both are present, they must be the same.

See [Delimiters](#) in the [mysql](#) client for more on delimiter usage in the client.

## See Also

- [LOOP in Oracle mode](#)
- [ITERATE](#)
- [LEAVE](#)
- [FOR Loops](#)

## 1.1.6.14 REPEAT LOOP

### Syntax

```
[begin_label:] REPEAT  
    statement_list  
UNTIL search_condition  
END REPEAT [end_label]
```

The statement list within a

REPEAT

statement is repeated until the search\_condition is true. Thus, a

REPEAT

always enters the loop at least once. statement\_list consists of one or more statements, each terminated by a semicolon (i.e.,

;

) statement delimiter.

A

REPEAT

statement can be [labeled](#). end\_label cannot be given unless begin\_label also is present. If both are present, they must be the same.

See [Delimiters](#) in the [mysql](#) client for more on client delimiter usage.

```

DELIMITER //

CREATE PROCEDURE dorepeat(p1 INT)
BEGIN
    SET @x = 0;
    REPEAT SET @x = @x + 1; UNTIL @x > p1 END REPEAT;
END
// 

CALL dorepeat(1000)//

SELECT @x//
+-----+
| @x   |
+-----+
| 1001 |
+-----+

```

## 1.1.6.15 RESIGNAL

### Syntax

```

RESIGNAL [error_condition]
    [SET error_property
    [, error_property] ...]

error_condition:
    SQLSTATE [VALUE] 'sqlstate_value'
    | condition_name

error_property:
    error_property_name = <error_property_value>

error_property_name:
    CLASS_ORIGIN
    | SUBCLASS_ORIGIN
    | MESSAGE_TEXT
    | MYSQL_ERRNO
    | CONSTRAINT_CATALOG
    | CONSTRAINT_SCHEMA
    | CONSTRAINT_NAME
    | CATALOG_NAME
    | SCHEMA_NAME
    | TABLE_NAME
    | COLUMN_NAME
    | CURSOR_NAME

```

### Contents

1. [Syntax](#)
2. [Description](#)
3. [See Also](#)

## Description

The syntax of

```

RESIGNAL
and its semantics are very similar to SIGNAL . This statement can only be used within an error HANDLER . It produces an error, like SIGNAL .
RESIGNAL
clauses are the same as SIGNAL, except that they all are optional, even SQLSTATE . All the properties which are not specified in
RESIGNAL
, will be identical to the properties of the error that was received by the error HANDLER . For a description of the clauses, see diagnostics area .

```

Note that

```

RESIGNAL
does not empty the diagnostics area: it just appends another error condition.

```

```

RESIGNAL
, without any clauses, produces an error which is identical to the error that was received by HANDLER .

```

If used out of a HANDLER construct, RESIGNAL produces the following error:

```
ERROR 1645 (0K000): RESIGNAL when handler not active
```

In MariaDB 5.5 , if a **HANDLER** contained a **CALL** to another procedure, that procedure could use **RESIGNAL** . Since MariaDB 10.0 , trying to do this raises the above error.

For a list of

SQLSTATE  
values and MariaDB error codes, see [MariaDB Error Codes](#) .

The following procedure tries to query two tables which don't exist, producing a 1146 error in both cases. Those errors will trigger the **HANDLER** . The first time the error will be ignored and the client will not receive it, but the second time, the error is re-signaled, so the client will receive it.

```
CREATE PROCEDURE test_error( )  
BEGIN  
    DECLARE CONTINUE HANDLER  
        FOR 1146  
    BEGIN  
        IF @hide_errors IS FALSE THEN  
            RESIGNAL;  
        END IF;  
    END;  
    SET @hide_errors = TRUE;  
    SELECT 'Next error will be ignored' AS msg;  
    SELECT `c` FROM `temptab_one`;  
    SELECT 'Next error won''t be ignored' AS msg;  
    SET @hide_errors = FALSE;  
    SELECT `c` FROM `temptab_two`;  
END;  
  
CALL test_error();  
  
+-----+  
| msg |  
+-----+  
| Next error will be ignored |  
+-----+  
  
+-----+  
| msg |  
+-----+  
| Next error won't be ignored |  
+-----+  
  
ERROR 1146 (42S02): Table 'test temptab_two' doesn't exist
```

The following procedure re-signals an error, modifying only the error message to clarify the cause of the problem.

```
CREATE PROCEDURE test_error()  
BEGIN  
    DECLARE CONTINUE HANDLER  
        FOR 1146  
    BEGIN  
        RESIGNAL SET  
        MESSAGE_TEXT = ``temptab` does not exist';  
    END;  
    SELECT `c` FROM `temptab`;  
END;  
  
CALL test_error();  
ERROR 1146 (42S02): `temptab` does not exist
```

As explained above, this works on [MariaDB 5.5](#) , but produces a 1645 error since 10.0.

```
CREATE PROCEDURE handle_error()  
BEGIN  
    RESIGNAL;  
END;  
CREATE PROCEDURE p()  
BEGIN  
    DECLARE EXIT HANDLER FOR SQLEXCEPTION CALL p();  
    SIGNAL SQLSTATE '45000';  
END;
```

## See Also

- [Diagnostics Area](#)
- [SIGNAL](#)
- [HANDLER](#)
- [Stored Routines](#)
- [MariaDB Error Codes](#)

## 1.1.6.16 RETURN

### Syntax

```
RETURN expr
```

The

```
RETURN  
statement terminates execution of a stored function and returns the value  
expr  
to the function caller. There must be at least one  
RETURN  
statement in a stored function. If the function has multiple exit points, all exit points must have a  
RETURN
```

This statement is not used in [stored procedures](#), [triggers](#), or [events](#). [LEAVE](#) can be used instead.

The following example shows that

```
RETURN  
can return the result of a scalar subquery:
```

```
CREATE FUNCTION users_count() RETURNS BOOL  
READS SQL DATA  
BEGIN  
    RETURN (SELECT COUNT(DISTINCT User) FROM mysql.user);  
END;
```

## 1.1.6.17 SELECT INTO

### Syntax

```
SELECT col_name [, col_name] ...  
    INTO var_name [, var_name] ...  
    table_expr
```

### Contents

1. [Syntax](#)
2. [Description](#)
3. [Examples](#)
4. [See Also](#)

### Description

`SELECT ... INTO` enables selected columns to be stored directly into variables. No resultset is produced. The query should return a single row. If the query returns no rows, a warning with error code 1329 occurs (No data), and the variable values remain unchanged. If the query returns multiple rows, error 1172 occurs (Result consisted of more than one row). If it is possible that the statement may retrieve multiple rows, you can use

```
LIMIT 1  
to limit the result set to a single row.
```

The `INTO` clause can also be specified at the end of the statement.

In the context of such statements that occur as part of events executed by the Event Scheduler, diagnostics messages (not only errors, but also warnings) are written to the error log, and, on Windows, to the application event log.

This statement can be used with both [local variables](#) and [user-defined variables](#).

For the complete syntax, see [SELECT](#).

Another way to set a variable's value is the [SET](#) statement.

```
SELECT ... INTO
results are not stored in the query cache even if
SQL_CACHE
is specified.
```

## Examples

```
SELECT id, data INTO @x,@y
FROM test.t1 LIMIT 1;
```

## See Also

- [SELECT](#) - full SELECT syntax.
- [SELECT INTO OUTFILE](#) - formatting and writing the result to an external file.
- [SELECT INTO DUMPFILE](#) - binary-safe writing of the unformatted results to an external file.

## 1.1.6.18 SET Variable

## 1.1.6.19 SIGNAL

### Syntax

```
SIGNAL error_condition
  [SET error_property
  [, error_property] ...]

error_condition:

## Contents

1. [Syntax](#)
2. [Errors](#)
3. [Examples](#)
4. [See Also](#)

#### SIGNAL

empties the [diagnostics area](#) and produces a custom error. This statement can be used anywhere, but is generally useful when used inside a [stored program](#). When the error is produced, it can be caught by a [HANDLER](#). If not, the current stored program, or the current statement, will terminate with the specified error.

Sometimes an error [HANDLER](#) just needs to [SIGNAL](#) the same error it received, optionally with some changes. Usually the [RESIGNAL](#) statement is the most convenient way to do this.

#### error\_condition

can be an [SQLSTATE](#) value or a named error condition defined via [DECLARE CONDITION](#). [SQLSTATE](#) must be a constant string consisting of five characters. These codes are standard to ODBC and ANSI SQL. For customized errors, the recommended [SQLSTATE](#) is '45000'. For a list of

SQLSTATE values used by MariaDB, see the [MariaDB Error Codes](#) page. The SQLSTATE can be read via the API method

```
mysql_sqlstate( )
```

To specify error properties user-defined variables and [local variables](#) can be used, as well as [character set conversions](#) (but you can't set a collation).

The error properties, their type and their default values are explained in the [diagnostics area](#) page.

## Errors

If the SQLSTATE is not valid, the following error like this will be produced:

```
ERROR 1407 (42000): Bad SQLSTATE: '123456'
```

If a property is specified more than once, an error like this will be produced:

```
ERROR 1641 (42000): Duplicate condition information item 'MESSAGE_TEXT'
```

If you specify a condition name which is not declared, an error like this will be produced:

```
ERROR 1319 (42000): Undefined CONDITION: cond_name
```

If MYSQL\_ERRNO is out of range, you will get an error like this:

```
ERROR 1231 (42000): Variable 'MYSQL_ERRNO' can't be set to the value of '0'
```

## Examples

Here's what happens if [SIGNAL](#) is used in the client to generate errors:

```
SIGNAL SQLSTATE '01000';
Query OK, 0 rows affected, 1 warning (0.00 sec)

SHOW WARNINGS;

+-----+-----+
| Level | Code  | Message          |
+-----+-----+
| Warning | 1642 | Unhandled user-defined warning condition |
+-----+-----+
1 row in set (0.06 sec)

SIGNAL SQLSTATE '02000';
ERROR 1643 (02000): Unhandled user-defined not found condition
```

How to specify MYSQL\_ERRNO and MESSAGE\_TEXT properties:

```
SIGNAL SQLSTATE '45000' SET MYSQL_ERRNO=30001, MESSAGE_TEXT='Hello, world!';

ERROR 30001 (45000): Hello, world!
```

The following code shows how to use user variables, local variables and character set conversion with SIGNAL:

```
CREATE PROCEDURE test_error(x INT)
BEGIN
    DECLARE errno SMALLINT UNSIGNED DEFAULT 31001;
    SET @errormsg = 'Hello, world!';
    IF x = 1 THEN
        SIGNAL SQLSTATE '45000' SET
        MYSQL_ERRNO = errno,
        MESSAGE_TEXT = @errormsg;
    ELSE
        SIGNAL SQLSTATE '45000' SET
        MYSQL_ERRNO = errno,
        MESSAGE_TEXT = _utf8'Hello, world!';
    END IF;
END;
```

How to use named error conditions:

```

CREATE PROCEDURE test_error(n INT)
BEGIN
    DECLARE `too_big` CONDITION FOR SQLSTATE '45000';
    IF n > 10 THEN
        SIGNAL `too_big`;
    END IF;
END;

```

In this example, we'll define a [HANDLER](#) for an error code. When the error occurs, we [SIGNAL](#) a more informative error which makes sense for our procedure:

```

CREATE PROCEDURE test_error()
BEGIN
    DECLARE EXIT HANDLER
    FOR 1146
    BEGIN
        SIGNAL SQLSTATE '45000' SET
        MESSAGE_TEXT = 'Temporary tables not found; did you call init() procedure?';
    END;
    -- this will produce a 1146 error
    SELECT `c` FROM `temptab`;
END;

```

## 1.1.6.20 WHILE

### Syntax

```
[begin_label:] WHILE search_condition DO
    statement_list
END WHILE [end_label]
```

### Description

The statement list within a

```
WHILE
    statement is repeated as long as the
    search_condition
    is true. statement_list consists of one or more statements. If the loop must be executed at least once,
```

```
REPEAT ... LOOP
```

can be used instead.

A

```
WHILE
    statement can be labeled. end_label cannot be given unless begin_label also is present. If both are present, they must be the same.
```

### Examples

```

CREATE PROCEDURE dowhile()
BEGIN
    DECLARE v1 INT DEFAULT 5;

    WHILE v1 > 0 DO
        ...
        SET v1 = v1 - 1;
    END WHILE;
END

```

## 1.1.7 Stored Routine Statements

### 1.1.7.1 CALL

#### Syntax

```
CALL sp_name([parameter[,...]])  
CALL sp_name[()]
```

#### Description

The

CALL  
statement invokes a [stored procedure](#) that was defined previously with [CREATE PROCEDURE](#).

Stored procedure names can be specified as

database\_name.procedure\_name  
. Procedure names and database names can be quoted with backticks (). This is necessary if they are reserved words, or contain special characters. See [identifier qualifiers](#) for details.

CALL p()  
and  
CALL p  
are equivalent.

If parentheses are used, any number of spaces, tab characters and newline characters are allowed between the procedure's name and the open parenthesis.

CALL  
can pass back values to its caller using parameters that are declared as  
OUT  
or  
INOUT  
parameters. If no value is assigned to an  
OUT  
parameter,  
NULL  
is assigned (and its former value is lost). To pass such values from another stored program you can use [user-defined variables](#), [local variables](#) or routine's parameters; in other contexts, you can only use user-defined variables.

CALL  
can also be executed as a prepared statement. Placeholders can be used for  
IN  
parameters in all versions of MariaDB; for  
OUT  
and  
INOUT  
parameters, placeholders can be used since [MariaDB 5.5](#).

When the procedure returns, a client program can also obtain the number of rows affected for the final statement executed within the routine: At the SQL level, call the

`ROW_COUNT()`  
function; from the C API, call the  
`mysql_affected_rows()`  
function.

If the

`CLIENT_MULTI_RESULTS`  
API flag is set,  
CALL  
can return any number of resultsets and the called stored procedure can execute prepared statements. If it is not set, at most one resultset can be returned and prepared statements cannot be used within procedures.

### 1.1.7.2 DO

# Syntax

```
DO expr [, expr] ...
```

## Description

DO  
executes the expressions but does not return any results. In most respects,  
DO  
is shorthand for  
SELECT expr, ...,  
but has the advantage that it is slightly faster when you do not care about the result.

DO  
is useful primarily with functions that have side effects, such as

```
RELEASE_LOCK()
```

## 1.1.8 Table Statements

### 1.1.9 Transactions

#### 1.1.9.1 START TRANSACTION

## Syntax

```
START TRANSACTION [transaction_property [, transaction_property] ...] | BEGIN [WORK]
COMMIT [WORK] [AND [NO] CHAIN] [[NO] RELEASE]
ROLLBACK [WORK] [AND [NO] CHAIN] [[NO] RELEASE]
SET autocommit = {0 | 1}

transaction_property:
  WITH CONSISTENT SNAPSHOT
  | READ WRITE
  | READ ONLY
```

## Contents

- 1. [Syntax](#)
- 2. [Description](#)
  - 1. [Access Mode](#)
  - 2. [autocommit](#)
  - 3. [DDL Statements](#)
  - 4. [in\\_transaction](#)
  - 5. [WITH CONSISTENT SNAPSHOT](#)
- 3. [Examples](#)
- 4. [See Also](#)

## Description

The

```
START TRANSACTION
or
BEGIN
```

statement begins a new transaction. [COMMIT](#) commits the current transaction, making its changes permanent. [ROLLBACK](#) rolls back the current transaction, canceling its changes. The [SET autocommit](#) statement disables or enables the default autocommit mode for the current session.

START TRANSACTION and SET autocommit = 1 implicitly commit the current transaction, if any.

The optional

```
WORK
keyword is supported for
COMMIT
```

and  
ROLLBACK  
, as are the  
CHAIN  
and  
RELEASE  
clauses.  
CHAIN  
and  
RELEASE  
can be used for additional control over transaction completion. The value of the [completion\\_type](#) system variable determines the default completion behavior.

The  
AND CHAIN  
clause causes a new transaction to begin as soon as the current one ends, and the new transaction has the same isolation level as the just-terminated transaction. The  
RELEASE  
clause causes the server to disconnect the current client session after terminating the current transaction. Including the  
NO  
keyword suppresses  
CHAIN  
or  
RELEASE  
completion, which can be useful if the [completion\\_type](#) system variable is set to cause chaining or release completion by default.

## Access Mode

The access mode specifies whether the transaction is allowed to write data or not. By default, transactions are in  
READ WRITE  
mode (see the [tx\\_read\\_only](#) system variable).  
READ ONLY  
mode allows the storage engine to apply optimizations that cannot be used for transactions which write data. The only exception to this rule is that read only transactions can perform DDL statements on temporary tables.

It is not permitted to specify both  
READ WRITE  
and  
READ ONLY  
in the same statement.

READ WRITE  
and  
READ ONLY  
can also be specified in the

[SET TRANSACTION](#)

statement, in which case the specified mode is valid for all sessions, or for all subsequent transaction used by the current session.

## autocommit

By default, MariaDB runs with [autocommit](#) mode enabled. This means that as soon as you execute a statement that updates (modifies) a table, MariaDB stores the update on disk to make it permanent. To disable autocommit mode, use the following statement:

```
SET autocommit=0;
```

After disabling autocommit mode by setting the autocommit variable to zero, changes to transaction-safe tables (such as those for InnoDB or NDBCLUSTER ) are not made permanent immediately. You must use COMMIT to store your changes to disk or ROLLBACK to ignore the changes.

To disable autocommit mode for a single series of statements, use the

```
START TRANSACTION  
statement.
```

## DDL Statements

DDL statements (

```

CREATE
,
ALTER
,
DROP
) and administrative statements (
FLUSH
,
RESET
,
OPTIMIZE
,
ANALYZE
,
CHECK
,
REPAIR
,
CACHE INDEX
), transaction management statements (
BEGIN
,
START TRANSACTION
) and
LOAD DATA INFILE
, cause an implicit
COMMIT
and start a new transaction. An exception to this rule are the DDL that operate on temporary tables: you can
CREATE
,
ALTER
and
DROP
them without causing any
COMMIT
, but those actions cannot be rolled back. This means that if you call
ROLLBACK
, the temporary tables you created in the transaction will remain, while the rest of the transaction will be rolled back.

```

Transactions cannot be used in Stored Functions or Triggers. In Stored Procedures and Events BEGIN is not allowed, so you should use START TRANSACTION instead.

A transaction acquires a [metadata lock](#) on every table it accesses to prevent other connections from altering their structure. The lock is released at the end of the transaction. This happens even with non-transactional storage engines (like [MEMORY](#) or [CONNECT](#) ), so it makes sense to use transactions with non-transactional tables.

## in\_transaction

The [in\\_transaction](#) system variable is a session-only, read-only variable that returns

```

1
inside a transaction, and
0
if not in a transaction.

```

## WITH CONSISTENT SNAPSHOT

The

```
WITH CONSISTENT SNAPSHOT
```

option starts a consistent read for storage engines such as [InnoDB](#) that can do so, the same as if a START TRANSACTION followed by a SELECT from any InnoDB table was issued.

See [Enhancements for START TRANSACTION WITH CONSISTENT SNAPSHOT](#).

## Examples

```

START TRANSACTION;
SELECT @A:=SUM(salary) FROM table1 WHERE type=1;
UPDATE table2 SET summary=@A WHERE type=1;
COMMIT;

```

## See Also

- [Enhancements for START TRANSACTION WITH CONSISTENT SNAPSHOT](#)
- [MyRocks and START TRANSACTION WITH CONSISTENT SNAPSHOT](#)

## 1.1.9.2 COMMIT

The

COMMIT

statement ends a transaction, saving any changes to the data so that they become visible to subsequent transactions. Also, [unlocks metadata](#) changed by current transaction. If [autocommit](#) is set to 1, an implicit commit is performed after each statement. Otherwise, all transactions which don't end with an explicit

COMMIT

are implicitly rolled back and the changes are lost. The

ROLLBACK

statement can be used to do this explicitly.

The required syntax for the

COMMIT

statement is as follows:

```
COMMIT [WORK] [AND [NO] CHAIN] [[NO] RELEASE]
```

COMMIT

is the more important transaction terminator, as well as the more interesting one. The basic form of the

COMMIT

statement is simply the keyword

COMMIT

(the keyword

WORK

is simply noise and can be omitted without changing the effect).

The optional

AND CHAIN

clause is a convenience for initiating a new transaction as soon as the old transaction terminates. If

AND CHAIN

is specified, then there is effectively nothing between the old and new transactions, although they remain separate. The characteristics of the new transaction will be the same as the characteristics of the old one — that is, the new transaction will have the same access mode, isolation level and diagnostics area size (we'll discuss all of these shortly) as the transaction just terminated.

RELEASE

tells the server to disconnect the client immediately after the current transaction.

There are

NO RELEASE

and

AND NO CHAIN

options. By default, commits do not

RELEASE

or

CHAIN

, but it's possible to change this default behavior with the [completion\\_type](#) server system variable. In this case, the

AND NO CHAIN

and

NO RELEASE

options override the server default.

## See Also

- [autocommit](#) - server system variable that determines whether statements are automatically committed.
- [completion\\_type](#) - server system variable that determines whether COMMIT's are standard, COMMIT AND CHAIN or COMMIT RELEASE.
- [SQL statements that cause an implicit commit](#)

## 1.1.9.3 ROLLBACK

The

ROLLBACK

statement rolls back (ends) a transaction, destroying any changes to SQL-data so that they never become visible to subsequent transactions.

The required syntax for the

ROLLBACK

statement is as follows.

```
ROLLBACK [ WORK ] [ AND [ NO ] CHAIN ]
[ TO [ SAVEPOINT ] {<savepoint name> | <simple target specification>} ]
```

The

ROLLBACK

statement will either end a transaction, destroying all data changes that happened during any of the transaction, or it will just destroy any data changes that happened since you established a savepoint. The basic form of the

ROLLBACK

statement is just the keyword

ROLLBACK

(the keyword

WORK

is simply noise and can be omitted without changing the effect).

The optional

AND CHAIN

clause is a convenience for initiating a new transaction as soon as the old transaction terminates. If

AND CHAIN

is specified, then there is effectively nothing between the old and new transactions, although they remain separate. The characteristics of the new transaction will be the same as the characteristics of the old one — that is, the new transaction will have the same access mode, isolation level and diagnostics area size (we'll discuss all of these shortly) as the transaction just terminated. The

AND NO CHAIN

option just tells your DBMS to end the transaction — that is, these four SQL statements are equivalent:

```
ROLLBACK;
ROLLBACK WORK;
ROLLBACK AND NO CHAIN;
ROLLBACK WORK AND NO CHAIN;
```

All of them end a transaction without saving any transaction characteristics. The only other options, the equivalent statements:

```
ROLLBACK AND CHAIN;
ROLLBACK WORK AND CHAIN;
```

both tell your DBMS to end a transaction, but to save that transaction's characteristics for the next transaction.

ROLLBACK

is much simpler than

COMMIT

: it may involve no more than a few deletions (of Cursors, locks, prepared SQL statements and log-file entries). It's usually assumed that

ROLLBACK

can't fail, although such a thing is conceivable (for example, an encompassing transaction might reject an attempt to

ROLLBACK

because it's lining up for a

COMMIT

).

ROLLBACK

cancels all effects of a transaction. It does not cancel effects on objects outside the DBMS's control (for example the values in host program variables or the settings made by some SQL/CLI function calls). But in general, it is a convenient statement for those situations when you say "oops, this isn't working" or when you simply don't care whether your temporary work becomes permanent or not.

Here is a moot question. If all you've been doing is

SELECT

s, so that there have been no data changes, should you end the transaction with

ROLLBACK

or

COMMIT

? It shouldn't really matter because both

ROLLBACK

and

COMMIT

do the same transaction-terminating job. However, the popular conception is that

ROLLBACK

implies failure, so after a successful series of

```

SELECT
statements the convention is to end the transaction with
COMMIT
rather than
ROLLBACK

```

MariaDB (and most other DBMSs) supports rollback of SQL-data change statements, but not of SQL-Schema statements. This means that if you use any of

```

CREATE
,
ALTER
,
DROP
,
GRANT
,
REVOKE
, you are implicitly committing at execution time.

```

```

INSERT INTO Table_2 VALUES(5);
DROP TABLE Table_3 CASCADE;
ROLLBACK;

```

The result will be that both the

```

INSERT
and the
DROP
will go through as separate transactions so the
ROLLBACK
will have no effect.

```

## 1.1.9.4 SET TRANSACTION

## 1.1.9.5 LOCK TABLES

### Syntax

```

LOCK TABLE[S]
tbl_name [[AS] alias] lock_type
[, tbl_name [[AS] alias] lock_type] ...
[WAIT n|NOWAIT]

```

```

lock_type:
  READ [LOCAL]
  | [LOW_PRIORITY] WRITE
  | WRITE CONCURRENT

```

```
UNLOCK TABLES
```

### Contents

1. [Syntax](#)
2. [Description](#)
  1. [WAIT/NOWAIT](#)
3. [Limitations](#)
4. [See Also](#)

### Description

The *lock\_type* can be one of:

Option	Description
READ	Read lock, no writes allowed
READ LOCAL	Read lock, but allow <a href="#">concurrent inserts</a>
WRITE	Exclusive write lock. No other connections can read or write to this table

LOW_PRIORITY WRITE	Exclusive write lock, but allow new read locks on the table until we get the write lock.
WRITE CONCURRENT	Exclusive write lock, but allow READ LOCAL locks to the table.

MariaDB enables client sessions to acquire table locks explicitly for the purpose of cooperating with other sessions for access to tables, or to prevent other sessions from modifying tables during periods when a session requires exclusive access to them. A session can acquire or release locks only for itself. One session cannot acquire locks for another session or release locks held by another session.

Locks may be used to emulate transactions or to get more speed when updating tables.

```
LOCK TABLES
explicitly acquires table locks for the current client session. Table locks can be acquired for base tables or views. To use
LOCK TABLES
, you must have the
LOCK TABLES
privilege, and the
SELECT
privilege for each object to be locked. See
```

[GRANT](#)

For view locking,

```
LOCK TABLES
adds all base tables used in the view to the set of tables to be locked and locks them automatically. If you lock a table explicitly with
LOCK TABLES
, any tables used in triggers are also locked implicitly, as described in Triggers and Implicit Locks.
```

[UNLOCK TABLES](#) explicitly releases any table locks held by the current session.

MariaDB starting with [10.3.0](#)

## WAIT/NOWAIT

Set the lock wait timeout. See [WAIT and NOWAIT](#).

## Limitations

- LOCK TABLES  
[doesn't work when using Galera cluster](#). You may experience crashes or locks when used with Galera.
- LOCK TABLES  
works on XtraDB/InnoDB tables only if the [innodb\\_table\\_locks](#) system variable is set to 1 (the default) and [autocommit](#) is set to 0 (1 is default). Please note that no error message will be returned on LOCK TABLES with innodb\_table\_locks = 0.
- LOCK TABLES  
[implicitly commits](#) the active transaction, if any. Also, starting a transaction always releases all table locks acquired with LOCK TABLES. This means that there is no way to have table locks and an active transaction at the same time. The only exceptions are the transactions in [autocommit](#) mode. To preserve the data integrity between transactional and non-transactional tables, the [GET\\_LOCK\(\)](#) function can be used.
- When using  
LOCK TABLES  
on a  
TEMPORARY  
table, it will always be locked with a  
WRITE  
lock.
- While a connection holds an explicit read lock on a table, it cannot modify it. If you try, the following error will be produced:

ERROR 1099 (HY000): Table 'tab\_name' was locked with a READ lock and can't be updated

- While a connection holds an explicit lock on a table, it cannot access a non-locked table. If you try, the following error will be produced:

ERROR 1100 (HY000): Table 'tab\_name' was not locked with LOCK TABLES

- While a connection holds an explicit lock on a table, it cannot issue the following: INSERT DELAYED, CREATE TABLE, CREATE TABLE ... LIKE, and DDL statements involving stored programs and views (except for triggers). If you try, the following error will be produced:

ERROR 1192 (HY000): Can't execute the given command because you have active locked tables or an active transaction

- **LOCK TABLES**

can not be used in stored routines - if you try, the following error will be produced on creation:

ERROR 1314 (0A000): LOCK is not allowed in stored procedures

## See Also

- [UNLOCK TABLES](#)

## 1.1.9.6 SAVEPOINT

### Syntax

```
SAVEPOINT identifier  
ROLLBACK [WORK] TO [SAVEPOINT] identifier  
RELEASE SAVEPOINT identifier
```

### Contents

1. [Syntax](#)
2. [Description](#)
3. [Errors](#)

### Description

InnoDB supports the SQL statements

```
SAVEPOINT  
,  
ROLLBACK TO SAVEPOINT  
,  
RELEASE SAVEPOINT  
and the optional  
WORK  
keyword for  
ROLLBACK
```

Each savepoint must have a legal [MariaDB identifier](#). A savepoint is a named sub-transaction.

Normally **ROLLBACK** undoes the changes performed by the whole transaction. When used with the TO clause, it undoes the changes performed after the specified savepoint, and erases all subsequent savepoints. However, all locks that have been acquired after the save point will survive. **RELEASE SAVEPOINT** does not rollback or commit any changes, but removes the specified savepoint.

When the execution of a trigger or a stored function begins, it is not possible to use statements which reference a savepoint which was defined from out of that stored program.

When a **COMMIT** (including implicit commits) or a **ROLLBACK** statement (with no TO clause) is performed, they act on the whole transaction, and all savepoints are removed.

### Errors

If COMMIT or ROLLBACK is issued and no transaction was started, no error is reported.

If SAVEPOINT is issued and no transaction was started, no error is reported but no savepoint is created. When ROLLBACK TO SAVEPOINT or RELEASE SAVEPOINT is called for a savepoint that does not exist, an error like this is issued:

ERROR 1305 (42000): SAVEPOINT *svp\_name* does not exist

## 1.1.9.7 Metadata Locking

MariaDB supports metadata locking. This means that when a transaction (including [XA transactions](#)) uses a table, it locks its metadata until the end of transaction. Non-transactional tables are also locked, as well as views and objects which are related to locked tables/views (stored functions, triggers, etc). When a connection tries to use a DDL statement (like an [ALTER TABLE](#)) which modifies a table that is locked, that connection is queued, and has to wait until it's unlocked. Using savepoints and performing a partial rollback does not release metadata locks.

[LOCK TABLES ... WRITE](#) are also queued. Some wrong statements which produce an error may not need to wait for the lock to be freed.

The metadata lock's timeout is determined by the value of the `lock_wait_timeout` server system variable (in seconds). However, note that its default value is 31536000 (1 year, MariaDB <= 10.2.3), or 86400 (1 day, MariaDB >= 10.2.4). If this timeout is exceeded, the following error is returned:

```
ERROR 1205 (HY000): Lock wait timeout exceeded; try restarting transaction
```

If the `metadata_lock_info` plugin is installed, the `Information Schema metadata_lock_info` table stores information about existing metadata locks.

MariaDB starting with 10.5.2

From MariaDB 10.5, the `Performance Schema metadata_locks` table contains metadata lock information.

## Example

Let's use the following MEMORY (non-transactional) table:

```
CREATE TABLE t (a INT) ENGINE = MEMORY;
```

Connection 1 starts a transaction, and INSERTs a row into t:

```
START TRANSACTION;  
  
INSERT INTO t SET a=1;
```

t  
's metadata is now locked by connection 1. Connection 2 tries to alter  
t  
, but has to wait:

```
ALTER TABLE t ADD COLUMN b INT;
```

Connection 2's prompt is blocked now.

Now connection 1 ends the transaction:

```
COMMIT;
```

...and connection 2 finally gets the output of its command:

```
Query OK, 1 row affected (35.23 sec)  
Records: 1 Duplicates: 0 Warnings: 0
```

## 1.1.9.8 SQL statements That Cause an Implicit Commit

Some SQL statements cause an implicit commit. As a rule of thumb, such statements are DDL statements. The same statements (except for `SHUTDOWN`) produce a 1400 error (`SQLSTATE 'XAE09'`) if a XA transaction is in effect.

Here is the list:

```
ALTER DATABASE ... UPGRADE DATA DIRECTORY NAME
ALTER EVENT
ALTER FUNCTION
ALTER PROCEDURE
ALTER SERVER
ALTER TABLE
ALTER VIEW
ANALYZE TABLE
BEGIN
CACHE INDEX
CHANGE MASTER TO
CHECK TABLE
CREATE DATABASE
CREATE EVENT
CREATE FUNCTION
CREATE INDEX
CREATE PROCEDURE
CREATE ROLE
CREATE SERVER
CREATE TABLE
CREATE TRIGGER
CREATE USER
CREATE VIEW
DROP DATABASE
DROP EVENT
DROP FUNCTION
DROP INDEX
DROP PROCEDURE
DROP ROLE
DROP SERVER
DROP TABLE
DROP TRIGGER
DROP USER
DROP VIEW
FLUSH
GRANT
LOAD INDEX INTO CACHE
LOCK TABLES
OPTIMIZE TABLE
RENAME TABLE
RENAME USER
REPAIR TABLE
RESET
REVOKE
SET PASSWORD
SHUTDOWN
START SLAVE
START TRANSACTION
STOP SLAVE
TRUNCATE TABLE
```

```
SET autocommit = 1
causes an implicit commit if the value was 0.
```

All these statements cause an implicit commit before execution. This means that, even if the statement fails with an error, the transaction is committed. Some of them, like

```
CREATE TABLE ... SELECT
, also cause a commit immediately after execution. Such statements couldn't be rolled back in any case.
```

If you are not sure whether a statement has implicitly committed the current transaction, you can query the [in\\_transaction](#) server system variable.

Note that when a transaction starts (not in autocommit mode), all locks acquired with [LOCK TABLES](#) are released. And acquiring such locks always commits the current transaction. To preserve the data integrity between transactional and non-transactional tables, the [GET\\_LOCK\(\)](#) function can be used.

## Exceptions

These statements do not cause an implicit commit in the following cases:

- CREATE TABLE  
and  
DROP TABLE  
, when the

- TEMPORARY keyword is used.
- However, TRUNCATE TABLE causes an implicit commit even when used on a temporary table.
- CREATE FUNCTION and DROP FUNCTION, when used to create a UDF (instead of a stored function). However, CREATE INDEX and DROP INDEX cause commits even when used with temporary tables.
- UNLOCK TABLES causes a commit only if a LOCK TABLES was used on non-transactional tables.
- START SLAVE,  
STOP SLAVE,  
RESET SLAVE and CHANGE MASTER TO only cause implicit commit since MariaDB 10.0.

## 1.1.9.9 Transaction Timeouts

MariaDB has always had the `wait_timeout` and `interactive_timeout` settings, which close connections after a certain period of inactivity.

However, these are by default set to a long wait period. In situations where transactions may be started, but not committed or rolled back, more granular control and a shorter timeout may be desirable so as to avoid locks being held for too long.

MariaDB 10.3 introduced three new variables to handle this situation.

- `idle_transaction_timeout` (all transactions)
- `idle_write_transaction_timeout` (write transactions - called `idle_readwrite_transaction_timeout` until MariaDB 10.3.2)
- `idle_READONLY_transaction_timeout` (read transactions)

These accept a time in seconds to time out, by closing the connection, transactions that are idle for longer than this period. By default all are set to zero, or no timeout.

`idle_transaction_timeout` affects all transactions, `idle_write_transaction_timeout` affects write transactions only and `idle_READONLY_transaction_timeout` affects read transactions only. The latter two variables work independently. However, if either is set along with `idle_transaction_timeout`, the settings for `idle_write_transaction_timeout` or `idle_READONLY_transaction_timeout` will take precedence.

## Examples

```
SET SESSION idle_transaction_timeout=2;
BEGIN;
SELECT * FROM t;
Empty set (0.000 sec)
## wait 3 seconds
SELECT * FROM t;
ERROR 2006 (HY000): MySQL server has gone away
```

```
SET SESSION idle_write_transaction_timeout=2;
BEGIN;
SELECT * FROM t;
Empty set (0.000 sec)
## wait 3 seconds
SELECT * FROM t;
Empty set (0.000 sec)
INSERT INTO t VALUES(1);
## wait 3 seconds
SELECT * FROM t;
ERROR 2006 (HY000): MySQL server has gone away
```

```
SET SESSION idle_transaction_timeout=2, SESSION idle_READONLY_transaction_timeout=10;
BEGIN;
SELECT * FROM t;
Empty set (0.000 sec)
## wait 3 seconds
SELECT * FROM t;
Empty set (0.000 sec)
## wait 11 seconds
SELECT * FROM t;
ERROR 2006 (HY000): MySQL server has gone away
```

## 1.1.9.10 UNLOCK TABLES

### Syntax

[UNLOCK TABLES](#)

### Contents

1. [Syntax](#)
2. [Description](#)

### Description

[UNLOCK TABLES](#)

explicitly releases any table locks held by the current session. See

[LOCK TABLES](#)

for more information.

In addition to releasing table locks acquired by the

[LOCK TABLES](#)

statement, the

[UNLOCK TABLES](#)

statement also releases the global read lock acquired by the

[FLUSH TABLES WITH READ LOCK](#)

statement. The

[FLUSH TABLES WITH READ LOCK](#)

statement is very useful for performing backups. See

[FLUSH](#)

for more information about

[FLUSH TABLES WITH READ LOCK](#)

## 1.1.9.11 WAIT and NOWAIT

MariaDB starting with [10.3.0](#)

MariaDB 10.3.0 introduced extended syntax so that it is possible to set [innodb\\_lock\\_wait\\_timeout](#) and [lock\\_wait\\_timeout](#) for the following statements:

### Syntax

```
ALTER TABLE tbl_name [WAIT n|NOWAIT] ...
CREATE ... INDEX ON tbl_name (index_col_name, ...) [WAIT n|NOWAIT] ...
DROP INDEX ... [WAIT n|NOWAIT]
DROP TABLE tbl_name [WAIT n|NOWAIT] ...
LOCK TABLE ... [WAIT n|NOWAIT]
OPTIMIZE TABLE tbl_name [WAIT n|NOWAIT]
RENAME TABLE tbl_name [WAIT n|NOWAIT] ...
SELECT ... FOR UPDATE [WAIT n|NOWAIT]
SELECT ... LOCK IN SHARE MODE [WAIT n|NOWAIT]
TRUNCATE TABLE tbl_name [WAIT n|NOWAIT]
```

## Description

The lock wait timeout can be explicitly set in the statement by using either

```
WAIT n
(to set the wait in seconds) or
NOWAIT
, in which case the statement will immediately fail if the lock cannot be obtained.
WAIT 0
is equivalent to
NOWAIT
```

## 1.1.9.12 XA Transactions

### Contents

1. [Overview](#)
2. [Internal XA vs External XA](#)
3. [Transaction Coordinator Log](#)
4. [Syntax](#)
5. [XA RECOVER](#)
6. [Examples](#)
7. [Known Issues](#)
  1. [MariaDB Galera Cluster](#)

## Overview

The MariaDB XA implementation is based on the X/Open CAE document Distributed Transaction Processing: The XA Specification. This document is published by The Open Group and available at <http://www.opengroup.org/public/pubs/catalog/c193.htm>.

XA transactions are designed to allow distributed transactions, where a transaction manager (the application) controls a transaction which involves multiple resources. Such resources are usually DBMSs, but could be resources of any type. The whole set of required transactional operations is called a global transaction. Each subset of operations which involve a single resource is called a local transaction. XA used a 2-phases commit (2PC). With the first commit, the transaction manager tells each resource to prepare an effective commit, and waits for a confirm message. The changes are not still made effective at this point. If any of the resources encountered an error, the transaction manager will rollback the global transaction. If all resources communicate that the first commit is successful, the transaction manager can require a second commit, which makes the changes effective.

In MariaDB, XA transactions can only be used with storage engines that support them. At least [InnoDB](#) , [TokuDB](#) , [SPIDER](#) and [MyRocks](#) support them. For InnoDB, until [MariaDB 10.2](#) , XA transactions can be disabled by setting the `innodb_support_xa` server system variable to 0. From [MariaDB 10.3](#) , XA transactions are always supported.

Like regular transactions, XA transactions create [metadata locks](#) on accessed tables.

XA transactions require [REPEATABLE READ](#) as a minimum isolation level. However, distributed transactions should always use [SERIALIZABLE](#).

Trying to start more than one XA transaction at the same time produces a 1400 error ( [SQLSTATE 'XAE09'](#) ). The same error is produced when attempting to start an XA transaction while a regular transaction is in effect. Trying to start a regular transaction while an XA transaction is in effect produces a 1399 error ( [SQLSTATE 'XAE07'](#) ).

The [statements that cause an implicit COMMIT](#) for regular transactions produce a 1400 error ( [SQLSTATE 'XAE09'](#)) if a XA transaction is in effect.

## Internal XA vs External XA

XA transactions are an overloaded term in MariaDB. If a [storage engine](#) is XA-capable, it can mean one or both of these:

- It supports MariaDB's internal two-phase commit API. This is transparent to the user. Sometimes this is called "internal XA", since MariaDB's [internal transaction coordinator log](#) can handle coordinating these transactions.
- It supports XA transactions, with the

XA START

,

XA PREPARE

,

XA COMMIT

, etc. statements. Sometimes this is called "external XA", since it requires the use of an external transaction coordinator to use this feature properly.

## Transaction Coordinator Log

If you have two or more XA-capable storage engines enabled, then a transaction coordinator log must be available.

There are currently two implementations of the transaction coordinator log:

- Binary log-based transaction coordinator log
- Memory-mapped file-based transaction coordinator log

If the [binary log](#) is enabled on a server, then the server will use the binary log-based transaction coordinator log. Otherwise, it will use the memory-mapped file-based transaction coordinator log.

See [Transaction Coordinator Log](#) for more information.

## Syntax

```
XA {START|BEGIN} xid [JOIN|RESUME]  
  
XA END xid [SUSPEND [FOR MIGRATE]]  
  
XA PREPARE xid  
  
XA COMMIT xid [ONE PHASE]  
  
XA ROLLBACK xid  
  
XA RECOVER [FORMAT=['RAW' | 'SQL']]  
  
xid: gtrid [, bqual [, formatID ]]
```

The interface to XA transactions is a set of SQL statements starting with

XA

. Each statement changes a transaction's state, determining which actions it can perform. A transaction which does not exist is in the NON-EXISTING state.

XA START

(or

BEGIN

) starts a transaction and defines its

xid

(a transaction identifier). The

JOIN

or

RESUME

keywords have no effect. The new transaction will be in

ACTIVE

state.

The

xid

can have 3 components, though only the first one is mandatory.

gtrid

is a quoted string representing a global transaction identifier.

bqual  
is a quoted string representing a local transaction identifier.  
formatID  
is an unsigned integer indicating the format used for the first two components; if not specified, defaults to 1. MariaDB does not interpret in any way these components, and only uses them to identify a transaction.  
xid  
s of transactions in effect must be unique.

XA END  
declares that the specified  
ACTIVE  
transaction is finished and it changes its state to  
IDLE  
  
SUSPEND [FOR MIGRATE]  
has no effect.

XA PREPARE  
prepares an  
IDLE  
transaction for commit, changing its state to  
PREPARED  
. This is the first commit.

XA COMMIT  
definitely commits and terminates a transaction which has already been  
PREPARED  
. If the  
ONE PHASE  
clause is specified, this statement performs a 1-phase commit on an  
IDLE  
transaction.

XA ROLLBACK  
rolls back and terminates an  
IDLE  
or  
PREPARED  
transaction.

XA RECOVER  
shows information about all  
PREPARED  
transactions.

When trying to execute an operation which is not allowed for the transaction's current state, an error is produced:

```
XA COMMIT 'test' ONE PHASE;  
ERROR 1399 (XAE07): XAER_RMFAIL: The command cannot be executed when global transaction is in the ACTIVE state  
  
XA COMMIT 'test2';  
ERROR 1399 (XAE07): XAER_RMFAIL: The command cannot be executed when global transaction is in the NON-EXISTING state
```

## XA RECOVER

The  
XA RECOVER  
statement shows information about all transactions which are in the  
PREPARED  
state. It does not matter which connection created the transaction: if it has been  
PREPARED  
, it appears. But this does not mean that a connection can commit or rollback a transaction which was started by another connection. Note that transactions using a 1-phase commit are never in the  
PREPARED

state, so they cannot be shown by

XA RECOVER

.

XA RECOVER

produces four columns:

```
XA RECOVER;
+-----+-----+-----+-----+
| formatID | gtrid_length | bqual_length | data |
+-----+-----+-----+-----+
|      1 |          4 |          0 | test  |
+-----+-----+-----+
```

MariaDB starting with 10.3.3

You can use

```
XA RECOVER FORMAT='SQL'
to get the data in a human readable form that can be directly copy-pasted into
XA COMMIT
or
XA ROLLBACK
. This is particularly useful for binary
xid
generated by some transaction coordinators.
```

formatID  
is the  
formatID  
part of  
xid

.

data  
are the  
gtrid  
and  
bqual  
parts of  
xid  
, concatenated.

gtrid\_length  
and  
bqual\_length  
are the lengths of  
gtrid  
and  
bqual  
, respectively.

## Examples

2-phases commit:

```
XA START 'test';
INSERT INTO t VALUES (1,2);
XA END 'test';
XA PREPARE 'test';
XA COMMIT 'test';
```

1-phase commit:

```

XA START 'test';

INSERT INTO t VALUES (1,2);

XA END 'test';

XA COMMIT 'test' ONE PHASE;

```

Human-readable:

```

xa start '12\r34\t67\v78', 'abc\ndef', 3;

insert t1 values (40);

xa end '12\r34\t67\v78', 'abc\ndef', 3;

xa prepare '12\r34\t67\v78', 'abc\ndef', 3;

xa recover format='RAW';
+-----+-----+-----+
| formatID | gtrid_length | bqual_length | data           |
+-----+-----+-----+
| 34      |       11        |         7       | 12             |
def |
+-----+-----+-----+
xa recover format='SQL';
+-----+-----+-----+
| formatID | gtrid_length | bqual_length | data           |
+-----+-----+-----+
| 3       |       11        |         7       | X'31320d3334093637763738',X'6162630a646566',3 |
+-----+-----+-----+
xa rollback X'31320d3334093637763738',X'6162630a646566',3;

```

## Known Issues

### MariaDB Galera Cluster

[MariaDB Galera Cluster](#) does not support XA transactions.

However, [MariaDB Galera Cluster](#) builds include a built-in plugin called

wsrep

Prior to [MariaDB 10.4.3](#), this plugin was internally considered an [XA-capable storage engine](#). Consequently, these [MariaDB Galera Cluster](#) builds have multiple XA-capable storage engines by default, even if the only "real" storage engine that supports external [XA transactions](#) enabled on these builds by default is [InnoDB](#). Therefore, when using one of these builds MariaDB would be forced to use a [transaction coordinator log](#) by default, which could have performance implications.

See [Transaction Coordinator Log Overview: MariaDB Galera Cluster](#) for more information.

## 1.1.10 HELP Command

## 1.1.11 Comment Syntax

There are three supported comment styles in MariaDB:

- From a '#'

#  
' to the end of a line:

```
SELECT * FROM users; # This is a comment
```

- From a '--'

--  
' to the end of a line. The space after the two dashes is required (as in MySQL).

```
SELECT * FROM users; -- This is a comment
```

- C style comments from an opening '/\*'

/\*  
' to a closing '\*/'

```
/*
'. Comments of this form can span multiple lines:
```

```
SELECT * FROM users; /* This is a
multi-line
comment */
```

Nested comments are possible in some situations, but they are not supported or recommended.

## Executable Comments

As an aid to portability between different databases, MariaDB supports executable comments. These special comments allow you to embed SQL code which will not execute when run on other databases, but will execute when run on MariaDB.

MariaDB supports both MySQL's executable comment format, and a slightly modified version specific to MariaDB. This way, if you have SQL code that works on MySQL and MariaDB, but not other databases, you can wrap it in a MySQL executable comment, and if you have code that specifically takes advantage of features only available in MariaDB you can use the MariaDB specific format to hide the code from MySQL.

### Executable Comment Syntax

MySQL and MariaDB executable comment syntax:

```
/*! MySQL or MariaDB-specific code */
```

Code that should be executed only starting from a specific MySQL or MariaDB version:

```
/*!##### MySQL or MariaDB-specific code */
```

The numbers, represented by '

#####

' in the syntax examples above specify the specific the minimum versions of MySQL and MariaDB that should execute the comment. The first number is the major version, the second 2 numbers are the minor version and the last 2 is the patch level.

For example, if you want to embed some code that should only execute on MySQL or MariaDB starting from 5.1.0, you would do the following:

```
/*!50100 MySQL and MariaDB 5.1.0 (and above) code goes here. */
```

MariaDB-only executable comment syntax (starting from [MariaDB 5.3.1](#) ):

```
/*M! MariaDB-specific code */
/*M!##### MariaDB-specific code */
```

MariaDB ignores MySQL-style executable comments that have a version number in the range

50700..99999

. This is needed to skip features introduced in MySQL-5.7 that are not ported to MariaDB 10.x yet.

```
/*!50701 MariaDB-10.x ignores MySQL-5.7 specific code */
```

**Note:** comments which have a version number in the range

50700..99999

that use MariaDB-style executable comment syntax are still executed.

```
/*M!50701 MariaDB-10.x does not ignore this */
```

Statement delimiters cannot be used within executable comments.

## Examples

In MySQL all the following will return 2: In MariaDB, the last 2 queries would return 3.

```
SELECT 2 /* +1 */;
SELECT 1 /*! +1 */;
SELECT 1 /*!50101 +1 */;
SELECT 2 /*M! +1 */;
SELECT 2 /*M!50301 +1 */;
```

The following executable statement will not work due to the delimiter inside the executable portion:

```
/*M!100100 select 1 ; */
ERROR 1064 (42000): You have an error in your SQL syntax; check the manual that corresponds to your MariaDB server version for t
```

Instead, the delimiter should be placed outside the executable portion:

```
/*M!100100 select 1 *;
+---+
| 1 |
+---+
| 1 |
+---+
```

## 1.1.12 Built-in Functions

### 1.1.12.1 Function and Operator Reference

Name	Description
+	Addition operator
/	Division operator
*	Multiplication operator
%	Modulo operator. Returns the remainder of N divided by M
-	Subtraction operator
!=	Not equals
<	Less than
<=	Less than or equal
<>	NULL-safe equal
=	Equal
>	Greater than
>=	Greater than or equal
&	Bitwise AND
<<	Shift left
>>	Shift right
^	Bitwise XOR
!	Logical NOT
&&	Logical AND
XOR	Logical XOR
	Logical OR
	Bitwise OR
:=	Assignment operator
=	Assignment and comparison operator
~	Bitwise NOT
ABS	Returns an absolute value
ACOS	Returns an arc cosine
ADD_MONTHS	Add months to a date
ADDDATE	Add days or another interval to a date
ADDTIME	Adds a time to a time or datetime
AES_DECRYPT	Decryption data encrypted with AES_ENCRYPT
AES_ENCRYPT	Encrypts a string with the AES algorithm
AREA	Synonym for ST_AREA
AsBinary	Synonym for ST_AsBinary
ASCII	Numeric ASCII value of leftmost character

ASIN	Returns the arc sine
AsText	Synonym for ST_AsText
AsWKB	Synonym for ST_AsBinary
AsWKT	Synonym for ST_AsText
ATAN	Returns the arc tangent
ATAN2	Returns the arc tangent of two variables
AVG	Returns the average value
BENCHMARK	Executes an expression repeatedly
BETWEEN AND	True if expression between two values
BIN	Returns binary value
BINARY OPERATOR	Casts to a binary string
BINLOG_GTID_POS	Returns a string representation of the corresponding GTID position
BIT_AND	Bitwise AND
BIT_COUNT	Returns the number of set bits
BIT_LENGTH	Returns the length of a string in bits
BIT_OR	Bitwise OR
BIT_XOR	Bitwise XOR
BOUNDARY	Synonym for ST_BOUNDARY
BUFFER	Synonym for ST_BUFFER
CASE	Returns the result where value=compare_value or for the first condition that is true
CAST	Casts a value of one type to another type
CEIL	Synonym for CEILING()
CEILING	Returns the smallest integer not less than X
CENTROID	Synonym for ST_CENTROID
CHAR Function	Returns string based on the integer values for the individual characters
CHARACTER_LENGTH	Synonym for CHAR_LENGTH()
CHAR_LENGTH	Length of the string in characters
CHARSET	Returns the character set
CHR	Returns a string consisting of the character given by the code values of the integer
COALESCE	Returns the first non-NULL parameter
COERCIBILITY	Returns the collation coercibility value
COLLATION	Collation of the string argument
COLUMN_ADD	Adds or updates dynamic columns
COLUMN_CHECK	Checks if a dynamic column blob is valid
COLUMN_CREATE	Returns a dynamic columns blob
COLUMN_DELETE	Deletes a dynamic column
COLUMN_EXISTS	Checks if a column exists
COLUMN_GET	Gets a dynamic column value by name
COLUMN_JSON	Returns a JSON representation of dynamic column blob data
COLUMN_LIST	Returns comma-separated list
COMPRESS	Returns a binary, compressed string
CONCAT	Returns concatenated string
CONCAT_WS	Concatenate with separator
CONNECTION_ID	Connection thread ID
CONTAINS	Whether one geometry contains another
CONVERT	Convert a value from one type to another type
CONV	Converts numbers between different number bases
CONVERT_TZ	Converts a datetime from one time zone to another
CONVEXHULL	Synonym for ST_CONVEXHULL
COS	Returns the cosine
COT	Returns the cotangent

COUNT	Returns count of non-null values
COUNT DISTINCT	Returns count of number of different non-NULL values
CRC32	Computes a cyclic redundancy check value
CROSSES	Whether two geometries spatially cross
CUME_DIST	Window function that returns the cumulative distribution of a given row
CURDATE	Returns the current date
CURRENT_DATE	Synonym for CURDATE()
CURRENT_ROLE	Current role name
CURRENT_TIME	Synonym for CURTIME()
CURRENT_TIMESTAMP	Synonym for NOW()
CURRENT_USER	Username/host that authenticated the current client
CURTIME	Returns the current time
DATABASE	Current default database
DATE FUNCTION	Extracts the date portion of a datetime
DATEDIFF	Difference in days between two date/time values
DATE_ADD	Date arithmetic - addition
DATE_FORMAT	Formats the date value according to the format string
DATE_SUB	Date arithmetic - subtraction
DAY	Synonym for DAYOFMONTH()
DAYNAME	Return the name of the weekday
DAYOFMONTH	Returns the day of the month
DAYOFWEEK	Returns the day of the week index
DAYOFYEAR	Returns the day of the year
DECODE	Decrypts a string encoded with ENCODE()
DECODE_HISTOGRAM	Returns comma separated numerics corresponding to a probability distribution represented by a histogram
DEFAULT	Returns column default
DEGREES	Converts from radians to degrees
DENSE_RANK	Rank of a given row with identical values receiving the same result, no skipping
DES_DECRYPT	Decrypts a string encrypted with DES_ENCRYPT()
DES_ENCRYPT	Encrypts a string using the Triple-DES algorithm
DIMENSION	Synonym for ST_DIMENSION
DISJOINT	Whether the two elements do not intersect
DIV	Integer division
ELT	Returns the N'th element from a set of strings
ENCODE	Encrypts a string
ENCRYPT	Encrypts a string with Unix crypt()
ENDPOINT	Synonym for ST_ENDPOINT
ENVELOPE	Synonym for ST_ENVELOPE
EQUALS	Indicates whether two geometries are spatially equal
EXP	e raised to the power of the argument
EXPORT_SET	Returns an on string for every bit set, an off string for every bit not set
ExteriorRing	Synonym for ST_ExteriorRing
EXTRACT	Extracts a portion of the date
EXTRACTVALUE	Returns the text of the first text node matched by the XPath expression
FIELD	Returns the index position of a string in a list
FIND_IN_SET	Returns the position of a string in a set of strings
FLOOR	Largest integer value not greater than the argument
FORMAT	Formats a number
FOUND_ROWS	Number of (potentially) returned rows
FROM_BASE64	Given a base-64 encoded string, returns the decoded result as a binary string

FROM_DAYS	Returns a date given a day
FROM_UNIXTIME	Returns a datetime from a Unix timestamp
GeomCollFromText	Synonym for ST_GeomCollFromText
GeomCollFromWKB	Synonym for ST_GeomCollFromWKB
GeometryCollectionFromText	Synonym for ST_GeomCollFromText
GeometryCollectionFromWKB	Synonym for ST_GeomCollFromWKB
GeometryFromText	Synonym for ST_GeomFromText
GeometryFromWKB	Synonym for ST_GeomFromWKB
GeomFromText	Synonym for ST_GeomFromText
GeomFromWKB	Synonym for ST_GeomFromWKB
GeometryN	Synonym for ST_GeometryN
GEOMETRYCOLLECTION	Constructs a WKB GeometryCollection
GeometryType	Synonym for ST_GeometryType
GET_FORMAT	Returns a format string
GET_LOCK	Obtain LOCK
GLENGTH	Length of a LineString value
GREATEST	Returns the largest argument
GROUP_CONCAT	Returns string with concatenated values from a group
HEX	Returns hexadecimal value
HOUR	Returns the hour
IF	If expr1 is TRUE, returns expr2; otherwise returns expr3
IFNULL	Check whether an expression is NULL
IN	True if expression equals any of the values in the list
INTERVAL	Index of the argument that is less than the first argument
INET6_ATON	Given an IPv6 or IPv4 network address, returns a VARBINARY numeric value
INET6_NTOA	Given an IPv6 or IPv4 network address, returns the address as a nonbinary string
INET_ATON	Returns numeric value of IPv4 address
INET_NTOA	Returns dotted-quad representation of IPv4 address
INSERT Function	Replaces a part of a string with another string
INSTR	Returns the position of a string within a string
InteriorRingN	Synonym for ST_InteriorRingN
INTERSECTS	Indicates whether two geometries spatially intersect
IS	Tests whether a boolean is TRUE, FALSE, or UNKNOWN
IsClosed	Synonym for ST_IsClosed
IsEmpty	Synonym for ST_IsEmpty
IS_FREE_LOCK	Checks whether lock is free to use
IS_IPV4	Whether or not an expression is a valid IPv4 address
IS_IPV4_COMPAT	Whether or not an IPv6 address is IPv4-compatible
IS_IPV4_MAPPED	Whether an IPv6 address is a valid IPv4-mapped address
IS_IPV6	Whether or not an expression is a valid IPv6 address
IS NOT	Tests whether a boolean value is not TRUE, FALSE, or UNKNOWN
IS NOT NULL	Tests whether a value is not NULL
IS NULL	Tests whether a value is NULL
ISNULL	Checks if an expression is NULL
IsRing	Synonym for ST_IsRing
IsSimple	Synonym for ST_IsSimple
IS_USED_LOCK	Check if lock is in use
JSON_ARRAY	Returns a JSON array containing the listed values
JSON_ARRAY_APPEND	Appends values to the end of the given arrays within a JSON document
JSON_ARRAY_INSERT	Inserts a value into a JSON document

JSON_COMPACT	Removes all unnecessary spaces so the json document is as short as possible
JSON_CONTAINS	Whether a value is found in a given JSON document or at a specified path within the document
JSON_CONTAINS_PATH	Indicates whether the given JSON document contains data at the specified path or paths
JSON_DEPTH	Maximum depth of a JSON document
JSON_DETAILED	Represents JSON in the most understandable way emphasizing nested structures
JSON_EQUALS	Check for equality between JSON objects.
JSON_EXISTS	Determines whether a specified JSON value exists in the given data
JSON_EXTRACT	Extracts data from a JSON document.
JSON_INSERT	Inserts data into a JSON document
JSON_KEYS	Returns keys from top-level value of a JSON object or top-level keys from the path
JSON_LENGTH	Returns the length of a JSON document, or the length of a value within the document
JSON_LOOSE	Adds spaces to a JSON document to make it look more readable
JSON_MERGE	Merges the given JSON documents
JSON_MERGE_PATCH	RFC 7396-compliant merge of the given JSON documents
JSON_MERGE_PRESERVE	Synonym for <code>JSON_MERGE_PATCH</code> .
JSON_NORMALIZE	Recursively sorts keys and removes spaces, allowing comparison of json documents for equality
JSON_OBJECT	Returns a JSON object containing the given key/value pairs
JSON_OBJECTAGG	Returns a JSON object containing key-value pairs
JSON_OVERLAPS	Compares two json documents for overlaps
JSON_QUERY	Given a JSON document, returns an object or array specified by the path
JSON_QUOTE	Quotes a string as a JSON value
JSON_REMOVE	Removes data from a JSON document
JSON_REPLACE	Replaces existing values in a JSON document
JSON_SEARCH	Returns the path to the given string within a JSON document
JSON_SET	Updates or inserts data into a JSON document
JSON_TABLE	Returns a representation of a JSON document as a relational table
JSON_TYPE	Returns the type of a JSON value
JSON_UNQUOTE	Unquotes a JSON value, returning a string
JSON_VALID	Whether a value is a valid JSON document or not
JSON_VALUE	Given a JSON document, returns the specified scalar
LAST_DAY	Returns the last day of the month
LAST_INSERT_ID	Last inserted autoinc value
LAST_VALUE	Returns the last value in a list
LASTVAL	Get last value generated from a sequence
LCASE	Synonym for <code>[LOWER()]</code>
LEAST	Returns the smallest argument
LEFT	Returns the leftmost characters from a string
LENGTH	Length of the string in bytes
LIKE	Whether expression matches a pattern
LineFromText	Synonym for <code>ST_LineFromText</code>
LineFromWKB	Synonym for <code>ST_LineFromWKB</code>
LINESTRING	Constructs a WKB LineString value from a number of WKB Point arguments
LineStringFromText	Synonym for <code>ST_LineFromText</code>
LineStringFromWKB	Synonym for <code>ST_LineFromWKB</code>
LN	Returns natural logarithm
LOAD_FILE	Returns file contents as a string
LOCALTIME	Synonym for <code>NOW()</code>
LOCALTIMESTAMP	Synonym for <code>NOW()</code>
LOCATE	Returns the position of a substring in a string
LOG	Returns the natural logarithm

LOG10	Returns the base-10 logarithm
LOG2	Returns the base-2 logarithm
LOWER	Returns a string with all characters changed to lowercase
LPAD	Returns the string left-padded with another string to a given length
LTRIM	Returns the string with leading space characters removed
MAKE_SET	Make a set of strings that matches a bitmask
MAKEDATE	Returns a date given a year and day
MAKETIME	Returns a time
MASTER_GTID_WAIT	Wait until slave reaches the GTID position
MASTER_POS_WAIT	Blocks until the slave has applied all specified updates
MATCH AGAINST	Perform a fulltext search on a fulltext index
MAX	Returns the maximum value
MBRContains	Indicates one Minimum Bounding Rectangle contains another
MBRDisjoint	Indicates whether the Minimum Bounding Rectangles of two geometries are disjoint
MBREqual	Whether the Minimum Bounding Rectangles of two geometries are the same.
MBRIntersects	Indicates whether the Minimum Bounding Rectangles of the two geometries intersect
MBROverlaps	Whether the Minimum Bounding Rectangles of two geometries overlap.
MBRTouches	Whether the Minimum Bounding Rectangles of two geometries touch.
MBRWithin	Indicates whether one Minimum Bounding Rectangle is within another
MD5	MD5 checksum
MEDIAN	Window function that returns the median value of a range of values
MICROSECOND	Returns microseconds from a date or datetime
MID	Synonym for SUBSTRING(str,pos,len)
MIN	Returns the minimum value
MINUTE	Returns a minute from 0 to 59
MLineFromText	Constructs MULTILINESTRING using its WKT representation and SRID
MLineFromWKB	Constructs a MULTILINESTRING
MOD	Modulo operation. Remainder of N divided by M
MONTH	Returns a month from 1 to 12
MONTHNAME	Returns the full name of the month
MPointFromText	Constructs a MULTIPOINT value using its WKT and SRID
MPointFromWKB	Constructs a MULTIPOINT value using its WKB representation and SRID
MPolyFromText	Constructs a MULTIPOLYGON value
MPolyFromWKB	Constructs a MULTIPOLYGON value using its WKB representation and SRID
MultiLineStringFromText	Synonym for MLineFromText
MultiLineStringFromWKB	A synonym for MLineFromWKB
MULTIPOINT	Constructs a WKB MultiPoint value
MultiPointFromText	Synonym for MPointFromText
MultiPointFromWKB	Synonym for MPointFromWKB
MULTIPOLYGON	Constructs a WKB MultiPolygon
MultiPolygonFromText	Synonym for MPolyFromText
MultiPolygonFromWKB	Synonym for MPolyFromWKB
MULTILINESTRING	Constructs a MultiLineString value
NAME_CONST	Returns the given value
NATURAL_SORT_KEY	Sorting that is more more similar to natural human sorting
NOT LIKE	Same as NOT(expr LIKE pat [ESCAPE 'escape_char'])
NOT REGEXP	Same as NOT (expr REGEXP pat)
NULLIF	Returns NULL if expr1 = expr2
NEXTVAL	Generate next value for sequence
NOT BETWEEN	Same as NOT (expr BETWEEN min AND max)
NOT IN	Same as NOT (expr IN (value,...))

NOW	Returns the current date and time
NTILE	Returns an integer indicating which group a given row falls into
NumGeometries	Synonym for ST_NumGeometries
NumInteriorRings	Synonym for NumInteriorRings
NumPoints	Synonym for ST_NumPoints
OCT	Returns octal value
OCTET_LENGTH	Synonym for LENGTH()
OLD_PASSWORD	Pre MySQL 4.1 password implementation
ORD	Return ASCII or character code
OVERLAPS	Indicates whether two elements spatially overlap
PASSWORD	Calculates a password string
PERCENT_RANK	Window function that returns the relative percent rank of a given row
PERCENTILE_CONT	Returns a value which corresponds to the given fraction in the sort order.
PERCENTILE_DISC	Returns the first value in the set whose ordered position is the same or more than the specified fraction.
PERIOD_ADD	Add months to a period
PERIOD_DIFF	Number of months between two periods
PI	Returns the value of π (pi)
POINT	Constructs a WKB Point
PointFromText	Synonym for ST_PointFromText
PointFromWKB	Synonym for PointFromWKB
PointN	Synonym for PointN
PointOnSurface	Synonym for ST_PointOnSurface
POLYGON	Constructs a WKB Polygon value from a number of WKB LineString arguments
PolyFromText	Synonym for ST_PolyFromText
PolyFromWKB	Synonym for ST_PolyFromWKB
PolygonFromText	Synonym for ST_PolyFromText
PolygonFromWKB	Synonym for ST_PolyFromWKB
POSITION	Returns the position of a substring in a string
POW	Returns X raised to the power of Y
POWER	Synonym for POW()
QUARTER	Returns year quarter from 1 to 4
QUOTE	Returns quoted, properly escaped string
RADIANS	Converts from degrees to radians
RAND	Random floating-point value
RANK	Rank of a given row with identical values receiving the same result
REGEXP	Performs pattern matching
REGEXP_INSTR	Position of the first appearance of a regex
REGEXP_REPLACE	Replaces all occurrences of a pattern
REGEXP_SUBSTR	Returns the matching part of a string
RELEASE_LOCK	Releases lock obtained with GET_LOCK()
REPEAT Function	Returns a string repeated a number of times
REPLACE Function	Replace occurrences of a string
REVERSE	Reverses the order of a string
RIGHT	Returns the rightmost N characters from a string
RLIKE	Synonym for REGEXP()
RPAD	Returns the string right-padded with another string to a given length
ROUND	Rounds a number
ROW_COUNT	Number of rows affected by previous statement
ROW_NUMBER	Row number of a given row with identical values receiving a different result
RTRIM	Returns the string with trailing space characters removed

SCHEMA	Synonym for DATABASE()
SECOND	Returns the second of a time
SEC_TO_TIME	Converts a second to a time
SETVAL	Set the next value to be returned by a sequence
SESSION_USER	Synonym for USER()
SHA	Synonym for SHA1()
SHA1	Calculates an SHA-1 checksum
SHA2	Calculates an SHA-2 checksum
SIGN	Returns 1, 0 or -1
SIN	Returns the sine
SLEEP	Pauses for the given number of seconds
SOUNDEX	Returns a string based on how the string sounds
SOUNDS LIKE	SOUNDEX(expr1) = SOUNDEX(expr2)
SPACE	Returns a string of space characters
SPIDER_BG_DIRECT_SQL	Background SQL execution
SPIDER_COPY_TABLES	Copy table data
SPIDER_DIRECT_SQL	Execute SQL on the remote server
SPIDER_FLUSH_TABLE_MON_CACHE	Refreshing Spider monitoring server information
SQRT	Square root
SRID	Synonym for ST_SRID
ST_AREA	Area of a Polygon
ST_AsBinary	Converts a value to its WKB representation
ST_AsText	Converts a value to its WKT-Definition
ST_AsWKB	Synonym for ST_AsBinary
ST_ASWKT	Synonym for ST_ASTEXT()
ST_BOUNDARY	Returns a geometry that is the closure of a combinatorial boundary
ST_BUFFER	A new geometry with a buffer added to the original geometry
ST_CENTROID	The mathematical centroid (geometric center) for a MultiPolygon
ST_CONTAINS	Whether one geometry is contained by another
ST_CONVEXHULL	The minimum convex geometry enclosing all geometries within the set
ST_CROSSES	Whether two geometries spatially cross
ST_DIFFERENCE	Point set difference
ST_DIMENSION	Inherent dimension of a geometry value
ST_DISJOINT	Whether one geometry is spatially disjoint from another
ST_DISTANCE	The distance between two geometries
ST_DISTANCE_SPHERE	The spherical distance between two geometries
ST_ENDPOINT	Returns the endpoint of a LineString
ST_ENVELOPE	Returns the Minimum Bounding Rectangle for a geometry value
ST_EQUALS	Whether two geometries are spatioially equal
ST_ExteriorRing	Returns the exterior ring of a Polygon as a LineString
ST_GeomCollFromText	Constructs a GEOMETRYCOLLECTION value
ST_GeomCollFromWKB	Constructs a GEOMETRYCOLLECTION value from a WKB
ST_GeometryCollectionFromText	Synonym for ST_GeomCollFromText
ST_GeometryCollectionFromWKB	Synonym for ST_GeomCollFromWKB
ST_GeometryFromText	Synonym for ST_GeomFromText
ST_GeometryFromWKB	Synonym for ST_GeomFromWKB
ST_GEOMETRYN	Returns the N-th geometry in a GeometryCollection
ST_GEOMETRYTYPE	Returns name of the geometry type of which a given geometry instance is a member
ST_GeomFromText	Constructs a geometry value using its WKT and SRID
ST_GeomFromWKB	Constructs a geometry value using its WKB representation and SRID
ST_InteriorRingN	Returns the N-th interior ring for a Polygon

ST_INTERSECTION	The intersection, or shared portion, of two geometries
ST_INTERSECTS	Whether two geometries spatially intersect
ST_ISCLOSED	Returns true if a given LINESTRING's start and end points are the same
ST_ISEMPTY	Indicated validity of geometry value
ST_IsRing	Returns true if a given LINESTRING is both ST_IsClosed and ST_IsSimple
ST_IsSimple	Returns true if the given Geometry has no anomalous geometric points
ST_LENGTH	Length of a LineString value
ST_LineFromText	Creates a linestring value
ST_LineFromWKB	Constructs a LINESTRING using its WKB and SRID
ST_LineStringFromText	Synonym for ST_LineFromText
ST_LineStringFromWKB	Synonym for ST_LineFromWKB
ST_NUMGEOMETRIES	Number of geometries in a GeometryCollection
ST_NumInteriorRings	Number of interior rings in a Polygon
ST_NUMPOINTS	Returns the number of Point objects in a LineString
ST_OVERLAPS	Whether two geometries overlap
ST_PointFromText	Constructs a POINT value
ST_PointFromWKB	Constructs POINT using its WKB and SRID
ST_POINTN	Returns the N-th Point in the LineString
ST_POINTONSURFACE	Returns a POINT guaranteed to intersect a surface
ST_PolyFromText	Constructs a POLYGON value
ST_PolyFromWKB	Constructs POLYGON value using its WKB representation and SRID
ST_PolygonFromText	Synonym for ST_PolyFromText
ST_PolygonFromWKB	Synonym for ST_PolyFromWKB
ST_RELATE	Returns true if two geometries are related
ST_SRID	Returns a Spatial Reference System ID
ST_STARTPOINT	Returns the start point of a LineString
ST_SYMDIFFERENCE	Portions of two geometries that don't intersect
ST_TOUCHES	Whether one geometry g1 spatially touches another
ST_UNION	Union of two geometries
ST_WITHIN	Whether one geometry is within another
ST_X	X-coordinate value for a point
ST_Y	Y-coordinate for a point
STARTPOINT	Synonym for ST_StartPoint
STD	Population standard deviation
STDDEV	Population standard deviation
STDDEV_POP	Returns the population standard deviation
STDDEV_SAMP	Standard deviation
STR_TO_DATE	Converts a string to date
STRCMP	Compares two strings in sort order
SUBDATE	Subtract a date unit or number of days
SUBSTR	Returns a substring from string starting at a given position
SUBSTRING	Returns a substring from string starting at a given position
SUBSTRING_INDEX	Returns the substring from string before count occurrences of a delimiter
SUBTIME	Subtracts a time from a date/time
SUM	Sum total
SYS_GUID	Generates a globally unique identifier
SYSDATE	Returns the current date and time
SYSTEM_USER	Synonym for USER()
TAN	Returns the tangent
TIME function	Extracts the time
TIMEDIFF	Returns the difference between two date/times

TIMESTAMP FUNCTION	Return the datetime, or add a time to a date/time
TIMESTAMPADD	Add interval to a date or datetime
TIMESTAMPDIFF	Difference between two datetimes
TIME_FORMAT	Formats the time value according to the format string
TIME_TO_SEC	Returns the time argument, converted to seconds
TO_BASE64	Converts a string to its base-64 encoded form
TO_CHAR	Converts a date/time type to a char
TO_DAYS	Number of days since year 0
TO_SECONDS	Number of seconds since year 0
TOUCHES	Whether two geometries spatially touch
TRIM	Returns a string with all given prefixes or suffixes removed
TRUNCATE	Truncates X to D decimal places
UCASE	Synonym for UPPER]]()
UNHEX	Interprets pairs of hex digits as a number and converts to the character represented by the number
UNCOMPRESS	Uncompresses string compressed with COMPRESS()
UNCOMPRESSED_LENGTH	Returns length of a string before being compressed with COMPRESS()
UNIX_TIMESTAMP	Returns a Unix timestamp
UPDATEXML	Replace XML
UPPER	Changes string to uppercase
USER	Current user/host
UTC_DATE	Returns the current UTC date
UTC_TIME	Returns the current UTC time
UTC_TIMESTAMP	Returns the current UTC date and time
UUID	Returns a Universal Unique Identifier
UUID_SHORT	Return short universal identifier
VALUES or VALUE	Refer to columns in INSERT ... ON DUPLICATE KEY UPDATE
VAR_POP	Population standard variance
VAR_SAMP	Returns the sample variance
VARIANCE	Population standard variance
VERSION	MariaDB server version
WEEK	Returns the week number
WEEKDAY	Returns the weekday index
WEEKOFYEAR	Returns the calendar week of the date as a number in the range from 1 to 53
WEIGHT_STRING	Weight of the input string
WITHIN	Indicate whether a geographic element is spacially within another
WSREP_LAST_SEEN_GTID	Returns the Global Transaction ID of the most recent write transaction observed by the client.
WSREP_LAST_WRITTEN_GTID	Returns the Global Transaction ID of the most recent write transaction performed by the client.
WSREP_SYNC_WAIT_UPTO_GTID	Blocks the client until the transaction specified by the given Global Transaction ID is applied and committed by the node
X	Synonym for ST_X
Y	Synonym for ST_Y
YEAR	Returns the year for the given date
YEARWEEK	Returns year and week for a date

## 1.1.12.2 String Functions

### 1.1.12.2.1 Regular Expressions Functions

#### 1.1.12.2.1.1 Regular Expressions Overview

## Contents

1. [Special Characters](#)
  1. ^
  2. \$
  3. .
  4. \*
  5. +
  6. ?
  7. ()
  8. {}
  9. []
    1. ^
    2. [Word boundaries](#)
    3. [Character Classes](#)
    4. [Character Names](#)
10. [Combining](#)
11. [Escaping](#)

Regular Expressions allow MariaDB to perform complex pattern matching on a string. In many cases, the simple pattern matching provided by [LIKE](#) is sufficient.

`LIKE`

performs two kinds of matches:

- \_
  - the underscore, matching a single character
- %
  - the percentage sign, matching any number of characters.

In other cases you may need more control over the returned matches, and will need to use regular expressions.

MariaDB starting with [10.0.5](#)

Until [MariaDB 10.0.5](#), MariaDB used the POSIX 1003.2 compliant regular expression library. The new PCRE library is mostly backwards compatible with what is described below - see the [PCRE Regular Expressions](#) article for the enhancements made in 10.0.5.

Regular expression matches are performed with the [REGEXP](#) function.

`RLIKE`

is a synonym for

`REGEXP`

Comparisons are performed on the byte value, so characters that are treated as equivalent by a collation, but do not have the same byte-value, such as accented characters, could evaluate as unequal. Also note that until [MariaDB 10.0.5](#), regular expressions were not multi-byte safe, and therefore could produce unexpected results in multi-byte character sets.

Without any special characters, a regular expression match is true if the characters match. The match is case-insensitive, except in the case of `BINARY` strings.

```
SELECT 'Maria' REGEXP 'Maria';
+-----+
| 'Maria' REGEXP 'Maria' |
+-----+
|           1 |
+-----+  
  
SELECT 'Maria' REGEXP 'maria';
+-----+
| 'Maria' REGEXP 'maria' |
+-----+
|           1 |
+-----+  
  
SELECT BINARY 'Maria' REGEXP 'maria';
+-----+
| BINARY 'Maria' REGEXP 'maria' |
+-----+
|           0 |
+-----+
```

Note that the word being matched must match the whole pattern:

```
SELECT 'Maria' REGEXP 'Mari';
```

```
+-----+
| 'Maria' REGEXP 'Mari' |
+-----+
|           1 |
+-----+
```

```
SELECT 'Mari' REGEXP 'Maria';
```

```
+-----+
| 'Mari' REGEXP 'Maria' |
+-----+
|           0 |
+-----+
```

The first returns true because the pattern "Mari" exists in the expression "Maria". When the order is reversed, the result is false, as the pattern "Maria" does not exist in the expression "Mari"

A match can be performed against more than one word with the

|

character. For example:

```
SELECT 'Maria' REGEXP 'Monty|Maria';
```

```
+-----+
| 'Maria' REGEXP 'Monty|Maria' |
+-----+
|           1 |
+-----+
```

## Special Characters

The above examples introduce the syntax, but are not very useful on their own. It's the special characters that give regular expressions their power.

^

^

matches the beginning of a string (inside square brackets it can also mean NOT - see below):

```
SELECT 'Maria' REGEXP '^Ma';
```

```
+-----+
| 'Maria' REGEXP '^Ma' |
+-----+
|           1 |
+-----+
```

\$

\$

matches the end of a string:

```
SELECT 'Maria' REGEXP 'ia$';
```

```
+-----+
| 'Maria' REGEXP 'ia$' |
+-----+
|           1 |
+-----+
```

matches any single character:

```
SELECT 'Maria' REGEXP 'Ma.ia';
```

```
+-----+  
| 'Maria' REGEXP 'Ma.ia' |  
+-----+  
| 1 |  
+-----+
```

```
SELECT 'Maria' REGEXP 'Ma..ia';
```

```
+-----+  
| 'Maria' REGEXP 'Ma..ia' |  
+-----+  
| 0 |  
+-----+
```

\*

x\*

matches zero or more of a character

x

. In the examples below, it's the

r

character.

```
SELECT 'Maria' REGEXP 'Mar*ia';
```

```
+-----+  
| 'Maria' REGEXP 'Mar*ia' |  
+-----+  
| 1 |  
+-----+
```

```
SELECT 'Maia' REGEXP 'Mar*ia';
```

```
+-----+  
| 'Maia' REGEXP 'Mar*ia' |  
+-----+  
| 1 |  
+-----+
```

```
SELECT 'Marrria' REGEXP 'Mar*ia';
```

```
+-----+  
| 'Marrria' REGEXP 'Mar*ia' |  
+-----+  
| 1 |  
+-----+
```

+

x+

matches one or more of a character

x

. In the examples below, it's the

r

character.

```

SELECT 'Maria' REGEXP 'Mar+ia';
+-----+
| 'Maria' REGEXP 'Mar+ia' |
+-----+
|           1 |
+-----+

SELECT 'Maia' REGEXP 'Mar+ia';
+-----+
| 'Maia' REGEXP 'Mar+ia' |
+-----+
|           0 |
+-----+

SELECT 'Marrria' REGEXP 'Mar+ia';
+-----+
| 'Marrria' REGEXP 'Mar+ia' |
+-----+
|           1 |
+-----+

```

?

x?  
 matches zero or one of a character  
 x  
 . In the examples below, it's the  
 r  
 character.

```

SELECT 'Maria' REGEXP 'Mar?ia';
+-----+
| 'Maria' REGEXP 'Mar?ia' |
+-----+
|           1 |
+-----+

SELECT 'Maia' REGEXP 'Mar?ia';
+-----+
| 'Maia' REGEXP 'Mar?ia' |
+-----+
|           1 |
+-----+

SELECT 'Marrria' REGEXP 'Mar?ia';
+-----+
| 'Marrria' REGEXP 'Mar?ia' |
+-----+
|           0 |
+-----+

```

()

(xyz)  
 - combine a sequence, for example  
 (xyz)+  
 or  
 (xyz)\*

```

SELECT 'Maria' REGEXP '(ari)+';
+-----+
| 'Maria' REGEXP '(ari)+' |
+-----+
|           1 |
+-----+

```

{}

```

x{n}
and
x{m,n}
This notation is used to match many instances of the
x
. In the case of
x{n}
the match must be exactly that many times. In the case of
x{m,n}
, the match can occur from
m
to
n
times. For example, to match zero or one instance of the string
ari
(which is identical to
(ari)?
), the following can be used:

```

```

SELECT 'Maria' REGEXP '(ari){0,1}';
+-----+
| 'Maria' REGEXP '(ari){0,1}' |
+-----+
|           1 |
+-----+

```

□

```

[xy]
groups characters for matching purposes. For example, to match either the
p
or the
r
character:

```

```

SELECT 'Maria' REGEXP 'Ma[pr]ia';
+-----+
| 'Maria' REGEXP 'Ma[pr]ia' |
+-----+
|           1 |
+-----+

```

The square brackets also permit a range match, for example, to match any character from a-z,

```

[a-z]
is used. Numeric ranges are also permitted.

```

```

SELECT 'Maria' REGEXP 'Ma[a-z]ia';
+-----+
| 'Maria' REGEXP 'Ma[a-z]ia' |
+-----+
|           1 |
+-----+

```

The following does not match, as

```

r
falls outside of the range
a-p
.
```

```

SELECT 'Maria' REGEXP 'Ma[a-p]ia';
+-----+
| 'Maria' REGEXP 'Ma[a-p]ia' |
+-----+
|           0 |
+-----+

```

^

The

^

character means does

NOT

match, for example:

```
SELECT 'Maria' REGEXP 'Ma[^p]ia';
+-----+
| 'Maria' REGEXP 'Ma[^p]ia' |
+-----+
|           1 |
+-----+

SELECT 'Maria' REGEXP 'Ma[^r]ia';
+-----+
| 'Maria' REGEXP 'Ma[^r]ia' |
+-----+
|           0 |
+-----+
```

The

[  
and  
]  
characters on their own can be literally matched inside a  
[]

block, without escaping, as long as they immediately match the opening bracket:

```
SELECT '[Maria' REGEXP '[[[';
+-----+
| '[Maria' REGEXP '[[[' |
+-----+
|           1 |
+-----+

SELECT '[Maria' REGEXP '][]';
+-----+
| '[Maria' REGEXP '][]' |
+-----+
|           0 |
+-----+

SELECT ']Maria' REGEXP '[]]';
+-----+
| ']Maria' REGEXP '[]]' |
+-----+
|           1 |
+-----+

SELECT ']Maria' REGEXP '[]a]';
+-----+
| ']Maria' REGEXP '[]a]' |
+-----+
|           1 |
+-----+
```

Incorrect order, so no match:

```
SELECT ']Maria' REGEXP '[a]]';
+-----+
| ']Maria' REGEXP '[a]]' |
+-----+
|           0 |
+-----+
```

The

- character can also be matched in the same way:

```

SELECT '-Maria' REGEXP '[1-10]';
+-----+
| '-Maria' REGEXP '[1-10]' |
+-----+
|          0 |
+-----+

SELECT '-Maria' REGEXP '[-1-10]';
+-----+
| '-Maria' REGEXP '[-1-10]' |
+-----+
|          1 |
+-----+

```

## Word boundaries

The

:<:

and

:>:

patterns match the beginning and the end of a word respectively. For example:

```

SELECT 'How do I upgrade MariaDB?' REGEXP '[[[:<:]]MariaDB[[:>:]]';
+-----+
| 'How do I upgrade MariaDB?' REGEXP '[[[:<:]]MariaDB[[:>:]]' |
+-----+
|          1 |
+-----+

SELECT 'How do I upgrade MariaDB?' REGEXP '[[[:<:]]Maria[[:>:]]';
+-----+
| 'How do I upgrade MariaDB?' REGEXP '[[[:<:]]Maria[[:>:]]' |
+-----+
|          0 |
+-----+

```

## Character Classes

There are a number of shortcuts to match particular preset character classes. These are matched with the

[**:character\_class:**]  
pattern (inside a  
[]  
set). The following character classes exist:

Character Class	Description
alnum	Alphanumeric
alpha	Alphabetic
blank	Whitespace
cntrl	Control characters
digit	Digits
graph	Graphic characters
lower	Lowercase alphabetic
print	Graphic or space characters
punct	Punctuation
space	Space, tab, newline, and carriage return
upper	Uppercase alphabetic
xdigit	Hexadecimal digit

For example:

```
SELECT 'Maria' REGEXP 'Mar[:alnum:]*' ;
+-----+
| 'Maria' REGEXP 'Mar[:alnum:]*' |
+-----+
| 1 |
+-----+
```

Remember that matches are by default case-insensitive, unless a binary string is used, so the following example, specifically looking for an uppercase, counter-intuitively matches a lowercase character:

```
SELECT 'Mari' REGEXP 'Mar[:upper:]+' ;
+-----+
| 'Mari' REGEXP 'Mar[:upper:]+' |
+-----+
| 1 |
+-----+

SELECT BINARY 'Mari' REGEXP 'Mar[:upper:]+' ;
+-----+
| BINARY 'Mari' REGEXP 'Mar[:upper:]+' |
+-----+
| 0 |
+-----+
```

## Character Names

There are also number of shortcuts to match particular preset character names. These are matched with the

[ .character . ]  
pattern (inside a  
[ ]  
set). The following character classes exist:

Name	Character
NUL	0
SOH	001
STX	002
ETX	003
EOT	004
ENQ	005
ACK	006
BEL	007
alert	007
BS	010
backspace	'\b'
HT	011
tab	'\t'
LF	012
newline	'\n'
VT	013
vertical-tab	'\v'
FF	014
form-feed	'\f'
CR	015
carriage-return	'\r'
SO	016
SI	017
DLE	020

DC1	021
DC2	022
DC3	023
DC4	024
NAK	025
SYN	026
ETB	027
CAN	030
EM	031
SUB	032
ESC	033
IS4	034
FS	034
IS3	035
GS	035
IS2	036
RS	036
IS1	037
US	037
space	' '
exclamation-mark	'!'
quotation-mark	'''
number-sign	'#'
dollar-sign	'\$'
percent-sign	'%'
ampersand	'&'
apostrophe	'\'
left-parenthesis	'('
right-parenthesis	')'
asterisk	'*'
plus-sign	'+'
comma	' ,'
hyphen	' -'
hyphen-minus	' -'
period	' .'
full-stop	' .'
slash	' /'
solidus	' /'
zero	' 0'
one	' 1'
two	' 2'
three	' 3'
four	' 4'
five	' 5'
six	' 6'

seven	'7'
eight	'8'
nine	'9'
colon	::
semicolon	::
less-than-sign	'<'
equals-sign	'='
greater-than-sign	'>'
question-mark	'?'
commercial-at	'@'
left-square-bracket	['
backslash	'\'
reverse-solidus	'\'
right-square-bracket	']'
circumflex	'^'
circumflex-accent	'^'
underscore	'_'
low-line	'—'
grave-accent	'`'
left-brace	'{'
left-curly-bracket	'{'
vertical-line	' '
right-brace	'}'
right-curly-bracket	'}'
tilde	"~"
DEL	177

For example:

```
SELECT '|'|' REGEXP '[[.vertical-line.]]';
+-----+
| '|' REGEXP '[[.vertical-line.]]' |
+-----+
|                               1 |
+-----+
```

## Combining

The true power of regular expressions is unleashed when the above is combined, to form more complex examples. Regular expression's reputation for complexity stems from the seeming complexity of multiple combined regular expressions, when in reality, it's simply a matter of understanding the characters and how they apply:

The first example fails to match, as while the

Ma  
matches, either  
i  
or  
r  
only matches once before the  
ia  
characters at the end.

```
SELECT 'Maria' REGEXP 'Ma[ir]{2}ia';
+-----+
| 'Maria' REGEXP 'Ma[ir]{2}ia' |
+-----+
|          0 |
+-----+
```

This example matches, as either

i  
or  
r  
match exactly twice after the  
Ma  
, in this case one  
r  
and one  
i  
.

```
SELECT 'Maria' REGEXP 'Ma[ir]{2}';
+-----+
| 'Maria' REGEXP 'Ma[ir]{2}' |
+-----+
|          1 |
+-----+
```

## Escaping

With the large number of special characters, care needs to be taken to properly escape characters. Two backslash characters,

(one for the MariaDB parser, one for the regex library), are required to properly escape a character. For example:

To match the literal

(Ma  
:

```
SELECT '(Maria)' REGEXP '(Ma';
ERROR 1139 (42000): Got error 'parentheses not balanced' from regexp
```

```
SELECT '(Maria)' REGEXP '\(Ma';
ERROR 1139 (42000): Got error 'parentheses not balanced' from regexp
```

```
SELECT '(Maria)' REGEXP '\\\\(Ma';
+-----+
| '(Maria)' REGEXP '\\\\(Ma' |
+-----+
|          1 |
+-----+
```

To match

r+  
: The first two examples are incorrect, as they match  
r  
one or more times, not  
r+  
:

```
SELECT 'Mar+ia' REGEXP 'r+';
+-----+
| 'Mar+ia' REGEXP 'r+' |
+-----+
|          1 |
+-----+

SELECT 'Maria' REGEXP 'r+';
+-----+
| 'Maria' REGEXP 'r+' |
+-----+
|          1 |
+-----+

SELECT 'Maria' REGEXP 'r\\\'';
+-----+
| 'Maria' REGEXP 'r\\\'' |
+-----+
|          0 |
+-----+

SELECT 'Maria' REGEXP 'r\'+';
+-----+
| 'Maria' REGEXP 'r\'' |
+-----+
|          1 |
+-----+
```

## PCRE Versions

PCRE Version	Introduced	Maturity
PCRE2 10.34	MariaDB 10.5.1	Stable
PCRE 8.43	MariaDB 10.1.39	Stable
PCRE 8.42	MariaDB 10.2.15 , MariaDB 10.1.33 , MariaDB 10.0.35	Stable
PCRE 8.41	MariaDB 10.2.8 , MariaDB 10.1.26 , MariaDB 10.0.32	Stable
PCRE 8.40	MariaDB 10.2.5 , MariaDB 10.1.22 , MariaDB 10.0.30	Stable
PCRE 8.39	MariaDB 10.1.15 , MariaDB 10.0.26	Stable
PCRE 8.38	MariaDB 10.1.10 , MariaDB 10.0.23	Stable
PCRE 8.37	MariaDB 10.1.5 , MariaDB 10.0.18	Stable
PCRE 8.36	MariaDB 10.1.2 , MariaDB 10.0.15	Stable
PCRE 8.35	MariaDB 10.1.0 , MariaDB 10.0.12	Stable
PCRE 8.34	MariaDB 10.0.8	Stable

## PCRE Enhancements

MariaDB 10.0.5 switched to the PCRE library, which significantly improved the power of the [REGEXP/RLIKE](#) operator.

The switch to PCRE added a number of features, including recursive patterns, named capture, look-ahead and look-behind assertions, non-capturing groups, non-greedy quantifiers, Unicode character properties, extended syntax for characters and character classes, multi-line matching, and many other.

Additionally, MariaDB 10.0.5 introduced three new functions that work with regular expressions: [REGEXP\\_REPLACE\(\)](#), [REGEXP\\_INSTR\(\)](#) and [REGEXP\\_SUBSTR\(\)](#).

Also, REGEXP/RLIKE, and the new functions, now work correctly with all multi-byte [character sets](#) supported by MariaDB, including East-Asian character sets (big5, gb2313, gbk, eucjp, eucjpm, cp932, ujis, euckr), and Unicode character sets (utf8, utf8mb4, ucs2, utf16, utf16le, utf32). In earlier versions of MariaDB (and all MySQL versions) REGEXP/RLIKE works correctly only with 8-bit character sets.

## New Regular Expression Functions

- [REGEXP\\_REPLACE\(subject, pattern, replace\)](#) - Replaces all occurrences of a pattern.
- [REGEXP\\_INSTR\(subject, pattern\)](#) - Position of the first appearance of a regex .
- [REGEXP\\_SUBSTR\(subject,pattern\)](#) - Returns the matching part of a string.

See the individual articles for more details and examples.

## PCRE Syntax

In most cases PCRE is backward compatible with the old POSIX 1003.2 compliant regexp library (see [Regular Expressions Overview](#) ), so you won't need to change your applications that use SQL queries with the REGEXP/RLIKE predicate.

MariaDB 10.0.11 introduced the [default\\_regex\\_flags](#) variable to address the remaining compatibilities between PCRE and the old regex library.

This section briefly describes the most important extended PCRE features. For more details please refer to the documentation on the [PCRE site](#) , or to the documentation which is bundled in the /pcre/doc/html/ directory of a MariaDB sources distribution. The pages pcresyntax.html and pcrepattern.html should be a good start. [Regular-Expressions.Info](#) is another good resource to learn about PCRE and regular expressions generally.

## Special Characters

PCRE supports the following escape sequences to match special characters:

Sequence	Description
\a	0x07 (BEL)
\cx	"control-x", where x is any ASCII character
\e	0x1B (escape)
\f	0x0C (form feed)
\n	0x0A (newline)
\r	0x0D (carriage return)
\t	0x09 (TAB)
\ddd	character with octal code ddd
\xhh	character with hex code hh
\x{hhh..}	character with hex code hhh..

Note, the backslash characters (here, and in all examples in the sections below) must be escaped with another backslash, unless you're using the [SQL\\_MODE](#) NO\_BACKSLASH\_ESCAPES

This example tests if a character has hex code 0x61:

```
SELECT 'a' RLIKE '\x{61}';  
-> 1
```

## Character Classes

PCRE supports the standard POSIX character classes such as

```
alnum  
,  
alpha  
,  
blank  
,  
cntrl
```

```
,
```

```
digit
```

```
,
```

```
graph
```

```
,
```

```
lower
```

```
,
```

```
print
```

```
,
```

```
punct
```

```
,
```

```
space
```

```
,
```

```
upper
```

```
,
```

```
xdigit
```

, with the following additional classes:

Class	Description
ascii	any ASCII character (0x00..0x7F)
word	any "word" character (a letter, a digit, or an underscore)

This example checks if the string consists of ASCII characters only:

```
SELECT 'abc' RLIKE '^[:ascii:]+$';
-> 1
```

## Generic Character Types

Generic character types complement the POSIX character classes and serve to simplify writing patterns:

Class	Description
\d	a decimal digit (same as [:digit:])
\D	a character that is not a decimal digit
\h	a horizontal white space character
\H	a character that is not a horizontal white space character
\N	a character that is not a new line
\R	a newline sequence
\s	a white space character
\S	a character that is not a white space character
\v	a vertical white space character
\V	a character that is not a vertical white space character
\w	a "word" character (same as [:word:])
\W	a "non-word" character

This example checks if the string consists of "word" characters only:

```
SELECT 'abc' RLIKE '^\\w+$';
-> 1
```

## Unicode Character Properties

```
\p{xx}
```

is a character with the

```
xx
```

property, and

```
\P{xx}
```

is a character without the

```
xx
```

property.

The property names represented by

above are limited to the Unicode script names, the general category properties, and "Any", which matches any character (including newline). Those that are not part of an identified script are lumped together as "Common".

## General Category Properties For \p and \P

Property	Description
C	Other
Cc	Control
Cf	Format
Cn	Unassigned
Co	Private use
Cs	Surrogate
L	Letter
Li	Lower case letter
Lm	Modifier letter
Lo	Other letter
Lt	Title case letter
Lu	Upper case letter
L&	Li, Lu, or Lt
M	Mark
Mc	Spacing mark
Me	Enclosing mark
Mn	Non-spacing mark
N	Number
Nd	Decimal number
NI	Letter number
No	Other number
P	Punctuation
Pc	Connector punctuation
Pd	Dash punctuation
Pe	Close punctuation
Pf	Final punctuation
Pi	Initial punctuation
Po	Other punctuation
Ps	Open punctuation
S	Symbol
Sc	Currency symbol
Sk	Modifier symbol
Sm	Mathematical symbol
So	Other symbol
Z	Separator
Zl	Line separator
Zp	Paragraph separator
Zs	Space separator

This example checks if the string consists only of characters with property N (number):

```
SELECT '1%' RLIKE '^\\p{N}+$';
-> 1
```

## Special Category Properties For \p and \P

Property	Description
Xan	Alphanumeric: union of properties L and N
Xps	POSIX space: property Z or tab, NL, VT, FF, CR
Xsp	Perl space: property Z or tab, NL, FF, CR
Xuc	A character than can be represented by a Universal Character Name
Xwd	Perl word: property Xan or underscore

The property

Xuc

matches any character that can be represented by a Universal Character Name (in C++ and other programming languages). These include

\$

,

@

,

, and all characters with Unicode code points greater than

U+00A0

, excluding the surrogates

U+D800

..

U+DFFF

## Script Names For \p and \P

Arabic, Armenian, Avestan, Balinese, Bamum, Batak, Bengali, Bopomofo, Brahmi, Braille, Buginese, Buhid, Canadian\_Aboriginal, Carian, Chakma, Cham, Cherokee, Common, Coptic, Cuneiform, Cypriot, Cyrillic, Deseret, Devanagari, Egyptian\_Hieroglyphs, Ethiopic, Georgian, Glagolitic, Gothic, Greek, Gujarati, Gurmukhi, Han, Hangul, Hanunoo, Hebrew, Hiragana, Imperial\_Aramaic, Inherited, Inscriptional\_Pahlavi, Inscriptional\_Parthian, Javanese, Kaithi, Kannada, Katakana, Kayah\_Li, Kharoshthi, Khmer, Lao, Latin, Lepcha, Limbu, Linear\_B, Lisu, Lycian, Lydian, Malayalam, Mandaic, Meetei\_Mayek, Meroitic\_Cursive, Meroitic\_Hieroglyphs, Miao, Mongolian, Myanmar, New\_Tai\_Lue, Nko, Ogham, Old\_Italic, Old\_Persian, Old\_South\_Arabian, Old\_Turkic, Ol\_Chiki, Oriya, Osmany, Phags\_Pa, Phoenician, Rejang, Runic, Samaritan, Saurashtra, Sharada, Shavian, Sinhala, Sora\_Sompeng, Sundanese, Syloti\_Nagri, Syriac, Tagalog, Tagbanwa, Tai\_Le, Tai\_Tham, Tai\_Viet, Takri, Tamil, Telugu, Thaana, Thai, Tibetan, Tifinagh, Ugaritic, Vai, Yi.

This example checks if the string consists only of Greek characters:

```
SELECT 'ΣΦΩ' RLIKE '^\\p{Greek}+$';
-> 1
```

## Extended Unicode Grapheme Sequence

The

\X

escape sequence matches a character sequence that makes an "extended grapheme cluster", i.e. a composite character that consists of multiple Unicode code points.

One of the examples of a composite character can be a letter followed by non-spacing accent marks. This example demonstrates that

U+0045 LATIN CAPITAL LETTER E

followed by

U+0302 COMBINING CIRCUMFLEX ACCENT

followed by

U+0323 COMBINING DOT BELOW

together form an extended grapheme cluster:

```
SELECT _ucs2 0x004503020323 RLIKE '^\\X$';
-> 1
```

See the [PCRE documentation](#) for the other types of extended grapheme clusters.

## Simple Assertions

An assertion specifies a certain condition that must match at a particular point, but without consuming characters from the subject string. In addition to the

standard POSIX simple assertions

^  
(that matches at the beginning of a line) and  
\$  
(that matches at the end of a line), PCRE supports a number of other assertions:

Assertion	Description
\b	matches at a word boundary
\B	matches when not at a word boundary
\A	matches at the start of the subject
\Z	matches at the end of the subject, also matches before a newline at the end of the subject
\z	matches only at the end of the subject
\G	matches at the first matching position in the subject

This example cuts a word that consists only of 3 characters from a string:

```
SELECT REGEXP_SUBSTR('---abcd---xyz---', '\b\w{3}\b');
-> xyz
```

Notice that the two

\b  
assertions checked the word boundaries but did not get into the matching pattern.

The

\b  
assertions work well in the beginning and the end of the subject string:

```
SELECT REGEXP_SUBSTR('xyz', '\b\w{3}\b');
-> xyz
```

By default, the

^  
and  
\$  
assertions have the same meaning with  
\A  
,  
\Z  
, and  
\z  
. However, the meanings of  
^  
and  
\$  
can change in multiline mode (see below). By contrast, the meanings of  
\A  
,  
\Z  
, and  
\z  
are always the same; they are independent of the multiline mode.

## Option Setting

A number of options that control the default match behavior can be changed within the pattern by a sequence of option letters enclosed between

(?  
and  
)

Option	Description
(?i)	case insensitive match
(?m)	multiline mode
(?s)	dotall mode (dot matches newline characters)

(?x)	extended (ignore white space)
(?U)	ungreedy (lazy) match
(?J)	allow named subpatterns with duplicate names
(?X)	extra PCRE functionality (e.g. force error on unknown escaped character)
(?-...)	unset option(s)

For example,

```
(?im)
sets case insensitive multiline matching.
```

A hyphen followed by the option letters unset the options. For example,

```
(?-im)
means case sensitive single line match.
```

A combined setting and unsetting is also possible, e.g.

```
(?im-sx)
```

If an option is set outside of subpattern parentheses, the option applies to the remainder of the pattern that follows the option. If an option is set inside a subpattern, it applies to the part of this subpattern that follows the option.

In this example the pattern

```
(?i)m((?-i)aria)db
matches the words
MariaDB
,
Mariadb
,
mariadb
, but not
MARIADB
:
```

```
SELECT 'MariaDB' RLIKE '(?i)m((?-i)aria)db';
-> 1

SELECT 'mariaDB' RLIKE '(?i)m((?-i)aria)db';
-> 1

SELECT 'Mariadb' RLIKE '(?i)m((?-i)aria)db';
-> 1

SELECT 'MARIADB' RLIKE '(?i)m((?-i)aria)db';
-> 0
```

This example demonstrates that the

```
(?x)
option makes the regexp engine ignore all white spaces in the pattern (other than in a class).
```

```
SELECT 'ab' RLIKE '(?x)a b';
-> 1
```

Note, putting spaces into a pattern in combination with the (?x) option can be useful to split different logical parts of a complex pattern, to make it more readable.

## Multiline Matching

Multiline matching changes the meaning of

```
^
and
$
```

from "the beginning of the subject string" and "the end of the subject string" to "the beginning of any line in the subject string" and "the end of any line in the subject string" respectively.

This example checks if the subject string contains two consequent lines that fully consist of digits:

```
SELECT 'abc\n123\n456\nxyz\n' RLIKE '(?m)^\\d+\\R\\d+$';
-> 1
```

Notice the

(?m)

option in the beginning of the pattern, which switches to the multiline matching mode.

## Newline Conventions

PCRE supports five line break conventions:

- CR (\r)  
- a single carriage return character
- LF (\n)  
- a single linefeed character
- CRLF (\r\n)  
- a carriage return followed by a linefeed
- any of the previous three
- any Unicode newline sequence

By default, the newline convention is set to any Unicode newline sequence, which includes:

Sequence	Description
LF	(U+000A, carriage return)
CR	(U+000D, carriage return)
CRLF	(a carriage return followed by a linefeed)
VT	(U+000B, vertical tab)
FF	(U+000C, form feed)
NEL	(U+0085, next line)
LS	(U+2028, line separator)
PS	(U+2029, paragraph separator)

The newline convention can be set by starting a pattern with one of the following sequences:

Sequence	Description
(*CR)	carriage return
(*LF)	linefeed
(*CRLF)	carriage return followed by linefeed
(*ANYCRLF)	any of the previous three
(*ANY)	all Unicode newline sequences

The newline conversion affects the

^

and

\$

assertions, the interpretation of the dot metacharacter, and the behavior of

\N

Note, the new line convention does not affect the meaning of

\R

This example demonstrates that the dot metacharacter matches

\n

, because it is not a newline sequence anymore:

```
SELECT 'a\nb' RLIKE '(*CR)a.b';
-> 1
```

## Newline Sequences

By default, the escape sequence

\R

matches any Unicode newline sequences.

The meaning of

\R

can be set by starting a pattern with one of the following sequences:

Sequence	Description
(*BSR_ANYCRLF)	any of CR, LF or CRLF
(*BSR_UNICODE)	any Unicode newline sequence

## Comments

It's possible to include comments inside a pattern. Comments do not participate in the pattern matching. Comments start at the

(?

# sequence and continue up to the next closing parenthesis:

```
SELECT 'ab12' RLIKE 'ab(?#expect digits)12';
-> 1
```

## Quoting

POSIX uses the backslash to remove a special meaning from a character. PCRE introduces a syntax to remove special meaning from a sequence of characters. The characters inside

\Q

...

\E

are treated literally, without their special meaning.

This example checks if the string matches a dollar sign followed by a parenthesized name (a variable reference in some languages):

```
SELECT '$(abc)' RLIKE '^\\Q$(\\E\\w+\\Q)\\E$';
-> 1
```

Note that the leftmost dollar sign and the parentheses are used literally, while the rightmost dollar sign is still used to match the end of the string.

## Resetting the Match Start

The escape sequence

\K

causes any previously matched characters to be excluded from the final matched sequence. For example, the pattern:

(foo)\Kbar

matches

foobar

, but reports that it has matched

bar

. This feature is similar to a look-behind assertion. However, in this case, the part of the subject before the real match does not have to be of fixed length:

```
SELECT REGEXP_SUBSTR('aaa123', '[a-z]*\\K[0-9]*');
-> 123
```

## Non-Capturing Groups

The question mark and the colon after the opening parenthesis create a non-capturing group:

(?:...)

This example removes an optional article from a word, for example for better sorting of the results.

```
SELECT REGEXP_REPLACE('The King', '(?:the|an|a)[^a-z]([a-z]+)', '\\1');
-> King
```

Note that the articles are listed inside the left parentheses using the alternation operator

|

but they do not produce a captured subpattern, so the word followed by the article is referenced by

'

1'

in the third argument to the function. Using non-capturing groups can be useful to save numbers on the sup-patterns that won't be used in the third argument of [REGEXP\\_REPLACE\(\)](#), as well as for performance purposes.

## Non-Greedy Quantifiers

By default, the repetition quantifiers

```
?  
,  
*  
,  
+  
and  
{n,m}
```

are "greedy", that is, they try to match as much as possible. Adding a question mark after a repetition quantifier makes it "non-greedy", so the pattern matches the minimum number of times possible.

This example cuts C comments from a line:

```
SELECT REGEXP_REPLACE('/* Comment1 */ i+= 1; /* Comment2 */', '/[*].*?[*]/', '');  
-> i+= 1;
```

The pattern without the non-greedy flag to the quantifier

```
/[*].*[*]/  
would match the entire string between the leftmost  
/*  
and the rightmost  
*/
```

## Atomic Groups

A sequence inside

```
(?>  
...  
)
```

makes an atomic group. Backtracking inside an atomic group is prevented once it has matched; however, backtracking past to the previous items works normally.

Consider the pattern

```
\d+foo  
applied to the subject string  
123bar  
. Once the engine scans  
123  
and fails on the letter  
b  
, it would normally backtrack to  
2  
and try to match again, then fail and backtrack to  
1  
and try to match and fail again, and finally fail the entire pattern. In case of an atomic group  
(?>\d+)foo  
with the same subject string  
123bar  
, the engine gives up immediately after the first failure to match  
foo  
. An atomic group with a quantifier can match all or nothing.
```

Atomic groups produce faster false results (i.e. in case when a long subject string does not match the pattern), because the regexp engine saves performance on backtracking. However, don't hurry to put everything into atomic groups. This example demonstrates the difference between atomic and non-atomic match:

```
SELECT 'abcc' RLIKE 'a(?>bc|b)c' AS atomic1;  
-> 1  
  
SELECT 'abc' RLIKE 'a(?>bc|b)c' AS atomic2;  
-> 0  
  
SELECT 'abcc' RLIKE 'a(bc|b)c' AS non_atomic1;  
-> 1  
  
SELECT 'abc' RLIKE 'a(bc|b)c' AS non_atomic2;  
-> 1
```

The non-atomic pattern matches both

```
abbc
and
abc
, while the atomic pattern matches
abbc
only.
```

The atomic group

```
(?>bc|b)
```

in the above example can be "translated" as "if there is  
bc  
, then don't try to match as  
b  
. So  
b  
can match only if  
bc  
is not found.

Atomic groups are not capturing. To make an atomic group capturing, put it into parentheses:

```
SELECT REGEXP_REPLACE('abcc','a((?>bc|b))c','\\1');
-> bc
```

## Possessive quantifiers

An atomic group which ends with a quantifier can be rewritten using a so called "possessive quantifier" syntax by putting an additional  
+  
sign following the quantifier.

The pattern

```
(?>\d+)foo
```

from the previous section's example can be rewritten as  
\d++foo

## Absolute and Relative Numeric Backreferences

Backreferences match the same text as previously matched by a capturing group. Backreferences can be written using:

- a backslash followed by a digit
- the  
    \g  
    escape sequence followed by a positive or negative number
- the  
    \g  
    escape sequence followed by a positive or negative number enclosed in braces

The following backreferences are identical and refer to the first capturing group:

- \1
- \g1
- \g{1}

This example demonstrates a pattern that matches "sense and sensibility" and "response and responsibility", but not "sense and responsibility":

```
SELECT 'sense and sensibility' RLIKE '(sens|respons)e and \\1ibility';
-> 1
```

This example removes doubled words that can unintentionally creep in when you edit a text in a text editor:

```
SELECT REGEXP_REPLACE('using using the the regexp regexp',
  '\\b(\\w+)\\s+\\1\\b','\\1');
-> using the regexp
```

Note that all double words were removed, in the beginning, in the middle and in the end of the subject string.

A negative number in a

\g

sequence means a relative reference. Relative references can be helpful in long patterns, and also in patterns that are created by joining fragments together that contain references within themselves. The sequence

\g{-1}

is a reference to the most recently started capturing subpattern before

\g

In this example

\g{-1}

is equivalent to

\2

:

```
SELECT 'abc123def123' RLIKE '(abc(123)def)\\g{-1}';  
-> 1
```

```
SELECT 'abc123def123' RLIKE '(abc(123)def)\\2';  
-> 1
```

## Named Subpatterns and Backreferences

Using numeric backreferences for capturing groups can be hard to track in a complicated regular expression. Also, the numbers can change if an expression is modified. To overcome these difficulties, PCRE supports named subpatterns.

A subpattern can be named in one of three ways:

(?<name>

...

)

or

(?'name'

...

)

as in Perl, or

(?P<name>

...

)

as in Python. References to capturing subpatterns from other parts of the pattern, can be made by name as well as by number.

Backreferences to a named subpattern can be written using the .NET syntax

\k{name}

, the Perl syntax

\k<name>

or

\k'name'

or

\g{name}

, or the Python syntax

(?P=name)

This example tests if the string is a correct HTML tag:

```
SELECT '<a href="..">Up</a>' RLIKE '<(?<tag>[a-z][a-z0-9]*[^>]*[^<]*</?P=tag>)>';  
-> 1
```

## Positive and Negative Look-Ahead and Look-Behind Assertions

Look-ahead and look-behind assertions serve to specify the context for the searched regular expression pattern. Note that the assertions only check the context, they do not capture anything themselves!

This example finds the letter which is not followed by another letter (negative look-ahead):

```
SELECT REGEXP_SUBSTR('ab1','[a-z](?! [a-z])');  
-> b
```

This example finds the letter which is followed by a digit (positive look-ahead):

```
SELECT REGEXP_SUBSTR('ab1','[a-z](?=[0-9])');  
-> b
```

This example finds the letter which does not follow a digit character (negative look-behind):

```
SELECT REGEXP_SUBSTR('1ab','(?![0-9])[a-z]');
-> b
```

This example finds the letter which follows another letter character (positive look-behind):

```
SELECT REGEXP_SUBSTR('1ab','(?<=[a-z])[a-z]');
-> b
```

Note that look-behind assertions can only be of fixed length; you cannot have repetition operators or alternations with different lengths:

```
SELECT 'aaa' RLIKE '(?<=(a|bc))a';
ERROR 1139 (42000): Got error 'lookbehind assertion is not fixed length at offset 10' from regexp
```

## Subroutine Reference and Recursive Patterns

PCRE supports a special syntax to recourse the entire pattern or its individual subpatterns:

Syntax	Description
(?R)	Recurse the entire pattern
(?n)	call subpattern by absolute number
(?+n)	call subpattern by relative number
(?-n)	call subpattern by relative number
(?&name)	call subpattern by name (Perl)
(?P>name)	call subpattern by name (Python)
\g<name>	call subpattern by name (Oniguruma)
\g'name'	call subpattern by name (Oniguruma)
\g<n>	call subpattern by absolute number (Oniguruma)
\g'n'	call subpattern by absolute number (Oniguruma)
\g<+n>	call subpattern by relative number
\g<-n>	call subpattern by relative number
\g'+n'	call subpattern by relative number
\g'-n'	call subpattern by relative number

This example checks for a correct additive arithmetic expression consisting of numbers, unary plus and minus, binary plus and minus, and parentheses:

```
SELECT '1+2-3+(+4-1)+(-2)+(+1)' RLIKE '^(([+-]?(\\d+|([(\\)?1][)]))(([+-](\\)?1))*$';
-> 1
```

The recursion is done using

(?1)

to call for the first parenthesized subpattern, which includes everything except the leading

^

and the trailing

\$

.

The regular expression in the above example implements the following BNF grammar:

1. 

```
<expression> ::= <term> [(<sign> <term>)...]
```
2. 

```
<term> ::= [ <sign> ] <primary>
```
3. 

```
<primary> ::= <number> | <left paren> <expression> <right paren>
```
4. 

```
<sign> ::= <plus sign> | <minus sign>
```

## Defining Subpatterns For Use By Reference

Use the

```
(?(DEFINE)
...
)
syntax to define subpatterns that can be referenced from elsewhere.
```

This example defines a subpattern with the name

```
letters
that matches one or more letters, which is further reused two times:
```

```
SELECT 'abc123xyz' RLIKE '^^(?<DEFINE>(?<letters>[a-z]+))(&letters)[0-9]+(&letters)$';
-> 1
```

The above example can also be rewritten to define the digit part as a subpattern as well:

```
SELECT 'abc123xyz' RLIKE
'^^(?<DEFINE>(?<letters>[a-z]+)(?<digits>[0-9]+))(&letters)(&digits)(&letters)$';
-> 1
```

## Conditional Subpatterns

There are two forms of conditional subpatterns:

```
(?(condition)yes-pattern)
(?(condition)yes-pattern|no-pattern)
```

The

```
yes-pattern
is used if the condition is satisfied, otherwise the
no-pattern
(if any) is used.
```

## Conditions With Subpattern References

If a condition consists of a number, it makes a condition with a subpattern reference. Such a condition is true if a capturing subpattern corresponding to the number has previously matched.

This example finds an optionally parenthesized number in a string:

```
SELECT REGEXP_SUBSTR('a(123)b', '([()]?[0-9]+(?:1)[)])');
-> (123)
```

The

```
([()])?
part makes a capturing subpattern that matches an optional opening parenthesis; the
[0-9]+
part matches a number, and the
(?:1)[)]
part matches a closing parenthesis, but only if the opening parenthesis has been previously found.
```

## Other Kinds of Conditions

The other possible condition kinds are: recursion references and assertions. See the [PCRE documentation](#) for details.

## Matching Zero Bytes (0x00)

PCRE correctly works with zero bytes in the subject strings:

```
SELECT 'a\0b' RLIKE '^a.b$';
-> 1
```

Zero bytes, however, are not supported literally in the pattern strings and should be escaped using the

```
\xhh
or
\x{hh}
syntax:
```

```
SELECT 'a\0b' RLIKE '^a\\x{00}b$';
-> 1
```

## Other PCRE Features

PCRE provides other extended features that were not covered in this document, such as duplicate subpattern numbers, backtracking control, breaking utf-8 sequences into individual bytes, setting the match limit, setting the recursion limit, optimization control, recursion conditions, assertion conditions and more types of extended grapheme clusters. Please refer to the [PCRE documentation](#) for details.

Enhanced regex was implemented as a GSoC 2013 project by Sudheera Palihakkara.

## default\_regex\_flags Examples

MariaDB starting with 10.0.11

The `default_regex_flags` variable was introduced in **MariaDB 10.0.11**

The `default_regex_flags` variable was introduced to address the remaining incompatibilities between PCRE and the old regex library. Here are some examples of its usage:

The default behaviour (multiline match is off)

```
SELECT 'a\nb\n' RLIKE '^b$';
+-----+
| '(?m)a\nb\n' RLIKE '^b$' |
+-----+
|          0 |
+-----+
```

Enabling the multiline option using the PCRE option syntax:

```
SELECT 'a\nb\n' RLIKE '(?m)^b$';
+-----+
| 'a\nb\n' RLIKE '(?m)^b$' |
+-----+
|          1 |
+-----+
```

Enabling the multiline option using `default_regex_flags`

```
SET default_regex_flags='MULTILINE';
SELECT 'a\nb\n' RLIKE '^b$';
+-----+
| 'a\nb\n' RLIKE '^b$' |
+-----+
|          1 |
+-----+
```

## See Also

- [MariaDB upgrades to PCRE-8.34](#)

## 1.1.12.2.1.3 NOT REGEXP

### Syntax

```
expr NOT REGEXP pat, expr NOT RLIKE pat
```

### Description

This is the same as [NOT \(expr REGEXP pat\)](#).

## 1.1.12.2.1.4 REGEXP

### Syntax

```
expr REGEXP pat, expr RLIKE pat
```

## Description

Performs a pattern match of a string expression

```
expr  
against a pattern  
pat
```

. The pattern can be an extended regular expression. See [Regular Expressions Overview](#) for details on the syntax for regular expressions (see also [PCRE Regular Expressions](#) ).

Returns

```
1  
if  
expr  
matches  
pat  
or  
0  
if it doesn't match. If either  
expr  
or  
pat  
are NULL, the result is NULL.
```

The negative form [NOT REGEXP](#) also exists, as an alias for

```
NOT (string REGEXP pattern)  
. RLIKE and NOT RLIKE are synonyms for REGEXP and NOT REGEXP, originally provided for mSQL compatibility.
```

The pattern need not be a literal string. For example, it can be specified as a string expression or table column.

**Note:** Because MariaDB uses the C escape syntax in strings (for example, "\n" to represent the newline character), you must double any "\" that you use in your REGEXP strings.

REGEXP is not case sensitive, except when used with binary strings.

[MariaDB 10.0.5](#) moved to the PCRE regex library - see [PCRE Regular Expressions](#) for enhancements to REGEXP introduced in [MariaDB 10.0.5](#) .

The [default\\_regex\\_flags](#) variable addresses the remaining compatibilities between PCRE and the old regex library.

## Examples

```

SELECT 'Monty!' REGEXP 'm%y%%';
+-----+
| 'Monty!' REGEXP 'm%y%%' |
+-----+
|          0 |
+-----+

SELECT 'Monty!' REGEXP '.';
+-----+
| 'Monty!' REGEXP '.' |
+-----+
|          1 |
+-----+

SELECT 'new*\n*line' REGEXP 'new\\*.\\*line';
+-----+
| 'new*\n*line' REGEXP 'new\\*.\\*line' |
+-----+
|          1 |
+-----+

SELECT 'a' REGEXP 'A', 'a' REGEXP BINARY 'A';
+-----+
| 'a' REGEXP 'A' | 'a' REGEXP BINARY 'A' |
+-----+
|          1 |          0 |
+-----+

SELECT 'a' REGEXP '^[a-d]';
+-----+
| 'a' REGEXP '^[a-d]' |
+-----+
|          1 |
+-----+

```

## default\_regex\_flags examples

MariaDB 10.0.11 introduced the [default\\_regex\\_flags](#) variable to address the remaining compatibilities between PCRE and the old regex library.

The default behaviour (multiline match is off)

```

SELECT 'a\nb\nc' RLIKE '^b$';
+-----+
| '(?m)a\nb\nc' RLIKE '^b$' |
+-----+
|          0 |
+-----+

```

Enabling the multiline option using the PCRE option syntax:

```

SELECT 'a\nb\nc' RLIKE '(?m)^b$';
+-----+
| 'a\nb\nc' RLIKE '(?m)^b$' |
+-----+
|          1 |
+-----+

```

Enabling the multiline option using default\_regex\_flags

```

SET default_regex_flags='MULTILINE';
SELECT 'a\nb\nc' RLIKE '^b$';
+-----+
| 'a\nb\nc' RLIKE '^b$' |
+-----+
|          1 |
+-----+

```

## 1.1.12.2.1.5 REGEXP\_INSTR

### Syntax

```
REGEXP_INSTR(subject, pattern)
```

Returns the position of the first occurrence of the regular expression

pattern  
in the string  
subject  
, or 0 if pattern was not found.

The positions start with 1 and are measured in characters (i.e. not in bytes), which is important for multi-byte character sets. You can cast a multi-byte character set to [BINARY](#) to get offsets in bytes.

The function follows the case sensitivity rules of the effective [collation](#). Matching is performed case insensitively for case insensitive collations, and case sensitively for case sensitive collations and for binary data.

The collation case sensitivity can be overwritten using the (?i) and (?-i) PCRE flags.

MariaDB uses the [PCRE regular expression](#) library for enhanced regular expression performance, and REGEXP\_INSTR was introduced as part of this enhancement.

## Examples

```
SELECT REGEXP_INSTR('abc','b');  
-> 2  
  
SELECT REGEXP_INSTR('abc','x');  
-> 0  
  
SELECT REGEXP_INSTR('BJÖRN','N');  
-> 5
```

Casting a multi-byte character set as BINARY to get offsets in bytes:

```
SELECT REGEXP_INSTR(BINARY 'BJÖRN','N') AS cast_utf8_to_binary;  
-> 6
```

Case sensitivity:

```
SELECT REGEXP_INSTR('ABC','b');  
-> 2  
  
SELECT REGEXP_INSTR('ABC' COLLATE utf8_bin,'b');  
-> 0  
  
SELECT REGEXP_INSTR(BINARY'ABC','b');  
-> 0  
  
SELECT REGEXP_INSTR('ABC','(?-i)b');  
-> 0  
  
SELECT REGEXP_INSTR('ABC' COLLATE utf8_bin,'(?i)b');  
-> 2
```

## 1.1.12.2.1.6 REGEXP\_REPLACE

### Syntax

```
REGEXP_REPLACE(subject, pattern, replace)
```

### Description

REGEXP\_REPLACE  
returns the string  
subject  
with all occurrences of the regular expression  
pattern  
replaced by the string  
replace

. If no occurrences are found, then  
subject  
is returned as is.

The replace string can have backreferences to the subexpressions in the form \N, where N is a number from 1 to 9.

The function follows the case sensitivity rules of the effective [collation](#). Matching is performed case insensitively for case insensitive collations, and case sensitively for case sensitive collations and for binary data.

The collation case sensitivity can be overwritten using the (?i) and (?-i) PCRE flags.

MariaDB uses the [PCRE regular expression](#) library for enhanced regular expression performance, and  
REGEXP\_REPLACE  
was introduced as part of this enhancement.

The [default\\_regex\\_flags](#) variable addresses the remaining compatibilities between PCRE and the old regex library.

## Examples

```
SELECT REGEXP_REPLACE('ab12cd','[0-9]', '') AS remove_digits;  
-> abcd  
  
SELECT REGEXP_REPLACE('<html><head><title>title</title><body>body</body></html>', '<.+?>', ' ')  
AS strip_html;  
-> title body
```

Backreferences to the subexpressions in the form

\N  
, where N is a number from 1 to 9:

```
SELECT REGEXP_REPLACE('James Bond','^(.*) (.*)$', '\2, \1') AS reorder_name;  
-> Bond, James
```

Case insensitive and case sensitive matches:

```
SELECT REGEXP_REPLACE('ABC','b','-') AS case_insensitive;  
-> A-C  
  
SELECT REGEXP_REPLACE('ABC' COLLATE utf8_bin,'b','-') AS case_sensitive;  
-> ABC  
  
SELECT REGEXP_REPLACE(BINARY 'ABC','b','-') AS binary_data;  
-> ABC
```

Overwriting the collation case sensitivity using the (?i) and (?-i) PCRE flags.

```
SELECT REGEXP_REPLACE('ABC','(?-i)b','-') AS force_case_sensitive;  
-> ABC  
  
SELECT REGEXP_REPLACE(BINARY 'ABC','(?i)b','-') AS force_case_insensitive;  
-> A-C
```

## 1.1.12.2.1.7 REGEXP\_SUBSTR

### Syntax

```
REGEXP_SUBSTR(subject,pattern)
```

### Description

Returns the part of the string

subject  
that matches the regular expression  
pattern  
, or an empty string if  
pattern  
was not found.

The function follows the case sensitivity rules of the effective [collation](#). Matching is performed case insensitively for case insensitive collations, and case

sensitively for case sensitive collations and for binary data.

The collation case sensitivity can be overwritten using the (?i) and (?-i) PCRE flags.

MariaDB uses the [PCRE regular expression](#) library for enhanced regular expression performance, and `REGEXP_SUBSTR` was introduced as part of this enhancement.

The `default_regex_flags` variable addresses the remaining compatibilities between PCRE and the old regex library.

## Examples

```
SELECT REGEXP_SUBSTR('ab12cd','[0-9]+');
-> 12

SELECT REGEXP_SUBSTR(
  'See https://mariadb.org/en/foundation/ for details',
  'https?://[^/]*');
-> https://mariadb.org
```

```
SELECT REGEXP_SUBSTR('ABC','b');
-> B

SELECT REGEXP_SUBSTR('ABC' COLLATE utf8_bin,'b');
->

SELECT REGEXP_SUBSTR(BINARY'ABC','b');
->

SELECT REGEXP_SUBSTR('ABC','(?i)b');
-> B

SELECT REGEXP_SUBSTR('ABC' COLLATE utf8_bin,'(?+i)b');
-> B
```

## 1.1.12.2.1.8 RLIKE

### Syntax

```
expr REGEXP pat, expr RLIKE pat
```

### Description

`RLIKE`  
is a synonym for [REGEXP](#).

## 1.1.12.2.2 Dynamic Columns Functions

### 1.1.12.2.2.1 COLUMN\_ADD

#### Syntax

```
COLUMN_ADD(dyncol_blob, column_nr, value [as type], [column_nr, value [as type]]...);
COLUMN_ADD(dyncol_blob, column_name, value [as type], [column_name, value [as type]]...);
```

### Description

Adds or updates [dynamic columns](#).

- - `dyncol_blob`  
must be either a valid dynamic columns blob (for example, `COLUMN_CREATE` returns such blob), or an empty string.

- **column\_name**  
specifies the name of the column to be added. If **dyncol\_blob** already has a column with this name, it will be overwritten.
- **value**  
specifies the new value for the column. Passing a NULL value will cause the column to be deleted.
- **as type**  
is optional. See [#datatypes](#) section for a discussion about types.

The return value is a dynamic column blob after the modifications.

## Examples

```
UPDATE t1 SET dyncol_blob=COLUMN_ADD(dyncol_blob, "column_name", "value") WHERE id=1;
```

Note:

`COLUMN_ADD()`

is a regular function (just like

`CONCAT()`

), hence, in order to update the value in the table you have to use the

```
UPDATE ... SET dynamic_col=COLUMN_ADD(dynamic_col,
....)
pattern.
```

## 1.1.12.2.2.2 COLUMN\_CHECK

### Syntax

```
COLUMN_CHECK(dyncol_blob);
```

### Description

Check if

`dyncol_blob`

is a valid packed dynamic columns blob. Return value of 1 means the blob is valid, return value of 0 means it is not.

**Rationale:** Normally, one works with valid dynamic column blobs. Functions like `COLUMN_CREATE`, `COLUMN_ADD`, `COLUMN_DELETE` always return valid dynamic column blobs. However, if a dynamic column blob is accidentally truncated, or transcoded from one character set to another, it will be corrupted. This function can be used to check if a value in a blob field is a valid dynamic column blob.

## 1.1.12.2.2.3 COLUMN\_CREATE

### Syntax

```
COLUMN_CREATE(column_nr, value [as type], [column_nr, value [as type]]...);
COLUMN_CREATE(column_name, value [as type], [column_name, value [as type]]...);
```

### Description

Returns a [dynamic columns](#) blob that stores the specified columns with values.

The return value is suitable for

- storing in a table
- further modification with other dynamic columns functions

The

`as type`

part allows one to specify the value type. In most cases, this is redundant because MariaDB will be able to deduce the type of the value. Explicit type specification may be needed when the type of the value is not apparent. For example, a literal

`'2012-12-01'`

has a CHAR type by default, one will need to specify

'2012-12-01' AS DATE  
to have it stored as a date. See [Dynamic Columns:Datatypes](#) for further details.

## Examples

```
INSERT INTO tbl SET dyncol_blob=COLUMN_CREATE("column_name", "value");
```

### 1.1.12.2.2.4 COLUMN\_DELETE

#### Syntax

```
COLUMN_DELETE(dyncol_blob, column_nr, column_nr...);  
COLUMN_DELETE(dyncol_blob, column_name, column_name...);
```

#### Description

Deletes a [dynamic column](#) with the specified name. Multiple names can be given. The return value is a dynamic column blob after the modification.

### 1.1.12.2.2.5 COLUMN\_EXISTS

#### Syntax

```
COLUMN_EXISTS(dyncol_blob, column_nr);  
COLUMN_EXISTS(dyncol_blob, column_name);
```

#### Description

Checks if a column with name

column\_name  
exists in  
dyncol\_blob  
. If yes, return  
1  
, otherwise return  
0  
. See [dynamic columns](#) for more information.

### 1.1.12.2.2.6 COLUMN\_GET

#### Syntax

```
COLUMN_GET(dyncol_blob, column_nr as type);  
COLUMN_GET(dyncol_blob, column_name as type);
```

#### Description

Gets the value of a [dynamic column](#) by its name. If no column with the given name exists,

NULL  
will be returned.

column\_name as type  
requires that one specify the datatype of the dynamic column they are reading.

This may seem counter-intuitive: why would one need to specify which datatype they're retrieving? Can't the dynamic columns system figure the datatype from the data being stored?

The answer is: SQL is a statically-typed language. The SQL interpreter needs to know the datatypes of all expressions before the query is run (for example, when one is using prepared statements and runs

"select COLUMN\_GET(...)"  
, the prepared statement API requires the server to inform the client about the datatype of the column being read before the query is executed and the server can see what datatype the column actually has).

## Lengths

If you're running queries like:

```
SELECT COLUMN_GET(blob, 'colname' as CHAR) ...
```

without specifying a maximum length (i.e. using

as CHAR

, not

as CHAR(n)

), MariaDB will report the maximum length of the resultset column to be 16,777,216. This may cause excessive memory usage in some client libraries, because they try to pre-allocate a buffer of maximum resultset width. To avoid this problem, use CHAR(n) whenever you're using COLUMN\_GET in the select list.

See [Dynamic Columns:Datatypes](#) for more information about datatypes.

## 1.1.12.2.2.7 COLUMN\_JSON

### Syntax

```
COLUMN_JSON(dyncol_blob)
```

### Description

Returns a JSON representation of data in

dyncol\_blob

. Can also be used to display nested columns. See [dynamic columns](#) for more information.

### Example

```
select item_name, COLUMN_JSON(dynamic_cols) from assets;
+-----+-----+
| item_name      | COLUMN_JSON(dynamic_cols)          |
+-----+-----+
| MariaDB T-shirt | {"size":"XL","color":"blue"}        |
| Thinkpad Laptop | {"color":"black","warranty":"3 years"} |
+-----+-----+
```

Limitation:

COLUMN\_JSON

will decode nested dynamic columns at a nesting level of not more than 10 levels deep. Dynamic columns that are nested deeper than 10 levels will be shown as BINARY string, without encoding.

## 1.1.12.2.3 ASCII

### Syntax

```
ASCII(str)
```

### Description

Returns the numeric ASCII value of the leftmost character of the string argument. Returns

0

if the given string is empty and

NULL

if it is

NULL

.

ASCII()

works for 8-bit characters.

### Examples

```
SELECT ASCII(9);
+-----+
| ASCII(9) |
+-----+
|      57   |
+-----+

SELECT ASCII('9');
+-----+
| ASCII('9') |
+-----+
|      57   |
+-----+

SELECT ASCII('abc');
+-----+
| ASCII('abc') |
+-----+
|      97   |
+-----+
```

## 1.1.12.2.4 BIN

### Syntax

```
BIN(N)
```

### Description

Returns a string representation of the binary value of the given longlong (that is,

`BIGINT`

) number. This is equivalent to

`CONV(N,10,2)`

. The argument should be positive. If it is a

`FLOAT`

, it will be truncated. Returns

`NULL`

if the argument is

`NULL`

.

### Examples

```
SELECT BIN(12);
+-----+
| BIN(12) |
+-----+
| 1100     |
+-----+
```

### See Also

- [Binary literals](#)
- [CONV\(\)](#)
- [OCT\(\)](#)
- [HEX\(\)](#)

## 1.1.12.2.5 BINARY Operator

This page describes the BINARY operator. For details about the data type, see [Binary Data Type](#).

# Syntax

BINARY

## Description

The

BINARY

operator casts the string following it to a binary string. This is an easy way to force a column comparison to be done byte by byte rather than character by character. This causes the comparison to be case sensitive even if the column isn't defined as

BINARY

or

BLOB

BINARY

also causes trailing spaces to be significant.

## Examples

```
SELECT 'a' = 'A';
+-----+
| 'a' = 'A' |
+-----+
|      1 |
+-----+

SELECT BINARY 'a' = 'A';
+-----+
| BINARY 'a' = 'A' |
+-----+
|      0 |
+-----+

SELECT 'a' = 'a ';
+-----+
| 'a' = 'a ' |
+-----+
|      1 |
+-----+

SELECT BINARY 'a' = 'a ';
+-----+
| BINARY 'a' = 'a ' |
+-----+
|      0 |
+-----+
```

## 1.1.12.2.6 BIT\_LENGTH

### Syntax

BIT\_LENGTH(str)

### Contents

1. [Syntax](#)
2. [Description](#)
3. [Examples](#)
4. [Compatibility](#)

## Description

Returns the length of the given string argument in bits. If the argument is not a string, it will be converted to string. If the argument is

NULL  
, it returns  
NULL

## Examples

```
SELECT BIT_LENGTH('text');
+-----+
| BIT_LENGTH('text') |
+-----+
|          32 |
+-----+
```

```
SELECT BIT_LENGTH('');
+-----+
| BIT_LENGTH('') |
+-----+
|          0 |
+-----+
```

## Compatibility

PostgreSQL and Sybase support `BIT_LENGTH()`.

### 1.1.12.2.7 CAST

#### Syntax

```
CAST(expr AS type)
```

#### Contents

1. [Syntax](#)
2. [Description](#)
3. [Examples](#)
4. [See Also](#)

#### Description

The

`CAST()`

function takes a value of one `type` and produces a value of another type, similar to the `CONVERT()` function.

The type can be one of the following values:

- `BINARY`
- `CHAR`
- `DATE`
- `DATETIME`
- `DECIMAL[(M,D)]`
- `DOUBLE`
- `FLOAT` (from [MariaDB 10.4.5](#) )
- `INTEGER`
  - Short for  
`SIGNED INTEGER`
  - `SIGNED [INTEGER]`
  - `UNSIGNED [INTEGER]`
  - `TIME`
  - `VARCHAR` (in [Oracle mode](#) , from [MariaDB 10.3](#) )

The main difference between

`CAST`

and `CONVERT()` is that

`CONVERT(expr,type)`

is ODBC syntax while

`CAST(expr as type)`

and

`CONVERT(... USING ...)`

are SQL92 syntax.

In MariaDB 10.4 and later, you can use the

`CAST()`  
function with the  
`INTERVAL`  
keyword.

Until MariaDB 5.5.31 ,

`X'HHHH'`  
, the standard SQL syntax for binary string literals, erroneously worked in the same way as  
`0xHHHH`  
. In 5.5.31 it was intentionally changed to behave as a string in all contexts (and never as a number).

This introduced an incompatibility with previous versions of MariaDB, and all versions of MySQL (see the example below).

## Examples

Simple casts:

```
SELECT CAST("abc" AS BINARY);
SELECT CAST("1" AS UNSIGNED INTEGER);
SELECT CAST(123 AS CHAR CHARACTER SET utf8)
```

Note that when one casts to `CHAR` without specifying the character set, the `collation_connection` character set collation will be used. When used with `CHAR CHARACTER SET`, the default collation for that character set will be used.

```
SELECT COLLATION(CAST(123 AS CHAR));
+-----+
| COLLATION(CAST(123 AS CHAR)) |
+-----+
| latin1_swedish_ci           |
+-----+

SELECT COLLATION(CAST(123 AS CHAR CHARACTER SET utf8));
+-----+
| COLLATION(CAST(123 AS CHAR CHARACTER SET utf8)) |
+-----+
| utf8_general_ci             |
+-----+
```

If you also want to change the collation, you have to use the

`COLLATE`

operator:

```
SELECT COLLATION(CAST(123 AS CHAR CHARACTER SET utf8)
    COLLATE utf8_unicode_ci);
+-----+
| COLLATION(CAST(123 AS CHAR CHARACTER SET utf8) COLLATE utf8_unicode_ci) |
+-----+
| utf8_unicode_ci               |
+-----+
```

Using

`CAST()`

to order an

`ENUM`

field as a

`CHAR`

rather than the internal numerical value:

```

CREATE TABLE enum_list (enum_field enum('c','a','b'));

INSERT INTO enum_list (enum_field)
VALUES('c'),('a'),('c'),('b');

SELECT * FROM enum_list
ORDER BY enum_field;
+-----+
| enum_field |
+-----+
| c          |
| c          |
| a          |
| b          |
+-----+

SELECT * FROM enum_list
ORDER BY CAST(enum_field AS CHAR);
+-----+
| enum_field |
+-----+
| a          |
| b          |
| c          |
| c          |
+-----+

```

From [MariaDB 5.5.31](#), the following will trigger warnings, since

x'aa'  
and  
'X'aa'

no longer behave as a number. Previously, and in all versions of MySQL, no warnings are triggered since they did erroneously behave as a number:

```

SELECT CAST(0xAA AS UNSIGNED), CAST(x'aa' AS UNSIGNED), CAST(X'aa' AS UNSIGNED);
+-----+-----+-----+
| CAST(0xAA AS UNSIGNED) | CAST(x'aa' AS UNSIGNED) | CAST(X'aa' AS UNSIGNED) |
+-----+-----+-----+
|          170 |             0 |            0 |
+-----+-----+-----+
1 row in set, 2 warnings (0.00 sec)

Warning (Code 1292): Truncated incorrect INTEGER value: '\xAA'
Warning (Code 1292): Truncated incorrect INTEGER value: '\xAA'

```

Casting to intervals:

```

SELECT CAST('2019-01-04 INTERVAL AS DAY_SECOND(2)' AS "Cast";

+-----+
| Cast      |
+-----+
| 00:20:17.00 |
+-----+

```

## 1.1.12.2.8 CHAR Function

### Syntax

```
CHAR(N,... [USING charset_name])
```

# Description

CHAR()  
interprets each argument as an

INT

and returns a string consisting of the characters given by the code values of those integers.

NULL  
values are skipped. By default,  
CHAR()  
returns a binary string. To produce a string in a given character set , use the optional  
USING  
clause:

```
SELECT CHARSET(CHAR(0x65)), CHARSET(CHAR(0x65 USING utf8));  
+-----+  
| CHARSET(CHAR(0x65)) | CHARSET(CHAR(0x65 USING utf8)) |  
+-----+  
| binary           | utf8                |  
+-----+
```

If

USING  
is given and the result string is illegal for the given character set, a warning is issued. Also, if strict SQL mode is enabled, the result from  
CHAR()  
becomes  
NULL

## Examples

```
SELECT CHAR(77,97,114,'105',97,'68',66);  
+-----+  
| CHAR(77,97,114,'105',97,'68',66) |  
+-----+  
| MariaDB          |  
+-----+  
  
SELECT CHAR(77,77.3,'77.3');  
+-----+  
| CHAR(77,77.3,'77.3') |  
+-----+  
| MMM              |  
+-----+  
1 row in set, 1 warning (0.00 sec)  
  
Warning (Code 1292): Truncated incorrect INTEGER value: '77.3'
```

## See Also

- [Character Sets and Collations](#)
- [ASCII\(\)](#) - Return ASCII value of first character
- [ORD\(\)](#) - Return value for character in single or multi-byte character sets
- [CHR](#) - Similar, Oracle-compatible, function

## 1.1.12.2.9 CHAR\_LENGTH

### Syntax

```
CHAR_LENGTH(str)  
CHARACTER_LENGTH(str)
```

## Contents

1. [Syntax](#)
2. [Description](#)
3. [Examples](#)
4. [See Also](#)

## Description

Returns the length of the given string argument, measured in characters. A multi-byte character counts as a single character. This means that for a string containing five two-byte characters, `LENGTH()` (or `OCTET_LENGTH()` in Oracle mode) returns 10, whereas

```
CHAR_LENGTH()  
returns 5. If the argument is  
NULL  
, it returns  
NULL
```

If the argument is not a string value, it is converted into a string.

It is synonymous with the

```
CHARACTER_LENGTH()  
function.
```

## Examples

```
SELECT CHAR_LENGTH('MariaDB');  
+-----+  
| CHAR_LENGTH('MariaDB') |  
+-----+  
| 7 |  
+-----+
```

When Oracle mode from MariaDB 10.3 is not set:

```
SELECT CHAR_LENGTH('π'), LENGTH('π'), LENGTHB('π'), OCTET_LENGTH('π');  
+-----+-----+-----+-----+  
| CHAR_LENGTH('π') | LENGTH('π') | LENGTHB('π') | OCTET_LENGTH('π') |  
+-----+-----+-----+-----+  
| 1 | 2 | 2 | 2 |  
+-----+-----+-----+-----+
```

In Oracle mode from MariaDB 10.3 :

```
SELECT CHAR_LENGTH('π'), LENGTH('π'), LENGTHB('π'), OCTET_LENGTH('π');  
+-----+-----+-----+-----+  
| CHAR_LENGTH('π') | LENGTH('π') | LENGTHB('π') | OCTET_LENGTH('π') |  
+-----+-----+-----+-----+  
| 1 | 1 | 2 | 2 |  
+-----+-----+-----+-----+
```

## See Also

- [LENGTHB\(\)](#)
- [OCTET\\_LENGTH\(\)](#)
- [Oracle mode from MariaDB 10.3](#)

## 1.1.12.2.10 CHARACTER\_LENGTH

### Syntax

```
CHARACTER_LENGTH(str)
```

### Description

`CHARACTER_LENGTH()`  
is a synonym for

`CHAR_LENGTH()`

## 1.1.12.2.11 CHR

MariaDB starting with [10.3.1](#)

The

`CHR()`  
function was introduced in [MariaDB 10.3.1](#) to provide Oracle compatibility

### Syntax

`CHR(N)`

### Description

`CHR()`  
interprets each argument N as an integer and returns a

`VARCHAR(1)`

string consisting of the character given by the code values of the integer. The character set and collation of the string are set according to the values of the

`character_set_database`

and

`collation_database`

system variables.

`CHR()`  
is similar to the

`CHAR()`

function, but only accepts a single argument.

`CHR()`  
is available in all `sql_modes`.

### Examples

```

SELECT CHR(67);
+-----+
| CHR(67) |
+-----+
| C       |
+-----+

SELECT CHR('67');
+-----+
| CHR('67') |
+-----+
| C          |
+-----+

SELECT CHR('C');
+-----+
| CHR('C') |
+-----+
|          |
+-----+
1 row in set, 1 warning (0.000 sec)

SHOW WARNINGS;
+-----+-----+
| Level | Code | Message           |
+-----+-----+
| Warning | 1292 | Truncated incorrect INTEGER value: 'C' |
+-----+-----+

```

## See Also

- [Character Sets and Collations](#)
- [ASCII\(\)](#) - Return ASCII value of first character
- [ORD\(\)](#) - Return value for character in single or multi-byte character sets
- [CHAR\(\)](#) - Similar function which accepts multiple integers

## 1.1.12.2.12 CONCAT

### Syntax

```
CONCAT(str1,str2,...)
```

### Contents

1. [Syntax](#)
2. [Description](#)
  1. [Oracle Mode](#)
3. [Examples](#)
4. [See Also](#)

### Description

Returns the string that results from concatenating the arguments. May have one or more arguments. If all arguments are non-binary strings, the result is a non-binary string. If the arguments include any binary strings, the result is a binary string. A numeric argument is converted to its equivalent binary string form; if you want to avoid that, you can use an explicit type cast, as in this example:

```
SELECT CONCAT(CAST(int_col AS CHAR), char_col);
```

```

CONCAT()
returns
NULL
if any argument is
NULL
.
```

A

NULL  
parameter hides all information contained in other parameters from the result. Sometimes this is not desirable; to avoid this, you can:

- Use the

[CONCAT\\_WS\(\)](#)

function with an empty separator, because that function is  
NULL  
-safe.

- Use

[IFNULL\(\)](#)

to turn NULLs into empty strings.

## Oracle Mode

MariaDB starting with [10.3](#)

In [Oracle mode from MariaDB 10.3](#),

CONCAT  
ignores **NULL**.

## Examples

```
SELECT CONCAT('Ma', 'ria', 'DB');
+-----+
| CONCAT('Ma', 'ria', 'DB') |
+-----+
| MariaDB |
+-----+

SELECT CONCAT('Ma', 'ria', NULL, 'DB');
+-----+
| CONCAT('Ma', 'ria', NULL, 'DB') |
+-----+
| NULL |
+-----+

SELECT CONCAT(42.0);
+-----+
| CONCAT(42.0) |
+-----+
| 42.0 |
+-----+
```

Using

[IFNULL\(\)](#)

to handle NULLs:

```
SELECT CONCAT('The value of @v is: ', IFNULL(@v, ''));
+-----+
| CONCAT('The value of @v is: ', IFNULL(@v, '')) |
+-----+
| The value of @v is: |
+-----+
```

In [Oracle mode](#), from [MariaDB 10.3](#):

```
SELECT CONCAT('Ma', 'ria', NULL, 'DB');
+-----+
| CONCAT('Ma', 'ria', NULL, 'DB') |
+-----+
| MariaDB |
+-----+
```

## See Also

- [GROUP\\_CONCAT\(\)](#)
- [Oracle mode from MariaDB 10.3](#)

## 1.1.12.2.13 CONCAT\_WS

### Syntax

```
CONCAT_WS(separator,str1,str2,...)
```

### Description

CONCAT\_WS()

stands for Concatenate With Separator and is a special form of

[CONCAT\(\)](#)

. The first argument is the separator for the rest of the arguments. The separator is added between the strings to be concatenated. The separator can be a string, as can the rest of the arguments.

If the separator is

NULL

, the result is

NULL

; all other

NULL

values are skipped. This makes

CONCAT\_WS()

suitable when you want to concatenate some values and avoid losing all information if one of them is

NULL

### Examples

```
SELECT CONCAT_WS(',','First name','Second name','Last Name');
+-----+
| CONCAT_WS(',',$First name','Second name','Last Name') |
+-----+
| First name,Second name,Last Name |
```

```
SELECT CONCAT_WS('-', 'Floor', NULL, 'Room');
+-----+
| CONCAT_WS('-', 'Floor', NULL, 'Room') |
+-----+
| Floor-Room |
```

In some cases, remember to include a space in the separator string:

```
SET @a = 'gnu', @b = 'penguin', @c = 'sea lion';
Query OK, 0 rows affected (0.00 sec)
```

```
SELECT CONCAT_WS(' ', @a, @b, @c);
+-----+
| CONCAT_WS(' ', @a, @b, @c) |
+-----+
| gnu, penguin, sea lion |
```

Using

CONCAT\_WS()

to handle

NULL

s:

```

SET @a = 'a', @b = NULL, @c = 'c';
SELECT CONCAT_WS('', @a, @b, @c);
+-----+
| CONCAT_WS('', @a, @b, @c) |
+-----+
| ac                                |
+-----+

```

## See Also

- [GROUP\\_CONCAT\(\)](#)

## 1.1.12.2.14 CONVERT

### Syntax

```
CONVERT(expr,type), CONVERT(expr USING transcoding_name)
```

### Contents

1. [Syntax](#)
2. [Description](#)
3. [Examples](#)
4. [See Also](#)

## Description

The

`CONVERT()`  
and `CAST()` functions take a value of one type and produce a value of another type.

The type can be one of the following values:

- [BINARY](#)
- [CHAR](#)
- [DATE](#)
- [DATETIME](#)
- [DECIMAL\[\(M,D\)\]](#)
- [DOUBLE](#)
- [FLOAT \(from MariaDB 10.4.5 \)](#)
- [INTEGER](#)
  - Short for  
`SIGNED INTEGER`
- [SIGNED \[INTEGER\]](#)
- [UNSIGNED \[INTEGER\]](#)
- [TIME](#)
- [VARCHAR \(in Oracle mode , from MariaDB 10.3 \)](#)

Note that in MariaDB,

`INT`  
and  
`INTEGER`  
are the same thing.

`BINARY`  
produces a string with the `BINARY` data type. If the optional length is given,  
`BINARY(N)`  
causes the cast to use no more than  
`N`  
bytes of the argument. Values shorter than the given number in bytes are padded with 0x00 bytes to make them equal the length value.

`CHAR(N)`  
causes the cast to use no more than the number of characters given in the argument.

The main difference between the `CAST()` and

`CONVERT()`  
is that

`CONVERT(expr,type)`  
is ODBC syntax while `CAST(expr as type)` and  
`CONVERT(... USING ...)`  
are SQL92 syntax.

`CONVERT()`  
with  
`USING`

is used to convert data between different [character sets](#). In MariaDB, transcoding names are the same as the corresponding character set names. For example, this statement converts the string 'abc' in the default character set to the corresponding string in the utf8 character set:

```
SELECT CONVERT('abc' USING utf8);
```

## Examples

```
SELECT enum_col FROM tbl_name
ORDER BY CAST(enum_col AS CHAR);
```

Converting a [BINARY](#) to string to permit the [LOWER](#) function to work:

```
SET @x = 'AardVark';
SET @x = BINARY 'AardVark';

SELECT LOWER(@x), LOWER(CONVERT (@x USING latin1));
+-----+-----+
| LOWER(@x) | LOWER(CONVERT (@x USING latin1)) |
+-----+-----+
| AardVark | aardvark
+-----+-----+
```

## See Also

- [Character Sets and Collations](#)

## 1.1.12.2.15 ELT

### Syntax

```
ELT(N, str1[, str2, str3,...])
```

### Description

Takes a numeric argument and a series of string arguments. Returns the string that corresponds to the given numeric position. For instance, it returns

`str1`  
if  
`N`  
is 1,  
`str2`  
if  
`N`  
is 2, and so on. If the numeric argument is a

[FLOAT](#)

, MariaDB rounds it to the nearest

[INTEGER](#)

. If the numeric argument is less than 1, greater than the total number of arguments, or not a number,

`ELT()`

returns

`NULL`

. It must have at least two arguments.

It is complementary to the

[FIELD\(\)](#)

function.

## Examples

```
SELECT ELT(1, 'ej', 'Heja', 'hej', 'foo');
+-----+
| ELT(1, 'ej', 'Heja', 'hej', 'foo') |
+-----+
| ej                                |
+-----+

SELECT ELT(4, 'ej', 'Heja', 'hej', 'foo');
+-----+
| ELT(4, 'ej', 'Heja', 'hej', 'foo') |
+-----+
| foo                               |
+-----+
```

## See also

- [FIND\\_IN\\_SET\(\)](#) function. Returns the position of a string in a set of strings.
- [FIELD\(\)](#) function. Returns the index position of a string in a list.

## 1.1.12.2.16 EXPORT\_SET

### Syntax

```
EXPORT_SET(bits, on, off[, separator[, number_of_bits]])
```

### Description

Takes a minimum of three arguments. Returns a string where each bit in the given

bits  
argument is returned, with the string values given for  
on  
and  
off

Bits are examined from right to left, (from low-order to high-order bits). Strings are added to the result from left to right, separated by a separator string (defaults as ' )

' ). You can optionally limit the number of bits the  
EXPORT\_SET()  
function examines using the  
number\_of\_bits  
option.

If any of the arguments are set as

NULL  
, the function returns  
NULL

## Examples

```

SELECT EXPORT_SET(5,'Y','N','','',4);
+-----+
| EXPORT_SET(5,'Y','N','','',4) |
+-----+
| Y,N,Y,N |
+-----+

SELECT EXPORT_SET(6,'1','0','','',10);
+-----+
| EXPORT_SET(6,'1','0','','',10) |
+-----+
| 0,1,1,0,0,0,0,0,0,0 |
+-----+

```

## 1.1.12.2.17 EXTRACTVALUE

### Syntax

```
EXTRACTVALUE(xml_frag, xpath_expr)
```

### Contents

1. [Syntax](#)
2. [Description](#)
  1. [Invalid Arguments](#)
  2. [Explicit text\(\) Expressions](#)
  3. [Count Matches](#)
  4. [Matches](#)
3. [Examples](#)

### Description

The

`EXTRACTVALUE()`

function takes two string arguments: a fragment of XML markup and an XPath expression, (also known as a locator). It returns the text (That is, CDDATA), of the first text node which is a child of the element or elements matching the XPath expression.

In cases where a valid XPath expression does not match any text nodes in a valid XML fragment, (including the implicit

```
/text()
expression), the
EXTRACTVALUE()
function returns an empty string.
```

### Invalid Arguments

When either the XML fragment or the XPath expression is

```
NULL
, the
EXTRACTVALUE()
function returns
NULL
```

. When the XML fragment is invalid, it raises a warning Code 1525:

```
Warning (Code 1525): Incorrect XML value: 'parse error at line 1 pos 11: unexpected END-OF-INPUT'
```

When the XPath value is invalid, it generates an Error 1105:

```
ERROR 1105 (HY000): XPATH syntax error: ''
```

### Explicit

`text()`  
`Expressions`

This function is the equivalent of performing a match using the XPath expression after appending

`/text()`

. In other words:

```

SELECT
EXTRACTVALUE('<cases><case>example</case></cases>', '/cases/case') AS 'Base Example',
EXTRACTVALUE('<cases><case>example</case></cases>', '/cases/case/text()') AS 'text() Example';

+-----+
| Base Example | text() Example |
+-----+
| example      | example       |
+-----+

```

## Count Matches

When

```
EXTRACTVALUE()
```

returns multiple matches, it returns the content of the first child text node of each matching element, in the matched order, as a single, space-delimited string.

By design, the

```
EXTRACTVALUE()
```

function makes no distinction between a match on an empty element and no match at all. If you need to determine whether no matching element was found in the XML fragment or if an element was found that contained no child text nodes, use the XPath

```
count()
function.
```

For instance, when looking for a value that exists, but contains no child text nodes, you would get a count of the number of matching instances:

```

SELECT
EXTRACTVALUE('<cases><case/></cases>', '/cases/case') AS 'Empty Example',
EXTRACTVALUE('<cases><case/></cases>', 'count(/cases/case)') AS 'count() Example';

+-----+
| Empty Example | count() Example |
+-----+
|                 |          1 |
+-----+

```

Alternatively, when looking for a value that doesn't exist,

```
count()
returns 0.
```

```

SELECT
EXTRACTVALUE('<cases><case/></cases>', '/cases/person') AS 'No Match Example',
EXTRACTVALUE('<cases><case/></cases>', 'count(/cases/person)') AS 'count() Example';

+-----+
| No Match Example | count() Example |
+-----+
|                   |          0 |
+-----+

```

## Matches

**Important :** The

```
EXTRACTVALUE()
```

function only returns CDDATA. It does not return tags that the element might contain or the text that these child elements contain.

```

SELECT EXTRACTVALUE('<cases><case>Person<email>x@example.com</email></case></cases>', '/cases') AS Case;

+-----+
| Case   |
+-----+
| Person |
+-----+

```

Note, in the above example, while the XPath expression matches to the parent

```
<case>
instance, it does not return the contained
<email>
tag or its content.
```

## Examples

```
SELECT
    ExtractValue('<a>ccc<b>ddd</b></a>', '/a')           AS val1,
    ExtractValue('<a>ccc<b>ddd</b></a>', '/a/b')        AS val2,
    ExtractValue('<a>ccc<b>ddd</b></a>', '//b')         AS val3,
    ExtractValue('<a>ccc<b>ddd</b></a>', '/b')          AS val4,
    ExtractValue('<a>ccc<b>ddd</b><b>eee</b></a>', '//b') AS val5;
+-----+-----+-----+-----+
| val1 | val2 | val3 | val4 | val5   |
+-----+-----+-----+-----+
| ccc  | ddd  | ddd  |      | ddd eee |
+-----+-----+-----+-----+
```

## 1.1.12.2.18 FIELD

### Syntax

```
FIELD(pattern, str1[,str2,...])
```

### Description

Returns the index position of the string or number matching the given pattern. Returns

0

in the event that none of the arguments match the pattern. Raises an Error 1582 if not given at least two arguments.

When all arguments given to the

```
FIELD()
```

function are strings, they are treated as case-insensitive. When all the arguments are numbers, they are treated as numbers. Otherwise, they are treated as doubles.

If the given pattern occurs more than once, the

```
FIELD()
```

function only returns the index of the first instance. If the given pattern is

NULL

, the function returns

0

, as a

NULL

pattern always fails to match.

This function is complementary to the

```
ELT()
```

function.

## Examples

```

SELECT FIELD('ej', 'Hej', 'ej', 'Heja', 'hej', 'foo')
  AS 'Field Results';
+-----+
| Field Results |
+-----+
|      2 |
+-----+

SELECT FIELD('fo', 'Hej', 'ej', 'Heja', 'hej', 'foo')
  AS 'Field Results';
+-----+
| Field Results |
+-----+
|      0 |
+-----+

SELECT FIELD(1, 2, 3, 4, 5, 1) AS 'Field Results';
+-----+
| Field Results |
+-----+
|      5 |
+-----+

SELECT FIELD(NULL, 2, 3) AS 'Field Results';
+-----+
| Field Results |
+-----+
|      0 |
+-----+

SELECT FIELD('fail') AS 'Field Results';
Error 1582 (42000): Incorrect parameter count in call
to native function 'field'

```

## See also

- [ELT\(\)](#) function. Returns the N'th element from a set of strings.

## 1.1.12.2.19 FIND\_IN\_SET

### Syntax

```
FIND_IN_SET(pattern, strlist)
```

### Description

Returns the index position where the given pattern occurs in a string list. The first argument is the pattern you want to search for. The second argument is a string containing comma-separated variables. If the second argument is of the

[SET](#)

data-type, the function is optimized to use bit arithmetic.

If the pattern does not occur in the string list or if the string list is an empty string, the function returns

0

. If either argument is

NULL

, the function returns

NULL

. The function does not return the correct result if the pattern contains a comma ("

,

") character.

## Examples

```
SELECT FIND_IN_SET('b','a,b,c,d') AS "Found Results";
+-----+
| Found Results |
+-----+
|      2      |
+-----+
```

## See Also

- [ELT\(\)](#) function. Returns the N'th element from a set of strings.

## 1.1.12.2.20 FORMAT

### Syntax

```
FORMAT(num, decimal_position[, locale])
```

### Description

Formats the given number for display as a string, adding separators to appropriate position and rounding the results to the given decimal position. For instance, it would format

```
15233.345
to
15,233.35
```

If the given decimal position is

```
0
```

, it rounds to return no decimal point or fractional part. You can optionally specify a [locale](#) value to format numbers to the pattern appropriate for the given region.

### Examples

```
SELECT FORMAT(1234567890.09876543210, 4) AS 'Format';
+-----+
| Format          |
+-----+
| 1,234,567,890.0988 |
+-----+
```

```
SELECT FORMAT(1234567.89, 4) AS 'Format';
+-----+
| Format          |
+-----+
| 1,234,567.8900 |
+-----+
```

```
SELECT FORMAT(1234567.89, 0) AS 'Format';
+-----+
| Format          |
+-----+
| 1,234,568      |
+-----+
```

```
SELECT FORMAT(123456789,2,'rm_CH') AS 'Format';
+-----+
| Format          |
+-----+
| 123'456'789,00 |
+-----+
```

## 1.1.12.2.21 FROM\_BASE64

### Syntax

```
FROM_BASE64(str)
```

## Description

Decodes the given base-64 encode string, returning the result as a binary string. Returns

NULL  
if the given string is  
NULL  
or if it's invalid.

It is the reverse of the

```
TO_BASE64
```

function.

There are numerous methods to base-64 encode a string. MariaDB uses the following:

- It encodes alphabet value 64 as '  
+'  
'.'
- It encodes alphabet value 63 as '  
/'  
'.'
- It codes output in groups of four printable characters. Each three byte of data encoded uses four characters. If the final group is incomplete, it pads the difference with the '=' character.
- It divides long output, adding a new line every 76 characters.
- In decoding, it recognizes and ignores newlines, carriage returns, tabs and space whitespace characters.

```
SELECT TO_BASE64('Maria') AS 'Input';
+-----+
| Input   |
+-----+
| TWFyaWE= |
+-----+
SELECT FROM_BASE64('TWFyaWE=') AS 'Output';
+-----+
| Output |
+-----+
| Maria  |
+-----+
```

## 1.1.12.2.22 HEX

### Syntax

```
HEX(N_or_S)
```

## Description

If

N\_or\_S  
is a number, returns a string representation of the hexadecimal value of  
N  
, where  
N  
is a  
longlong  
(  
  
BIGINT  
  
) number. This is equivalent to

```
CONV
```

```
(N,10,16)

If
N_or_S
is a string, returns a hexadecimal string representation of
N_or_S
where each byte of each character in
N_or_S
is converted to two hexadecimal digits. If
N_or_S
is NULL, returns NULL. The inverse of this operation is performed by the UNHEX \(\) function.
```

MariaDB starting with [10.5.0](#)

`HEX()` with an `INET6` argument returns a hexadecimal representation of the underlying 16-byte binary string.

## Examples

```
SELECT HEX(255);
+-----+
| HEX(255) |
+-----+
| FF         |
+-----+

SELECT 0x4D617269614442;
+-----+
| 0x4D617269614442 |
+-----+
| MariaDB          |
+-----+

SELECT HEX('MariaDB');
+-----+
| HEX('MariaDB') |
+-----+
| 4D617269614442 |
+-----+
```

From [MariaDB 10.5.0](#) :

```
SELECT HEX(CAST('2001:db8::ff00:42:8329' AS INET6));
+-----+
| HEX(CAST('2001:db8::ff00:42:8329' AS INET6)) |
+-----+
| 20010DB800000000000FF0000428329               |
+-----+
```

## See Also

- [Hexadecimal literals](#)
- [UNHEX\(\)](#)
- [CONV\(\)](#)
- [BIN\(\)](#)
- [OCT\(\)](#)

## 1.1.12.2.23 INSERT Function

### Syntax

```
INSERT(str,pos,len,newstr)
```

### Description

Returns the string

```
str  
, with the substring beginning at position  
pos  
and  
len  
characters long replaced by the string  
newstr  
. Returns the original string if  
pos  
is not within the length of the string. Replaces the rest of the string from position  
pos  
if  
len  
is not within the length of the rest of the string. Returns NULL if any argument is NULL.
```

## Examples

```
SELECT INSERT('Quadratic', 3, 4, 'What');  
+-----+  
| INSERT('Quadratic', 3, 4, 'What') |  
+-----+  
| QuWhattic |  
+-----+  
  
SELECT INSERT('Quadratic', -1, 4, 'What');  
+-----+  
| INSERT('Quadratic', -1, 4, 'What') |  
+-----+  
| Quadratic |  
+-----+  
  
SELECT INSERT('Quadratic', 3, 100, 'What');  
+-----+  
| INSERT('Quadratic', 3, 100, 'What') |  
+-----+  
| QuWhat |  
+-----+
```

## 1.1.12.2.24 LENGTH

### Syntax

```
LENGTH(str)
```

### Contents

1. [Syntax](#)
2. [Description](#)
3. [Examples](#)
4. [See Also](#)

### Description

Returns the length of the string

```
str
```

In the default mode, when [Oracle mode from MariaDB 10.3](#) is not set, the length is measured in bytes. In this case, a multi-byte character counts as multiple bytes. This means that for a string containing five two-byte characters,

```
LENGTH()  
returns 10, whereas CHAR_LENGTH() returns 5.
```

When running [Oracle mode from MariaDB 10.3](#), the length is measured in characters, and

```
LENGTH  
is a synonym for CHAR_LENGTH().
```

If

```
str
```

is not a string value, it is converted into a string. If

```
str  
is  
NULL  
, the function returns  
NULL
```

## Examples

```
SELECT LENGTH('MariaDB');  
+-----+  
| LENGTH('MariaDB') |  
+-----+  
| 7 |  
+-----+
```

When [Oracle mode](#) from MariaDB 10.3 is not set:

```
SELECT CHAR_LENGTH('π'), LENGTH('π'), LENGTHB('π'), OCTET_LENGTH('π');  
+-----+-----+-----+  
| CHAR_LENGTH('π') | LENGTH('π') | LENGTHB('π') | OCTET_LENGTH('π') |  
+-----+-----+-----+  
| 1 | 2 | 2 | 2 |  
+-----+-----+-----+
```

In [Oracle mode](#) from MariaDB 10.3 :

```
SELECT CHAR_LENGTH('π'), LENGTH('π'), LENGTHB('π'), OCTET_LENGTH('π');  
+-----+-----+-----+  
| CHAR_LENGTH('π') | LENGTH('π') | LENGTHB('π') | OCTET_LENGTH('π') |  
+-----+-----+-----+  
| 1 | 1 | 2 | 2 |  
+-----+-----+-----+
```

## See Also

- [CHAR\\_LENGTH\(\)](#)
- [LENGTHB\(\)](#)
- [OCTET\\_LENGTH\(\)](#)
- [Oracle mode from MariaDB 10.3](#)

## 1.1.12.2.25 LENGTHB

MariaDB starting with [10.3.1](#)

Introduced in [MariaDB 10.3.1](#) as part of the [Oracle compatibility enhancements](#).

## Syntax

```
LENGTHB(str)
```

## Description

`LENGTHB()`

returns the length of the given string, in bytes. When [Oracle mode](#) is not set, this is a synonym for [LENGTH](#).

A multi-byte character counts as multiple bytes. This means that for a string containing five two-byte characters,

```
LENGTHB()  
returns 10, whereas CHAR_LENGTH() returns 5.
```

If

```
str  
is not a string value, it is converted into a string. If  
str  
is
```

NULL  
, the function returns  
NULL

## Examples

When Oracle mode from MariaDB 10.3 is not set:

```
SELECT CHAR_LENGTH('π'), LENGTH('π'), LENGTHB('π'), OCTET_LENGTH('π');
+-----+-----+-----+
| CHAR_LENGTH('π') | LENGTH('π') | LENGTHB('π') | OCTET_LENGTH('π') |
+-----+-----+-----+
|          1 |         2 |         2 |         2 |
+-----+-----+-----+
```

In Oracle mode from MariaDB 10.3 :

```
SELECT CHAR_LENGTH('π'), LENGTH('π'), LENGTHB('π'), OCTET_LENGTH('π');
+-----+-----+-----+
| CHAR_LENGTH('π') | LENGTH('π') | LENGTHB('π') | OCTET_LENGTH('π') |
+-----+-----+-----+
|          1 |         1 |         2 |         2 |
+-----+-----+-----+
```

## See Also

- [CHAR\\_LENGTH\(\)](#)
- [LENGTH\(\)](#)
- [OCTET\\_LENGTH\(\)](#)

## 1.1.12.2.26 LIKE

### Syntax

```
expr LIKE pat [ESCAPE 'escape_char']
expr NOT LIKE pat [ESCAPE 'escape_char']
```

### Contents

1. [Syntax](#)
2. [Description](#)
3. [Examples](#)
4. [Optimizing LIKE](#)
5. [See Also](#)

## Description

Tests whether *expr* matches the pattern *pat*. Returns either 1 (

TRUE  
) or 0 (

FALSE

). Both *expr* and *pat* may be any valid expression and are evaluated to strings. Patterns may use the following wildcard characters:

- %  
matches any number of characters, including zero.
- \_  
matches any single character.

### Use

NOT LIKE

to test if a string does not match a pattern. This is equivalent to using the

NOT

operator on the entire  
LIKE

expression.

If either the expression or the pattern is

NULL  
, the result is  
NULL

LIKE

performs case-insensitive substring matches if the collation for the expression and pattern is case-insensitive. For case-sensitive matches, declare either argument to use a binary collation using

COLLATE

, or coerce either of them to a

BINARY

string using

CAST

. Use

SHOW COLLATION

to get a list of available collations. Collations ending in

\_bin

are case-sensitive.

Numeric arguments are coerced to binary strings.

The

— wildcard matches a single character, not byte. It will only match a multi-byte character if it is valid in the expression's character set. For example

— will match  
\_utf8"€"  
, but it will not match  
\_latin1"€"  
because the Euro sign is not a valid latin1 character. If necessary, use

CONVERT

to use the expression in a different character set.

If you need to match the characters

—  
or  
%

, you must escape them. By default, you can prefix the wildcard characters the backslash character

\

to escape them. The backslash is used both to encode special characters like newlines when a string is parsed as well as to escape wildcards in a pattern after parsing. Thus, to match an actual backslash, you sometimes need to double-escape it as

"\

\

\

\"

To avoid difficulties with the backslash character, you can change the wildcard escape character using

ESCAPE  
in a  
LIKE  
expression. The argument to  
ESCAPE  
must be a single-character string.

# Examples

Select the days that begin with "T":

```
CREATE TABLE t1 (d VARCHAR(16));
INSERT INTO t1 VALUES ("Monday"), ("Tuesday"), ("Wednesday"), ("Thursday"), ("Friday"), ("Saturday"), ("Sunday");
SELECT * FROM t1 WHERE d LIKE "T%";
```

```
SELECT * FROM t1 WHERE d LIKE "T%";
+-----+
| d      |
+-----+
| Tuesday |
| Thursday|
+-----+
```

Select the days that contain the substring "es":

```
SELECT * FROM t1 WHERE d LIKE "%es%";
```

```
SELECT * FROM t1 WHERE d LIKE "%es%";
+-----+
| d      |
+-----+
| Tuesday |
| Wednesday|
+-----+
```

Select the six-character day names:

```
SELECT * FROM t1 WHERE d like "__day";
```

```
SELECT * FROM t1 WHERE d like "__day%";
+-----+
| d      |
+-----+
| Monday |
| Friday |
| Sunday |
+-----+
```

With the default collations,

LIKE

is case-insensitive:

```
SELECT * FROM t1 where d like "t%";
```

```
SELECT * FROM t1 where d like "t%";
+-----+
| d      |
+-----+
| Tuesday |
| Thursday|
+-----+
```

Use

COLLATE

to specify a binary collation, forcing case-sensitive matches:

```
SELECT * FROM t1 WHERE d like "t%" COLLATE latin1_bin;
```

```
SELECT * FROM t1 WHERE d like "t%" COLLATE latin1_bin;
Empty set (0.00 sec)
```

You can include functions and operators in the expression to match. Select dates based on their day name:

```
CREATE TABLE t2 (d DATETIME);
INSERT INTO t2 VALUES
  ("2007-01-30 21:31:07"),
  ("1983-10-15 06:42:51"),
  ("2011-04-21 12:34:56"),
  ("2011-10-30 06:31:41"),
  ("2011-01-30 14:03:25"),
  ("2004-10-07 11:19:34");
SELECT * FROM t2 WHERE DAYNAME(d) LIKE "T%";
```

```
SELECT * FROM t2 WHERE DAYNAME(d) LIKE "T%";
+-----+
| d      |
+-----+
| 2007-01-30 21:31 |
| 2011-04-21 12:34 |
| 2004-10-07 11:19 |
+-----+
3 rows in set, 7 warnings (0.00 sec)
```

## Optimizing LIKE

- MariaDB can use indexes for LIKE on string columns in the case where the LIKE doesn't start with % or \_.
- Starting from [MariaDB 10.0](#), one can set the `optimizer_use_condition_selectivity` variable to 5. If this is done, then the optimizer will read `optimizer_selectivity_sampling_limit` rows to calculate the selectivity of the LIKE expression before starting to calculate the query plan. This can help speed up some LIKE queries by providing the optimizer with more information about your data.

## See Also

- For searches on text columns, with results sorted by relevance, see [full-text](#) indexes.
- For more complex searches and operations on strings, you can use [regular expressions](#), which were enhanced in MariaDB 10 (see [PCRE Regular Expressions](#)).

## 1.1.12.2.27 LOAD\_FILE

## 1.1.12.2.28 LOCATE

### Syntax

```
LOCATE(substr,str), LOCATE(substr,str,pos)
```

### Description

The first syntax returns the position of the first occurrence of substring

substr  
in string  
str  
. The second syntax returns the position of the first occurrence of substring  
substr  
in string  
str  
, starting at position  
pos  
. Returns 0 if  
substr  
is not in  
str  
.

`LOCATE()`  
performs a case-insensitive search.

If any argument is

`NULL`  
, returns  
`NULL`.

`INSTR()` is the same as the two-argument form of  
`LOCATE()`, except that the order of the arguments is reversed.

## Examples

```
SELECT LOCATE('bar', 'foobarbar');
+-----+
| LOCATE('bar', 'foobarbar') |
+-----+
|          4 |
+-----+  
  
SELECT LOCATE('My', 'Maria');
+-----+
| LOCATE('My', 'Maria') |
+-----+
|          0 |
+-----+  
  
SELECT LOCATE('bar', 'foobarbar', 5);
+-----+
| LOCATE('bar', 'foobarbar', 5) |
+-----+
|          7 |
+-----+
```

## See Also

- [INSTR\(\)](#) ; Returns the position of a string within a string
- [SUBSTRING\\_INDEX\(\)](#) ; Returns the substring from string before count occurrences of a delimiter

## 1.1.12.2.29 LOWER

### Syntax

```
LOWER(str)
```

#### Contents

1. [Syntax](#)
2. [Description](#)
3. [Examples](#)

### Description

Returns the string

`str`

with all characters changed to lowercase according to the current character set mapping. The default is latin1 (cp1252 West European).

## Examples

```
SELECT LOWER('QUADRATICALLY');
+-----+
| LOWER('QUADRATICALLY') |
+-----+
| quadratically         |
+-----+
```

LOWER()  
(and  
UPPER()

) are ineffective when applied to binary strings (

BINARY

,

VARBINARY

,

BLOB

). To perform lowercase conversion, [CONVERT](#) the string to a non-binary string:

```
SET @str = BINARY 'North Carolina';

SELECT LOWER(@str), LOWER(CONVERT(@str USING latin1));
+-----+-----+
| LOWER(@str) | LOWER(CONVERT(@str USING latin1)) |
+-----+-----+
| North Carolina | north carolina           |
+-----+-----+
```

## 1.1.12.2.30 LPAD

### Syntax

```
LPAD(str, len [,padstr])
```

### Contents

1. [Syntax](#)
2. [Description](#)
3. [Examples](#)
4. [See Also](#)

### Description

Returns the string

str  
, left-padded with the string  
padstr  
to a length of  
len  
characters. If  
str  
is longer than  
len  
, the return value is shortened to  
len  
characters. If  
padstr  
is omitted, the LPAD function pads spaces.

Prior to [MariaDB 10.3.1](#) , the

padstr  
parameter was mandatory.

Returns NULL if given a NULL argument. If the result is empty (zero length), returns either an empty string or, from [MariaDB 10.3.6](#) with [SQL\\_MODE=Oracle](#) , NULL.

The Oracle mode version of the function can be accessed outside of Oracle mode by using

LPAD\_ORACLE

as the function name.

## Examples

```
SELECT LPAD('hello',10,'.');
+-----+
| LPAD('hello',10,'.') |
+-----+
| .....hello         |
+-----+

SELECT LPAD('hello',2,'.');
+-----+
| LPAD('hello',2,'.') |
+-----+
| he                  |
+-----+
```

From [MariaDB 10.3.1](#), with the pad string defaulting to space.

```
SELECT LPAD('hello',10);
+-----+
| LPAD('hello',10) |
+-----+
|      hello      |
+-----+
```

Oracle mode version from [MariaDB 10.3.6](#):

```
SELECT LPAD('',0),LPAD_ORACLE('');
+-----+
| LPAD('',0) | LPAD_ORACLE('') |
+-----+
|          | NULL           |
+-----+
```

## See Also

- [RPAD](#) - Right-padding instead of left-padding.

## 1.1.12.2.31 LTRIM

### Syntax

```
LTRIM(str)
```

### Contents

1. [Syntax](#)
2. [Description](#)
3. [Examples](#)
4. [See Also](#)

## Description

Returns the string

str

with leading space characters removed.

Returns NULL if given a NULL argument. If the result is empty, returns either an empty string, or, from [MariaDB 10.3.6](#) with `SQL_MODE=Oracle`, NULL.

The Oracle mode version of the function can be accessed outside of Oracle mode by using

`LTRIM_ORACLE`

as the function name.

## Examples

```
SELECT QUOTE(LTRIM(' MariaDB '));
+-----+
| QUOTE(LTRIM(' MariaDB ')) |
+-----+
| 'MariaDB' |
+-----+
```

Oracle mode version from MariaDB 10.3.6 :

```
SELECT LTRIM(''),LTRIM_ORACLE('');
+-----+
| LTRIM('') | LTRIM_ORACLE('') |
+-----+
|        | NULL |
+-----+
```

## See Also

- [RTRIM](#) - trailing spaces removed
- [TRIM](#) - removes all given prefixes or suffixes

## 1.1.12.2.32 MAKE\_SET

### Syntax

```
MAKE_SET(bits,str1,str2,...)
```

### Description

Returns a set value (a string containing substrings separated by "," characters) consisting of the strings that have the corresponding bit in bits set.

*str1*  
corresponds to bit 0,  
*str2*  
to bit 1, and so on. NULL values in  
*str1*  
,  
*str2*  
, ... are not appended to the result.

### Examples

```

SELECT MAKE_SET(1,'a','b','c');
+-----+
| MAKE_SET(1,'a','b','c') |
+-----+
| a |
+-----+

SELECT MAKE_SET(1 | 4,'hello','nice','world');
+-----+
| MAKE_SET(1 | 4,'hello','nice','world') |
+-----+
| hello,world |
+-----+

SELECT MAKE_SET(1 | 4,'hello','nice',NULL,'world');
+-----+
| MAKE_SET(1 | 4,'hello','nice',NULL,'world') |
+-----+
| hello |
+-----+

SELECT QUOTE(MAKE_SET(0,'a','b','c'));
+-----+
| QUOTE(MAKE_SET(0,'a','b','c')) |
+-----+
| '' |
+-----+

```

## 1.1.12.2.33 MATCH AGAINST

### Syntax

```
MATCH (col1,col2,...) AGAINST (expr [search_modifier])
```

### Description

A special construct used to perform a fulltext search on a fulltext index.

See [Fulltext Index Overview](#) for a full description, and [Full-text Indexes](#) for more articles on the topic.

### Examples

```

CREATE TABLE ft_myisam(copy TEXT,FULLTEXT(copy)) ENGINE=MyISAM;

INSERT INTO ft_myisam(copy) VALUES ('Once upon a time'), ('There was a wicked witch'),
('Who ate everybody up');

SELECT * FROM ft_myisam WHERE MATCH(copy) AGAINST('wicked');
+-----+
| copy |
+-----+
| There was a wicked witch |
+-----+

```

```

SELECT id, body, MATCH (title,body) AGAINST
('Security implications of running MySQL as root'
IN NATURAL LANGUAGE MODE) AS score
FROM articles WHERE MATCH (title,body) AGAINST
('Security implications of running MySQL as root'
IN NATURAL LANGUAGE MODE);
+-----+-----+
| id | body | score |
+-----+-----+
| 4 | 1. Never run mysqld as root. 2. ... | 1.5219271183014 |
| 6 | When configured properly, MySQL ... | 1.3114095926285 |
+-----+-----+

```

## 1.1.12.2.34 Full-Text Index Stopwords

## Contents

1. MyISAM Stopwords
2. InnoDB Stopwords

Stopwords are used to provide a list of commonly-used words that can be ignored for the purposes of [Full-text-indexes](#).

Full-text indexes built in [MyISAM](#) and [InnoDB](#) have different stopword lists by default.

## MyISAM Stopwords

For full-text indexes on MyISAM tables, by default, the list is built from the file

`storage/myisam/ft_static.c`

, and searched using the server's character set and collation. The [ft\\_stopword\\_file](#) system variable allows the default list to be overridden with words from another file, or for stopwords to be ignored altogether.

If the stopword list is changed, any existing full-text indexes need to be rebuilt

The following table shows the default list of stopwords, although you should always treat

`storage/myisam/ft_static.c`

as the definitive list. See the [Fulltext Index Overview](#) for more details, and [Full-text-indexes](#) for related articles.

## InnoDB Stopwords

Stopwords on full-text indexes are only enabled if the `innodb_ft_enable_stopword` system variable is set (by default it is) at the time the index was created.

The stopword list is determined as follows:

- If the `innodb_ft_user_stopword_table` system variable is set, that table is used as a stopword list.
- If
  - `innodb_ft_user_stopword_table` is not set, the table set by `innodb_ft_server_stopword_table` is used.
- If neither variable is set, the built-in list is used, which can be viewed by querying the `INNODB_FT_DEFAULT_STOPWORD` table in the `Information Schema`.

In the first two cases, the specified table must exist at the time the system variable is set and the full-text index created. It must be an InnoDB table with a single column, a `VARCHAR` named `VALUE`.

The default InnoDB stopword list differs from the default MyISAM list, being much shorter, and contains the following words:

a	about	an	are
as	at	be	by
com	de	en	for
from	how	i	in
is	it	la	of
on	or	that	the
this	to	was	what
when	where	who	will
with	und	the	www

## 1.1.12.2.35 MID

### Syntax

```
MID(str,pos,len)
```

### Description

`MID(str,pos,len)` is a synonym for `SUBSTRING(str,pos,len)`.

### Examples

```
SELECT MID('abcd',4,1);
+-----+
| MID('abcd',4,1) |
+-----+
| d               |
+-----+

SELECT MID('abcd',2,2);
+-----+
| MID('abcd',2,2) |
+-----+
| bc              |
+-----+
```

A negative starting position:

```
SELECT MID('abcd',-2,4);
+-----+
| MID('abcd',-2,4) |
+-----+
| cd              |
+-----+
```

## 1.1.12.2.36 NOT LIKE

### Syntax

```
expr NOT LIKE pat [ESCAPE 'escape_char']
```

### Description

This is the same as [NOT \(expr LIKE pat \[ESCAPE 'escape\\_char'\]\)](#).

## 1.1.12.2.37 NOT REGEXP

## 1.1.12.2.38 OCTET\_LENGTH

### Syntax

```
OCTET_LENGTH(str)
```

### Description

`OCTET_LENGTH()`

returns the length of the given string, in octets (bytes). This is a synonym for [LENGTHB\(\)](#), and, when [Oracle mode](#) from [MariaDB 10.3](#) is not set, a synonym for [LENGTH\(\)](#).

A multi-byte character counts as multiple bytes. This means that for a string containing five two-byte characters,

`OCTET_LENGTH()`

returns 10, whereas [CHAR\\_LENGTH\(\)](#) returns 5.

If

str

is not a string value, it is converted into a string. If

str

is

NULL

, the function returns

NULL

## Examples

When Oracle mode from MariaDB 10.3 is not set:

```
SELECT CHAR_LENGTH('π'), LENGTH('π'), LENGTHB('π'), OCTET_LENGTH('π');
+-----+-----+-----+
| CHAR_LENGTH('π') | LENGTH('π') | LENGTHB('π') | OCTET_LENGTH('π') |
+-----+-----+-----+
|          1 |         2 |         2 |         2 |
+-----+-----+
```

In Oracle mode from MariaDB 10.3 :

```
SELECT CHAR_LENGTH('π'), LENGTH('π'), LENGTHB('π'), OCTET_LENGTH('π');
+-----+-----+-----+
| CHAR_LENGTH('π') | LENGTH('π') | LENGTHB('π') | OCTET_LENGTH('π') |
+-----+-----+-----+
|          1 |         1 |         2 |         2 |
+-----+-----+
```

## See Also

- [CHAR\\_LENGTH\(\)](#)
- [LENGTH\(\)](#)
- [LENGTHB\(\)](#)
- Oracle mode from MariaDB 10.3

## 1.1.12.2.39 ORD

### Syntax

```
ORD(str)
```

### Description

If the leftmost character of the string

str

is a multi-byte character, returns the code for that character, calculated from the numeric values of its constituent bytes using this formula:

```
(1st byte code)
+ (2nd byte code x 256)
+ (3rd byte code x 256 x 256) ...
```

If the leftmost character is not a multi-byte character, ORD() returns the same value as the [ASCII\(\)](#) function.

### Examples

```
SELECT ORD('2');
+-----+
| ORD('2') |
+-----+
|      50 |
+-----+
```

## See Also

- [ASCII\(\)](#) - Return ASCII value of first character
- [CHAR\(\)](#) - Create a character from an integer value

## 1.1.12.2.40 POSITION

### Syntax

```
POSITION(substr IN str)
```

## Description

POSITION(substr IN str) is a synonym for LOCATE(substr,str).

It's part of ODBC 3.0.

### 1.1.12.2.41 QUOTE

#### Syntax

```
QUOTE(str)
```

#### Description

Quotes a string to produce a result that can be used as a properly escaped data value in an SQL statement. The string is returned enclosed by single quotes and with each instance of single quote ("

"), backslash ("\\"), ASCII NUL , and Control-Z preceded by a backslash. If the argument is NULL , the return value is the word "NULL" without enclosing single quotes.

#### Examples

```
SELECT QUOTE("Don't!");
+-----+
| QUOTE("Don't!") |
+-----+
| 'Don\''t!' |
+-----+
SELECT QUOTE(NULL);
+-----+
| QUOTE(NULL) |
+-----+
| NULL |
+-----+
```

### 1.1.12.2.42 QUOTE\_IDENTIFIER

#### Syntax

```
SYS.QUOTE_IDENTIFIER(str)
```

#### Description

Quotes a string to produce a result that can be used as an identifier in an SQL statement. The string is returned enclosed by backticks (`

`) and with each instance of backtick (`") doubled. If the argument is NULL , the return value is the word "NULL" without enclosing backticks.

#### Examples

```
SELECT SYS.QUOTE_IDENTIFIER("Identifier with spaces");
+-----+
| SYS.QUOTE_IDENTIFIER("Identifier with spaces") |
+-----+
| `Identifier with spaces` |
+-----+  
  
SELECT SYS.QUOTE_IDENTIFIER("Identifier` containing `backticks");
+-----+
| SYS.QUOTE_IDENTIFIER("Identifier` containing `backticks") |
+-----+
| `Identifier`` containing ``backticks` |
+-----+
```

## 1.1.12.2.43 REPEAT Function

### Syntax

```
REPEAT(str,count)
```

### Description

Returns a string consisting of the string

str  
repeated  
count  
times. If  
count  
is less than 1, returns an empty string. Returns NULL if  
str  
or  
count  
are NULL.

### Examples

```
SELECT QUOTE(REPEAT('MariaDB ',4));
+-----+
| QUOTE(REPEAT('MariaDB ',4)) |
+-----+
| 'MariaDB MariaDB MariaDB MariaDB ' |
+-----+
```

## 1.1.12.2.44 REPLACE Function

### Syntax

```
REPLACE(str,from_str,to_str)
```

### Description

Returns the string

str  
with all occurrences of the string  
from\_str  
replaced by the string  
to\_str  
. REPLACE() performs a case-sensitive match when searching for  
from\_str

### Examples

```
SELECT REPLACE('www.mariadb.org', 'w', 'Ww');
+-----+
| REPLACE('www.mariadb.org', 'w', 'Ww') |
+-----+
| WwWwWw.mariadb.org           |
+-----+
```

## 1.1.12.2.45 REVERSE

### Syntax

```
REVERSE(str)
```

### Description

Returns the string

*str*

with the order of the characters reversed.

### Examples

```
SELECT REVERSE('desserts');
+-----+
| REVERSE('desserts') |
+-----+
| stressed            |
+-----+
```

## 1.1.12.2.46 RIGHT

### Syntax

```
RIGHT(str,len)
```

### Description

Returns the rightmost

*Len*

characters from the string

*str*

, or NULL if any argument is NULL.

### Examples

```
SELECT RIGHT('MariaDB', 2);
+-----+
| RIGHT('MariaDB', 2) |
+-----+
| DB                 |
+-----+
```

## 1.1.12.2.47 RPAD

### Syntax

```
RPAD(str, len [, padstr])
```

## Contents

1. [Syntax](#)
2. [Description](#)
3. [Examples](#)
4. [See Also](#)

## Description

Returns the string

```
str
, right-padded with the string
padstr
to a length of
len
characters. If
str
is longer than
len
, the return value is shortened to
len
characters. If
padstr
is omitted, the RPAD function pads spaces.
```

Prior to [MariaDB 10.3.1](#), the

```
padstr
parameter was mandatory.
```

Returns NULL if given a NULL argument. If the result is empty (a length of zero), returns either an empty string, or, from [MariaDB 10.3.6](#) with [SQL\\_MODE=Oracle](#), NULL.

The Oracle mode version of the function can be accessed outside of Oracle mode by using

```
RPAD_ORACLE
as the function name.
```

## Examples

```
SELECT RPAD('hello',10,'.');
+-----+
| RPAD('hello',10,'.') |
+-----+
| hello..... |
+-----+

SELECT RPAD('hello',2,'.');
+-----+
| RPAD('hello',2,'.') |
+-----+
| he |
+-----+
```

From [MariaDB 10.3.1](#), with the pad string defaulting to space.

```
SELECT RPAD('hello',30);
+-----+
| RPAD('hello',30) |
+-----+
| hello |
+-----+
```

Oracle mode version from [MariaDB 10.3.6](#):

```
SELECT RPAD('',0),RPAD_ORACLE('',0);
+-----+
| RPAD('',0) | RPAD_ORACLE('',0) |
+-----+
|          | NULL           |
+-----+
```

## See Also

- [LPAD](#) - Left-padding instead of right-padding.

## 1.1.12.2.48 RTRIM

### Syntax

```
RTRIM(str)
```

#### Contents

1. [Syntax](#)
2. [Description](#)
3. [Examples](#)
4. [See Also](#)

### Description

Returns the string

```
str
with trailing space characters removed.
```

Returns NULL if given a NULL argument. If the result is empty, returns either an empty string, or, from [MariaDB 10.3.6](#) with `SQL_MODE=Oracle`, NULL.

The Oracle mode version of the function can be accessed outside of Oracle mode by using

```
RTRIM_ORACLE
as the function name.
```

### Examples

```
SELECT QUOTE(RTRIM('MariaDB    '));
+-----+
| QUOTE(RTRIM('MariaDB    ')) |
+-----+
| 'MariaDB'                   |
+-----+
```

Oracle mode version from [MariaDB 10.3.6](#):

```
SELECT RTRIM(''),RTRIM_ORACLE('');
+-----+
| RTRIM('') | RTRIM_ORACLE('') |
+-----+
|        | NULL           |
+-----+
```

### See Also

- [LTRIM](#) - leading spaces removed
- [TRIM](#) - removes all given prefixes or suffixes

## 1.1.12.2.49 SFORMAT

MariaDB starting with [10.7.0](#)

SFORMAT was added in [MariaDB 10.7.0](#).

### Description

The

```
SFORMAT
```

function takes an input string and a formatting specification and returns the string formatted using the rules the user passed in the specification.

It uses the [fmtlib library](#) for Python-like (as well as Rust, C++20, etc) string formatting.

Only fmtlib 7.0.0+ is supported.

There is no native support for temporal and decimal values:

- TIME\_RESULT is handled as STRING\_RESULT

- DECIMAL\_RESULT as REAL\_RESULT

## Examples

```

SELECT SFORMAT("The answer is {}.", 42);
+-----+
| SFORMAT("The answer is {}.", 42) |
+-----+
| The answer is 42.                |
+-----+

CREATE TABLE test_sformat(mdb_release char(6), mdev int, feature char(20));

INSERT INTO test_sformat VALUES('10.7.0', 25015, 'Python style sformat'),
 ('10.7.0', 4958, 'UUID');

SELECT * FROM test_sformat;
+-----+-----+
| mdb_release | mdev   | feature      |
+-----+-----+
| 10.7.0     | 25015  | Python style sformat |
| 10.7.0     | 4958   | UUID          |
+-----+-----+

SELECT SFORMAT('MariaDB Server {} has a preview for MDEV-{} which is about {}',
    mdb_release, mdev, feature) AS 'Preview Release Examples'
FROM test_sformat;
+-----+
| Preview Release Examples           |
+-----+
| MariaDB Server 10.7.0 has a preview for MDEV-25015 which is about Python style sformat |
| MariaDB Server 10.7.0 has a preview for MDEV-4958 which is about UUID                      |
+-----+

```

## See Also

- [10.7 preview feature: Python-like string formatting](#)

## 1.1.12.2.50 SOUNDEx

### Syntax

`SOUNDEx(str)`

### Description

Returns a soundex string from

`str`  
 . Two strings that sound almost the same should have identical soundex strings. A standard soundex string is four characters long, but the `SOUNDEx()` function returns an arbitrarily long string. You can use `SUBSTRING()` on the result to get a standard soundex string. All non-alphabetic characters in `str` are ignored. All international alphabetic characters outside the A-Z range are treated as vowels.

**Important:** When using `SOUNDEx()`, you should be aware of the following details:

- This function, as currently implemented, is intended to work well with strings that are in the English language only. Strings in other languages may not produce reasonable results.
- This function implements the original Soundex algorithm, not the more popular enhanced version (also described by D. Knuth). The difference is that original version discards vowels first and duplicates second, whereas the enhanced version discards duplicates first and vowels second.

## Examples

```
SOUNDEX('Hello');
+-----+
| SOUNDEX('Hello') |
+-----+
| H400           |
+-----+
```

```
SELECT SOUNDEX('MariaDB');
+-----+
| SOUNDEX('MariaDB') |
+-----+
| M631           |
+-----+
```

```
SELECT SOUNDEX('Knowledgebase');
+-----+
| SOUNDEX('Knowledgebase') |
+-----+
| K543212          |
+-----+
```

```
SELECT givenname, surname FROM users WHERE SOUNDEX(givenname) = SOUNDEX("robert");
+-----+-----+
| givenname | surname |
+-----+-----+
| Roberto   | Castro  |
+-----+-----+
```

## See Also

- [SOUNDS LIKE \(\)](#)

## 1.1.12.2.51 SOUNDS LIKE

### Syntax

```
expr1 SOUNDS LIKE expr2
```

### Description

This is the same as

```
SOUNDEX
```

```
(expr1) = SOUNDEX(expr2)
```

### Example

```
SELECT givenname, surname FROM users WHERE givenname SOUNDS LIKE "robert";
+-----+-----+
| givenname | surname |
+-----+-----+
| Roberto   | Castro  |
+-----+-----+
```

## 1.1.12.2.52 SPACE

### Syntax

```
SPACE(N)
```

## Description

Returns a string consisting of

$N$   
space characters. If  
 $N$   
is NULL, returns NULL.

## Examples

```
SELECT QUOTE(SPACE(6));  
+-----+  
| QUOTE(SPACE(6)) |  
+-----+  
| ' ' ' ' ' ' '|  
+-----+
```

## 1.1.12.2.53 STRCMP

### Syntax

```
STRCMP(expr1,expr2)
```

### Description

STRCMP()  
returns  
0  
if the strings are the same,  
-1  
if the first argument is smaller than the second according to the current sort order, and  
1  
if the strings are otherwise not the same. Returns  
NULL  
is either argument is  
NULL  
.

## Examples

```
SELECT STRCMP('text', 'text2');  
+-----+  
| STRCMP('text', 'text2') |  
+-----+  
| -1 |  
+-----+  
  
SELECT STRCMP('text2', 'text');  
+-----+  
| STRCMP('text2', 'text') |  
+-----+  
| 1 |  
+-----+  
  
SELECT STRCMP('text', 'text');  
+-----+  
| STRCMP('text', 'text') |  
+-----+  
| 0 |  
+-----+
```

## 1.1.12.2.54 SUBSTR

# Description

SUBSTR()  
is a synonym for

[SUBSTRING](#)

()

## 1.1.12.2.55 SUBSTRING

### Syntax

```
SUBSTRING(str,pos),  
SUBSTRING(str FROM pos),  
SUBSTRING(str,pos,len),  
SUBSTRING(str FROM pos FOR len)  
  
SUBSTR(str,pos),  
SUBSTR(str FROM pos),  
SUBSTR(str,pos,len),  
SUBSTR(str FROM pos FOR len)
```

### Contents

1. [Syntax](#)
2. [Description](#)
3. [Examples](#)
4. [See Also](#)

### Description

The forms without a

*Len*  
argument return a substring from string  
*str*  
starting at position  
*pos*

The forms with a

*Len*  
argument return a substring  
*Len*  
characters long from string  
*str*  
, starting at position  
*pos*

The forms that use

*FROM*  
are standard SQL syntax.

It is also possible to use a negative value for

*pos*  
. In this case, the beginning of the substring is  
*pos*  
characters from the end of the string, rather than the beginning. A negative value may be used for  
*pos*  
in any of the forms of this function.

By default, the position of the first character in the string from which the substring is to be extracted is reckoned as 1. For [Oracle-compatibility](#) , from [MariaDB 10.3.3](#) , when `sql_mode` is set to 'oracle', position zero is treated as position 1 (although the first character is still reckoned as 1).

If any argument is

NULL  
, returns  
NULL

## Examples

```
SELECT SUBSTRING('Knowledgebase',5);
+-----+
| SUBSTRING('Knowledgebase',5) |
+-----+
| ledgebase                   |
+-----+

SELECT SUBSTRING('MariaDB' FROM 6);
+-----+
| SUBSTRING('MariaDB' FROM 6) |
+-----+
| DB                           |
+-----+

SELECT SUBSTRING('Knowledgebase',3,7);
+-----+
| SUBSTRING('Knowledgebase',3,7) |
+-----+
| owledge                      |
+-----+

SELECT SUBSTRING('Knowledgebase', -4);
+-----+
| SUBSTRING('Knowledgebase', -4) |
+-----+
| base                         |
+-----+

SELECT SUBSTRING('Knowledgebase', -8, 4);
+-----+
| SUBSTRING('Knowledgebase', -8, 4) |
+-----+
| edge                          |
+-----+

SELECT SUBSTRING('Knowledgebase' FROM -8 FOR 4);
+-----+
| SUBSTRING('Knowledgebase' FROM -8 FOR 4) |
+-----+
| edge                         |
+-----+
```

Oracle mode from MariaDB 10.3.3 :

```

SELECT SUBSTR('abc',0,3);
+-----+
| SUBSTR('abc',0,3) |
+-----+
|      |
+-----+

SELECT SUBSTR('abc',1,2);
+-----+
| SUBSTR('abc',1,2) |
+-----+
| ab            |
+-----+

SET sql_mode='oracle';

SELECT SUBSTR('abc',0,3);
+-----+
| SUBSTR('abc',0,3) |
+-----+
| abc           |
+-----+

SELECT SUBSTR('abc',1,2);
+-----+
| SUBSTR('abc',1,2) |
+-----+
| ab            |
+-----+

```

## See Also

- [INSTR\(\)](#) - Returns the position of a string within a string
- [LOCATE\(\)](#) - Returns the position of a string within a string
- [SUBSTRING\\_INDEX\(\)](#) - Returns a string based on substring

## 1.1.12.2.56 SUBSTRING\_INDEX

### Syntax

```
SUBSTRING_INDEX(str,delim,count)
```

### Contents

1. [Syntax](#)
2. [Description](#)
3. [Examples](#)
4. [See Also](#)

### Description

Returns the substring from string

str  
before count occurrences of the delimiter  
delim  
. If  
count  
is positive, everything to the left of the final delimiter (counting from the left) is returned. If  
count  
is negative, everything to the right of the final delimiter (counting from the right) is returned.  
SUBSTRING\_INDEX()  
performs a case-sensitive match when searching for  
delim

If any argument is

NULL  
, returns  
NULL

For example

```
SUBSTRING_INDEX('www.mariadb.org', '.', 2)
```

means "Return all of the characters up to the 2nd occurrence of ."

## Examples

```
SELECT SUBSTRING_INDEX('www.mariadb.org', '.', 2);
+-----+
| SUBSTRING_INDEX('www.mariadb.org', '.', 2) |
+-----+
| www.mariadb                         |
+-----+

SELECT SUBSTRING_INDEX('www.mariadb.org', '.', -2);
+-----+
| SUBSTRING_INDEX('www.mariadb.org', '.', -2) |
+-----+
| mariadb.org                          |
+-----+
```

## See Also

- [INSTR\(\)](#) - Returns the position of a string within a string
- [LOCATE\(\)](#) - Returns the position of a string within a string
- [SUBSTRING\(\)](#) - Returns a string based on position

## 1.1.12.2.57 TO\_BASE64

### Syntax

```
TO_BASE64(str)
```

### Description

Converts the string argument

str

to its base-64 encoded form, returning the result as a character string in the connection character set and collation.

The argument

str

will be converted to string first if it is not a string. A NULL argument will return a NULL result.

The reverse function, [FROM\\_BASE64\(\)](#), decodes an encoded base-64 string.

There are a numerous different methods to base-64 encode a string. The following are used by MariaDB and MySQL:

- Alphabet value 64 is encoded as '+'.
- Alphabet value 63 is encoded as '/'.
- Encoding output is made up of groups of four printable characters, with each three bytes of data encoded using four characters. If the final group is not complete, it is padded with '=' characters to make up a length of four.
- To divide long output, a newline is added after every 76 characters.
- Decoding will recognize and ignore newlines, carriage returns, tabs, and spaces.

## Examples

```
SELECT TO_BASE64('Maria');
+-----+
| TO_BASE64('Maria') |
+-----+
| TWFyaWE=          |
+-----+
```

## 1.1.12.2.58 TO\_CHAR

MariaDB starting with 10.6.1

The TO\_CHAR function was introduced in MariaDB 10.6.1 to enhance Oracle compatibility.

## Syntax

```
TO_CHAR(expr[, fmt])
```

### Contents

1. [Syntax](#)
2. [Description](#)
3. [Examples](#)
4. [See Also](#)

## Description

The

TO\_CHAR

function converts an *expr* of type `date`, `datetime`, `time` or `timestamp` to a string. The optional *fmt* argument supports `YYYY/YYYY/YY/RRRR/RR/MM/MON/MONTH/MI/DD/DY/HH/HH12/HH24/SS` and special characters. The default value is "YYYY-MM-DD HH24:MI:SS".

In Oracle, TO\_CHAR can also be used to convert numbers to strings, but this is not supported in MariaDB and will give an error.

## Examples

```
SELECT TO_CHAR('1980-01-11 04:50:39', 'YYYY-MM-DD');
+-----+
| TO_CHAR('1980-01-11 04:50:39', 'YYYY-MM-DD') |
+-----+
| 1980-01-11 |
+-----+  
  
SELECT TO_CHAR('1980-01-11 04:50:39', 'HH24-MI-SS');
+-----+
| TO_CHAR('1980-01-11 04:50:39', 'HH24-MI-SS') |
+-----+
| 04-50-39 |
+-----+  
  
SELECT TO_CHAR('00-01-01 00:00:00', 'YY-MM-DD HH24:MI:SS');
+-----+
| TO_CHAR('00-01-01 00:00:00', 'YY-MM-DD HH24:MI:SS') |
+-----+
| 00-01-01 00:00:00 |
+-----+  
  
SELECT TO_CHAR('99-12-31 23:59:59', 'YY-MM-DD HH24:MI:SS');
+-----+
| TO_CHAR('99-12-31 23:59:59', 'YY-MM-DD HH24:MI:SS') |
+-----+
| 99-12-31 23:59:59 |
+-----+  
  
SELECT TO_CHAR('9999-12-31 23:59:59', 'YY-MM-DD HH24:MI:SS');
+-----+
| TO_CHAR('9999-12-31 23:59:59', 'YY-MM-DD HH24:MI:SS') |
+-----+
| 99-12-31 23:59:59 |
+-----+  
  
SELECT TO_CHAR('21-01-03 08:30:00', 'Y-MONTH-DY HH:MI:SS');
+-----+
| TO_CHAR('21-01-03 08:30:00', 'Y-MONTH-DY HH:MI:SS') |
+-----+
| 1-January -Sun 08:30:00 |
+-----+
```

## See Also

- [SQL\\_MODE=ORACLE](#)

## 1.1.12.2.59 TRIM

### Syntax

```
TRIM([{BOTH | LEADING | TRAILING} [remstr] FROM] str), TRIM([remstr FROM] str)
```

From [MariaDB 10.3.6](#)

```
TRIM_ORACLE([{BOTH | LEADING | TRAILING} [remstr] FROM] str), TRIM([remstr FROM] str)
```

### Contents

1. [Syntax](#)
2. [Description](#)
3. [Examples](#)
4. [See Also](#)

### Description

Returns the string

str  
with all  
remstr  
prefixes or suffixes removed. If none of the specifiers  
BOTH  
,

LEADING  
, or  
TRAILING  
is given,  
BOTH  
is assumed.  
remstr  
is optional and, if not specified, spaces are removed.

Returns NULL if given a NULL argument. If the result is empty, returns either an empty string, or, from [MariaDB 10.3.6](#) with [SQL\\_MODE=Oracle](#), NULL.

[SQL\\_MODE=Oracle](#)  
is not set by default.

The Oracle mode version of the function can be accessed in any mode by using

TRIM\_ORACLE  
as the function name.

### Examples

```
SELECT TRIM(' bar ')\\G
***** 1. row *****
TRIM(' bar '): bar

SELECT TRIM(LEADING 'x' FROM 'xxxbarxxx')\\G
***** 1. row *****
TRIM(LEADING 'x' FROM 'xxxbarxxx'): barxxx

SELECT TRIM(BOTH 'x' FROM 'xxxbarxxx')\\G
***** 1. row *****
TRIM(BOTH 'x' FROM 'xxxbarxxx'): bar

SELECT TRIM(TRAILING 'xyz' FROM 'barxyz')\\G
***** 1. row *****
TRIM(TRAILING 'xyz' FROM 'barxyz'): barx
```

From [MariaDB 10.3.6](#), with [SQL\\_MODE=Oracle](#) not set:

```
SELECT TRIM(''),TRIM_ORACLE('');
+-----+-----+
| TRIM('') | TRIM_ORACLE('') |
+-----+-----+
|       | NULL           |
+-----+-----+
```

From MariaDB 10.3.6 , with SQL\_MODE=Oracle set:

```
SELECT TRIM(''),TRIM_ORACLE('');
+-----+-----+
| TRIM('') | TRIM_ORACLE('') |
+-----+-----+
| NULL     | NULL           |
+-----+-----+
```

## See Also

- [LTRIM](#) - leading spaces removed
- [RTRIM](#) - trailing spaces removed

## 1.1.12.2.60 TRIM\_ORACLE

MariaDB starting with 10.3.6

TRIM\_ORACLE  
is a synonym for the [Oracle mode](#) version of the [TRIM function](#) , and is available in all modes.

## 1.1.12.2.61 UCASE

### Syntax

```
UCASE(str)
```

### Description

UCASE()  
is a synonym for

UPPER

()

## 1.1.12.2.62 UNCOMPRESS

### Syntax

```
UNCOMPRESS(string_to_uncompress)
```

### Description

Uncompresses a string compressed by the

[COMPRESS\(\)](#)

function. If the argument is not a compressed value, the result is

NULL

. This function requires MariaDB to have been compiled with a compression library such as zlib. Otherwise, the return value is always

NULL

. The [have\\_compress](#) server system variable indicates whether a compression library is present.

## Examples

```
SELECT UNCOMPRESS(COMPRESS('a string'));
+-----+
| UNCOMPRESS(COMPRESS('a string')) |
+-----+
| a string                         |
+-----+  
  
SELECT UNCOMPRESS('a string');
+-----+
| UNCOMPRESS('a string') |
+-----+
| NULL                      |
+-----+
```

## 1.1.12.2.63 UNCOMPRESSED\_LENGTH

### Syntax

```
UNCOMPRESSED_LENGTH(compressed_string)
```

### Description

Returns the length that the compressed string had before being compressed with

[COMPRESS\(\)](#)

UNCOMPRESSED\_LENGTH()  
returns  
NULL  
or an incorrect result if the string is not compressed.

Until [MariaDB 10.3.1](#) , returns

MySQL\_Type\_LONGLONG  
, or [bigint\(10\)](#) , in all cases. From [MariaDB 10.3.1](#) , returns  
MySQL\_Type\_LONG  
, or [int\(10\)](#) , when the result would fit within 32-bits.

## Examples

```
SELECT UNCOMPRESSED_LENGTH(COMPRESS(REPEAT('a',30)));
+-----+
| UNCOMPRESSED_LENGTH(COMPRESS(REPEAT('a',30))) |
+-----+
|                                         30 |
+-----+
```

## 1.1.12.2.64 UNHEX

### Syntax

```
UNHEX(str)
```

### Description

Performs the inverse operation of [HEX](#) (str). That is, it interprets each pair of hexadecimal digits in the argument as a number and converts it to the character represented by the number. The resulting characters are returned as a binary string.

If  
str

```
is  
NULL  
,  
UNHEX()  
returns  
NULL
```

## Examples

```
SELECT HEX('MariaDB');  
+-----+  
| HEX('MariaDB') |  
+-----+  
| 4D617269614442 |  
+-----+  
  
SELECT UNHEX('4D617269614442');  
+-----+  
| UNHEX('4D617269614442') |  
+-----+  
| MariaDB |  
+-----+  
  
SELECT 0x4D617269614442;  
+-----+  
| 0x4D617269614442 |  
+-----+  
| MariaDB |  
+-----+  
  
SELECT UNHEX(HEX('string'));  
+-----+  
| UNHEX(HEX('string')) |  
+-----+  
| string |  
+-----+  
  
SELECT HEX(UNHEX('1267'));  
+-----+  
| HEX(UNHEX('1267')) |  
+-----+  
| 1267 |  
+-----+
```

## See Also

- [Hexadecimal literals](#)
- [HEX\(\)](#)
- [CONV\(\)](#)

## 1.1.12.2.65 UPDATEXML

### Syntax

```
UpdateXML(xml_target, xpath_expr, new_xml)
```

### Description

This function replaces a single portion of a given fragment of XML markup

xml\_target  
with a new XML fragment  
new\_xml  
, and then returns the changed XML. The portion of  
xml\_target  
that is replaced matches an XPath expression  
xpath\_expr  
supplied by the user. If no expression matching

`xpath_expr`  
is found, or if multiple matches are found, the function returns the original  
`xml_target`  
XML fragment. All three arguments should be strings.

## Examples

```
SELECT
    UpdateXML('<a><b>ccc</b><d></d></a>', '/a', '<e>fff</e>') AS val1,
    UpdateXML('<a><b>ccc</b><d></d></a>', '/b', '<e>fff</e>') AS val2,
    UpdateXML('<a><b>ccc</b><d></d></a>', '//b', '<e>fff</e>') AS val3,
    UpdateXML('<a><b>ccc</b><d></d></a>', '/a/d', '<e>fff</e>') AS val4,
    UpdateXML('<a><d></d><b>ccc</b><d></d></a>', '/a/d', '<e>fff</e>') AS val5
    G
*****
1. row ****
val1: <e>fff</e>
val2: <a><b>ccc</b><d></d></a>
val3: <a><e>fff</e><d></d></a>
val4: <a><b>ccc</b><e>fff</e></a>
val5: <a><d></d><b>ccc</b><d></d></a>
1 row in set (0.00 sec)
```

## 1.1.12.2.66 UPPER

### Syntax

```
UPPER(str)
```

### Description

Returns the string

`str`

with all characters changed to uppercase according to the current character set mapping. The default is latin1 (cp1252 West European).

```
SELECT UPPER(surname), givenname FROM users ORDER BY surname;
+-----+-----+
| UPPER(surname) | givenname |
+-----+-----+
| ABEL          | Jacinto    |
| CASTRO        | Robert     |
| COSTA         | Phestos   |
| MOSCHELLA    | Hippolytos|
+-----+-----+
```

`UPPER()`

is ineffective when applied to binary strings (

`BINARY`

,

`VARBINARY`

,

`BLOB`

). The description of

`LOWER`

( )

shows how to perform lettercase conversion of binary strings.

## 1.1.12.2.67 WEIGHT\_STRING

# Syntax

```
WEIGHT_STRING(str [AS {CHAR|BINARY}(N)] [LEVEL levels] [flags])
  levels: N [ASC|DESC|REVERSE] [, N [ASC|DESC|REVERSE]] ...
```

## Description

Returns a binary string representing the string's sorting and comparison value. A string with a lower result means that for sorting purposes the string appears before a string with a higher result.

`WEIGHT_STRING()` is particularly useful when adding new collations, for testing purposes.

If

str

is a non-binary string ( `CHAR` , `VARCHAR` or `TEXT` ), `WEIGHT_STRING` returns the string's collation weight. If str

is a binary string ( `BINARY` , `VARBINARY` or `BLOB` ), the return value is simply the input value, since the weight for each byte in a binary string is the byte value.

`WEIGHT_STRING()` returns NULL if given a NULL input.

The optional AS clause permits casting the input string to a binary or non-binary string, as well as to a particular length.

AS BINARY(N) measures the length in bytes rather than characters, and right pads with 0x00 bytes to the desired length.

AS CHAR(N) measures the length in characters, and right pads with spaces to the desired length.

N has a minimum value of 1, and if it is less than the length of the input string, the string is truncated without warning.

The optional LEVEL clause specifies that the return value should contain weights for specific collation levels. The

levels

specifier can either be a single integer, a comma-separated list of integers, or a range of integers separated by a dash (whitespace is ignored). Integers can range from 1 to a maximum of 6, dependent on the collation, and need to be listed in ascending order.

If the LEVEL clause is not provided, a default of 1 to the maximum for the collation is assumed.

If the LEVEL is specified without using a range, an optional modifier is permitted.

ASC

, the default, returns the weights without any modification.

DESC

returns bitwise-inverted weights.

REVERSE

returns the weights in reverse order.

## Examples

The examples below use the `HEX()` function to represent non-printable results in hexadecimal format.

```

SELECT HEX(WEIGHT_STRING('x'));
+-----+
| HEX(WEIGHT_STRING('x')) |
+-----+
| 0058 |
+-----+

SELECT HEX(WEIGHT_STRING('x' AS BINARY(4)));
+-----+
| HEX(WEIGHT_STRING('x' AS BINARY(4))) |
+-----+
| 78000000 |
+-----+

SELECT HEX(WEIGHT_STRING('x' AS CHAR(4)));
+-----+
| HEX(WEIGHT_STRING('x' AS CHAR(4))) |
+-----+
| 0058002000200020 |
+-----+

SELECT HEX(WEIGHT_STRING(0xaa22ee LEVEL 1));
+-----+
| HEX(WEIGHT_STRING(0xaa22ee LEVEL 1)) |
+-----+
| AA22EE |
+-----+

SELECT HEX(WEIGHT_STRING(0xaa22ee LEVEL 1 DESC));
+-----+
| HEX(WEIGHT_STRING(0xaa22ee LEVEL 1 DESC)) |
+-----+
| 55DD11 |
+-----+

SELECT HEX(WEIGHT_STRING(0xaa22ee LEVEL 1 REVERSE));
+-----+
| HEX(WEIGHT_STRING(0xaa22ee LEVEL 1 REVERSE)) |
+-----+
| EE22AA |
+-----+

```

## 1.1.12.2.68 Type Conversion

### Contents

- 1. Rules for Conversion on Comparison
  - 1. Comparison Examples
- 2. Rules for Conversion on Dyadic Arithmetic Operations
  - 1. Arithmetic Examples

Implicit type conversion takes place when MariaDB is using operands of different types, in order to make the operands compatible.

It is best practice not to rely upon implicit conversion; rather use [CAST](#) to explicitly convert types.

### Rules for Conversion on Comparison

- If either argument is NULL, the result of the comparison is NULL unless the NULL-safe `<=>` equality comparison operator is used.
- If both arguments are integers, they are compared as integers.
- If both arguments are strings, they are compared as strings.
- If one argument is decimal and the other argument is decimal or integer, they are compared as decimals.
- If one argument is decimal and the other argument is a floating point, they are compared as floating point values.
- If a hexadecimal argument is not compared to a number, it is treated as a binary string.
- If a constant is compared to a TIMESTAMP or DATETIME, the constant is converted to a timestamp, unless used as an argument to the IN function.
- In other cases, arguments are compared as floating point, or real, numbers.

Note that if a string column is being compared with a numeric value, MariaDB will not use the index on the column, as there are numerous alternatives that may evaluate as equal (see examples below).

### Comparison Examples

Converting a string to a number:

```
SELECT 15+'15';
+-----+
| 15+'15' |
+-----+
|      30 |
+-----+
```

Converting a number to a string:

```
SELECT CONCAT(15, '15');
+-----+
| CONCAT(15, '15') |
+-----+
| 1515             |
+-----+
```

Floating point number errors:

```
SELECT '9746718491924563214' = 9746718491924563213;
+-----+
| '9746718491924563214' = 9746718491924563213 |
+-----+
|                                         1 |
+-----+
```

Numeric equivalence with strings:

```
SELECT '5' = 5;
+-----+
| '5' = 5 |
+-----+
|      1 |
+-----+

SELECT ' 5' = 5;
+-----+
| ' 5' = 5 |
+-----+
|      1 |
+-----+

SELECT ' 5  ' = 5;
+-----+
| ' 5  ' = 5 |
+-----+
|      1 |
+-----+
1 row in set, 1 warning (0.000 sec)

SHOW WARNINGS;
+-----+-----+
| Level | Code | Message           |
+-----+-----+
| Note  | 1292 | Truncated incorrect DOUBLE value: ' 5  ' |
+-----+-----+
```

As a result of the above, MariaDB cannot use the index when comparing a string with a numeric value in the example below:

```

CREATE TABLE t (a VARCHAR(10), b VARCHAR(10), INDEX idx_a (a));

INSERT INTO t VALUES ('1', '1'), ('2', '2'), ('3', '3'), ('4', '4'), ('5', '5'), ('1', '5');

EXPLAIN SELECT * FROM t WHERE a = '3' 
***** 1. row *****
    id: 1
  select_type: SIMPLE
      table: t
        type: ref
possible_keys: idx_a
      key: idx_a
     key_len: 13
       ref: const
      rows: 1
  Extra: Using index condition

EXPLAIN SELECT * FROM t WHERE a = 3 
***** 1. row *****
    id: 1
  select_type: SIMPLE
      table: t
        type: ALL
possible_keys: idx_a
      key: NULL
     key_len: NULL
       ref: NULL
      rows: 6
  Extra: Using where

```

## Rules for Conversion on Dyadic Arithmetic Operations

Implicit type conversion also takes place on dyadic arithmetic operations ( `+` , `-` , `*` , `/` ). MariaDB chooses the minimum data type that is guaranteed to fit the result and converts both arguments to the result data type.

For [addition \(+\)](#) , [subtraction \(-\)](#) and [multiplication \(\\*\)](#) , the result data type is chosen as follows:

- If either of the arguments is an approximate number (float, double), the result is double.
- If either of the arguments is a string (char, varchar, text), the result is double.
- If either of the arguments is a decimal number, the result is decimal.
- If either of the arguments is of a temporal type with a non-zero fractional second precision (time(N), datetime(N), timestamp(N)), the result is decimal.
- If either of the arguments is of a temporal type with a zero fractional second precision (time(0), date, datetime(0), timestamp(0)), the result may vary between int, int unsigned, bigint or bigint unsigned, depending on the exact data type combination.
- If both arguments are integer numbers (tinyint, smallint, mediumint, bigint), the result may vary between int, int unsigned, bigint or bigint unsigned, depending of the exact data types and their signs.

For [division \(/\)](#) , the result data type is chosen as follows:

- If either of the arguments is an approximate number (float, double), the result is double.
- If either of the arguments is a string (char, varchar, text), the result is double.
- Otherwise, the result is decimal.

## Arithmetic Examples

Note, the above rules mean that when an argument of a temporal data type appears in addition or subtraction, it's treated as a number by default.

```

SELECT TIME'10:20:30' + 1;
+-----+
| TIME'10:20:30' + 1 |
+-----+
|      102031 |
+-----+

```

In order to do temporal addition or subtraction instead, use the [DATE\\_ADD\(\)](#) or [DATE\\_SUB\(\)](#) functions, or an [INTERVAL](#) expression as the second argument:

```

SELECT TIME'10:20:30' + INTERVAL 1 SECOND;
+-----+
| TIME'10:20:30' + INTERVAL 1 SECOND |
+-----+
| 10:20:31 |
+-----+

```

```

SELECT "2.2" + 3;
+-----+
| "2.2" + 3 |
+-----+
| 5.2 |
+-----+

SELECT 2.2 + 3;
+-----+
| 2.2 + 3 |
+-----+
| 5.2 |
+-----+

SELECT 2.2 / 3;
+-----+
| 2.2 / 3 |
+-----+
| 0.73333 |
+-----+

SELECT "2.2" / 3;
+-----+
| "2.2" / 3 |
+-----+
| 0.733333333333334 |
+-----+

```

## 1.1.12.3 Date and Time Functions

### 1.1.12.3.1 Microseconds in MariaDB

#### Contents

1. Additional Information
2. MySQL 5.6 Microseconds
3. See Also

The `TIME`, `DATETIME`, and `TIMESTAMP` types, along with the temporal functions, `CAST` and `dynamic columns`, support microseconds. The datetime precision of a column can be specified when creating the table with `CREATE TABLE`, for example:

```

CREATE TABLE example(
    col_microsec DATETIME(6),
    col_millisec TIME(3)
);

```

Generally, the precision can be specified for any

```

TIME
,
DATETIME
, or
TIMESTAMP

```

column, in parentheses, after the type name. The datetime precision specifies number of digits after the decimal dot and can be any integer number from 0 to 6. If no precision is specified it is assumed to be 0, for backward compatibility reasons.

A datetime precision can be specified wherever a type name is used. For example:

- when declaring arguments of stored routines.
- when specifying a return type of a stored function.
- when declaring variables.
- in a

```

CAST
function:

```

```

create function example(x datetime(5)) returns time(4)
begin
    declare y timestamp(6);
    return cast(x as time(2));
end;

```

`%f`

is used as the formatting option for microseconds in the `STR_TO_DATE`, `DATE_FORMAT` and `FROM_UNIXTIME` functions, for example:

```

SELECT STR_TO_DATE('20200809 020917076','%Y%m%d %H%i%s%f');
+-----+
| STR_TO_DATE('20200809 020917076','%Y%m%d %H%i%s%f') |
+-----+
| 2020-08-09 02:09:17.076000 |
+-----+

```

## Additional Information

- when comparing anything to a temporal value (

DATETIME  
,  
TIME  
,  
  
DATE  
  
, or  
TIMESTAMP

), both values are compared as temporal values, not as strings.

- The [INFORMATION\\_SCHEMA.COLUMNS table](#) has a new column

DATETIME\_PRECISION

- [NOW\(\)](#) , [CURTIME\(\)](#) , [UTC\\_TIMESTAMP\(\)](#) , [UTC\\_TIME\(\)](#) , [CURRENT\\_TIME\(\)](#) , [CURRENT\\_TIMESTAMP\(\)](#) , [LOCALTIME\(\)](#) and [LOCALTIMESTAMP\(\)](#) now accept datetime precision as an optional argument. For example:

```

SELECT CURTIME(4);
--> 10:11:12.3456

```

- [TIME\\_TO\\_SEC\(\)](#) and [UNIX\\_TIMESTAMP\(\)](#) preserve microseconds of the argument. These functions will return a [decimal](#) number if the result non-zero datetime precision and an [integer](#) otherwise (for backward compatibility).

```

SELECT TIME_TO_SEC('10:10:10.12345');
--> 36610.12345

```

- Current versions of this patch fix a bug in the following optimization: in certain queries with

DISTINCT

MariaDB can ignore this clause if it can prove that all result rows are unique anyway, for example, when a primary key is compared with a constant. Sometimes this optimization was applied incorrectly, though — for example, when comparing a string with a date constant. This is now fixed.

- 

DATE\_ADD()  
and  
DATE\_SUB()  
functions can now take a  
TIME  
expression as an argument (not just  
DATETIME  
as before).

```

SELECT TIME('10:10:10') + INTERVAL 100 MICROSECOND;
--> 10:10:10.000100

```

- The

event\_time  
field in the [mysql.general\\_log](#) table and the  
start\_time  
,  
query\_time  
, and  
lock\_time  
fields in the [mysql.slow\\_log](#) table now store values with microsecond precision.

- This patch fixed a bug when comparing a temporal value using the

BETWEEN  
operator and one of the operands is  
NULL

- The old syntax

TIMESTAMP(N)  
, where  
N

is the display width, is no longer supported. It was deprecated in MySQL 4.1.0 (released on 2003-04-03).

- when a

DATETIME  
value is compared to a  
TIME  
value, the latter is treated as a full datetime with a zero date part, similar to comparing  
DATE  
to a  
DATETIME  
, or to comparing  
DECIMAL

numbers. Earlier versions of MariaDB used to compare only the time part of both operands in such a case.

- In MariaDB, an extra column

TIME\_MS

has been added to the

INFORMATION\_SCHEMA.PROCESSLIST

table, as well as to the output of

SHOW FULL PROCESSLIST

**Note:** When you convert a temporal value to a value with a smaller precision, it will be truncated, not rounded. This is done to guarantee that the date part is not changed. For example:

```
SELECT CAST('2009-12-31 23:59:59.998877' as DATETIME(3));
-> 2009-12-31 23:59:59.998
```

## MySQL 5.6 Microseconds

MySQL 5.6 introduced microseconds using a slightly different implementation to [MariaDB 5.3](#). Since [MariaDB 10.1](#), MariaDB has defaulted to the MySQL format, by means of the `--mysql56-temporal-format` variable. The MySQL version requires slightly [more storage](#) but has some advantages in permitting the eventual support of negative dates, and in replication.

### See Also

- [Data Type Storage Requirements](#)

### 1.1.12.3.2 Date and Time Units

The

INTERVAL

keyword can be used to add or subtract a time interval of time to a

DATETIME

,

DATE

or

TIME

value.

The syntax is:

```
INTERVAL time_quantity time_unit
```

For example, the

SECOND

unit is used below by the

## DATE\_ADD()

function:

```
SELECT '2008-12-31 23:59:59' + INTERVAL 1 SECOND;
+-----+
| '2008-12-31 23:59:59' + INTERVAL 1 SECOND |
+-----+
| 2009-01-01 00:00:00 |
+-----+
```

The following units are valid:

Unit	Description
MICROSECOND	Microseconds
SECOND	Seconds
MINUTE	Minutes
HOUR	Hours
DAY	Days
WEEK	Weeks
MONTH	Months
QUARTER	Quarters
YEAR	Years
SECOND_MICROSECOND	Seconds.Microseconds
MINUTE_MICROSECOND	Minutes.Seconds.Microseconds
MINUTE_SECOND	Minutes.Seconds
HOUR_MICROSECOND	Hours.Minutes.Seconds.Microseconds
HOUR_SECOND	Hours.Minutes.Seconds
HOUR_MINUTE	Hours.Minutes
DAY_MICROSECOND	Days Hours.Minutes.Seconds.Microseconds

DAY_SECOND	Days Hours.Minutes.Seconds
DAY_MINUTE	Days Hours.Minutes
DAY_HOUR	Days Hours
YEAR_MONTH	Years-Months

The time units containing an underscore are composite; that is, they consist of multiple base time units. For base time units,

`time_quantity`

is an integer number. For composite units, the quantity must be expressed as a string with multiple integer numbers separated by any punctuation character.

Example of composite units:

```
INTERVAL '2:2' YEAR_MONTH
INTERVAL '1:30:30' HOUR_SECOND
INTERVAL '1!30!30' HOUR_SECOND -- same as above
```

Time units can be used in the following contexts:

- after a

`+`

or a

`-`

operator;

- with the following

`DATE`

or

`TIME`

functions:

`ADDDATE()`

`SUBDATE()`

`DATE_ADD()`

`DATE_SUB()`

`TIMESTAMPADD()`

`TIMESTAMPDIFF()`

`EXTRACT()`

`;`

- in the

`ON SCHEDULE`  
clause of

[CREATE EVENT](#)

and

[ALTER EVENT](#)

- when defining a [partitioning](#)  
BY SYSTEM\_TIME

### 1.1.12.3.3 ADD\_MONTHS

MariaDB starting with [10.6.1](#)

The ADD\_MONTHS function was introduced in [MariaDB 10.6.1](#) to enhance Oracle compatibility. Similar functionality can be achieved with the [DATE\\_ADD](#) function.

## Syntax

```
ADD_MONTHS(date, months)
```

### Contents

1. [Syntax](#)
2. [Description](#)
3. [Examples](#)
4. [See Also](#)

## Description

`ADD_MONTHS`

adds an integer *months* to a given *date* ([DATE](#), [DATETIME](#) or [TIMESTAMP](#)), returning the resulting date.

*months* can be positive or negative.

The resulting day component will remain the same as that specified in *date* , unless the resulting month has fewer days than the day component of the given date, in which case the day will be the last day of the resulting month.

Returns NULL if given an invalid date, or a NULL argument.

## Examples

```

SELECT ADD_MONTHS('2012-01-31', 2);
+-----+
| ADD_MONTHS('2012-01-31', 2) |
+-----+
| 2012-03-31 |
+-----+

SELECT ADD_MONTHS('2012-01-31', -5);
+-----+
| ADD_MONTHS('2012-01-31', -5) |
+-----+
| 2011-08-31 |
+-----+

SELECT ADD_MONTHS('2011-01-31', 1);
+-----+
| ADD_MONTHS('2011-01-31', 1) |
+-----+
| 2011-02-28 |
+-----+

SELECT ADD_MONTHS('2012-01-31', 1);
+-----+
| ADD_MONTHS('2012-01-31', 1) |
+-----+
| 2012-02-29 |
+-----+

SELECT ADD_MONTHS('2012-01-31', 2);
+-----+
| ADD_MONTHS('2012-01-31', 2) |
+-----+
| 2012-03-31 |
+-----+

SELECT ADD_MONTHS('2012-01-31', 3);
+-----+
| ADD_MONTHS('2012-01-31', 3) |
+-----+
| 2012-04-30 |
+-----+

```

## See Also

- [SQL\\_MODE=ORACLE](#)

### 1.1.12.3.4 ADDDATE

## Syntax

```
ADDDATE(date,INTERVAL expr unit), ADDDATE(expr,days)
```

## Description

When invoked with the

INTERVAL  
form of the second argument,  
ADDDATE()  
is a synonym for

[DATE\\_ADD\(\)](#)

. The related function

[SUBDATE\(\)](#)

is a synonym for

[DATE\\_SUB\(\)](#)

. For information on the  
INTERVAL  
unit argument, see the discussion for

[DATE\\_ADD\(\)](#)

When invoked with the days form of the second argument, MariaDB treats it as an integer number of days to be added to *expr*.

## Examples

```
SELECT DATE_ADD('2008-01-02', INTERVAL 31 DAY);
+-----+
| DATE_ADD('2008-01-02', INTERVAL 31 DAY) |
+-----+
| 2008-02-02                                |
+-----+
```

```
SELECT ADDDATE('2008-01-02', INTERVAL 31 DAY);
+-----+
| ADDDATE('2008-01-02', INTERVAL 31 DAY) |
+-----+
| 2008-02-02                                |
+-----+
```

```
SELECT ADDDATE('2008-01-02', 31);
+-----+
| ADDDATE('2008-01-02', 31) |
+-----+
| 2008-02-02                                |
+-----+
```

```
CREATE TABLE t1 (d DATETIME);
INSERT INTO t1 VALUES
    ("2007-01-30 21:31:07"),
    ("1983-10-15 06:42:51"),
    ("2011-04-21 12:34:56"),
    ("2011-10-30 06:31:41"),
    ("2011-01-30 14:03:25"),
    ("2004-10-07 11:19:34");
```

```
SELECT d, ADDDATE(d, 10) from t1;
+-----+
| d           | ADDDATE(d, 10)   |
+-----+
| 2007-01-30 21:31:07 | 2007-02-09 21:31:07 |
| 1983-10-15 06:42:51 | 1983-10-25 06:42:51 |
| 2011-04-21 12:34:56 | 2011-05-01 12:34:56 |
| 2011-10-30 06:31:41 | 2011-11-09 06:31:41 |
| 2011-01-30 14:03:25 | 2011-02-09 14:03:25 |
| 2004-10-07 11:19:34 | 2004-10-17 11:19:34 |
+-----+
```

```
SELECT d, ADDDATE(d, INTERVAL 10 HOUR) from t1;
+-----+
| d           | ADDDATE(d, INTERVAL 10 HOUR) |
+-----+
| 2007-01-30 21:31:07 | 2007-01-31 07:31:07 |
| 1983-10-15 06:42:51 | 1983-10-15 16:42:51 |
| 2011-04-21 12:34:56 | 2011-04-21 22:34:56 |
| 2011-10-30 06:31:41 | 2011-10-30 16:31:41 |
| 2011-01-30 14:03:25 | 2011-01-31 00:03:25 |
| 2004-10-07 11:19:34 | 2004-10-07 21:19:34 |
+-----+
```

## 1.1.12.3.5 ADDTIME

# Syntax

```
ADDTIME(expr1,expr2)
```

## Description

ADDTIME()

adds *expr2* to *expr1* and returns the result. *expr1* is a time or datetime expression, and *expr2* is a time expression.

## Examples

```
SELECT ADDTIME('2007-12-31 23:59:59.999999', '1 1:1:1.000002');
+-----+
| ADDTIME('2007-12-31 23:59:59.999999', '1 1:1:1.000002') |
+-----+
| 2008-01-02 01:01:01.000001 |
+-----+

SELECT ADDTIME('01:00:00.999999', '02:00:00.999998');
+-----+
| ADDTIME('01:00:00.999999', '02:00:00.999998') |
+-----+
| 03:00:01.999997 |
+-----+
```

## 1.1.12.3.6 CONVERT\_TZ

### Syntax

```
CONVERT_TZ(dt,from_tz,to_tz)
```

## Description

CONVERT\_TZ() converts a datetime value *dt* from the [time zone](#) given by *from\_tz* to the time zone given by *to\_tz* and returns the resulting value.

In order to use named time zones, such as GMT, MET or Africa/Johannesburg, the `time_zone` tables must be loaded (see [mysql\\_tzinfo\\_to\\_sql](#) ).

No conversion will take place if the value falls outside of the supported TIMESTAMP range ('1970-01-01 00:00:01' to '2038-01-19 05:14:07' UTC) when converted from *from\_tz* to UTC.

This function returns NULL if the arguments are invalid (or named time zones have not been loaded).

See [time zones](#) for more information.

## Examples

```
SELECT CONVERT_TZ('2016-01-01 12:00:00','+00:00','+10:00');
+-----+
| CONVERT_TZ('2016-01-01 12:00:00','+00:00','+10:00') |
+-----+
| 2016-01-01 22:00:00 |
+-----+
```

Using named time zones (with the time zone tables loaded):

```
SELECT CONVERT_TZ('2016-01-01 12:00:00','GMT','Africa/Johannesburg');
+-----+
| CONVERT_TZ('2016-01-01 12:00:00','GMT','Africa/Johannesburg') |
+-----+
| 2016-01-01 14:00:00 |
+-----+
```

The value is out of the TIMESTAMP range, so no conversion takes place:

```
SELECT CONVERT_TZ('1969-12-31 22:00:00','+00:00','+10:00');
+-----+
| CONVERT_TZ('1969-12-31 22:00:00','+00:00','+10:00') |
+-----+
| 1969-12-31 22:00:00 |
+-----+
```

## 1.1.12.3.7 CURDATE

### Syntax

```
CURDATE()
CURRENT_DATE
CURRENT_DATE()
```

### Description

CURDATE  
returns the current date as a value in 'YYYY-MM-DD' or YYYYMMDD format, depending on whether the function is used in a string or numeric context.

CURRENT\_DATE  
and  
CURRENT\_DATE()  
are synonyms.

### Examples

```
SELECT CURDATE();
+-----+
| CURDATE() |
+-----+
| 2019-03-05 |
+-----+
```

In a numeric context (note this is not performing date calculations):

```
SELECT CURDATE() +0;
+-----+
| CURDATE() +0 |
+-----+
| 20190305 |
+-----+
```

Data calculation:

```
SELECT CURDATE() - INTERVAL 5 DAY;
+-----+
| CURDATE() - INTERVAL 5 DAY |
+-----+
| 2019-02-28 |
+-----+
```

## 1.1.12.3.8 CURRENT\_DATE

### Syntax

```
CURRENT_DATE, CURRENT_DATE()
```

### Description

`CURRENT_DATE`  
and  
`CURRENT_DATE()`  
are synonyms for [CURDATE\(\)](#).

## 1.1.12.3.9 CURRENT\_TIME

### Syntax

```
CURRENT_TIME  
CURRENT_TIME([precision])
```

### Description

`CURRENT_TIME`  
and  
`CURRENT_TIME()`  
are synonyms for  
  
[CURTIME\(\)](#)

### See Also

- [Microseconds in MariaDB](#)

## 1.1.12.3.10 CURRENT\_TIMESTAMP

### Syntax

```
CURRENT_TIMESTAMP  
CURRENT_TIMESTAMP([precision])
```

### Description

`CURRENT_TIMESTAMP`  
and  
`CURRENT_TIMESTAMP()`  
are synonyms for  
  
[NOW\(\)](#)

### See Also

- [Microseconds in MariaDB](#)
- The [TIMESTAMP](#) data type

## 1.1.12.3.11 CURTIME

### Syntax

```
CURTIME([precision])
```

### Description

Returns the current time as a value in 'HH:MM:SS' or HHMMSS.ududu format, depending on whether the function is used in a string or numeric context. The value is expressed in the current [time zone](#).

The optional *precision* determines the microsecond precision. See [Microseconds in MariaDB](#).

## Examples

```
SELECT CURTIME();
+-----+
| CURTIME() |
+-----+
| 12:45:39 |
+-----+

SELECT CURTIME() + 0;
+-----+
| CURTIME() + 0 |
+-----+
| 124545.00000 |
+-----+
```

With precision:

```
SELECT CURTIME(2);
+-----+
| CURTIME(2) |
+-----+
| 09:49:08.09 |
+-----+
```

## See Also

- [Microseconds in MariaDB](#)

### 1.1.12.3.12 DATE FUNCTION

#### Syntax

```
DATE(expr)
```

#### Description

Extracts the date part of the date or datetime expression expr.

## Examples

```
SELECT DATE('2013-07-18 12:21:32');
+-----+
| DATE('2013-07-18 12:21:32') |
+-----+
| 2013-07-18 |
+-----+
```

#### Error Handling

Until [MariaDB 5.5.32](#), some versions of MariaDB returned  
0000-00-00  
when passed an invalid date. From 5.5.32, NULL is returned.

### 1.1.12.3.13 DATEDIFF

#### Syntax

```
DATEDIFF(expr1,expr2)
```

## Description

DATEDIFF()

returns (*expr1 – expr2*) expressed as a value in days from one date to the other. *expr1* and *expr2* are date or date-and-time expressions. Only the date parts of the values are used in the calculation.

## Examples

```
SELECT DATEDIFF('2007-12-31 23:59:59','2007-12-30');
+-----+
| DATEDIFF('2007-12-31 23:59:59','2007-12-30') |
+-----+
| 1 |
+-----+  
  
SELECT DATEDIFF('2010-11-30 23:59:59','2010-12-31');
+-----+
| DATEDIFF('2010-11-30 23:59:59','2010-12-31') |
+-----+
| -31 |
+-----+
```

```
CREATE TABLE t1 (d DATETIME);
INSERT INTO t1 VALUES
    ("2007-01-30 21:31:07"),
    ("1983-10-15 06:42:51"),
    ("2011-04-21 12:34:56"),
    ("2011-10-30 06:31:41"),
    ("2011-01-30 14:03:25"),
    ("2004-10-07 11:19:34");
```

```
SELECT NOW();
+-----+
| NOW() |
+-----+
| 2011-05-23 10:56:05 |
+-----+  
  
SELECT d, DATEDIFF(NOW(),d) FROM t1;
+-----+
| d | DATEDIFF(NOW(),d) |
+-----+
| 2007-01-30 21:31:07 | 1574 |
| 1983-10-15 06:42:51 | 10082 |
| 2011-04-21 12:34:56 | 32 |
| 2011-10-30 06:31:41 | -160 |
| 2011-01-30 14:03:25 | 113 |
| 2004-10-07 11:19:34 | 2419 |
+-----+
```

## 1.1.12.3.14 DATE\_ADD

### Syntax

```
DATE_ADD(date,INTERVAL expr unit)
```

### Contents

1. [Syntax](#)
2. [Description](#)
3. [Examples](#)
4. [See Also](#)

# Description

Performs date arithmetic. The *date* argument specifies the starting date or datetime value. *expr* is an expression specifying the interval value to be added or subtracted from the starting date. *expr* is a string; it may start with a "

" for negative intervals. *unit* is a keyword indicating the units in which the expression should be interpreted. See [Date and Time Units](#) for a complete list of permitted units.

## Examples

```
SELECT '2008-12-31 23:59:59' + INTERVAL 1 SECOND;
+-----+
| '2008-12-31 23:59:59' + INTERVAL 1 SECOND |
+-----+
| 2009-01-01 00:00:00 |
+-----+
```

```
SELECT INTERVAL 1 DAY + '2008-12-31';
+-----+
| INTERVAL 1 DAY + '2008-12-31' |
+-----+
| 2009-01-01 |
+-----+
```

```
SELECT '2005-01-01' - INTERVAL 1 SECOND;
+-----+
| '2005-01-01' - INTERVAL 1 SECOND |
+-----+
| 2004-12-31 23:59:59 |
+-----+
```

```
SELECT DATE_ADD('2000-12-31 23:59:59', INTERVAL 1 SECOND);
+-----+
| DATE_ADD('2000-12-31 23:59:59', INTERVAL 1 SECOND) |
+-----+
| 2001-01-01 00:00:00 |
+-----+
```

```
SELECT DATE_ADD('2010-12-31 23:59:59', INTERVAL 1 DAY);
+-----+
| DATE_ADD('2010-12-31 23:59:59', INTERVAL 1 DAY) |
+-----+
| 2011-01-01 23:59:59 |
+-----+
```

```
SELECT DATE_ADD('2100-12-31 23:59:59', INTERVAL '1:1' MINUTE_SECOND);
+-----+
| DATE_ADD('2100-12-31 23:59:59', INTERVAL '1:1' MINUTE_SECOND) |
+-----+
| 2101-01-01 00:01:00 |
+-----+
```

```
SELECT DATE_ADD('1900-01-01 00:00:00', INTERVAL '-1 10' DAY_HOUR);
+-----+
| DATE_ADD('1900-01-01 00:00:00', INTERVAL '-1 10' DAY_HOUR) |
+-----+
| 1899-12-30 14:00:00 |
+-----+
```

```
SELECT DATE_ADD('1992-12-31 23:59:59.000002', INTERVAL '1.999999' SECOND_MICROSECOND);
+-----+
| DATE_ADD('1992-12-31 23:59:59.000002', INTERVAL '1.999999' SECOND_MICROSECOND) |
+-----+
| 1993-01-01 00:00:01.000001 |
+-----+
```

## 1.1.12.3.15 DATE\_FORMAT

### Syntax

```
DATE_FORMAT(date, format[, locale])
```

### Contents

1. [Syntax](#)
2. [Description](#)
3. [Examples](#)
4. [See Also](#)

### Description

Formats the date value according to the format string.

The language used for the names is controlled by the value of the [lc\\_time\\_names](#) system variable. See [server locale](#) for more on the supported locales.

The options that can be used by DATE\_FORMAT(), as well as its inverse [STR\\_TO\\_DATE\(\)](#) and the [FROM\\_UNIXTIME\(\)](#) function, are:

Option	Description
%a	Short weekday name in current locale (Variable <a href="#">lc_time_names</a> ).
%b	Short form month name in current locale. For locale en_US this is one of: Jan, Feb, Mar, Apr, May, Jun, Jul, Aug, Sep, Oct, Nov or Dec.
%c	Month with 1 or 2 digits.
%d	Day with English suffix 'th', 'nd', 'st' or 'rd'. (1st, 2nd, 3rd...).
%d	Day with 2 digits.
%e	Day with 1 or 2 digits.
%f	<a href="#">Microseconds</a> 6 digits.
%H	Hour with 2 digits between 00-23.
%h	Hour with 2 digits between 01-12.
%I	Hour with 2 digits between 01-12.
%i	Minute with 2 digits.
%j	Day of the year (001-366)

%k	Hour with 1 digits between 0-23.
%l	Hour with 1 digits between 1-12.
%M	Full month name in current locale (Variable <a href="#">lc_time_names</a> ).
%m	Month with 2 digits.
%p	AM/PM according to current locale (Variable <a href="#">lc_time_names</a> ).
%r	Time in 12 hour format, followed by AM/PM. Short for '%l:%i:%S %p'.
%S	Seconds with 2 digits.
%s	Seconds with 2 digits.
%T	Time in 24 hour format. Short for '%H:%i:%S'.
%U	Week number (00-53), when first day of the week is Sunday.
%u	Week number (00-53), when first day of the week is Monday.
%v	Week number (01-53), when first day of the week is Sunday. Used with %X.
%v	Week number (01-53), when first day of the week is Monday. Used with %x.
%w	Full weekday name in current locale (Variable <a href="#">lc_time_names</a> ).
%w	Day of the week. 0 = Sunday, 6 = Saturday.
%x	Year with 4 digits when first day of the week is Sunday. Used with %V.
%x	Year with 4 digits when first day of the week is Monday. Used with %v.
%y	Year with 4 digits.
%y	Year with 2 digits.

	%# For <code>str_to_date</code> (), skip all numbers.
%.	For <code>str_to_date</code> (), skip all punctuation characters.
%@	For <code>str_to_date</code> (), skip all alpha characters.
%%	A literal % character.

To get a date in one of the standard formats,

`GET_FORMAT()`

can be used.

## Examples

```
SELECT DATE_FORMAT('2009-10-04 22:23:00', '%W %M %Y');
+-----+
| DATE_FORMAT('2009-10-04 22:23:00', '%W %M %Y') |
+-----+
| Sunday October 2009 |
+-----+

SELECT DATE_FORMAT('2007-10-04 22:23:00', '%H:%i:%s');
+-----+
| DATE_FORMAT('2007-10-04 22:23:00', '%H:%i:%s') |
+-----+
| 22:23:00 |
+-----+

SELECT DATE_FORMAT('1900-10-04 22:23:00', '%D %y %a %d %m %b %j');
+-----+
| DATE_FORMAT('1900-10-04 22:23:00', '%D %y %a %d %m %b %j') |
+-----+
| 4th 00 Thu 04 10 Oct 277 |
+-----+

SELECT DATE_FORMAT('1997-10-04 22:23:00', '%H %k %I %r %T %S %w');
+-----+
| DATE_FORMAT('1997-10-04 22:23:00', '%H %k %I %r %T %S %w') |
+-----+
| 22 22 10 10:23:00 PM 22:23:00 00 6 |
+-----+

SELECT DATE_FORMAT('1999-01-01', '%X %V');
+-----+
| DATE_FORMAT('1999-01-01', '%X %V') |
+-----+
| 1998 52 |
+-----+

SELECT DATE_FORMAT('2006-06-00', '%d');
+-----+
| DATE_FORMAT('2006-06-00', '%d') |
+-----+
| 00 |
+-----+
```

MariaDB starting with 10.3.2

Optionally, the locale can be explicitly specified as the third `DATE_FORMAT()` argument. Doing so makes the function independent from the session settings, and the three argument version of `DATE_FORMAT()` can be used in virtual indexed and persistent [generated-columns](#) :

```
SELECT DATE_FORMAT('2006-01-01', '%W', 'el_GR');
+-----+
| DATE_FORMAT('2006-01-01', '%W', 'el_GR') |
+-----+
| Κυριακή |
+-----+
```

## See Also

- [STR\\_TO\\_DATE\(\)](#)
- [FROM\\_UNIXTIME\(\)](#)

## 1.1.12.3.16 DATE\_SUB

### Syntax

```
DATE_SUB(date, INTERVAL expr unit)
```

### Description

Performs date arithmetic. The *date* argument specifies the starting date or datetime value. *expr* is an expression specifying the interval value to be added or subtracted from the starting date. *expr* is a string; it may start with a "

" for negative intervals. *unit* is a keyword indicating the units in which the expression should be interpreted. See [Date and Time Units](#) for a complete list of permitted units.

See also

[DATE\\_ADD\(\)](#)

### Examples

```
SELECT DATE_SUB('1998-01-02', INTERVAL 31 DAY);
+-----+
| DATE_SUB('1998-01-02', INTERVAL 31 DAY) |
+-----+
| 1997-12-02 |
+-----+
```

```
SELECT DATE_SUB('2005-01-01 00:00:00', INTERVAL '1 1:1:1' DAY_SECOND);
+-----+
| DATE_SUB('2005-01-01 00:00:00', INTERVAL '1 1:1:1' DAY_SECOND) |
+-----+
| 2004-12-30 22:58:59 |
+-----+
```

## 1.1.12.3.17 DAY

### Syntax

```
DAY(date)
```

### Description

DAY()  
is a synonym for

[DAYOFMONTH\(\)](#)

## 1.1.12.3.18 DAYNAME

### Syntax

```
DAYNAME(date)
```

### Description

Returns the name of the weekday for date. The language used for the name is controlled by the value of the [lc\\_time\\_names](#) system variable. See [server locale](#) for more on the supported locales.

### Examples

```
SELECT DAYNAME('2007-02-03');
+-----+
| DAYNAME('2007-02-03') |
+-----+
| Saturday           |
+-----+
```

```
CREATE TABLE t1 (d DATETIME);
INSERT INTO t1 VALUES
  ("2007-01-30 21:31:07"),
  ("1983-10-15 06:42:51"),
  ("2011-04-21 12:34:56"),
  ("2011-10-30 06:31:41"),
  ("2011-01-30 14:03:25"),
  ("2004-10-07 11:19:34");
```

```
SELECT d, DAYNAME(d) FROM t1;
+-----+-----+
| d          | DAYNAME(d) |
+-----+-----+
| 2007-01-30 21:31:07 | Tuesday    |
| 1983-10-15 06:42:51 | Saturday   |
| 2011-04-21 12:34:56 | Thursday   |
| 2011-10-30 06:31:41 | Sunday     |
| 2011-01-30 14:03:25 | Sunday     |
| 2004-10-07 11:19:34 | Thursday   |
+-----+-----+
```

Changing the locale:

```
SET lc_time_names = 'fr_CA';

SELECT DAYNAME('2013-04-01');
+-----+
| DAYNAME('2013-04-01') |
+-----+
| lundi                 |
+-----+
```

## 1.1.12.3.19 DAYOFMONTH

### Syntax

```
DAYOFMONTH(date)
```

### Description

Returns the day of the month for date, in the range

```
1  
to  
31  
, or  
0  
for dates such as  
'0000-00-00'  
or  
'2008-00-00'  
which have a zero day part.
```

DAY() is a synonym.

## Examples

```
SELECT DAYOFMONTH('2007-02-03');  
+-----+  
| DAYOFMONTH('2007-02-03') |  
+-----+  
| 3 |  
+-----+
```

```
CREATE TABLE t1 (d DATETIME);  
INSERT INTO t1 VALUES  
    ("2007-01-30 21:31:07"),  
    ("1983-10-15 06:42:51"),  
    ("2011-04-21 12:34:56"),  
    ("2011-10-30 06:31:41"),  
    ("2011-01-30 14:03:25"),  
    ("2004-10-07 11:19:34");
```

```
SELECT d FROM t1 WHERE DAYOFMONTH(d) = 30;  
+-----+  
| d |  
+-----+  
| 2007-01-30 21:31:07 |  
| 2011-10-30 06:31:41 |  
| 2011-01-30 14:03:25 |  
+-----+
```

## 1.1.12.3.20 DAYOFWEEK

### Syntax

```
DAYOFWEEK(date)
```

### Description

Returns the day of the week index for the date (1 = Sunday, 2 = Monday, ..., 7 = Saturday). These index values correspond to the ODBC standard.

This contrasts with

[WEEKDAY\(\)](#)

which follows a different index numbering (

```
0  
= Monday,  
1  
= Tuesday, ...  
6  
= Sunday).
```

## Examples

```
SELECT DAYOFWEEK('2007-02-03');
+-----+
| DAYOFWEEK('2007-02-03') |
+-----+
| 7 |
+-----+
```

```
CREATE TABLE t1 (d DATETIME);
INSERT INTO t1 VALUES
    ("2007-01-30 21:31:07"),
    ("1983-10-15 06:42:51"),
    ("2011-04-21 12:34:56"),
    ("2011-10-30 06:31:41"),
    ("2011-01-30 14:03:25"),
    ("2004-10-07 11:19:34");
```

```
SELECT d, DAYNAME(d), DAYOFWEEK(d), WEEKDAY(d) from t1;
+-----+-----+-----+
| d | DAYNAME(d) | DAYOFWEEK(d) | WEEKDAY(d) |
+-----+-----+-----+
| 2007-01-30 21:31:07 | Tuesday | 3 | 1 |
| 1983-10-15 06:42:51 | Saturday | 7 | 5 |
| 2011-04-21 12:34:56 | Thursday | 5 | 3 |
| 2011-10-30 06:31:41 | Sunday | 1 | 6 |
| 2011-01-30 14:03:25 | Sunday | 1 | 6 |
| 2004-10-07 11:19:34 | Thursday | 5 | 3 |
+-----+-----+-----+
```

## 1.1.12.3.21 DAYOFYEAR

### Syntax

```
DAYOFYEAR(date)
```

### Description

Returns the day of the year for date, in the range 1 to 366.

### Examples

```
SELECT DAYOFYEAR('2018-02-16');
+-----+
| DAYOFYEAR('2018-02-16') |
+-----+
| 47 |
+-----+
```

## 1.1.12.3.22 EXTRACT

### Syntax

```
EXTRACT(unit FROM date)
```

### Contents

1. [Syntax](#)
2. [Description](#)
3. [Examples](#)
4. [See Also](#)

### Description

The EXTRACT() function extracts the required unit from the date. See [Date and Time Units](#) for a complete list of permitted units.

In MariaDB 10.0.7 and MariaDB 5.5.35 ,

EXTRACT (HOUR FROM ...)

was changed to return a value from 0 to 23, adhering to the SQL standard. Until MariaDB 10.0.6 and MariaDB 5.5.34 , and in all versions of MySQL at least as of MySQL 5.7, it could return a value > 23. HOUR() is not a standard function, so continues to adhere to the old behaviour inherited from MySQL.

## Examples

```
SELECT EXTRACT(YEAR FROM '2009-07-02');
+-----+
| EXTRACT(YEAR FROM '2009-07-02') |
+-----+
|          2009 |
+-----+  
  
SELECT EXTRACT(YEAR_MONTH FROM '2009-07-02 01:02:03');
+-----+
| EXTRACT(YEAR_MONTH FROM '2009-07-02 01:02:03') |
+-----+
|          200907 |
+-----+  
  
SELECT EXTRACT(DAY_MINUTE FROM '2009-07-02 01:02:03');
+-----+
| EXTRACT(DAY_MINUTE FROM '2009-07-02 01:02:03') |
+-----+
|          20102 |
+-----+  
  
SELECT EXTRACT(MICROSECOND FROM '2003-01-02 10:30:00.000123');
+-----+
| EXTRACT(MICROSECOND FROM '2003-01-02 10:30:00.000123') |
+-----+
|          123 |
+-----+
```

From MariaDB 10.0.7 and MariaDB 5.5.35 ,

EXTRACT (HOUR FROM...)

returns a value from 0 to 23, as per the SQL standard.

HOUR

is not a standard function, so continues to adhere to the old behaviour inherited from MySQL.

```
SELECT EXTRACT(HOUR FROM '26:30:00'), HOUR('26:30:00');
+-----+-----+
| EXTRACT(HOUR FROM '26:30:00') | HOUR('26:30:00') |
+-----+-----+
|          2 |          26 |
+-----+-----+
```

## See Also

- [Date and Time Units](#)
- [Date and Time Literals](#)
- [HOUR\(\)](#)

## 1.1.12.3.23 FROM\_DAYS

### Syntax

```
FROM_DAYS(N)
```

### Description

Given a day number N, returns a DATE value. The day count is based on the number of days from the start of the standard calendar (0000-00-00).

The function is not designed for use with dates before the advent of the Gregorian calendar in October 1582. Results will not be reliable since it doesn't account for the lost days when the calendar changed from the Julian calendar.

This is the converse of the [TO\\_DAYS\(\)](#) function.

## Examples

```
SELECT FROM_DAYS(730669);
+-----+
| FROM_DAYS(730669) |
+-----+
| 2000-07-03 |
+-----+
```

## 1.1.12.3.24 FROM\_UNIXTIME

### Syntax

```
FROM_UNIXTIME(unix_timestamp), FROM_UNIXTIME(unix_timestamp,format)
```

### Contents

1. [Syntax](#)
2. [Description](#)
3. [Performance Considerations](#)
4. [Examples](#)
5. [See Also](#)

### Description

Returns a representation of the unix\_timestamp argument as a value in 'YYYY-MM-DD HH:MM:SS' or YYYYMMDDHHMMSS.uduuuu format, depending on whether the function is used in a string or numeric context. The value is expressed in the current [time zone](#). unix\_timestamp is an internal timestamp value such as is produced by the [UNIX\\_TIMESTAMP\(\)](#) function.

If format is given, the result is formatted according to the format string, which is used the same way as listed in the entry for the [DATE\\_FORMAT\(\)](#) function.

Timestamps in MariaDB have a maximum value of 2147483647, equivalent to 2038-01-19 05:14:07. This is due to the underlying 32-bit limitation. Using the function on a timestamp beyond this will result in NULL being returned. Use [DATETIME](#) as a storage type if you require dates beyond this.

The options that can be used by `FROM_UNIXTIME()`, as well as [DATE\\_FORMAT\(\)](#) and [STR\\_TO\\_DATE\(\)](#) , are:

Option	Description
%a	Short weekday name in current locale (Variable <a href="#">lc_time_names</a> ).
%b	Short form month name in current locale. For locale en_US this is one of: Jan, Feb, Mar, Apr, May, Jun, Jul, Aug, Sep, Oct, Nov or Dec.
%c	Month with 1 or 2 digits.
%d	Day with English suffix 'th', 'nd', 'st' or 'rd'. (1st, 2nd, 3rd...).
%d	Day with 2 digits.
%e	Day with 1 or 2 digits.
%f	<a href="#">Microseconds</a> 6 digits.
%H	Hour with 2 digits between 00-23.

%h	Hour with 2 digits between 01-12.
%I	Hour with 2 digits between 01-12.
%i	Minute with 2 digits.
%j	Day of the year (001-366)
%k	Hour with 1 digits between 0-23.
%l	Hour with 1 digits between 1-12.
%M	Full month name in current locale (Variable <a href="#">lc_time_names</a> ).
%m	Month with 2 digits.
%p	AM/PM according to current locale (Variable <a href="#">lc_time_names</a> ).
%r	Time in 12 hour format, followed by AM/PM. Short for "%l:%i:%S %p".
%S	Seconds with 2 digits.
%s	Seconds with 2 digits.
%T	Time in 24 hour format. Short for "%H:%i:%S".
%U	Week number (00-53), when first day of the week is Sunday.
%u	Week number (00-53), when first day of the week is Monday.
%v	Week number (01-53), when first day of the week is Sunday. Used with %X.
%v	Week number (01-53), when first day of the week is Monday. Used with %x.
%w	Full weekday name in current locale (Variable <a href="#">lc_time_names</a> ).
%w	Day of the week. 0 = Sunday, 6 = Saturday.
%x	Year with 4 digits when first day of the week is Sunday. Used with %V.

%x	Year with 4 digits when first day of the week is Sunday. Used with %v.
%Y	Year with 4 digits.
%y	Year with 2 digits.
%#	For <code>str_to_date</code> (), skip all numbers.
%.	For <code>str_to_date</code> (), skip all punctuation characters.
%@	For <code>str_to_date</code> (), skip all alpha characters.
%%	A literal % character.

## Performance Considerations

If your session time zone is set to

```
SYSTEM
(the default),
FROM_UNIXTIME()
will call the OS function to convert the data using the system time zone. At least on Linux, the corresponding function (
localtime_r
) uses a global mutex inside glibc that can cause contention under high concurrent load.
```

Set your time zone to a named time zone to avoid this issue. See [mysql time zone tables](#) for details on how to do this.

## Examples

```
SELECT FROM_UNIXTIME(1196440219);
+-----+
| FROM_UNIXTIME(1196440219) |
+-----+
| 2007-11-30 11:30:19 |
+-----+

SELECT FROM_UNIXTIME(1196440219) + 0;
+-----+
| FROM_UNIXTIME(1196440219) + 0 |
+-----+
| 20071130113019.000000 |
+-----+

SELECT FROM_UNIXTIME(UNIX_TIMESTAMP(), '%Y %D %M %h:%i:%s %x');
+-----+
| FROM_UNIXTIME(UNIX_TIMESTAMP(), '%Y %D %M %h:%i:%s %x') |
+-----+
| 2010 27th March 01:03:47 |
+-----+
```

## See Also

- [UNIX\\_TIMESTAMP\(\)](#)
- [DATE\\_FORMAT\(\)](#)
- [STR\\_TO\\_DATE\(\)](#)

## 1.1.12.3.25 GET\_FORMAT

# Syntax

```
GET_FORMAT({DATE|DATETIME|TIME}, {'EUR' | 'USA' | 'JIS' | 'ISO' | 'INTERNAL'})
```

## Description

Returns a format string. This function is useful in combination with the [DATE\\_FORMAT\(\)](#) and the [STR\\_TO\\_DATE\(\)](#) functions.

Possible result formats are:

Function Call	Result Format
GET_FORMAT(DATE,'EUR')	'%d.%m.%Y'
GET_FORMAT(DATE,'USA')	'%m.%d.%Y'
GET_FORMAT(DATE,'JIS')	'%Y-%m-%d'
GET_FORMAT(DATE,'ISO')	'%Y-%m-%d'
GET_FORMAT(DATE,'INTERNAL')	'%Y%m%d'
GET_FORMAT(DATETIME,'EUR')	'%Y-%m-%d %H.%i.%s'
GET_FORMAT(DATETIME,'USA')	'%Y-%m-%d %H.%i.%s'
GET_FORMAT(DATETIME,'JIS')	'%Y-%m-%d %H:%i:%s'
GET_FORMAT(DATETIME,'ISO')	'%Y-%m-%d %H:%i:%s'
GET_FORMAT(DATETIME,'INTERNAL')	'%Y%m%d%H%i%s'
GET_FORMAT(TIME,'EUR')	'%H.%i.%s'
GET_FORMAT(TIME,'USA')	'%h:%i:%s %p'
GET_FORMAT(TIME,'JIS')	'%H:%i:%s'
GET_FORMAT(TIME,'ISO')	'%H:%i:%s'
GET_FORMAT(TIME,'INTERNAL')	'%H%i%s'

## Examples

Obtaining the string matching to the standard European date format:

```
SELECT GET_FORMAT(DATE, 'EUR');
+-----+
| GET_FORMAT(DATE, 'EUR') |
+-----+
| %d.%m.%Y |
+-----+
```

Using the same string to format a date:

```
SELECT DATE_FORMAT('2003-10-03',GET_FORMAT(DATE, 'EUR'));
+-----+
| DATE_FORMAT('2003-10-03',GET_FORMAT(DATE, 'EUR')) |
+-----+
| 03.10.2003 |
+-----+
SELECT STR_TO_DATE('10.31.2003',GET_FORMAT(DATE, 'USA'));
+-----+
| STR_TO_DATE('10.31.2003',GET_FORMAT(DATE, 'USA')) |
+-----+
| 2003-10-31 |
+-----+
```

## 1.1.12.3.26 HOUR

### Syntax

```
HOUR(time)
```

## Description

Returns the hour for time. The range of the return value is 0 to 23 for time-of-day values. However, the range of TIME values actually is much larger, so HOUR can return values greater than 23.

The return value is always positive, even if a negative TIME value is provided.

## Examples

```
SELECT HOUR('10:05:03');
+-----+
| HOUR('10:05:03') |
+-----+
|          10 |
+-----+
SELECT HOUR('272:59:59');
+-----+
| HOUR('272:59:59') |
+-----+
|         272 |
+-----+
```

Difference between

[EXTRACT \(HOUR FROM ...\)](#)

( $\geq$  MariaDB 10.0.7 and MariaDB 5.5.35) and  
HOUR  
:

```
SELECT EXTRACT(HOUR FROM '26:30:00'), HOUR('26:30:00');
+-----+-----+
| EXTRACT(HOUR FROM '26:30:00') | HOUR('26:30:00') |
+-----+-----+
|          2 |           26 |
+-----+-----+
```

## See Also

- [Date and Time Units](#)
- [Date and Time Literals](#)
- [EXTRACT\(\)](#)

## 1.1.12.3.27 LAST\_DAY

### Syntax

```
LAST_DAY(date)
```

## Description

Takes a date or datetime value and returns the corresponding value for the last day of the month. Returns NULL if the argument is invalid.

## Examples

```
SELECT LAST_DAY('2003-02-05');
+-----+
| LAST_DAY('2003-02-05') |
+-----+
| 2003-02-28 |
+-----+

SELECT LAST_DAY('2004-02-05');
+-----+
| LAST_DAY('2004-02-05') |
+-----+
| 2004-02-29 |
+-----+

SELECT LAST_DAY('2004-01-01 01:01:01');
+-----+
| LAST_DAY('2004-01-01 01:01:01') |
+-----+
| 2004-01-31 |
+-----+

SELECT LAST_DAY('2003-03-32');
+-----+
| LAST_DAY('2003-03-32') |
+-----+
| NULL |
+-----+
1 row in set, 1 warning (0.00 sec)

Warning (Code 1292): Incorrect datetime value: '2003-03-32'
```

## 1.1.12.3.28 LOCALTIME

### Syntax

```
LOCALTIME
LOCALTIME([precision])
```

### Description

LOCALTIME  
and  
LOCALTIME()  
are synonyms for

NOW()

### See Also

- [Microseconds in MariaDB](#)

## 1.1.12.3.29 LOCALTIMESTAMP

### Syntax

```
LOCALTIMESTAMP
LOCALTIMESTAMP([precision])
```

### Description

LOCALTIMESTAMP  
and

`LOCALTIMESTAMP()`  
are synonyms for

`NOW()`

## See Also

- [Microseconds in MariaDB](#)

## 1.1.12.3.30 MAKEDATE

### Syntax

```
MAKEDATE(year,dayofyear)
```

### Description

Returns a date, given

year  
and  
day-of-year values  
  
dayofyear  
must be greater than 0 or the result is NULL.

### Examples

```
SELECT MAKEDATE(2011,31), MAKEDATE(2011,32);
+-----+-----+
| MAKEDATE(2011,31) | MAKEDATE(2011,32) |
+-----+-----+
| 2011-01-31       | 2011-02-01       |
+-----+-----+

SELECT MAKEDATE(2011,365), MAKEDATE(2014,365);
+-----+-----+
| MAKEDATE(2011,365) | MAKEDATE(2014,365) |
+-----+-----+
| 2011-12-31       | 2014-12-31       |
+-----+-----+

SELECT MAKEDATE(2011,0);
+-----+
| MAKEDATE(2011,0) |
+-----+
| NULL            |
+-----+
```

## 1.1.12.3.31 MAKETIME

### Syntax

```
MAKETIME(hour,minute,second)
```

### Description

Returns a time value calculated from the

hour  
,  
minute  
, and  
second

arguments.

If  
minute  
or  
second  
are out of the range 0 to 60, NULL is returned. The  
hour  
can be in the range -838 to 838, outside of which the value is truncated with a warning.

## Examples

```
SELECT MAKETIME(13,57,33);
+-----+
| MAKETIME(13,57,33) |
+-----+
| 13:57:33           |
+-----+

SELECT MAKETIME(-13,57,33);
+-----+
| MAKETIME(-13,57,33) |
+-----+
| -13:57:33          |
+-----+

SELECT MAKETIME(13,67,33);
+-----+
| MAKETIME(13,67,33) |
+-----+
| NULL               |
+-----+

SELECT MAKETIME(-1000,57,33);
+-----+
| MAKETIME(-1000,57,33) |
+-----+
| -838:59:59          |
+-----+

## 1.1.12.3.32 MICROSECOND

### Syntax

```
MICROSECOND(expr)
```

#### Contents

1. [Syntax](#)
2. [Description](#)
3. [Examples](#)
4. [See Also](#)

### Description

Returns the microseconds from the time or datetime expression *expr* as a number in the range from 0 to 999999.

If *expr* is a time with no microseconds, zero is returned, while if *expr* is a date with no time, zero with a warning is returned.

## Examples

```

SELECT MICROSECOND('12:00:00.123456');
+-----+
| MICROSECOND('12:00:00.123456') |
+-----+
|          123456 |
+-----+

SELECT MICROSECOND('2009-12-31 23:59:59.000010');
+-----+
| MICROSECOND('2009-12-31 23:59:59.000010') |
+-----+
|                  10 |
+-----+

SELECT MICROSECOND('2013-08-07 12:13:14');
+-----+
| MICROSECOND('2013-08-07 12:13:14') |
+-----+
|                  0 |
+-----+

SELECT MICROSECOND('2013-08-07');
+-----+
| MICROSECOND('2013-08-07') |
+-----+
|                  0 |
+-----+
1 row in set, 1 warning (0.00 sec)

SHOW WARNINGS;
+-----+
| Level | Code | Message           |
+-----+
| Warning | 1292 | Truncated incorrect time value: '2013-08-07' |
+-----+

```

## See Also

- [Microseconds in MariaDB](#)

## 1.1.12.3.33 MINUTE

### Syntax

`MINUTE(time)`

### Description

Returns the minute for `time`, in the range 0 to 59.

### Examples

```

SELECT MINUTE('2013-08-03 11:04:03');
+-----+
| MINUTE('2013-08-03 11:04:03') |
+-----+
|                  4 |
+-----+

SELECT MINUTE ('23:12:50');
+-----+
| MINUTE ('23:12:50') |
+-----+
|                 12 |
+-----+

```

## 1.1.12.3.34 MONTH

## Syntax

```
MONTH(date)
```

## Description

Returns the month for

date

in the range 1 to 12 for January to December, or 0 for dates such as '0000-00-00' or '2008-00-00' that have a zero month part.

## Examples

```
SELECT MONTH('2019-01-03');
+-----+
| MONTH('2019-01-03') |
+-----+
|          1 |
+-----+

SELECT MONTH('2019-00-03');
+-----+
| MONTH('2019-00-03') |
+-----+
|          0 |
+-----+
```

## 1.1.12.3.35 MONTHNAME

## Syntax

```
MONTHNAME(date)
```

## Description

Returns the full name of the month for date. The language used for the name is controlled by the value of the `lc_time_names` system variable. See [server locale](#) for more on the supported locales.

## Examples

```
SELECT MONTHNAME('2019-02-03');
+-----+
| MONTHNAME('2019-02-03') |
+-----+
| February           |
+-----+
```

Changing the locale:

```
SET lc_time_names = 'fr_CA';

SELECT MONTHNAME('2019-05-21');
+-----+
| MONTHNAME('2019-05-21') |
+-----+
| mai                 |
+-----+
```

## 1.1.12.3.36 NOW

## Syntax

```
NOW([precision])
CURRENT_TIMESTAMP
CURRENT_TIMESTAMP([precision])
LOCALTIME, LOCALTIME([precision])
LOCALTIMESTAMP
LOCALTIMESTAMP([precision])
```

## Contents

1. [Syntax](#)
2. [Description](#)
3. [Examples](#)
4. [See Also](#)

## Description

Returns the current date and time as a value in

```
'YYYY-MM-DD HH:MM:SS'
```

or

```
YYYYMMDDHHMMSS.uduuuu
```

format, depending on whether the function is used in a string or numeric context. The value is expressed in the current [time zone](#).

The optional *precision* determines the microsecond precision. See [Microseconds in MariaDB](#).

```
NOW()
```

(or its synonyms) can be used as the default value for [TIMESTAMP](#) columns as well as, since [MariaDB 10.0.1](#), [DATETIME](#) columns. Before [MariaDB 10.0.1](#), it was only possible for a single [TIMESTAMP](#) column per table to contain the [CURRENT\\_TIMESTAMP](#) as its default.

When displayed in the [INFORMATION\\_SCHEMA.COLUMNS](#) table, a default [CURRENT\\_TIMESTAMP](#) is displayed as

```
CURRENT_TIMESTAMP
```

up until [MariaDB 10.2.2](#), and as

```
current_timestamp()
```

from [MariaDB 10.2.3](#), due to [MariaDB 10.2](#) accepting expressions in the [DEFAULT](#) clause.

## Examples

```
SELECT NOW();
+-----+
| NOW()           |
+-----+
| 2010-03-27 13:13:25 |
+-----+

SELECT NOW() + 0;
+-----+
| NOW() + 0          |
+-----+
| 20100327131329.000000 |
+-----+
```

With precision:

```
SELECT CURRENT_TIMESTAMP(2);
+-----+
| CURRENT_TIMESTAMP(2)   |
+-----+
| 2018-07-10 09:47:26.24 |
+-----+
```

Used as a default [TIMESTAMP](#):

```
CREATE TABLE t (createdTS TIMESTAMP NOT NULL DEFAULT CURRENT_TIMESTAMP);
```

From [MariaDB 10.2.2](#):

```
SELECT * FROM INFORMATION_SCHEMA.COLUMNS WHERE TABLE_SCHEMA='test'  
AND COLUMN_NAME LIKE '%ts%'  
***** 1. row *****  
TABLE_CATALOG: def  
TABLE_SCHEMA: test  
TABLE_NAME: t  
COLUMN_NAME: ts  
ORDINAL_POSITION: 1  
COLUMN_DEFAULT: current_timestamp()  
...
```

<= MariaDB 10.2.1

```
SELECT * FROM INFORMATION_SCHEMA.COLUMNS WHERE TABLE_SCHEMA='test'  
AND COLUMN_NAME LIKE '%ts%'  
***** 1. row *****  
TABLE_CATALOG: def  
TABLE_SCHEMA: test  
TABLE_NAME: t  
COLUMN_NAME: createdTS  
ORDINAL_POSITION: 1  
COLUMN_DEFAULT: CURRENT_TIMESTAMP  
...
```

## See Also

- [Microseconds in MariaDB](#)

## 1.1.12.3.37 PERIOD\_ADD

### Syntax

```
PERIOD_ADD(P,N)
```

### Description

Adds

N

months to period

P

.

P

is in the format YYMM or YYYYMM, and is not a date value. If

P

contains a two-digit year, values from 00 to 69 are converted to from 2000 to 2069, while values from 70 are converted to 1970 upwards.

Returns a value in the format YYYYMM.

### Examples

```
SELECT PERIOD_ADD(200801,2);
```

```
+-----+
| PERIOD_ADD(200801,2) |
+-----+
|      200803 |
+-----+
```

```
SELECT PERIOD_ADD(6910,2);
```

```
+-----+
| PERIOD_ADD(6910,2) |
+-----+
|      206912 |
+-----+
```

```
SELECT PERIOD_ADD(7010,2);
```

```
+-----+
| PERIOD_ADD(7010,2) |
+-----+
|      197012 |
+-----+
```

## 1.1.12.3.38 PERIOD\_DIFF

### Syntax

```
PERIOD_DIFF(P1,P2)
```

### Description

Returns the number of months between periods P1 and P2. P1 and P2 can be in the format

YYMM

or

YYYYMM

, and are not date values.

If P1 or P2 contains a two-digit year, values from 00 to 69 are converted to from 2000 to 2069, while values from 70 are converted to 1970 upwards.

### Examples

```
SELECT PERIOD_DIFF(200802,200703);
```

```
+-----+
| PERIOD_DIFF(200802,200703) |
+-----+
|      11 |
+-----+
```

```
SELECT PERIOD_DIFF(6902,6803);
```

```
+-----+
| PERIOD_DIFF(6902,6803) |
+-----+
|      11 |
+-----+
```

```
SELECT PERIOD_DIFF(7002,6803);
```

```
+-----+
| PERIOD_DIFF(7002,6803) |
+-----+
|     -1177 |
+-----+
```

## 1.1.12.3.39 QUARTER

### Syntax

```
QUARTER(date)
```

## Description

Returns the quarter of the year for

date  
, in the range 1 to 4. Returns 0 if month contains a zero value, or  
NULL  
if the given value is not otherwise a valid date (zero values are accepted).

## Examples

```
SELECT QUARTER('2008-04-01');
+-----+
| QUARTER('2008-04-01') |
+-----+
|          2          |
+-----+
SELECT QUARTER('2019-00-01');
+-----+
| QUARTER('2019-00-01') |
+-----+
|          0          |
+-----+
```

## 1.1.12.3.40 SECOND

### Syntax

```
SECOND(time)
```

## Description

Returns the second for a given

time  
(which can include microseconds ), in the range 0 to 59, or  
NULL  
if not given a valid time value.

## Examples

```
SELECT SECOND('10:05:03');
+-----+
| SECOND('10:05:03') |
+-----+
|          3          |
+-----+
SELECT SECOND('10:05:01.999999');
+-----+
| SECOND('10:05:01.999999') |
+-----+
|          1          |
+-----+
```

## 1.1.12.3.41 SEC\_TO\_TIME

### Syntax

```
SEC_TO_TIME(seconds)
```

## Description

Returns the seconds argument, converted to hours, minutes, and seconds, as a TIME value. The range of the result is constrained to that of the TIME

[data type](#). A warning occurs if the argument corresponds to a value outside that range.

The time will be returned in the format

hh:mm:ss  
, or  
hhmmss  
if used in a numeric calculation.

## Examples

```
SELECT SEC_TO_TIME(12414);
+-----+
| SEC_TO_TIME(12414) |
+-----+
| 03:26:54           |
+-----+

SELECT SEC_TO_TIME(12414)+0;
+-----+
| SEC_TO_TIME(12414)+0 |
+-----+
|            32654   |
+-----+

SELECT SEC_TO_TIME(9999999);
+-----+
| SEC_TO_TIME(9999999) |
+-----+
| 838:59:59           |
+-----+
1 row in set, 1 warning (0.00 sec)

SHOW WARNINGS;
+-----+
| Level | Code | Message          |
+-----+
| Warning | 1292 | Truncated incorrect time value: '9999999' |
+-----+
```

## 1.1.12.3.42 STR\_TO\_DATE

### Syntax

```
STR_TO_DATE(str,format)
```

### Contents

1. [Syntax](#)
2. [Description](#)
3. [Examples](#)
4. [See Also](#)

### Description

This is the inverse of the [DATE\\_FORMAT \(\)](#) function. It takes a string

str  
and a format string  
format  
  
STR\_TO\_DATE()  
returns a  
DATETIME  
value if the format string contains both date and time parts, or a  
DATE  
or  
TIME  
value if the string contains only date or time parts.

The date, time, or datetime values contained in

str

```

should be given in the format indicated by format. If str contains an illegal date, time, or datetime value,
STR_TO_DATE()
returns
NULL
. An illegal value also produces a warning.

```

The options that can be used by STR\_TO\_DATE(), as well as its inverse [DATE\\_FORMAT\(\)](#) and the [FROM\\_UNIXTIME\(\)](#) function, are:

Option	Description
%a	Short weekday name in current locale (Variable <a href="#">lc_time_names</a> ).
%b	Short form month name in current locale. For locale en_US this is one of: Jan, Feb, Mar, Apr, May, Jun, Jul, Aug, Sep, Oct, Nov or Dec.
%c	Month with 1 or 2 digits.
%d	Day with English suffix 'th', 'nd', 'st' or 'rd'. (1st, 2nd, 3rd...).
%d	Day with 2 digits.
%e	Day with 1 or 2 digits.
%f	<a href="#">Microseconds</a> 6 digits.
%H	Hour with 2 digits between 00-23.
%h	Hour with 2 digits between 01-12.
%I	Hour with 2 digits between 01-12.
%i	Minute with 2 digits.
%j	Day of the year (001-366)
%k	Hour with 1 digits between 0-23.
%l	Hour with 1 digits between 1-12.
%M	Full month name in current locale (Variable <a href="#">lc_time_names</a> ).
%m	Month with 2 digits.
%p	AM/PM according to current locale (Variable <a href="#">lc_time_names</a> ).

%r	Time in 12 hour format, followed by AM/PM. Short for '%l:%i:%S %p'.
%s	Seconds with 2 digits.
%s	Seconds with 2 digits.
%T	Time in 24 hour format. Short for '%H:%i:%S'.
%U	Week number (00-53), when first day of the week is Sunday.
%u	Week number (00-53), when first day of the week is Monday.
%v	Week number (01-53), when first day of the week is Sunday. Used with %X.
%v	Week number (01-53), when first day of the week is Monday. Used with %x.
%w	Full weekday name in current locale (Variable <a href="#">lc_time_names</a> ).
%w	Day of the week. 0 = Sunday, 6 = Saturday.
%x	Year with 4 digits when first day of the week is Sunday. Used with %V.
%x	Year with 4 digits when first day of the week is Monday. Used with %v.
%Y	Year with 4 digits.
%y	Year with 2 digits.
%#	For <a href="#">str_to_date</a> (), skip all numbers.
%.	For <a href="#">str_to_date</a> (), skip all punctuation characters.
%@	For <a href="#">str_to_date</a> (), skip all alpha characters.
%%	A literal % character.

## Examples

```

SELECT STR_TO_DATE('Wednesday, June 2, 2014', '%W, %M %e, %Y');
+-----+
| STR_TO_DATE('Wednesday, June 2, 2014', '%W, %M %e, %Y') |
+-----+
| 2014-06-02 |
+-----+

SELECT STR_TO_DATE('Wednesday23423, June 2, 2014', '%W, %M %e, %Y');
+-----+
| STR_TO_DATE('Wednesday23423, June 2, 2014', '%W, %M %e, %Y') |
+-----+
| NULL |
+-----+
1 row in set, 1 warning (0.00 sec)

SHOW WARNINGS;
+-----+-----+
| Level | Code | Message |
+-----+-----+
| Warning | 1411 | Incorrect datetime value: 'Wednesday23423, June 2, 2014' for function str_to_date |
+-----+-----+

SELECT STR_TO_DATE('Wednesday23423, June 2, 2014', '%W%, %M %e, %Y');
+-----+
| STR_TO_DATE('Wednesday23423, June 2, 2014', '%W%, %M %e, %Y') |
+-----+
| 2014-06-02 |
+-----+

```

- [FROM\\_UNIXTIME\(\)](#)

## 1.1.12.3.43 SUBDATE

### Syntax

```
SUBDATE(date,INTERVAL expr unit), SUBDATE(expr,days)
```

### Description

When invoked with the

INTERVAL  
form of the second argument,  
SUBDATE()  
is a synonym for

[DATE\\_SUB\(\)](#)

. See [Date and Time Units](#) for a complete list of permitted units.

The second form allows the use of an integer value for days. In such cases, it is interpreted as the number of days to be subtracted from the date or datetime expression expr.

### Examples

```

SELECT DATE_SUB('2008-01-02', INTERVAL 31 DAY);
+-----+
| DATE_SUB('2008-01-02', INTERVAL 31 DAY) |
+-----+
| 2007-12-02                                |
+-----+

SELECT SUBDATE('2008-01-02', INTERVAL 31 DAY);
+-----+
| SUBDATE('2008-01-02', INTERVAL 31 DAY) |
+-----+
| 2007-12-02                                |
+-----+

```

```

SELECT SUBDATE('2008-01-02 12:00:00', 31);
+-----+
| SUBDATE('2008-01-02 12:00:00', 31) |
+-----+
| 2007-12-02 12:00:00                   |
+-----+

```

```

CREATE TABLE t1 (d DATETIME);
INSERT INTO t1 VALUES
    ("2007-01-30 21:31:07"),
    ("1983-10-15 06:42:51"),

| 2004-10-07 11:19:34 | 2004-10-07 11:09:34 |
+-----+

```

## 1.1.12.3.44 SUBTIME

### Syntax

```
SUBTIME(expr1,expr2)
```

### Description

SUBTIME() returns

```

expr1
-
expr2
expressed as a value in the same format as
expr1

```

expr1  
is a time or datetime expression, and expr2 is a time expression.

## Examples

```
SELECT SUBTIME('2007-12-31 23:59:59.999999','1 1:1:1.000002');
+-----+
| SUBTIME('2007-12-31 23:59:59.999999','1 1:1:1.000002') |
+-----+
| 2007-12-30 22:58:58.999997 |
+-----+

SELECT SUBTIME('01:00:00.999999', '02:00:00.999998');
+-----+
| SUBTIME('01:00:00.999999', '02:00:00.999998') |
+-----+
| -00:59:59.999999 |
+-----+
```

## 1.1.12.3.45 SYSDATE

### Syntax

```
SYSDATE([precision])
```

#### Contents

1. [Syntax](#)
2. [Description](#)
3. [Examples](#)
4. [See Also](#)

### Description

Returns the current date and time as a value in 'YYYY-MM-DD HH:MM:SS' or YYYYMMDDHHMMSS.uduuuu format, depending on whether the function is used in a string or numeric context.

The optional *precision* determines the microsecond precision. See [Microseconds in MariaDB](#).

SYSDATE() returns the time at which it executes. This differs from the behavior for [NOW\(\)](#), which returns a constant time that indicates the time at which the statement began to execute. (Within a stored routine or trigger, NOW() returns the time at which the routine or triggering statement began to execute.)

In addition, changing the [timestamp system variable](#) with a [SET](#)

timestamp

statement affects the value returned by NOW() but not by SYSDATE(). This means that timestamp settings in the [binary log](#) have no effect on invocations of SYSDATE().

Because SYSDATE() can return different values even within the same statement, and is not affected by SET TIMESTAMP, it is non-deterministic and therefore unsafe for replication if statement-based binary logging is used. If that is a problem, you can use row-based logging, or start the server with the mysqld option [--sysdate-is-now](#) to cause SYSDATE() to be an alias for NOW(). The non-deterministic nature of SYSDATE() also means that indexes cannot be used for evaluating expressions that refer to it, and that statements using the SYSDATE() function are [unsafe for statement-based replication](#).

## Examples

Difference between NOW() and SYSDATE():

```
SELECT NOW(), SLEEP(2), NOW();
+-----+-----+-----+
| NOW() | SLEEP(2) | NOW() |
+-----+-----+-----+
| 2010-03-27 13:23:40 | 0 | 2010-03-27 13:23:40 |
+-----+-----+-----+

SELECT SYSDATE(), SLEEP(2), SYSDATE();
+-----+-----+-----+
| SYSDATE() | SLEEP(2) | SYSDATE() |
+-----+-----+-----+
| 2010-03-27 13:23:52 | 0 | 2010-03-27 13:23:54 |
+-----+-----+-----+
```

With precision:

```
SELECT SYSDATE(4);
+-----+
| SYSDATE(4)           |
+-----+
| 2018-07-10 10:17:13.1689 |
+-----+
```

## See Also

- [Microseconds in MariaDB](#)
- [timestamp server system variable](#)

## 1.1.12.3.46 TIME Function

### Syntax

```
TIME(expr)
```

### Description

Extracts the time part of the time or datetime expression

expr  
and returns it as a string.

### Examples

```
SELECT TIME('2003-12-31 01:02:03');
+-----+
| TIME('2003-12-31 01:02:03') |
+-----+
| 01:02:03           |
+-----+

SELECT TIME('2003-12-31 01:02:03.000123');
+-----+
| TIME('2003-12-31 01:02:03.000123') |
+-----+
| 01:02:03.000123           |
+-----+
```

## 1.1.12.3.47 TIMEDIFF

### Syntax

```
TIMEDIFF(expr1,expr2)
```

### Description

TIMEDIFF() returns

expr1  
-  
expr2  
expressed as a time value.  
expr1  
and  
expr2  
are time or date-and-time expressions, but both must be of the same type.

### Examples

```

SELECT TIMEDIFF('2000:01:01 00:00:00', '2000:01:01 00:00:00.000001');
+-----+
| TIMEDIFF('2000:01:01 00:00:00', '2000:01:01 00:00:00.000001') |
+-----+
| -00:00:00.000001 |
+-----+

SELECT TIMEDIFF('2008-12-31 23:59:59.000001', '2008-12-30 01:01:01.000002');
+-----+
| TIMEDIFF('2008-12-31 23:59:59.000001', '2008-12-30 01:01:01.000002') |
+-----+
| 46:58:57.999999 |
+-----+

```

## 1.1.12.3.48 TIMESTAMP FUNCTION

### Syntax

```
TIMESTAMP(expr), TIMESTAMP(expr1,expr2)
```

### Description

With a single argument, this function returns the date or datetime expression

expr

as a datetime value. With two arguments, it adds the time expression

expr2

to the date or datetime expression

expr1

and returns the result as a datetime value.

### Examples

```

SELECT TIMESTAMP('2003-12-31');
+-----+
| TIMESTAMP('2003-12-31') |
+-----+
| 2003-12-31 00:00:00 |
+-----+

SELECT TIMESTAMP('2003-12-31 12:00:00','6:30:00');
+-----+
| TIMESTAMP('2003-12-31 12:00:00','6:30:00') |
+-----+
| 2003-12-31 18:30:00 |
+-----+

```

## 1.1.12.3.49 TIMESTAMPADD

### Syntax

```
TIMESTAMPADD(unit,interval,datetime_expr)
```

### Description

Adds the integer expression interval to the date or datetime expression datetime\_expr. The unit for interval is given by the unit argument, which should be one of the following values: MICROSECOND, SECOND, MINUTE, HOUR, DAY, WEEK, MONTH, QUARTER, or YEAR.

The unit value may be specified using one of keywords as shown, or with a prefix of SQL\_TSI\_. For example, DAY and SQL\_TSI\_DAY both are legal.

Before MariaDB 5.5 , FRAC\_SECOND was permitted as a synonym for MICROSECOND.

### Examples

```

SELECT TIMESTAMPADD(MINUTE,1,'2003-01-02');
+-----+
| TIMESTAMPADD(MINUTE,1,'2003-01-02') |
+-----+
| 2003-01-02 00:01:00 |
+-----+

SELECT TIMESTAMPADD(WEEK,1,'2003-01-02');
+-----+
| TIMESTAMPADD(WEEK,1,'2003-01-02') |
+-----+
| 2003-01-09 |
+-----+

```

## 1.1.12.3.50 TIMESTAMPDIFF

### Syntax

```
TIMESTAMPDIFF(unit,datetime_expr1,datetime_expr2)
```

### Description

Returns

```

datetime_expr2
-
datetime_expr1
, where
datetime_expr1
and
datetime_expr2

```

are date or datetime expressions. One expression may be a date and the other a datetime; a date value is treated as a datetime having the time part '00:00:00' where necessary. The unit for the result (an integer) is given by the unit argument. The legal values for unit are the same as those listed in the description of the [TIMESTAMPADD\(\)](#) function, i.e MICROSECOND, SECOND, MINUTE, HOUR, DAY, WEEK, MONTH, QUARTER, or YEAR.

`TIMESTAMPDIFF`

can also be used to calculate age.

### Examples

```

SELECT TIMESTAMPDIFF(MONTH,'2003-02-01','2003-05-01');
+-----+
| TIMESTAMPDIFF(MONTH,'2003-02-01','2003-05-01') |
+-----+
| 3 |
+-----+

SELECT TIMESTAMPDIFF(YEAR,'2002-05-01','2001-01-01');
+-----+
| TIMESTAMPDIFF(YEAR,'2002-05-01','2001-01-01') |
+-----+
| -1 |
+-----+

SELECT TIMESTAMPDIFF(MINUTE,'2003-02-01','2003-05-01 12:05:55');
+-----+
| TIMESTAMPDIFF(MINUTE,'2003-02-01','2003-05-01 12:05:55') |
+-----+
| 128885 |
+-----+

```

Calculating age:

```

SELECT CURDATE();
+-----+
| CURDATE() |
+-----+
| 2019-05-27 |
+-----+

SELECT TIMESTAMPDIFF(YEAR, '1971-06-06', CURDATE()) AS age;
+-----+
| age |
+-----+
| 47 |
+-----+

SELECT TIMESTAMPDIFF(YEAR, '1971-05-06', CURDATE()) AS age;
+-----+
| age |
+-----+
| 48 |
+-----+

```

Age as of 2014-08-02:

```

SELECT name, date_of_birth, TIMESTAMPDIFF(YEAR,date_of_birth,'2014-08-02') AS age
  FROM student_details;
+-----+-----+-----+
| name | date_of_birth | age |
+-----+-----+-----+
| Chun | 1993-12-31 | 20 |
| Esben | 1946-01-01 | 68 |
| Kaolin | 1996-07-16 | 18 |
| Tatiana | 1988-04-13 | 26 |
+-----+-----+-----+

```

## 1.1.12.3.51 TIME\_FORMAT

### Syntax

```
TIME_FORMAT(time,format)
```

### Description

This is used like the [DATE\\_FORMAT\(\)](#) function, but the format string may contain format specifiers only for hours, minutes, and seconds. Other specifiers produce a NULL value or 0.

### Examples

```

SELECT TIME_FORMAT('100:00:00', '%H %k %h %I %l');
+-----+
| TIME_FORMAT('100:00:00', '%H %k %h %I %l') |
+-----+
| 100 100 04 04 4 |
+-----+

```

## 1.1.12.3.52 TIME\_TO\_SEC

### Syntax

```
TIME_TO_SEC(time)
```

### Description

Returns the time argument, converted to seconds.

The value returned by

TIME\_TO\_SEC  
is of type

DOUBLE

. Before MariaDB 5.3 (and MySQL 5.6), the type was

INT

. The returned value preserves microseconds of the argument. See also [Microseconds in MariaDB](#).

## Examples

```
SELECT TIME_TO_SEC('22:23:00');
+-----+
| TIME_TO_SEC('22:23:00') |
+-----+
|          80580 |
+-----+
```

```
SELECT TIME_TO_SEC('00:39:38');
+-----+
| TIME_TO_SEC('00:39:38') |
+-----+
|          2378 |
+-----+
```

```
SELECT TIME_TO_SEC('09:12:55.2355');
+-----+
| TIME_TO_SEC('09:12:55.2355') |
+-----+
|          33175.2355 |
+-----+
1 row in set (0.000 sec)
```

## 1.1.12.3.53 TO\_DAYS

### Syntax

```
TO_DAYS(date)
```

### Description

Given a date

date  
, returns the number of days since the start of the current calendar (0000-00-00).

The function is not designed for use with dates before the advent of the Gregorian calendar in October 1582. Results will not be reliable since it doesn't account for the lost days when the calendar changed from the Julian calendar.

This is the converse of the [FROM\\_DAYS\(\)](#) function.

## Examples

```
SELECT TO_DAYS('2007-10-07');
+-----+
| TO_DAYS('2007-10-07') |
+-----+
|      733321 |
+-----+

SELECT TO_DAYS('0000-01-01');
+-----+
| TO_DAYS('0000-01-01') |
+-----+
|          1 |
+-----+

SELECT TO_DAYS(950501);
+-----+
| TO_DAYS(950501) |
+-----+
|      728779 |
+-----+
```

## 1.1.12.3.54 TO\_SECONDS

### Syntax

```
TO_SECONDS(expr)
```

### Description

Returns the number of seconds from year 0 till

expr  
, or NULL if  
expr  
is not a valid date or [datetime](#).

### Examples

```

SELECT TO_SECONDS('2013-06-13');
+-----+
| TO_SECONDS('2013-06-13') |
+-----+
|          63538300800 |
+-----+

SELECT TO_SECONDS('2013-06-13 21:45:13');
+-----+
| TO_SECONDS('2013-06-13 21:45:13') |
+-----+
|          63538379113 |
+-----+

SELECT TO_SECONDS(NOW());
+-----+
| TO_SECONDS(NOW()) |
+-----+
|      63543530875 |
+-----+

SELECT TO_SECONDS(20130513);
+-----+
| TO_SECONDS(20130513) |
+-----+
|          63535622400 |
+-----+
1 row in set (0.00 sec)

SELECT TO_SECONDS(130513);
+-----+
| TO_SECONDS(130513) |
+-----+
|          63535622400 |
+-----+

```

## 1.1.12.3.55 UNIX\_TIMESTAMP

### Contents

1. [Syntax](#)
2. [Description](#)
  1. [Error Handling](#)
  2. [Compatibility](#)
3. [Examples](#)
4. [See Also](#)

### Syntax

```

UNIX_TIMESTAMP()
UNIX_TIMESTAMP(date)

```

### Description

If called with no argument, returns a Unix timestamp (seconds since '1970-01-01 00:00:00' UTC ) as an unsigned integer. If

`UNIX_TIMESTAMP()`

is called with a date argument, it returns the value of the argument as seconds since '1970-01-01 00:00:00' UTC. date may be a

`DATE`

`string, a`

`DATETIME`

`string, a`

`TIMESTAMP`

, or a number in the format YYMMDD or YYYYMMDD. The server interprets date as a value in the current [time zone](#) and converts it to an internal value in [UTC](#) . Clients can set their time zone as described in [time zones](#) .

The inverse function of

UNIX\_TIMESTAMP()  
is

FROM\_UNIXTIME()

UNIX\_TIMESTAMP()  
supports microseconds .

Timestamps in MariaDB have a maximum value of 2147483647, equivalent to 2038-01-19 05:14:07. This is due to the underlying 32-bit limitation. Using the function on a date beyond this will result in NULL being returned. Use DATETIME as a storage type if you require dates beyond this.

## Error Handling

Returns NULL for wrong arguments to

UNIX\_TIMESTAMP()  
. In MySQL and MariaDB before 5.3 wrong arguments to  
UNIX\_TIMESTAMP()  
returned 0.

## Compatibility

As you can see in the examples above, UNIX\_TIMESTAMP(constant-date-string) returns a timestamp with 6 decimals while MariaDB 5.2 and before returns it without decimals. This can cause a problem if you are using UNIX\_TIMESTAMP() as a partitioning function. You can fix this by using FLOOR(UNIX\_TIMESTAMP(..)) or changing the date string to a date number, like 20080101000000.

## Examples

```
SELECT UNIX_TIMESTAMP();
+-----+
| UNIX_TIMESTAMP() |
+-----+
|      1269711082 |
+-----+

SELECT UNIX_TIMESTAMP('2007-11-30 10:30:19');
+-----+
| UNIX_TIMESTAMP('2007-11-30 10:30:19') |
+-----+
|          1196436619.000000 |
+-----+

SELECT UNIX_TIMESTAMP("2007-11-30 10:30:19.123456");
+-----+
| unix_timestamp("2007-11-30 10:30:19.123456") |
+-----+
|          1196411419.123456 |
+-----+

SELECT FROM_UNIXTIME(UNIX_TIMESTAMP('2007-11-30 10:30:19'));
+-----+
| FROM_UNIXTIME(UNIX_TIMESTAMP('2007-11-30 10:30:19')) |
+-----+
| 2007-11-30 10:30:19.000000 |
+-----+

SELECT FROM_UNIXTIME(FLOOR(UNIX_TIMESTAMP('2007-11-30 10:30:19')));
+-----+
| FROM_UNIXTIME(FLOOR(UNIX_TIMESTAMP('2007-11-30 10:30:19'))) |
+-----+
| 2007-11-30 10:30:19 |
+-----+
```

## See Also

- [FROM\\_UNIXTIME\(\)](#)

## 1.1.12.3.56 UTC\_DATE

### Syntax

```
UTC_DATE, UTC_DATE()
```

### Description

Returns the current [UTC date](#) as a value in 'YYYY-MM-DD' or YYYYMMDD format, depending on whether the function is used in a string or numeric context.

### Examples

```
SELECT UTC_DATE(), UTC_DATE() + 0;
+-----+
| UTC_DATE() | UTC_DATE() + 0 |
+-----+
| 2010-03-27 |      20100327 |
+-----+
```

## 1.1.12.3.57 UTC\_TIME

### Syntax

```
UTC_TIME
UTC_TIME([precision])
```

### Description

Returns the current [UTC time](#) as a value in 'HH:MM:SS' or HHMMSS.uduuuu format, depending on whether the function is used in a string or numeric context.

The optional *precision* determines the microsecond precision. See [Microseconds in MariaDB](#).

### Examples

```
SELECT UTC_TIME(), UTC_TIME() + 0;
+-----+
| UTC_TIME() | UTC_TIME() + 0 |
+-----+
| 17:32:34 | 173234.000000 |
+-----+
```

With precision:

```
SELECT UTC_TIME(5);
+-----+
| UTC_TIME(5) |
+-----+
| 07:52:50.78369 |
+-----+
```

### See Also

- [Microseconds in MariaDB](#)

## 1.1.12.3.58 UTC\_TIMESTAMP

### Syntax

```
UTC_TIMESTAMP  
UTC_TIMESTAMP([precision])
```

## Description

Returns the current [UTC](#) date and time as a value in 'YYYY-MM-DD HH:MM:SS' or YYYYMMDDHHMMSS.uduuuu format, depending on whether the function is used in a string or numeric context.

The optional *precision* determines the microsecond precision. See [Microseconds in MariaDB](#).

## Examples

```
SELECT UTC_TIMESTAMP(), UTC_TIMESTAMP() + 0;  
+-----+  
| UTC_TIMESTAMP() | UTC_TIMESTAMP() + 0 |  
+-----+  
| 2010-03-27 17:33:16 | 20100327173316.000000 |  
+-----+
```

With precision:

```
SELECT UTC_TIMESTAMP(4);  
+-----+  
| UTC_TIMESTAMP(4) |  
+-----+  
| 2018-07-10 07:51:09.1019 |  
+-----+
```

## See Also

- [Time Zones](#)
- [Microseconds in MariaDB](#)

## 1.1.12.3.59 WEEK

### Syntax

```
WEEK(date[,mode])
```

## Description

This function returns the week number for

date

. The two-argument form of

WEEK()

allows you to specify whether the week starts on Sunday or Monday and whether the return value should be in the range from 0 to 53 or from 1 to 53. If the

mode

argument is omitted, the value of the [default\\_week\\_format](#) system variable is used.

### Modes

Mode	1st day of week	Range	Week 1 is the 1st week with
0	Sunday	0-53	a Sunday in this year
1	Monday	0-53	more than 3 days this year
2	Sunday	1-53	a Sunday in this year
3	Monday	1-53	more than 3 days this year
4	Sunday	0-53	more than 3 days this year
5	Monday	0-53	a Monday in this year

6	Sunday	1-53	more than 3 days this year
7	Monday	1-53	a Monday in this year

With the mode value of 3, which means “more than 3 days this year”, weeks are numbered according to ISO 8601:1988.

## Examples

```
SELECT WEEK('2008-02-20');
```

```
+-----+
| WEEK('2008-02-20') |
+-----+
| 7 |
+-----+
```

```
SELECT WEEK('2008-02-20',0);
```

```
+-----+
| WEEK('2008-02-20',0) |
+-----+
| 7 |
+-----+
```

```
SELECT WEEK('2008-02-20',1);
```

```
+-----+
| WEEK('2008-02-20',1) |
+-----+
| 8 |
+-----+
```

```
SELECT WEEK('2008-12-31');
```

```
+-----+
| WEEK('2008-12-31') |
+-----+
| 52 |
+-----+
```

```
SELECT WEEK('2008-12-31',1);
```

```
+-----+
| WEEK('2008-12-31',1) |
+-----+
| 53 |
+-----+
```

```
SELECT WEEK('2019-12-30',3);
```

```
+-----+
| WEEK('2019-12-30',3) |
+-----+
| 1 |
+-----+
```

```
CREATE TABLE t1 (d DATETIME);
INSERT INTO t1 VALUES
    ("2007-01-30 21:31:07"),
    ("1983-10-15 06:42:51"),
    ("2011-04-21 12:34:56"),
    ("2011-10-30 06:31:41"),
    ("2011-01-30 14:03:25"),
    ("2004-10-07 11:19:34");
```

```
SELECT d, WEEK(d,0), WEEK(d,1) from t1;
```

```
+-----+-----+-----+
| d | WEEK(d,0) | WEEK(d,1) |
+-----+-----+-----+
| 2007-01-30 21:31:07 | 4 | 5 |
| 1983-10-15 06:42:51 | 41 | 41 |
| 2011-04-21 12:34:56 | 16 | 16 |
| 2011-10-30 06:31:41 | 44 | 43 |
| 2011-01-30 14:03:25 | 5 | 4 |
| 2004-10-07 11:19:34 | 40 | 41 |
+-----+-----+-----+
```

## 1.1.12.3.60 WEEKDAY

### Syntax

```
WEEKDAY(date)
```

### Description

Returns the weekday index for

```
date
(
0
= Monday,
1
= Tuesday, ...
6
= Sunday).
```

This contrasts with

```
DAYOFWEEK()
```

which follows the ODBC standard (

```
1
= Sunday,
2
= Monday, ...,
7
= Saturday).
```

### Examples

```
SELECT WEEKDAY('2008-02-03 22:23:00');
+-----+
| WEEKDAY('2008-02-03 22:23:00') |
+-----+
| 6 |
+-----+

SELECT WEEKDAY('2007-11-06');
+-----+
| WEEKDAY('2007-11-06') |
+-----+
| 1 |
+-----+
```

```
CREATE TABLE t1 (d DATETIME);
INSERT INTO t1 VALUES
("2007-01-30 21:31:07"),
("1983-10-15 06:42:51"),
("2011-04-21 12:34:56"),
("2011-10-30 06:31:41"),
("2011-01-30 14:03:25"),
("2004-10-07 11:19:34");
```

```
SELECT d FROM t1 WHERE WEEKDAY(d) = 6;
+-----+
| d |
+-----+
| 2011-10-30 06:31:41 |
| 2011-01-30 14:03:25 |
+-----+
```

## 1.1.12.3.61 WEEKOFYEAR

# Syntax

```
WEEKOFYEAR(date)
```

## Description

Returns the calendar week of the date as a number in the range from 1 to 53.

`WEEKOFYEAR()`

is a compatibility function that is equivalent to

```
WEEK(date,3)
```

## Examples

```
SELECT WEEKOFYEAR('2008-02-20');
+-----+
| WEEKOFYEAR('2008-02-20') |
+-----+
|          8 |
+-----+
```

```
CREATE TABLE t1 (d DATETIME);
INSERT INTO t1 VALUES
    ("2007-01-30 21:31:07"),
    ("1983-10-15 06:42:51"),
    ("2011-04-21 12:34:56"),
    ("2011-10-30 06:31:41"),
    ("2011-01-30 14:03:25"),
    ("2004-10-07 11:19:34");
```

```
select * from t1;
+-----+
| d           |
+-----+
| 2007-01-30 21:31:07 |
| 1983-10-15 06:42:51 |
| 2011-04-21 12:34:56 |
| 2011-10-30 06:31:41 |
| 2011-01-30 14:03:25 |
| 2004-10-07 11:19:34 |
+-----+
```

```
SELECT d, WEEKOFYEAR(d), WEEK(d,3) from t1;
+-----+-----+-----+
| d           | WEEKOFYEAR(d) | WEEK(d,3) |
+-----+-----+-----+
| 2007-01-30 21:31:07 |      5 |      5 |
| 1983-10-15 06:42:51 |     41 |     41 |
| 2011-04-21 12:34:56 |     16 |     16 |
| 2011-10-30 06:31:41 |     43 |     43 |
| 2011-01-30 14:03:25 |      4 |      4 |
| 2004-10-07 11:19:34 |     41 |     41 |
+-----+-----+-----+
```

## 1.1.12.3.62 YEAR

### Syntax

```
YEAR(date)
```

## Description

Returns the year for the given date, in the range 1000 to 9999, or 0 for the "zero" date.

## Examples

```
CREATE TABLE t1 (d DATETIME);
INSERT INTO t1 VALUES
    ("2007-01-30 21:31:07"),
    ("1983-10-15 06:42:51"),
    ("2011-04-21 12:34:56"),
    ("2011-10-30 06:31:41"),
    ("2011-01-30 14:03:25"),
    ("2004-10-07 11:19:34");
```

```
SELECT * FROM t1;
+-----+
| d
+-----+
| 2007-01-30 21:31:07 |
| 1983-10-15 06:42:51 |
| 2011-04-21 12:34:56 |
| 2011-10-30 06:31:41 |
| 2011-01-30 14:03:25 |
| 2004-10-07 11:19:34 |
+-----+

SELECT * FROM t1 WHERE YEAR(d) = 2011;
+-----+

| 1987 |
+-----+
```

## See Also

- [YEAR data type](#)

## 1.1.12.3.63 YEARWEEK

### Syntax

```
YEARWEEK(date), YEARWEEK(date,mode)
```

### Description

Returns year and week for a date. The mode argument works exactly like the mode argument to [WEEK\(\)](#). The year in the result may be different from the year in the date argument for the first and the last week of the year.

## Examples

```
SELECT YEARWEEK('1987-01-01');
+-----+
| YEARWEEK('1987-01-01') |
+-----+
| 198652 |
+-----+
```

```
CREATE TABLE t1 (d DATETIME);
INSERT INTO t1 VALUES
    ("2007-01-30 21:31:07"),
    ("1983-10-15 06:42:51"),
    ("2011-04-21 12:34:56"),
    ("2011-10-30 06:31:41"),
    ("2011-01-30 14:03:25"),
    ("2004-10-07 11:19:34");
```

```
SELECT * FROM t1;
+-----+
| d      |
+-----+
| 2007-01-30 21:31:07 |
| 1983-10-15 06:42:51 |
| 2011-04-21 12:34:56 |
| 2011-10-30 06:31:41 |
| 2011-01-30 14:03:25 |
| 2004-10-07 11:19:34 |
+-----+
6 rows in set (0.02 sec)
```

```
SELECT YEARWEEK(d) FROM t1 WHERE YEAR(d) = 2011;
+-----+
| YEARWEEK(d) |
+-----+
| 201116      |
| 201144      |
| 201105      |
+-----+
3 rows in set (0.03 sec)
```

## 1.1.12.4 Aggregate Functions

### 1.1.12.4.1 Stored Aggregate Functions

MariaDB starting with [10.3.3](#)

The ability to create stored aggregate functions was added in [MariaDB 10.3.3](#).

#### Contents

- 1. Standard Syntax
  - 1. Using SQL/PL
- 2. Examples
  - 1. SQL/PL Example
- 3. See Also

[Aggregate functions](#) are functions that are computed over a sequence of rows and return one result for the sequence of rows.

Creating a custom aggregate function is done using the [CREATE FUNCTION](#) statement with two main differences:

- The addition of the AGGREGATE keyword, so

```
CREATE AGGREGATE FUNCTION
```

- The

```
FETCH GROUP NEXT ROW
```

instruction inside the loop

- Oracle PL/SQL compatibility using SQL/PL is provided

## Standard Syntax

```

CREATE AGGREGATE FUNCTION function_name (parameters) RETURNS return_type
BEGIN
    All types of declarations
    DECLARE CONTINUE HANDLER FOR NOT FOUND RETURN return_val;
    LOOP
        FETCH GROUP NEXT ROW; // fetches next row from table
        other instructions
    END LOOP;
END

```

Stored aggregate functions were a [2016 Google Summer of Code](#) project by Varun Gupta.

## Using SQL/PL

```

SET sql_mode=Oracle;
DELIMITER //

CREATE AGGREGATE FUNCTION function_name (parameters) RETURN return_type
    declarations
BEGIN
    LOOP
        FETCH GROUP NEXT ROW; -- fetches next row from table
        -- other instructions

    END LOOP;
EXCEPTION
    WHEN NO_DATA_FOUND THEN
        RETURN return_val;
END //

DELIMITER ;

```

## Examples

First a simplified example:

```

CREATE TABLE marks(stud_id INT, grade_count INT);

INSERT INTO marks VALUES (1,6), (2,4), (3,7), (4,5), (5,8);

SELECT * FROM marks;
+-----+-----+
| stud_id | grade_count |
+-----+-----+
|      1 |         6 |
|      2 |         4 |
|      3 |         7 |
|      4 |         5 |
|      5 |         8 |
+-----+-----+

DELIMITER //
CREATE AGGREGATE FUNCTION IF NOT EXISTS aggregate_count(x INT) RETURNS INT
BEGIN
    DECLARE count_students INT DEFAULT 0;
    DECLARE CONTINUE HANDLER FOR NOT FOUND
    RETURN count_students;
    LOOP
        FETCH GROUP NEXT ROW;
        IF x THEN
            SET count_students = count_students+1;
        END IF;
    END LOOP;
END //
DELIMITER ;

```

A non-trivial example that cannot easily be rewritten using existing functions:

```

DELIMITER //
CREATE AGGREGATE FUNCTION medi_int(x INT) RETURNS DOUBLE
BEGIN
    DECLARE CONTINUE HANDLER FOR NOT FOUND
    BEGIN
        DECLARE res DOUBLE;
        DECLARE cnt INT DEFAULT (SELECT COUNT(*) FROM tt);
        DECLARE lim INT DEFAULT (cnt-1) DIV 2;
        IF cnt % 2 = 0 THEN
            SET res = (SELECT AVG(a) FROM (SELECT a FROM tt ORDER BY a LIMIT lim,2) ttt);
        ELSE
            SET res = (SELECT a FROM tt ORDER BY a LIMIT lim,1);
        END IF;
        DROP TEMPORARY TABLE tt;
        RETURN res;
    END;
    CREATE TEMPORARY TABLE tt (a INT);
    LOOP
        FETCH GROUP NEXT ROW;
        INSERT INTO tt VALUES (x);
    END LOOP;
END //
DELIMITER ;

```

## SQL/PL Example

This uses the same marks table as created above.

```

SET sql_mode=Oracle;
DELIMITER //

CREATE AGGREGATE FUNCTION aggregate_count(x INT) RETURN INT AS count_students INT DEFAULT 0;
BEGIN
    LOOP
        FETCH GROUP NEXT ROW;
        IF x THEN
            SET count_students := count_students+1;
        END IF;
    END LOOP;
EXCEPTION
    WHEN NO_DATA_FOUND THEN
        RETURN count_students;
END aggregate_count //
DELIMITER ;

SELECT aggregate_count(stud_id) FROM marks;

```

## 1.1.12.4.2 AVG

### Syntax

```
AVG([DISTINCT] expr)
```

### Contents

1. [Syntax](#)
2. [Description](#)
3. [Examples](#)
4. [See Also](#)

# Description

Returns the average value of expr. The DISTINCT option can be used to return the average of the distinct values of expr. NULL values are ignored. It is an [aggregate function](#), and so can be used with the [GROUP BY](#) clause.

AVG() returns NULL if there were no matching rows.

From [MariaDB 10.2.0](#), AVG() can be used as a [window function](#).

## Examples

```
CREATE TABLE sales (sales_value INT);

INSERT INTO sales VALUES(10),(20),(20),(40);

SELECT AVG(sales_value) FROM sales;
+-----+
| AVG(sales_value) |
+-----+
|      22.5000 |
+-----+

SELECT AVG(DISTINCT(sales_value)) FROM sales;
+-----+
| AVG(DISTINCT(sales_value)) |
+-----+
|          23.3333 |
+-----+
```

Commonly, AVG() is used with a [GROUP BY](#) clause:

```
CREATE TABLE student (name CHAR(10), test CHAR(10), score TINYINT);

INSERT INTO student VALUES
('Chun', 'SQL', 75), ('Chun', 'Tuning', 73),
('Esben', 'SQL', 43), ('Esben', 'Tuning', 31),
('Kaolin', 'SQL', 56), ('Kaolin', 'Tuning', 88),
('Tatiana', 'SQL', 87), ('Tatiana', 'Tuning', 83);

SELECT name, AVG(score) FROM student GROUP BY name;
+-----+
| name    | AVG(score) |
+-----+
| Chun    | 74.0000 |
| Esben   | 37.0000 |
| Kaolin  | 72.0000 |
| Tatiana | 85.0000 |
+-----+
```

Be careful to avoid this common mistake, not grouping correctly and returning mismatched data:

```
SELECT name,test,AVG(score) FROM student;
+-----+
| name | test | MIN(score) |
+-----+
| Chun | SQL  |      31 |
+-----+
```

As a [window function](#):

```

CREATE TABLE student_test (name CHAR(10), test CHAR(10), score TINYINT);

INSERT INTO student_test VALUES
    ('Chun', 'SQL', 75), ('Chun', 'Tuning', 73),
    ('Esben', 'SQL', 43), ('Esben', 'Tuning', 31),
    ('Kaolin', 'SQL', 56), ('Kaolin', 'Tuning', 88),
    ('Tatiana', 'SQL', 87), ('Tatiana', 'Tuning', 83);

SELECT name, test, score, AVG(score) OVER (PARTITION BY test)
    AS average_by_test FROM student_test;
+-----+-----+-----+-----+
| name   | test   | score | average_by_test |
+-----+-----+-----+-----+
| Chun   | SQL    | 75   | 65.2500 |
| Chun   | Tuning | 73   | 68.7500 |
| Esben  | SQL    | 43   | 65.2500 |
| Esben  | Tuning | 31   | 68.7500 |
| Kaolin | SQL    | 56   | 65.2500 |
| Kaolin | Tuning | 88   | 68.7500 |
| Tatiana| SQL    | 87   | 65.2500 |
| Tatiana| Tuning | 83   | 68.7500 |
+-----+-----+-----+-----+

```

## 1.1.12.4.3 BIT\_AND

### Syntax

```
BIT_AND(expr) [over_clause]
```

### Description

Returns the bitwise AND of all bits in *expr*. The calculation is performed with 64-bit (`BIGINT`) precision. It is an [aggregate function](#), and so can be used with the `GROUP BY` clause.

If no rows match,

`BIT_AND`

will return a value with all bits set to 1. NULL values have no effect on the result unless all results are NULL, which is treated as no match.

From [MariaDB 10.2.0](#),

`BIT_AND`

can be used as a [window function](#) with the addition of the *over\_clause*.

### Examples

```

CREATE TABLE vals (x INT);

INSERT INTO vals VALUES(111),(110),(100);

SELECT BIT_AND(x), BIT_OR(x), BIT_XOR(x) FROM vals;
+-----+-----+-----+
| BIT_AND(x) | BIT_OR(x) | BIT_XOR(x) |
+-----+-----+-----+
|      100   |       111  |        101 |
+-----+-----+-----+

```

As an [aggregate function](#):

```

CREATE TABLE vals2 (category VARCHAR(1), x INT);

INSERT INTO vals2 VALUES
('a',111),('a',110),('a',100),
('b','000'),('b',001),('b',011);

SELECT category, BIT_AND(x), BIT_OR(x), BIT_XOR(x)
  FROM vals2 GROUP BY category;
+-----+-----+-----+
| category | BIT_AND(x) | BIT_OR(x) | BIT_XOR(x) |
+-----+-----+-----+
| a        |      100 |      111 |      101 |
| b        |       0 |       11 |       10 |
+-----+-----+-----+

```

No match:

```

SELECT BIT_AND(NULL);
+-----+
| BIT_AND(NULL) |
+-----+
| 18446744073709551615 |
+-----+

```

## See Also

- [BIT\\_OR](#)
- [BIT\\_XOR](#)

## 1.1.12.4.4 BIT\_OR

### Syntax

```
BIT_OR(expr) [over_clause]
```

### Contents

1. [Syntax](#)
2. [Description](#)
3. [Examples](#)
4. [See Also](#)

### Description

Returns the bitwise OR of all bits in

`expr`

. The calculation is performed with 64-bit ( `BIGINT` ) precision. It is an [aggregate function](#) , and so can be used with the `GROUP BY` clause.

If no rows match,

`BIT_OR`

will return a value with all bits set to

`0`

. `NULL` values have no effect on the result unless all results are `NULL`, which is treated as no match.

From [MariaDB 10.2.0](#) ,

`BIT_OR`

can be used as a [window function](#) with the addition of the `over_clause` .

### Examples

```

CREATE TABLE vals (x INT);

INSERT INTO vals VALUES(111),(110),(100);

SELECT BIT_AND(x), BIT_OR(x), BIT_XOR(x) FROM vals;
+-----+-----+-----+
| BIT_AND(x) | BIT_OR(x) | BIT_XOR(x) |
+-----+-----+-----+
|      100   |      111   |      101   |
+-----+-----+-----+

```

As an [aggregate function](#) :

```

CREATE TABLE vals2 (category VARCHAR(1), x INT);

INSERT INTO vals2 VALUES
('a',111),('a',110),('a',100),
('b','000'),('b',001),('b',011);

SELECT category, BIT_AND(x), BIT_OR(x), BIT_XOR(x)
  FROM vals2 GROUP BY category;
+-----+-----+-----+
| category | BIT_AND(x) | BIT_OR(x) | BIT_XOR(x) |
+-----+-----+-----+
| a        |      100   |      111   |      101   |
| b        |          0  |      11    |      10    |
+-----+-----+-----+

```

No match:

```

SELECT BIT_OR(NULL);
+-----+
| BIT_OR(NULL) |
+-----+
|          0  |
+-----+

```

## See Also

- [BIT\\_AND](#)
- [BIT\\_XOR](#)

## 1.1.12.4.5 BIT\_XOR

### Syntax

```
BIT_XOR(expr) [over_clause]
```

### Contents

1. [Syntax](#)
2. [Description](#)
3. [Examples](#)
4. [See Also](#)

### Description

Returns the bitwise XOR of all bits in

expr

. The calculation is performed with 64-bit ( [BIGINT](#) ) precision. It is an [aggregate function](#) , and so can be used with the [GROUP BY](#) clause.

If no rows match,

BIT\_XOR

will return a value with all bits set to

0

. NULL values have no effect on the result unless all results are NULL, which is treated as no match.

From [MariaDB 10.2.0](#) ,

BIT\_XOR

can be used as a [window function](#) with the addition of the [over\\_clause](#) .

## Examples

```
CREATE TABLE vals (x INT);

INSERT INTO vals VALUES(111),(110),(100);

SELECT BIT_AND(x), BIT_OR(x), BIT_XOR(x) FROM vals;
+-----+-----+-----+
| BIT_AND(x) | BIT_OR(x) | BIT_XOR(x) |
+-----+-----+-----+
|      100   |      111   |      101   |
+-----+-----+-----+
```

As an aggregate function :

```
CREATE TABLE vals2 (category VARCHAR(1), x INT);

INSERT INTO vals2 VALUES
    ('a',111),('a',110),('a',100),
    ('b','000'),('b',001),('b',011);

SELECT category, BIT_AND(x), BIT_OR(x), BIT_XOR(x)
    FROM vals2 GROUP BY category;
+-----+-----+-----+
| category | BIT_AND(x) | BIT_OR(x) | BIT_XOR(x) |
+-----+-----+-----+
| a        |      100   |      111   |      101   |
| b        |          0  |       11    |       10    |
+-----+-----+-----+
```

No match:

```
SELECT BIT_XOR(NULL);
+-----+
| BIT_XOR(NULL) |
+-----+
|          0   |
+-----+
```

## See Also

- [BIT\\_AND](#)
- [BIT\\_OR](#)

## 1.1.12.4.6 COUNT

### Syntax

```
COUNT(expr)
```

### Contents

1. [Syntax](#)
2. [Description](#)
3. [Examples](#)
4. [See Also](#)

### Description

Returns a count of the number of non-NULL values of expr in the rows retrieved by a `SELECT` statement. The result is a `BIGINT` value. It is an [aggregate function](#), and so can be used with the `GROUP BY` clause.

`COUNT(*)` counts the total number of rows in a table.

`COUNT()` returns 0 if there were no matching rows.

From [MariaDB 10.2.0](#), `COUNT()` can be used as a [window function](#).

## Examples

```

CREATE TABLE student (name CHAR(10), test CHAR(10), score TINYINT);

INSERT INTO student VALUES
('Chun', 'SQL', 75), ('Chun', 'Tuning', 73),
('Esben', 'SQL', 43), ('Esben', 'Tuning', 31),
('Kaolin', 'SQL', 56), ('Kaolin', 'Tuning', 88),
('Tatiana', 'SQL', 87), ('Tatiana', 'Tuning', 83);

SELECT COUNT(*) FROM student;
+-----+
| COUNT(*) |
+-----+
|      8   |
+-----+

```

COUNT(DISTINCT) example:

```

SELECT COUNT(DISTINCT name) FROM student;
+-----+
| COUNT(DISTINCT name) |
+-----+
|          4           |
+-----+

```

As a window function

```

CREATE OR REPLACE TABLE student_test (name CHAR(10), test CHAR(10), score TINYINT);

INSERT INTO student_test VALUES
('Chun', 'SQL', 75), ('Chun', 'Tuning', 73),
('Esben', 'SQL', 43), ('Esben', 'Tuning', 31),
('Kaolin', 'SQL', 56), ('Kaolin', 'Tuning', 88),
('Tatiana', 'SQL', 87);

SELECT name, test, score, COUNT(score) OVER (PARTITION BY name)
  AS tests_written FROM student_test;
+-----+-----+-----+-----+
| name    | test   | score | tests_written |
+-----+-----+-----+-----+
| Chun    | SQL    | 75   |        2       |
| Chun    | Tuning | 73   |        2       |
| Esben   | SQL    | 43   |        2       |
| Esben   | Tuning | 31   |        2       |
| Kaolin  | SQL    | 56   |        2       |
| Kaolin  | Tuning | 88   |        2       |
| Tatiana | SQL    | 87   |        1       |
+-----+-----+-----+-----+

```

## See Also

- [SELECT](#)
- [COUNT DISTINCT](#)
- [Window Functions](#)

## 1.1.12.4.7 COUNT DISTINCT

### Syntax

```
COUNT(DISTINCT expr,[expr...])
```

### Contents

1. [Syntax](#)
2. [Description](#)
3. [Examples](#)
4. [See Also](#)

### Description

Returns a count of the number of different non-NULL values.

COUNT(DISTINCT) returns 0 if there were no matching rows.

Although, from MariaDB 10.2.0 , COUNT can be used as a window function , COUNT DISTINCT cannot be.

## Examples

```
CREATE TABLE student (name CHAR(10), test CHAR(10), score TINYINT);

INSERT INTO student VALUES
    ('Chun', 'SQL', 75), ('Chun', 'Tuning', 73),
    ('Esben', 'SQL', 43), ('Esben', 'Tuning', 31),
    ('Kaolin', 'SQL', 56), ('Kaolin', 'Tuning', 88),
    ('Tatiana', 'SQL', 87), ('Tatiana', 'Tuning', 83);

SELECT COUNT(*) FROM student;
+-----+
| COUNT(*) |
+-----+
|      8   |
+-----+

SELECT COUNT(DISTINCT (name)) FROM student;
+-----+
| COUNT(DISTINCT (name)) |
+-----+
|             4          |
+-----+
```

## See Also

- [SELECT](#)
- [COUNT](#)

## 1.1.12.4.8 GROUP\_CONCAT

### Syntax

```
GROUP_CONCAT(expr)
```

### Contents

1. [Syntax](#)
2. [Description](#)
  - 1. [LIMIT](#)
3. [Examples](#)
4. [See Also](#)

### Description

This function returns a string result with the concatenated non-NULL values from a group. It returns NULL if there are no non-NULL values.

The maximum returned length in bytes is determined by the `group_concat_max_len` server system variable, which defaults to 1M (>= MariaDB 10.2.4 ) or 1K (<= MariaDB 10.2.3 ).

If `group_concat_max_len <= 512`, the return type is `VARBINARY` or `VARCHAR` ; otherwise, the return type is `BLOB` or `TEXT` . The choice between binary or non-binary types depends from the input.

The full syntax is as follows:

```
GROUP_CONCAT([DISTINCT] expr [,expr ...]
            [ORDER BY {unsigned_integer | col_name | expr}
             [ASC | DESC] [,col_name ...]]
            [SEPARATOR str_val]
            [LIMIT {[offset,] row_count | row_count OFFSET offset}])
```

`DISTINCT`

eliminates duplicate values from the output string.

`ORDER BY` determines the order of returned values.

SEPARATOR  
specifies a separator between the values. The default separator is a comma ( , ). It is possible to avoid using a separator by specifying an empty string.

## LIMIT

MariaDB starting with 10.3.3

Until MariaDB 10.3.2 , it was not possible to use the LIMIT clause with GROUP\_CONCAT . This restriction was lifted in MariaDB 10.3.3 .

## Examples

```
SELECT student_name,  
       GROUP_CONCAT(test_score)  
  FROM student  
 GROUP BY student_name;
```

Get a readable list of MariaDB users from the mysql.user table:

```
SELECT GROUP_CONCAT(DISTINCT User ORDER BY User SEPARATOR '\n')  
      FROM mysql.user;
```

In the former example,

DISTINCT  
is used because the same user may occur more than once. The new line ( \n ) used as a  
SEPARATOR  
makes the results easier to read.

Get a readable list of hosts from which each user can connect:

```
SELECT User, GROUP_CONCAT(Host ORDER BY Host SEPARATOR ', ')  
      FROM mysql.user GROUP BY User ORDER BY User;
```

The former example shows the difference between the

GROUP\_CONCAT  
's ORDER BY (which sorts the concatenated hosts), and the  
SELECT  
's ORDER BY (which sorts the rows).

From MariaDB 10.3.3 , LIMIT can be used with

GROUP\_CONCAT  
, so, for example, given the following table:

```
CREATE TABLE d (dd DATE, cc INT);  
  
INSERT INTO d VALUES ('2017-01-01',1);  
INSERT INTO d VALUES ('2017-01-02',2);  
INSERT INTO d VALUES ('2017-01-04',3);
```

the following query:

```
SELECT SUBSTRING_INDEX(GROUP_CONCAT(CONCAT_WS(":",dd,cc) ORDER BY cc DESC),",",1) FROM d;  
+-----+  
| SUBSTRING_INDEX(GROUP_CONCAT(CONCAT_WS(":",dd,cc) ORDER BY cc DESC),",",1) |  
+-----+  
| 2017-01-04:3 |  
+-----+
```

can be more simply rewritten as:

```

SELECT GROUP_CONCAT(CONCAT_WS(":",dd,cc) ORDER BY cc DESC LIMIT 1) FROM d;
+-----+
| GROUP_CONCAT(CONCAT_WS(":",dd,cc) ORDER BY cc DESC LIMIT 1) |
+-----+
| 2017-01-04:3 |
+-----+

```

## 1.1.12.4.9 JSON\_ARRAYAGG

MariaDB starting with [10.5.0](#)

`JSON_ARRAYAGG` was added in [MariaDB 10.5.0](#).

## Syntax

```
JSON_ARRAYAGG(column_or_expression)
```

## Description

`JSON_ARRAYAGG`

returns a JSON array containing an element for each value in a given set of JSON or SQL values. It acts on a column or an expression that evaluates to a single value.

Returns NULL in the case of an error, or if the result contains no rows.

`JSON_ARRAYAGG`

cannot currently be used as a [window function](#).

The full syntax is as follows:

```

JSON_ARRAYAGG([DISTINCT] expr [,expr ...]
              [ORDER BY {unsigned_integer | col_name | expr}
               [ASC | DESC] [,col_name ...]]
              [LIMIT {[offset,] row_count | row_count OFFSET offset}])

```

## Examples

```

CREATE TABLE t1 (a INT, b INT);

INSERT INTO t1 VALUES (1, 1),(2, 1), (1, 1),(2, 1), (3, 2),(2, 2),(2, 2);

SELECT JSON_ARRAYAGG(a), JSON_ARRAYAGG(b) FROM t1;
+-----+-----+
| JSON_ARRAYAGG(a) | JSON_ARRAYAGG(b) |
+-----+-----+
| [1,2,1,2,3,2,2] | [1,1,1,2,2,2] |
+-----+-----+

SELECT JSON_ARRAYAGG(a), JSON_ARRAYAGG(b) FROM t1 GROUP BY b;
+-----+-----+
| JSON_ARRAYAGG(a) | JSON_ARRAYAGG(b) |
+-----+-----+
| [1,2,1,2]        | [1,1,1,1]          |
| [3,2,2,2]        | [2,2,2,2]          |
+-----+-----+

```

## 1.1.12.4.10 JSON\_OBJECTAGG

MariaDB starting with 10.5.0

JSON\_OBJECTAGG was added in MariaDB 10.5.0 .

## Syntax

```
JSON_OBJECTAGG(key, value)
```

## Description

JSON\_OBJECTAGG

returns a JSON object containing key-value pairs. It takes two expressions that evaluate to a single value, or two column names, as arguments, the first used as a key, and the second as a value.

Returns NULL in the case of an error, or if the result contains no rows.

JSON\_OBJECTAGG

cannot currently be used as a [window function](#) .

## Examples

```
select * from t1;
+-----+
| a      | b      |
+-----+
| 1      | Hello  |
| 1      | World  |
| 2      | This   |
+-----+

SELECT JSON_OBJECTAGG(a, b) FROM t1;
+-----+
| JSON_OBJECTAGG(a, b)           |
+-----+
| {"1":"Hello", "1":"World", "2":"This"} |
+-----+
```

## 1.1.12.4.11 MAX

### Syntax

```
MAX([DISTINCT] expr)
```

#### Contents

1. [Syntax](#)
2. [Description](#)
3. [Examples](#)
4. [See Also](#)

### Description

Returns the largest, or maximum, value of

*expr*

MAX()

can also take a string argument in which case it returns the maximum string value. The

DISTINCT

keyword can be used to find the maximum of the distinct values of

*expr*

, however, this produces the same result as omitting

DISTINCT

Note that **SET** and **ENUM** fields are currently compared by their string value rather than their relative position in the set, so **MAX()** may produce a different highest result than **ORDER BY DESC**.

It is an [aggregate function](#), and so can be used with the [GROUP BY](#) clause.

From [MariaDB 10.2.2](#), **MAX()** can be used as a [window function](#).

```
MAX()  
returns  
NULL  
if there were no matching rows.
```

## Examples

```
CREATE TABLE student (name CHAR(10), test CHAR(10), score TINYINT);  
  
INSERT INTO student VALUES  
('Chun', 'SQL', 75), ('Chun', 'Tuning', 73),  
('Esben', 'SQL', 43), ('Esben', 'Tuning', 31),  
('Kaolin', 'SQL', 56), ('Kaolin', 'Tuning', 88),  
('Tatiana', 'SQL', 87), ('Tatiana', 'Tuning', 83);  
  
SELECT name, MAX(score) FROM student GROUP BY name;  
+-----+  
| name | MAX(score) |  
+-----+  
| Chun | 75 |  
| Esben | 43 |  
| Kaolin | 88 |  
| Tatiana | 87 |  
+-----+
```

MAX string:

```
SELECT MAX(name) FROM student;  
+-----+  
| MAX(name) |  
+-----+  
| Tatiana |  
+-----+
```

Be careful to avoid this common mistake, not grouping correctly and returning mismatched data:

```
SELECT name,test,MAX(SCORE) FROM student;  
+-----+-----+  
| name | test | MAX(SCORE) |  
+-----+-----+  
| Chun | SQL | 88 |  
+-----+-----+
```

Difference between **ORDER BY DESC** and **MAX()**:

```
CREATE TABLE student2(name CHAR(10),grade ENUM('b','c','a'));  
  
INSERT INTO student2 VALUES('Chun','b'),('Esben','c'),('Kaolin','a');  
  
SELECT MAX(grade) FROM student2;  
+-----+  
| MAX(grade) |  
+-----+  
| c |  
+-----+  
  
SELECT grade FROM student2 ORDER BY grade DESC LIMIT 1;  
+-----+  
| grade |  
+-----+  
| a |  
+-----+
```

As a [window function](#):

```

CREATE OR REPLACE TABLE student_test (name CHAR(10), test CHAR(10), score TINYINT);
INSERT INTO student_test VALUES
    ('Chun', 'SQL', 75), ('Chun', 'Tuning', 73),
    ('Esben', 'SQL', 43), ('Esben', 'Tuning', 31),
    ('Kaolin', 'SQL', 56), ('Kaolin', 'Tuning', 88),
    ('Tatiana', 'SQL', 87);

SELECT name, test, score, MAX(score)
    OVER (PARTITION BY name) AS highest_score FROM student_test;
+-----+-----+-----+-----+
| name | test | score | highest_score |
+-----+-----+-----+-----+
| Chun | SQL | 75 | 75 |
| Chun | Tuning | 73 | 75 |
| Esben | SQL | 43 | 43 |
| Esben | Tuning | 31 | 43 |
| Kaolin | SQL | 56 | 88 |
| Kaolin | Tuning | 88 | 88 |
| Tatiana | SQL | 87 | 87 |
+-----+-----+-----+-----+

```

## See Also

- [AVG](#) (average)
- [MIN](#) (minimum)
- [SUM](#) (sum total)
- [MIN/MAX optimization](#) used by the optimizer
- [GREATEST\(\)](#) returns the largest value from a list

## 1.1.12.4.12 MIN

### Syntax

```
MIN([DISTINCT] expr)
```

### Contents

1. [Syntax](#)
2. [Description](#)
3. [Examples](#)
4. [See Also](#)

### Description

Returns the minimum value of

*expr*

`MIN()`

may take a string argument, in which case it returns the minimum string value. The

`DISTINCT`

keyword can be used to find the minimum of the distinct values of

*expr*

, however, this produces the same result as omitting

`DISTINCT`

Note that `SET` and `ENUM` fields are currently compared by their string value rather than their relative position in the set, so `MIN()` may produce a different lowest result than `ORDER BY ASC`.

It is an [aggregate function](#) , and so can be used with the [GROUP BY](#) clause.

From [MariaDB 10.2.2](#) , `MIN()` can be used as a [window function](#) .

```

MIN()
returns
NULL
if there were no matching rows.

```

### Examples

```

CREATE TABLE student (name CHAR(10), test CHAR(10), score TINYINT);

INSERT INTO student VALUES
('Chun', 'SQL', 75), ('Chun', 'Tuning', 73),
('Esben', 'SQL', 43), ('Esben', 'Tuning', 31),
('Kaolin', 'SQL', 56), ('Kaolin', 'Tuning', 88),
('Tatiana', 'SQL', 87), ('Tatiana', 'Tuning', 83);

SELECT name, MIN(score) FROM student GROUP BY name;
+-----+-----+
| name | MIN(score) |
+-----+-----+
| Chun |      73 |
| Esben |     31 |
| Kaolin |    56 |
| Tatiana |   83 |
+-----+-----+

```

MIN() with a string:

```

SELECT MIN(name) FROM student;
+-----+
| MIN(name) |
+-----+
| Chun      |
+-----+

```

Be careful to avoid this common mistake, not grouping correctly and returning mismatched data:

```

SELECT name,test,MIN(score) FROM student;
+-----+-----+
| name | test | MIN(score) |
+-----+-----+
| Chun | SQL |      31 |
+-----+-----+

```

Difference between ORDER BY ASC and MIN():

```

CREATE TABLE student2(name CHAR(10),grade ENUM('b','c','a'));

INSERT INTO student2 VALUES('Chun','b'),('Esben','c'),('Kaolin','a');

SELECT MIN(grade) FROM student2;
+-----+
| MIN(grade) |
+-----+
| a          |
+-----+

SELECT grade FROM student2 ORDER BY grade ASC LIMIT 1;
+-----+
| grade |
+-----+
| b      |
+-----+

```

As a [window function](#):

```

CREATE OR REPLACE TABLE student_test (name CHAR(10), test CHAR(10), score TINYINT);
INSERT INTO student_test VALUES
    ('Chun', 'SQL', 75), ('Chun', 'Tuning', 73),
    ('Esben', 'SQL', 43), ('Esben', 'Tuning', 31),
    ('Kaolin', 'SQL', 56), ('Kaolin', 'Tuning', 88),
    ('Tatiana', 'SQL', 87);

SELECT name, test, score, MIN(score)
    OVER (PARTITION BY name) AS lowest_score FROM student_test;
+-----+-----+-----+-----+
| name | test | score | lowest_score |
+-----+-----+-----+-----+
| Chun | SQL | 75 | 73 |
| Chun | Tuning | 73 | 73 |
| Esben | SQL | 43 | 31 |
| Esben | Tuning | 31 | 31 |
| Kaolin | SQL | 56 | 56 |
| Kaolin | Tuning | 88 | 56 |
| Tatiana | SQL | 87 | 87 |
+-----+-----+-----+-----+

```

## See Also

- [AVG](#) (average)
- [MAX](#) (maximum)
- [SUM](#) (sum total)
- [MIN/MAX optimization](#) used by the optimizer
- [LEAST\(\)](#) returns the smallest value from a list.

## 1.1.12.4.13 STD

### Syntax

`STD(expr)`

### Description

Returns the population standard deviation of

*expr*  
. This is an extension to standard SQL. The standard SQL function

[STDDEV\\_POP\(\)](#)

can be used instead.

It is an [aggregate function](#), and so can be used with the [GROUP BY](#) clause.

From [MariaDB 10.2.2](#), `STD()` can be used as a [window function](#).

This function returns

`NULL`  
if there were no matching rows.

## Examples

As an [aggregate function](#):

```

CREATE OR REPLACE TABLE stats (category VARCHAR(2), x INT);

INSERT INTO stats VALUES
('a',1),('a',2),('a',3),
('b',11),('b',12),('b',20),('b',30),('b',60);

SELECT category, STDDEV_POP(x), STDDEV_SAMP(x), VAR_POP(x)
  FROM stats GROUP BY category;
+-----+-----+-----+
| category | STDDEV_POP(x) | STDDEV_SAMP(x) | VAR_POP(x) |
+-----+-----+-----+
| a        |      0.8165 |      1.0000 |     0.6667 |
| b        |    18.0400 |    20.1693 |  325.4400 |
+-----+-----+-----+

```

As a window function :

```

CREATE OR REPLACE TABLE student_test (name CHAR(10), test CHAR(10), score TINYINT);

INSERT INTO student_test VALUES
('Chun', 'SQL', 75), ('Chun', 'Tuning', 73),
('Esben', 'SQL', 43), ('Esben', 'Tuning', 31),
('Kaolin', 'SQL', 56), ('Kaolin', 'Tuning', 88),
('Tatiana', 'SQL', 87);

SELECT name, test, score, STDDEV_POP(score)
  OVER (PARTITION BY test) AS stddev_results FROM student_test;
+-----+-----+-----+-----+
| name   | test   | score | stddev_results |
+-----+-----+-----+-----+
| Chun   | SQL    | 75   |      16.9466 |
| Chun   | Tuning | 73   |      24.1247 |
| Esben  | SQL    | 43   |      16.9466 |
| Esben  | Tuning | 31   |      24.1247 |
| Kaolin | SQL    | 56   |      16.9466 |
| Kaolin | Tuning | 88   |      24.1247 |
| Tatiana| SQL    | 87   |      16.9466 |
+-----+-----+-----+-----+

```

## See Also

- [STDDEV\\_POP](#) (equivalent, standard SQL)
- [STDDEV](#) (equivalent, Oracle-compatible non-standard SQL)
- [VAR\\_POP](#) (variance)
- [STDDEV\\_SAMP](#) (sample standard deviation)

## 1.1.12.4.14 STDDEV

### Syntax

`STDDEV(expr)`

### Contents

1. [Syntax](#)
2. [Description](#)
3. [Examples](#)
4. [See Also](#)

### Description

Returns the population standard deviation of

*expr*

. This function is provided for compatibility with Oracle. The standard SQL function

[STDDEV\\_POP\(\)](#)

can be used instead.

It is an [aggregate function](#), and so can be used with the [GROUP BY](#) clause.

From MariaDB 10.2.2 , STDDEV() can be used as a [window function](#) .

This function returns

NULL

if there were no matching rows.

## Examples

As an [aggregate function](#) :

```
CREATE OR REPLACE TABLE stats (category VARCHAR(2), x INT);

INSERT INTO stats VALUES
('a',1),('a',2),('a',3),
('b',11),('b',12),('b',20),('b',30),('b',60);

SELECT category, STDDEV_POP(x), STDDEV_SAMP(x), VAR_POP(x)
  FROM stats GROUP BY category;
+-----+-----+-----+
| category | STDDEV_POP(x) | STDDEV_SAMP(x) | VAR_POP(x) |
+-----+-----+-----+
| a        |      0.8165 |       1.0000 |     0.6667 |
| b        |    18.0400 |    20.1693 | 325.4400 |
+-----+-----+-----+
```

As a [window function](#) :

```
CREATE OR REPLACE TABLE student_test (name CHAR(10), test CHAR(10), score TINYINT);

INSERT INTO student_test VALUES
('Chun', 'SQL', 75), ('Chun', 'Tuning', 73),
('Esben', 'SQL', 43), ('Esben', 'Tuning', 31),
('Kaolin', 'SQL', 56), ('Kaolin', 'Tuning', 88),
('Tatiana', 'SQL', 87);

SELECT name, test, score, STDDEV_POP(score)
  OVER (PARTITION BY test) AS stddev_results FROM student_test;
+-----+-----+-----+-----+
| name   | test   | score | stddev_results |
+-----+-----+-----+-----+
| Chun   | SQL    | 75   | 16.9466 |
| Chun   | Tuning | 73   | 24.1247 |
| Esben  | SQL    | 43   | 16.9466 |
| Esben  | Tuning | 31   | 24.1247 |
| Kaolin | SQL    | 56   | 16.9466 |
| Kaolin | Tuning | 88   | 24.1247 |
| Tatiana| SQL    | 87   | 16.9466 |
+-----+-----+-----+-----+
```

## See Also

- [STDDEV\\_POP](#) (equivalent, standard SQL)
- [STD](#) (equivalent, non-standard SQL)
- [VAR\\_POP](#) (variance)
- [STDDEV\\_SAMP](#) (sample standard deviation)

## 1.1.12.4.15 STDDEV\_POP

### Syntax

```
STDDEV_POP(expr)
```

### Contents

1. [Syntax](#)
2. [Description](#)
3. [Examples](#)
4. [See Also](#)

### Description

Returns the population standard deviation of

*expr*  
(the square root of

`VAR_POP()`

). You can also use

`STD()`

or

`STDDEV()`

, which are equivalent but not standard SQL.

It is an [aggregate function](#) , and so can be used with the `GROUP BY` clause.

From [MariaDB 10.2.2](#) , `STDDEV_POP()` can be used as a [window function](#) .

`STDDEV_POP()` returns

`NULL`

if there were no matching rows.

## Examples

As an [aggregate function](#) :

```
CREATE OR REPLACE TABLE stats (category VARCHAR(2), x INT);

INSERT INTO stats VALUES
  ('a',1),('a',2),('a',3),
  ('b',11),('b',12),('b',20),('b',30),('b',60);

SELECT category, STDDEV_POP(x), STDDEV_SAMP(x), VAR_POP(x)
  FROM stats GROUP BY category;
+-----+-----+-----+
| category | STDDEV_POP(x) | STDDEV_SAMP(x) | VAR_POP(x) |
+-----+-----+-----+
| a        |     0.8165 |      1.0000 |    0.6667 |
| b        |   18.0400 |    20.1693 | 325.4400 |
+-----+-----+-----+
```

As a [window function](#) :

```
CREATE OR REPLACE TABLE student_test (name CHAR(10), test CHAR(10), score TINYINT);

INSERT INTO student_test VALUES
  ('Chun', 'SQL', 75), ('Chun', 'Tuning', 73),
  ('Esben', 'SQL', 43), ('Esben', 'Tuning', 31),
  ('Kaolin', 'SQL', 56), ('Kaolin', 'Tuning', 88),
  ('Tatiana', 'SQL', 87);

SELECT name, test, score, STDDEV_POP(score)
  OVER (PARTITION BY test) AS stddev_results FROM student_test;
+-----+-----+-----+
| name   | test   | score | stddev_results |
+-----+-----+-----+
| Chun   | SQL    | 75   |    16.9466 |
| Chun   | Tuning | 73   |    24.1247 |
| Esben  | SQL    | 43   |    16.9466 |
| Esben  | Tuning | 31   |    24.1247 |
| Kaolin | SQL    | 56   |    16.9466 |
| Kaolin | Tuning | 88   |    24.1247 |
| Tatiana| SQL    | 87   |    16.9466 |
+-----+-----+-----+
```

## See Also

- [STD](#) (equivalent, non-standard SQL)
- [STDDEV](#) (equivalent, Oracle-compatible non-standard SQL)
- [VAR\\_POP](#) (variance)
- [STDDEV\\_SAMP](#) (sample standard deviation)

## 1.1.12.4.16 STDDEV\_SAMP

### Syntax

```
STDDEV_SAMP(expr)
```

### Description

Returns the sample standard deviation of

expr  
(the square root of [VAR\\_SAMP\(\)](#) ).

It is an [aggregate function](#) , and so can be used with the [GROUP BY](#) clause.

From [MariaDB 10.2.2](#) , STDDEV\_SAMP() can be used as a [window function](#) .

STDDEV\_SAMP() returns

NULL  
if there were no matching rows.

## 1.1.12.4.17 SUM

### Syntax

```
SUM([DISTINCT] expr)
```

### Contents

1. [Syntax](#)
2. [Description](#)
3. [Examples](#)
4. [See Also](#)

### Description

Returns the sum of

expr  
. If the return set has no rows,  
SUM()  
returns  
NULL  
. The  
DISTINCT  
keyword can be used to sum only the distinct values of  
expr  
.

From [MariaDB 10.2.0](#) , SUM() can be used as a [window function](#) , although not with the DISTINCT specifier.

### Examples

```
CREATE TABLE sales (sales_value INT);
INSERT INTO sales VALUES(10),(20),(20),(40);

SELECT SUM(sales_value) FROM sales;
+-----+
| SUM(sales_value) |
+-----+
|          90      |
+-----+

SELECT SUM(DISTINCT(sales_value)) FROM sales;
+-----+
| SUM(DISTINCT(sales_value)) |
+-----+
|          70      |
+-----+
```

Commonly, SUM is used with a [GROUP BY](#) clause:

```
CREATE TABLE sales (name CHAR(10), month CHAR(10), units INT);

INSERT INTO sales VALUES
    ('Chun', 'Jan', 75), ('Chun', 'Feb', 73),
    ('Esben', 'Jan', 43), ('Esben', 'Feb', 31),
    ('Kaolin', 'Jan', 56), ('Kaolin', 'Feb', 88),
    ('Tatiana', 'Jan', 87), ('Tatiana', 'Feb', 83);

SELECT name, SUM(units) FROM sales GROUP BY name;
+-----+
| name | SUM(units) |
+-----+
| Chun |      148 |
| Esben |       74 |
| Kaolin |     144 |
| Tatiana |    170 |
+-----+
```

The [GROUP BY](#) clause is required when using an aggregate function along with regular column data, otherwise the result will be a mismatch, as in the following common type of mistake:

```
SELECT name, SUM(units) FROM sales
+-----+
| name | SUM(units) |
+-----+
| Chun |      536 |
+-----+
```

As a [window function](#):

```
CREATE OR REPLACE TABLE student_test (name CHAR(10), test CHAR(10), score TINYINT);
INSERT INTO student_test VALUES
    ('Chun', 'SQL', 75), ('Chun', 'Tuning', 73),
    ('Esben', 'SQL', 43), ('Esben', 'Tuning', 31),
    ('Kaolin', 'SQL', 56), ('Kaolin', 'Tuning', 88),
    ('Tatiana', 'SQL', 87);

SELECT name, test, score, SUM(score) OVER (PARTITION BY name) AS total_score FROM student_test;
+-----+
| name | test | score | total_score |
+-----+
| Chun | SQL | 75 | 148 |
| Chun | Tuning | 73 | 148 |
| Esben | SQL | 43 | 74 |
| Esben | Tuning | 31 | 74 |
| Kaolin | SQL | 56 | 144 |
| Kaolin | Tuning | 88 | 144 |
| Tatiana | SQL | 87 | 87 |
+-----+
```

## See Also

- [AVG](#) (average)
- [MAX](#) (maximum)
- [MIN](#) (minimum)

## 1.1.12.4.18 VARIANCE

### Syntax

```
VARIANCE(expr)
```

### Contents

1. [Syntax](#)
2. [Description](#)
3. [Examples](#)
4. [See Also](#)

# Description

Returns the population standard variance of

expr

. This is an extension to standard SQL. The standard SQL function `VAR_POP()` can be used instead.

Variance is calculated by

- working out the mean for the set
- for each number, subtracting the mean and squaring the result
- calculate the average of the resulting differences

It is an [aggregate function](#), and so can be used with the `GROUP BY` clause.

From [MariaDB 10.2.2](#), `VARIANCE()` can be used as a [window function](#).

`VARIANCE()` returns

`NULL`

if there were no matching rows.

## Examples

```
CREATE TABLE v(i tinyint);

INSERT INTO v VALUES(101),(99);

SELECT VARIANCE(i) FROM v;
+-----+
| VARIANCE(i) |
+-----+
|      1.0000 |
+-----+

INSERT INTO v VALUES(120),(80);

SELECT VARIANCE(i) FROM v;
+-----+
| VARIANCE(i) |
+-----+
|    200.5000 |
+-----+
```

As an [aggregate function](#):

```
CREATE OR REPLACE TABLE stats (category VARCHAR(2), x INT);

INSERT INTO stats VALUES
('a',1),('a',2),('a',3),
('b',11),('b',12),('b',20),('b',30),('b',60);

SELECT category, STDDEV_POP(x), STDDEV_SAMP(x), VAR_POP(x)
  FROM stats GROUP BY category;
+-----+-----+-----+
| category | STDDEV_POP(x) | STDDEV_SAMP(x) | VAR_POP(x) |
+-----+-----+-----+
| a        |      0.8165 |      1.0000 |     0.6667 |
| b        |     18.0400 |     20.1693 |  325.4400 |
+-----+-----+-----+
```

As a [window function](#):

```

CREATE OR REPLACE TABLE student_test (name CHAR(10), test CHAR(10), score TINYINT);

INSERT INTO student_test VALUES
    ('Chun', 'SQL', 75), ('Chun', 'Tuning', 73),
    ('Esben', 'SQL', 43), ('Esben', 'Tuning', 31),
    ('Kaolin', 'SQL', 56), ('Kaolin', 'Tuning', 88),
    ('Tatiana', 'SQL', 87);

SELECT name, test, score, VAR_POP(score)
    OVER (PARTITION BY test) AS variance_results FROM student_test;
+-----+-----+-----+-----+
| name   | test   | score | variance_results |
+-----+-----+-----+-----+
| Chun   | SQL    | 75   | 287.1875 |

- [STDDEV\\_POP](#) (population standard deviation)
- [STDDEV\\_SAMP](#) (sample standard deviation)

## 1.1.12.4.19 VAR\_POP

### Syntax

`VAR_POP(expr)`

### Contents

1. [Syntax](#)
2. [Description](#)
3. [Examples](#)
4. [See Also](#)

### Description

Returns the population standard variance of

`expr`

. It considers rows as the whole population, not as a sample, so it has the number of rows as the denominator. You can also use [VARIANCE\(\)](#), which is equivalent but is not standard SQL.

Variance is calculated by

- working out the mean for the set
- for each number, subtracting the mean and squaring the result
- calculate the average of the resulting differences

It is an [aggregate function](#), and so can be used with the [GROUP BY](#) clause.

From [MariaDB 10.2.2](#), `VAR_POP()` can be used as a [window function](#).

`VAR_POP()` returns

`NULL`

if there were no matching rows.

### Examples

```

CREATE TABLE v(i tinyint);

INSERT INTO v VALUES(101),(99);

SELECT VAR_POP(i) FROM v;
+-----+
| VAR_POP(i) |
+-----+
| 1.0000 |
+-----+

INSERT INTO v VALUES(120),(80);

SELECT VAR_POP(i) FROM v;
+-----+
| VAR_POP(i) |
+-----+
| 200.5000 |
+-----+

```

As an [aggregate function](#) :

```

CREATE OR REPLACE TABLE stats (category VARCHAR(2), x INT);

INSERT INTO stats VALUES
('a',1),('a',2),('a',3),
('b',11),('b',12),('b',20),('b',30),('b',60);

SELECT category, STDDEV_POP(x), STDDEV_SAMP(x), VAR_POP(x)
  FROM stats GROUP BY category;
+-----+-----+-----+
| category | STDDEV_POP(x) | STDDEV_SAMP(x) | VAR_POP(x) |
+-----+-----+-----+
| a        |      0.8165 |       1.0000 |     0.6667 |
| b        |    18.0400 |    20.1693 | 325.4400 |
+-----+-----+-----+

```

As a [window function](#) :

```

CREATE OR REPLACE TABLE student_test (name CHAR(10), test CHAR(10), score TINYINT);

INSERT INTO student_test VALUES
('Chun', 'SQL', 75), ('Chun', 'Tuning', 73),
('Esben', 'SQL', 43), ('Esben', 'Tuning', 31),
('Kaolin', 'SQL', 56), ('Kaolin', 'Tuning', 88),
('Tatiana', 'SQL', 87);

SELECT name, test, score, VAR_POP(score)
  OVER (PARTITION BY test) AS variance_results FROM student_test;
+-----+-----+-----+-----+
| name   | test   | score | variance_results |
+-----+-----+-----+-----+
| Chun   | SQL    | 75   | 287.1875 |
| Esben  | SQL    | 43   | 287.1875 |
| Kaolin | SQL    | 56   | 287.1875 |
| Tatiana| SQL    | 87   | 287.1875 |
| Chun   | Tuning | 73   | 582.0000 |
| Esben  | Tuning | 31   | 582.0000 |
| Kaolin | Tuning | 88   | 582.0000 |
+-----+-----+-----+-----+

```

## 1.1.12.4.20 VAR\_SAMP

### Syntax

## Contents

1. [Syntax](#)
2. [Description](#)
3. [Examples](#)
4. [See Also](#)

## Description

Returns the sample variance of

*expr*

. That is, the denominator is the number of rows minus one.

It is an [aggregate function](#), and so can be used with the [GROUP BY](#) clause.

From [MariaDB 10.2.2](#), VAR\_SAMP() can be used as a [window function](#).

VAR\_SAMP() returns

NULL

if there were no matching rows.

## Examples

As an [aggregate function](#):

```
CREATE OR REPLACE TABLE stats (category VARCHAR(2), x INT);

INSERT INTO stats VALUES
    ('a',1),('a',2),('a',3),
    ('b',11),('b',12),('b',20),('b',30),('b',60);

SELECT category, STDDEV_POP(x), STDDEV_SAMP(x), VAR_POP(x)
    FROM stats GROUP BY category;
+-----+-----+-----+
| category | STDDEV_POP(x) | STDDEV_SAMP(x) | VAR_POP(x) |
+-----+-----+-----+
| a        |      0.8165 |      1.0000 |     0.6667 |
| b        |     18.0400 |     20.1693 |  325.4400 |
+-----+-----+-----+
```

As a [window function](#):

```
CREATE OR REPLACE TABLE student_test (name CHAR(10), test CHAR(10), score TINYINT);

INSERT INTO student_test VALUES
    ('Chun', 'SQL', 75), ('Chun', 'Tuning', 73),
    ('Esben', 'SQL', 43), ('Esben', 'Tuning', 31),
    ('Kaolin', 'SQL', 56), ('Kaolin', 'Tuning', 88),
    ('Tatiana', 'SQL', 87);

SELECT name, test, score, VAR_SAMP(score)
    OVER (PARTITION BY test) AS variance_results FROM student_test;
+-----+-----+-----+-----+
| name   | test   | score | variance_results |
+-----+-----+-----+-----+
| Chun   | SQL    | 75   |      382.9167 |
| Chun   | Tuning | 73   |      873.0000 |
| Esben  | SQL    | 43   |      382.9167 |
| Esben  | Tuning | 31   |      873.0000 |
| Kaolin | SQL    | 56   |      382.9167 |
| Kaolin | Tuning | 88   |      873.0000 |
| Tatiana| SQL    | 87   |      382.9167 |
+-----+-----+-----+-----+
```

## 1.1.12.5 Numeric Functions

## 1.1.12.5.1 Addition Operator (+)

### Syntax

```
+
```

### Contents

1. [Syntax](#)
2. [Description](#)
3. [Examples](#)
4. [See Also](#)

### Description

Addition.

If both operands are integers, the result is calculated with [BIGINT](#) precision. If either integer is unsigned, the result is also an unsigned integer.

For real or string operands, the operand with the highest precision determines the result precision.

### Examples

```
SELECT 3+5;
+-----+
| 3+5 |
+-----+
|   8 |
+-----+
```

### See Also

- [Type Conversion](#)
- [Subtraction Operator \(-\)](#)
- [Multiplication Operator \(\\*\)](#)
- [Division Operator \(/\)](#)

## 1.1.12.5.2 Subtraction Operator (-)

### Syntax

```
-
```

### Description

Subtraction. The operator is also used as the unary minus for changing sign.

If both operands are integers, the result is calculated with [BIGINT](#) precision. If either integer is unsigned, the result is also an unsigned integer, unless the [NO\\_UNSIGNED\\_SUBTRACTION SQL MODE](#) is enabled, in which case the result is always signed.

For real or string operands, the operand with the highest precision determines the result precision.

### Examples

```

SELECT 96-9;
+-----+
| 96-9 |
+-----+
|   87 |
+-----+

SELECT 15-17;
+-----+
| 15-17 |
+-----+
|    -2 |
+-----+

SELECT 3.66 + 1.333;
+-----+
| 3.66 + 1.333 |
+-----+
|      4.993 |
+-----+

```

Unary minus:

```

SELECT - (3+5);
+-----+
| - (3+5) |
+-----+
|    -8 |
+-----+

```

## See Also

- [Type Conversion](#)
- [Addition Operator \(+\)](#)
- [Multiplication Operator \(\\*\)](#)
- [Division Operator \(/\)](#)

## 1.1.12.5.3 Division Operator (/)

### Syntax

/

### Contents

1. [Syntax](#)
2. [Description](#)
3. [Examples](#)
4. [See Also](#)

### Description

Division operator. Dividing by zero will return NULL. By default, returns four digits after the decimal. This is determined by the server system variable `div_precision_increment` which by default is four. It can be set from 0 to 30.

Dividing by zero returns

```

NULL
. If the
ERROR_ON_DIVISION_BY_ZERO
SQL_MODE is used (the default since MariaDB 10.2.4 ), a division by zero also produces a warning.

```

### Examples

```

SELECT 4/5;
+-----+
| 4/5   |
+-----+
| 0.8000 |
+-----+

SELECT 300/(2-2);
+-----+
| 300/(2-2) |
+-----+
|      NULL  |
+-----+

SELECT 300/7;
+-----+
| 300/7   |
+-----+
| 42.8571  |
+-----+

```

Changing `div_precision_increment` for the session from the default of four to six:

```

SET div_precision_increment = 6;

SELECT 300/7;
+-----+
| 300/7   |
+-----+
| 42.857143 |
+-----+

SELECT 300/7;
+-----+
| 300/7   |
+-----+
| 42.857143 |
+-----+

```

## See Also

- [Type Conversion](#)
- [Addition Operator \(+\)](#)
- [Subtraction Operator \(-\)](#)
- [Multiplication Operator \(\\*\)](#)

## 1.1.12.5.4 Multiplication Operator (\*)

### Syntax

\*

### Contents

1. [Syntax](#)
2. [Description](#)
3. [Examples](#)
4. [See Also](#)

### Description

Multiplication operator.

### Examples

```

SELECT 7*6;
+-----+
| 7*6 |
+-----+
|   42 |
+-----+

SELECT 1234567890*9876543210;
+-----+
| 1234567890*9876543210 |
+-----+
| -6253480962446024716 |
+-----+

SELECT 18014398509481984*18014398509481984.0;
+-----+
| 18014398509481984*18014398509481984.0 |
+-----+
| 324518553658426726783156020576256.0 |
+-----+

SELECT 18014398509481984*18014398509481984;
+-----+
| 18014398509481984*18014398509481984 |
+-----+
|          0 |
+-----+

```

## See Also

- [Type Conversion](#)
- [Addition Operator \(+\)](#)
- [Subtraction Operator \(-\)](#)
- [Division Operator \(/\)](#)

## 1.1.12.5.5 Modulo Operator (%)

### Syntax

N % M

### Description

Modulo operator. Returns the remainder of

N  
divided by  
M  
. See also [MOD](#) .

### Examples

```

SELECT 1042 % 50;
+-----+
| 1042 % 50 |
+-----+
|      42 |
+-----+

```

## 1.1.12.5.6 DIV

### Syntax

DIV

## Description

Integer division. Similar to [FLOOR\(\)](#), but is safe with **BIGINT** values. Incorrect results may occur for non-integer operands that exceed BIGINT range.

If the

`ERROR_ON_DIVISION_BY_ZERO`

`SQL_MODE` is used, a division by zero produces an error. Otherwise, it returns NULL.

The remainder of a division can be obtained using the [MOD](#) operator.

## Examples

```
SELECT 300 DIV 7;
+-----+
| 300 DIV 7 |
+-----+
|        42 |
+-----+  
  
SELECT 300 DIV 0;
+-----+
| 300 DIV 0 |
+-----+
|      NULL |
+-----+
```

## 1.1.12.5.7 ABS

### Syntax

`ABS(X)`

#### Contents

1. [Syntax](#)
2. [Description](#)
3. [Examples](#)
4. [See Also](#)

### Description

Returns the absolute (non-negative) value of

`X`  
. If  
`X`

is not a number, it is converted to a numeric type.

## Examples

```
SELECT ABS(42);
+-----+
| ABS(42) |
+-----+
|      42 |
+-----+

SELECT ABS(-42);
+-----+
| ABS(-42) |
+-----+
|      42 |
+-----+

SELECT ABS(DATE '1994-01-01');
+-----+
| ABS(DATE '1994-01-01') |
+-----+
|          19940101 |
+-----+
```

## See Also

- [SIGN\(\)](#)

## 1.1.12.5.8 ACOS

### Syntax

ACOS(X)

#### Contents

1. [Syntax](#)
2. [Description](#)
3. [Examples](#)

### Description

Returns the arc cosine of

X  
, that is, the value whose cosine is  
X  
. Returns  
NULL  
if  
X  
is not in the range  
-1  
to  
1  
.

### Examples

```

SELECT ACOS(1);
+-----+
| ACOS(1) |
+-----+
|      0   |
+-----+

SELECT ACOS(1.0001);
+-----+
| ACOS(1.0001) |
+-----+
|      NULL    |
+-----+

SELECT ACOS(0);
+-----+
| ACOS(0)      |
+-----+
| 1.5707963267949 |
+-----+

SELECT ACOS(0.234);
+-----+
| ACOS(0.234)    |
+-----+
| 1.33460644244679 |
+-----+

```

## 1.1.12.5.9 ASIN

### Syntax

ASIN(X)

### Contents

1. [Syntax](#)
2. [Description](#)
3. [Examples](#)

### Description

Returns the arc sine of X, that is, the value whose sine is X. Returns NULL if X is not in the range -1 to 1.

### Examples

```

SELECT ASIN(0.2);
+-----+
| ASIN(0.2)      |
+-----+
| 0.2013579207903308 |
+-----+

SELECT ASIN('foo');
+-----+
| ASIN('foo')    |
+-----+
|      0         |
+-----+

SHOW WARNINGS;
+-----+-----+
| Level | Code | Message           |
+-----+-----+
| Warning | 1292 | Truncated incorrect DOUBLE value: 'foo' |
+-----+-----+

```

## 1.1.12.5.10 ATAN

# Syntax

ATAN(X)

## Contents

1. [Syntax](#)
2. [Description](#)
3. [Examples](#)

## Description

Returns the arc tangent of X, that is, the value whose tangent is X.

## Examples

```
SELECT ATAN(2);
+-----+
| ATAN(2)           |
+-----+
| 1.1071487177940904 |
+-----+

SELECT ATAN(-2);
+-----+
| ATAN(-2)           |
+-----+
| -1.1071487177940904 |
+-----+
```

## 1.1.12.5.11 ATAN2

# Syntax

ATAN(Y,X), ATAN2(Y,X)

## Description

Returns the arc tangent of the two variables X and Y. It is similar to calculating the arc tangent of Y / X, except that the signs of both arguments are used to determine the quadrant of the result.

## Examples

```
SELECT ATAN(-2,2);
+-----+
| ATAN(-2,2)           |
+-----+
| -0.7853981633974483 |
+-----+

SELECT ATAN2(PI(),0);
+-----+
| ATAN2(PI(),0)           |
+-----+
| 1.5707963267948966 |
+-----+
```

## 1.1.12.5.12 CEIL

# Syntax

CEIL(X)

## Description

CEIL() is a synonym for [CEILING\(\)](#).

### 1.1.12.5.13 CEILING

#### Syntax

```
CEILING(X)
```

#### Description

Returns the smallest integer value not less than X.

#### Examples

```
SELECT CEILING(1.23);
+-----+
| CEILING(1.23) |
+-----+
|          2   |
+-----+  
  
SELECT CEILING(-1.23);
+-----+
| CEILING(-1.23) |
+-----+
|         -1   |
+-----+
```

### 1.1.12.5.14 CONV

#### Syntax

```
CONV(N,from_base,to_base)
```

#### Description

Converts numbers between different number bases. Returns a string representation of the number

*N*

, converted from base

*from\_base*

to base

*to\_base*

.

Returns

NULL

if any argument is

NULL

, or if the second or third argument are not in the allowed range.

The argument

*N*

is interpreted as an integer, but may be specified as an integer or a string. The minimum base is 2 and the maximum base is 36. If

*to\_base*

is a negative number,

*N*

is regarded as a signed number. Otherwise,

*N*

is treated as unsigned.

[CONV\(\)](#)

works with 64-bit precision.

Some shortcuts for this function are also available:

```
BIN()  
  
,  
  
OCT()  
  
,  
  
HEX()  
  
,  
  
UNHEX()
```

. Also, MariaDB allows [binary](#) literal values and [hexadecimal](#) literal values.

## Examples

```
SELECT CONV('a',16,2);  
+-----+  
| CONV('a',16,2) |  
+-----+  
| 1010 |  
+-----+  
  
SELECT CONV('6E',18,8);  
+-----+  
| CONV('6E',18,8) |  
+-----+  
| 172 |  
+-----+  
  
SELECT CONV(-17,10,-18);  
+-----+  
| CONV(-17,10,-18) |  
+-----+  
| -H |  
+-----+  
  
SELECT CONV(12+'10'+'10'+0xa,10,10);  
+-----+  
| CONV(12+'10'+'10'+0xa,10,10) |  
+-----+  
| 42 |  
+-----+
```

## 1.1.12.5.15 COS

### Syntax

```
COS(X)
```

### Description

Returns the cosine of X, where X is given in radians.

## Examples

```
SELECT COS(PI());  
+-----+  
| COS(PI()) |  
+-----+  
| -1 |  
+-----+
```

## 1.1.12.5.16 COT

### Syntax

```
COT(X)
```

### Description

Returns the cotangent of X.

### Examples

```
SELECT COT(42);
+-----+
| COT(42)      |
+-----+
| 0.4364167060752729 |
+-----+

SELECT COT(12);
+-----+
| COT(12)      |
+-----+
| -1.5726734063976893 |
+-----+

SELECT COT(0);
ERROR 1690 (22003): DOUBLE value is out of range in 'cot(0)'
```

## 1.1.12.5.17 CRC32

### Syntax

<= MariaDB 10.7

```
CRC32(expr)
```

From MariaDB 10.8

```
CRC32([par,]expr)
```

### Description

Computes a cyclic redundancy check (CRC) value and returns a 32-bit unsigned value. The result is NULL if the argument is NULL. The argument is expected to be a string and (if possible) is treated as one if it is not.

Uses the ISO 3309 polynomial that used by zlib and many others. MariaDB 10.8 introduced the [CRC32C\(\)](#) function, which uses the alternate Castagnoli polynomia.

MariaDB starting with 10.8

Often, CRC is computed in pieces. To facilitate this, MariaDB 10.8.0 introduced an optional parameter:  
CRC32('MariaDB')=CRC32(CRC32('Maria'), 'DB').

### Examples

```
SELECT CRC32('MariaDB');
```

```
+-----+
| CRC32('MariaDB') |
+-----+
| 4227209140 |
+-----+
```

```
SELECT CRC32('mariadb');
```

```
+-----+
| CRC32('mariadb') |
+-----+
| 2594253378 |
+-----+
```

From MariaDB 10.8.0

```
SELECT CRC32(CRC32('Maria'), 'DB');
```

```
+-----+
| CRC32(CRC32('Maria'), 'DB') |
+-----+
| 4227209140 |
+-----+
```

## See Also

- [CRC32C\(\)](#)

### 1.1.12.5.18 CRC32C

MariaDB starting with 10.8

Introduced in MariaDB 10.8.0 to compute a cyclic redundancy check (CRC) value using the Castagnoli polynomial.

## Syntax

```
CRC32C([par,]expr)
```

## Description

MariaDB has always included a native unary function [CRC32\(\)](#) that computes the CRC-32 of a string using the ISO 3309 polynomial that used by zlib and many others.

InnoDB and MyRocks use a different polynomial, which was implemented in SSE4.2 instructions that were introduced in the Intel Nehalem microarchitecture. This is commonly called CRC-32C (Castagnoli).

The CRC32C function uses the Castagnoli polynomial.

This allows

```
SELECT...INTO DUMPFILE  
to be used for the creation of files with valid checksums, such as a logically empty InnoDB redo log file  
ib_logfile0  
corresponding to a particular log sequence number.
```

The optional parameter allows the checksum to be computed in pieces:  $\text{CRC32C('MariaDB')} = \text{CRC32C}(\text{CRC32C('Maria')}, 'DB')$ .

## Examples

```

SELECT CRC32C('MariaDB');
+-----+
| CRC32C('MariaDB') |
+-----+
|      809606978 |
+-----+

SELECT CRC32C(CRC32C('Maria'), 'DB');
+-----+
| CRC32C(CRC32C('Maria'), 'DB') |
+-----+
|          809606978 |
+-----+

```

## 1.1.12.5.19 DEGREES

### Syntax

`DEGREES(X)`

### Description

Returns the argument

$x$ , converted from radians to degrees.

This is the converse of the [RADIAN\(\)](#) function.

### Examples

```

SELECT DEGREES(PI());
+-----+
| DEGREES(PI()) |
+-----+
|      180 |
+-----+

SELECT DEGREES(PI() / 2);
+-----+
| DEGREES(PI() / 2) |
+-----+
|        90 |
+-----+

SELECT DEGREES(45);
+-----+
| DEGREES(45) |
+-----+
| 2578.3100780887 |
+-----+

```

## 1.1.12.5.20 EXP

### Syntax

`EXP(X)`

### Description

Returns the value of e (the base of natural logarithms) raised to the power of X. The inverse of this function is [LOG\(\)](#) (using a single argument only) or [LN\(\)](#).

If

$x$   
is

NULL  
, this function returns  
NULL

## Examples

```
SELECT EXP(2);
+-----+
| EXP(2)      |
+-----+
| 7.38905609893065 |
+-----+

SELECT EXP(-2);
+-----+
| EXP(-2)      |
+-----+
| 0.1353352832366127 |
+-----+

SELECT EXP(0);
+-----+
| EXP(0)      |
+-----+
| 1           |
+-----+

SELECT EXP(NULL);
+-----+
| EXP(NULL)   |
+-----+
| NULL        |
+-----+
```

## 1.1.12.5.21 FLOOR

### Syntax

```
FLOOR(X)
```

### Description

Returns the largest integer value not greater than X.

### Examples

```
SELECT FLOOR(1.23);
+-----+
| FLOOR(1.23) |
+-----+
| 1           |
+-----+

SELECT FLOOR(-1.23);
+-----+
| FLOOR(-1.23) |
+-----+
| -2          |
+-----+
```

## 1.1.12.5.22 GREATEST

### Syntax

```
GREATEST(value1,value2,...)
```

## Description

With two or more arguments, returns the largest (maximum-valued) argument. The arguments are compared using the same rules as for [LEAST\(\)](#).

## Examples

```
SELECT GREATEST(2,0);
+-----+
| GREATEST(2,0) |
+-----+
|      2      |
+-----+
```

```
SELECT GREATEST(34.0,3.0,5.0,767.0);
+-----+
| GREATEST(34.0,3.0,5.0,767.0) |
+-----+
|          767.0      |
+-----+
```

```
SELECT GREATEST('B','A','C');
+-----+
| GREATEST('B','A','C') |
+-----+
|  C                  |
+-----+
```

## 1.1.12.5.23 LEAST

### Syntax

```
LEAST(value1,value2,...)
```

## Description

With two or more arguments, returns the smallest (minimum-valued) argument. The arguments are compared using the following rules:

- If the return value is used in an INTEGER context or all arguments are integer-valued, they are compared as integers.
- If the return value is used in a REAL context or all arguments are real-valued, they are compared as reals.
- If any argument is a case-sensitive string, the arguments are compared as case-sensitive strings.
- In all other cases, the arguments are compared as case-insensitive strings.

LEAST() returns NULL if any argument is NULL.

## Examples

```
SELECT LEAST(2,0);
+-----+
| LEAST(2,0) |
+-----+
|      0      |
+-----+
```

```
SELECT LEAST(34.0,3.0,5.0,767.0);
+-----+
| LEAST(34.0,3.0,5.0,767.0) |
+-----+
|          3.0      |
+-----+
```

```
SELECT LEAST('B','A','C');
+-----+
| LEAST('B','A','C') |
+-----+
| A |
+-----+
```

## 1.1.12.5.24 LN

### Syntax

```
LN(X)
```

### Description

Returns the natural logarithm of X; that is, the base-e logarithm of X. If X is less than or equal to 0, or

NULL

, then NULL is returned.

The inverse of this function is

[EXP\(\)](#)

### Examples

```
SELECT LN(2);
+-----+
| LN(2) |
+-----+
| 0.693147180559945 |
+-----+
```

```
SELECT LN(-2);
+-----+
| LN(-2) |
+-----+
| NULL |
+-----+
```

## 1.1.12.5.25 LOG

### Syntax

```
LOG(X), LOG(B,X)
```

### Description

If called with one parameter, this function returns the natural logarithm of X. If X is less than or equal to 0, then NULL is returned.

If called with two parameters, it returns the logarithm of X to the base B. If B is <= 1 or X <= 0, the function returns NULL.

If any argument is

NULL

, the function returns

NULL

The inverse of this function (when called with a single argument) is the [EXP\(\)](#) function.

### Examples

LOG(X):

```
SELECT LOG(2);
+-----+
| LOG(2) |
+-----+
| 0.693147180559945 |
+-----+

SELECT LOG(-2);
+-----+
| LOG(-2) |
+-----+
| NULL |
+-----+
```

LOG(B,X)

```
SELECT LOG(2,16);
+-----+
| LOG(2,16) |
+-----+
| 4 |
+-----+

SELECT LOG(3,27);
+-----+
| LOG(3,27) |
+-----+
| 3 |
+-----+

SELECT LOG(3,1);
+-----+
| LOG(3,1) |
+-----+
| 0 |
+-----+

SELECT LOG(3,0);
+-----+
| LOG(3,0) |
+-----+
| NULL |
+-----+
```

## 1.1.12.5.26 LOG10

### Syntax

```
LOG10(X)
```

### Description

Returns the base-10 logarithm of X.

### Examples

```
SELECT LOG10(2);
+-----+
| LOG10(2) |
+-----+
| 0.301029995663981 |
+-----+

SELECT LOG10(100);
+-----+
| LOG10(100) |
+-----+
|      2 |
+-----+

SELECT LOG10(-100);
+-----+
| LOG10(-100) |
+-----+
|      NULL |
+-----+
```

## 1.1.12.5.27 LOG2

### Syntax

```
LOG2(X)
```

### Description

Returns the base-2 logarithm of X.

### Examples

```
SELECT LOG2(4398046511104);
+-----+
| LOG2(4398046511104) |
+-----+
|      42 |
+-----+

SELECT LOG2(65536);
+-----+
| LOG2(65536) |
+-----+
|      16 |
+-----+

SELECT LOG2(-100);
+-----+
| LOG2(-100) |
+-----+
|      NULL |
+-----+
```

## 1.1.12.5.28 MOD

### Syntax

```
MOD(N,M), N % M, N MOD M
```

### Description

Modulo operation. Returns the remainder of N divided by M. See also [Modulo Operator](#).

If the

ERROR\_ON\_DIVISION\_BY\_ZERO

**SQL\_MODE** is used, any number modulus zero produces an error. Otherwise, it returns NULL.

The integer part of a division can be obtained using **DIV**.

## Examples

```
SELECT 1042 % 50;
+-----+
| 1042 % 50 |
+-----+
|      42 |
+-----+

SELECT MOD(234, 10);
+-----+
| MOD(234, 10) |
+-----+
|        4 |
+-----+

SELECT 253 % 7;
+-----+
| 253 % 7 |
+-----+
|       1 |
+-----+

SELECT MOD(29,9);
+-----+
| MOD(29,9) |
+-----+
|       2 |
+-----+

SELECT 29 MOD 9;
+-----+
| 29 MOD 9 |
+-----+
|       2 |
+-----+
```

## 1.1.12.5.29 OCT

### Syntax

OCT(N)

#### Contents

1. [Syntax](#)
2. [Description](#)
3. [Examples](#)
4. [See Also](#)

### Description

Returns a string representation of the octal value of N, where N is a longlong ( **BIGINT** ) number. This is equivalent to **CONV(N,10,8)** . Returns NULL if N is NULL.

## Examples

```
SELECT OCT(34);
```

```
+-----+
| OCT(34) |
+-----+
| 42      |
+-----+
```

```
SELECT OCT(12);
```

```
+-----+
| OCT(12) |
+-----+
| 14      |
+-----+
```

## See Also

- [CONV\(\)](#)
- [BIN\(\)](#)
- [HEX\(\)](#)

## 1.1.12.5.30 PI

### Syntax

```
PI()
```

### Description

Returns the value of  $\pi$  (pi). The default number of decimal places displayed is six, but MariaDB uses the full double-precision value internally.

### Examples

```
SELECT PI();
```

```
+-----+
| PI()      |
+-----+
| 3.141593 |
+-----+
```

```
SELECT PI()+0.00000000000000000000;
```

```
+-----+
| PI()+0.00000000000000000000 |
+-----+
| 3.1415926535897931159980 |
+-----+
```

## 1.1.12.5.31 POW

### Syntax

```
POW(X,Y)
```

### Description

Returns the value of X raised to the power of Y.

POWER() is a synonym.

### Examples

```
SELECT POW(2,3);
+-----+
| POW(2,3) |
+-----+
|      8   |
+-----+

SELECT POW(2,-2);
+-----+
| POW(2,-2) |
+-----+
|     0.25  |
+-----+
```

## 1.1.12.5.32 POWER

### Syntax

```
POWER(X,Y)
```

### Description

This is a synonym for [POW\(\)](#) , which returns the value of X raised to the power of Y.

## 1.1.12.5.33 RADIANS

### Syntax

```
RADIANS(X)
```

### Description

Returns the argument

X

, converted from degrees to radians. Note that  $\pi$  radians equals 180 degrees.

This is the converse of the [DEGREES\(\)](#) function.

### Examples

```

SELECT RADIANS(45);
+-----+
| RADIANS(45) |
+-----+
| 0.785398163397448 |
+-----+

SELECT RADIANS(90);
+-----+
| RADIANS(90) |
+-----+
| 1.5707963267949 |
+-----+

SELECT RADIANS(PI());
+-----+
| RADIANS(PI()) |
+-----+
| 0.0548311355616075 |
+-----+

SELECT RADIANS(180);
+-----+
| RADIANS(180) |
+-----+
| 3.14159265358979 |
+-----+

```

## 1.1.12.5.34 RAND

### Contents

1. [Syntax](#)
2. [Description](#)
3. [Practical uses](#)
4. [Examples](#)
5. [See Also](#)

## Syntax

RAND(), RAND(N)

## Description

Returns a random

`DOUBLE`

precision floating point value v in the range  $0 \leq v < 1.0$ . If a constant integer argument N is specified, it is used as the seed value, which produces a repeatable sequence of column values. In the example below, note that the sequences of values produced by RAND(3) is the same both places where it occurs.

In a WHERE clause, RAND() is evaluated each time the WHERE is executed.

Statements using the RAND() function are not [safe for statement-based replication](#).

## Practical uses

The expression to get a random integer from a given range is the following:

```
FLOOR(min_value + RAND() * (max_value - min_value +1))
```

RAND() is often used to read random rows from a table, as follows:

```
SELECT * FROM my_table ORDER BY RAND() LIMIT 10;
```

Note, however, that this technique should never be used on a large table as it will be extremely slow. MariaDB will read all rows in the table, generate a random value for each of them, order them, and finally will apply the LIMIT clause.

# Examples

```
CREATE TABLE t (i INT);

INSERT INTO t VALUES(1),(2),(3);

SELECT i, RAND() FROM t;
+-----+
| i    | RAND()          |
+-----+
| 1   | 0.255651095188829 |
| 2   | 0.833920199269355 |
| 3   | 0.40264774151393 |
+-----+

SELECT i, RAND(3) FROM t;
+-----+
| i    | RAND(3)          |
+-----+
| 1   | 0.90576975597606 |
| 2   | 0.373079058130345 |
| 3   | 0.148086053457191 |
+-----+

SELECT i, RAND() FROM t;
+-----+
| i    | RAND()          |
+-----+
| 1   | 0.511478140495232 |
| 2   | 0.349447508668012 |
| 3   | 0.212803152588013 |
+-----+
```

Using the same seed, the same sequence will be returned:

```
SELECT i, RAND(3) FROM t;
+-----+
| i    | RAND(3)          |
+-----+
| 1   | 0.90576975597606 |
| 2   | 0.373079058130345 |
| 3   | 0.148086053457191 |
+-----+
```

Generating a random number from 5 to 15:

```
SELECT FLOOR(5 + (RAND() * 11));
```

## See Also

- [Techniques for Efficiently Finding a Random Row](#)
- [rand\\_seed1 and rand\\_seed2 system variables](#)

## 1.1.12.5.35 ROUND

### Syntax

```
ROUND(X), ROUND(X,D)
```

### Description

Rounds the argument

X  
to  
D  
decimal places. The rounding algorithm depends on the data type of  
X  
.

D  
defaults to  
0  
if not specified.  
D  
can be negative to cause  
D  
digits left of the decimal point of the value  
X  
to become zero.

## Examples

```
SELECT ROUND(-1.23);
+-----+
| ROUND(-1.23) |
+-----+
|          -1 |
+-----+  
  
SELECT ROUND(-1.58);
+-----+
| ROUND(-1.58) |
+-----+
|          -2 |
+-----+  
  
SELECT ROUND(1.58);
+-----+
| ROUND(1.58) |
+-----+
|          2 |
+-----+  
  
SELECT ROUND(1.298, 1);
+-----+
| ROUND(1.298, 1) |
+-----+
|          1.3 |
+-----+  
  
SELECT ROUND(1.298, 0);
+-----+
| ROUND(1.298, 0) |
+-----+
|          1 |
+-----+  
  
SELECT ROUND(23.298, -1);
+-----+
| ROUND(23.298, -1) |
+-----+
|          20 |
+-----+
```

## 1.1.12.5.36 SIGN

### Syntax

```
SIGN(X)
```

### Description

Returns the sign of the argument as -1, 0, or 1, depending on whether X is negative, zero, or positive.

## Examples

```
SELECT SIGN(-32);
+-----+
| SIGN(-32) |
+-----+
|      -1   |
+-----+

SELECT SIGN(0);
+-----+
| SIGN(0) |
+-----+
|      0   |
+-----+

SELECT SIGN(234);
+-----+
| SIGN(234) |
+-----+
|         1  |
+-----+
```

## See Also

- [ABS\(\)](#)

## 1.1.12.5.37 SIN

### Syntax

```
SIN(X)
```

### Description

Returns the sine of X, where X is given in radians.

### Examples

```
SELECT SIN(1.5707963267948966);
+-----+
| SIN(1.5707963267948966) |
+-----+
|          1   |
+-----+

SELECT SIN(PI());
+-----+
| SIN(PI()) |
+-----+
| 1.22460635382238e-16 |
+-----+

SELECT ROUND(SIN(PI()));
+-----+
| ROUND(SIN(PI())) |
+-----+
|        0   |
+-----+
```

## 1.1.12.5.38 SQRT

### Syntax

```
SQRT(X)
```

## Description

Returns the square root of X. If X is negative, NULL is returned.

## Examples

```
SELECT SQRT(4);
+-----+
| SQRT(4) |
+-----+
|      2   |
+-----+

SELECT SQRT(20);
+-----+
| SQRT(20)        |
+-----+
| 4.47213595499958 |
+-----+

SELECT SQRT(-16);
+-----+
| SQRT(-16) |
+-----+
|    NULL   |
+-----+

SELECT SQRT(1764);
+-----+
| SQRT(1764) |
+-----+
|      42   |
+-----+
```

## 1.1.12.5.39 TAN

### Syntax

```
TAN(X)
```

## Description

Returns the tangent of X, where X is given in radians.

## Examples

```
SELECT TAN(0.7853981633974483);
+-----+
| TAN(0.7853981633974483) |
+-----+
| 0.9999999999999999 |
+-----+  
  
SELECT TAN(PI());
+-----+
| TAN(PI()) |
+-----+
| -1.22460635382238e-16 |
+-----+  
  
SELECT TAN(PI()+1);
+-----+
| TAN(PI()+1) |
+-----+
| 1.5574077246549 |
+-----+  
  
SELECT TAN(RADIANS(PI()));
+-----+
| TAN(RADIANS(PI())) |
+-----+
| 0.0548861508080033 |
+-----+
```

## 1.1.12.5.40 TRUNCATE

This page documents the TRUNCATE function. See [TRUNCATE TABLE](#) for the DDL statement.

### Syntax

```
TRUNCATE(X,D)
```

### Contents

1. [Syntax](#)
2. [Description](#)
3. [Examples](#)
4. [See Also](#)

### Description

Returns the number X, truncated to D decimal places. If D is 0, the result has no decimal point or fractional part. D can be negative to cause D digits left of the decimal point of the value X to become zero.

### Examples

```

SELECT TRUNCATE(1.223,1);
+-----+
| TRUNCATE(1.223,1) |
+-----+
|      1.2      |
+-----+

SELECT TRUNCATE(1.999,1);
+-----+
| TRUNCATE(1.999,1) |
+-----+
|      1.9      |
+-----+

SELECT TRUNCATE(1.999,0);
+-----+
| TRUNCATE(1.999,0) |
+-----+
|      1      |
+-----+

SELECT TRUNCATE(-1.999,1);
+-----+
| TRUNCATE(-1.999,1) |
+-----+
|     -1.9     |
+-----+

SELECT TRUNCATE(122,-2);
+-----+
| TRUNCATE(122,-2) |
+-----+
|      100      |
+-----+

SELECT TRUNCATE(10.28*100,0);
+-----+
| TRUNCATE(10.28*100,0) |
+-----+
|      1028      |
+-----+

```

## See Also

- [TRUNCATE TABLE](#)

### 1.1.12.6 Control Flow Functions

#### 1.1.12.6.1 CASE OPERATOR

## Syntax

```

CASE value WHEN [compare_value] THEN result [WHEN [compare_value] THEN
result ...] [ELSE result] END

CASE WHEN [condition] THEN result [WHEN [condition] THEN result ...]
[ELSE result] END

```

## Contents

1. [Syntax](#)
2. [Description](#)
3. [Examples](#)

## Description

The first version returns the result where value=compare\_value. The second version returns the result for the first condition that is true. If there was no matching result value, the result after ELSE is returned, or NULL if there is no ELSE part.

There is also a [CASE statement](#), which differs from the CASE operator described here.

## Examples

```
SELECT CASE 1 WHEN 1 THEN 'one' WHEN 2 THEN 'two' ELSE 'more' END;
+-----+
| CASE 1 WHEN 1 THEN 'one' WHEN 2 THEN 'two' ELSE 'more' END |
+-----+
| one |
+-----+

SELECT CASE WHEN 1>0 THEN 'true' ELSE 'false' END;
+-----+
| CASE WHEN 1>0 THEN 'true' ELSE 'false' END |
+-----+
| true |
+-----+

SELECT CASE BINARY 'B' WHEN 'a' THEN 1 WHEN 'b' THEN 2 END;
+-----+
| CASE BINARY 'B' WHEN 'a' THEN 1 WHEN 'b' THEN 2 END |
+-----+
| NULL |
+-----+
```

### 1.1.12.6.2 DECODE

#### Syntax

```
DECODE(crypt_str,pass_str)
```

In [Oracle mode](#) from [MariaDB 10.3.2](#) :

```
DECODE(expr, search_expr, result_expr [, search_expr2, result_expr2 ...] [default_expr])
```

In all modes from [MariaDB 10.3.2](#) :

```
DECODE_ORACLE(expr, search_expr, result_expr [, search_expr2, result_expr2 ...] [default_expr])
```

#### Description

In the default mode,

DECODE

decrypts the encrypted string *crypt\_str* using *pass\_str* as the password. *crypt\_str* should be a string returned from [ENCODE\(\)](#). The resulting string will be the original string only if *pass\_str* is the same.

In [Oracle mode](#) from [MariaDB 10.3.2](#),

DECODE

compares *expr* to the search expressions, in order. If it finds a match, the corresponding result expression is returned. If no matches are found, the default expression is returned, or NULL if no default is provided.

NULLs are treated as equivalent.

DECODE\_ORACLE

is a synonym for the Oracle-mode version of the function, and is available in all modes.

## Examples

From [MariaDB 10.3.2](#) :

```

SELECT DECODE_ORACLE(2+1,3*1,'found1',3*2,'found2','default');
+
| DECODE_ORACLE(2+1,3*1,'found1',3*2,'found2','default') |
+
| found1 |
+
+-----+
| DECODE_ORACLE(2+4,3*1,'found1',3*2,'found2','default');
+
| DECODE_ORACLE(2+4,3*1,'found1',3*2,'found2','default') |
+
| found2 |
+
+-----+
| DECODE_ORACLE(2+2,3*1,'found1',3*2,'found2','default');
+
| DECODE_ORACLE(2+2,3*1,'found1',3*2,'found2','default') |
+
| default |
+
+-----+

```

Nulls are treated as equivalent:

```

SELECT DECODE_ORACLE(NULL,NULL,'Nulls are equivalent','Nulls are not equivalent');
+
| DECODE_ORACLE(NULL,NULL,'Nulls are equivalent','Nulls are not equivalent') |
+
| Nulls are equivalent |
+
+-----+

```

## 1.1.12.6.3 DECODE\_ORACLE

MariaDB starting with 10.3.2

`DECODE_ORACLE`  
is a synonym for the [Oracle mode](#) version of the [DECODE function](#), and is available in all modes.

## 1.1.12.6.4 IF Function

### Syntax

```
IF(expr1,expr2,expr3)
```

### Contents

1. [Syntax](#)
2. [Description](#)
3. [Examples](#)
4. [See Also](#)

### Description

If

```

expr1
is
TRUE
(
expr1 <> 0
and
expr1 <> NULL
) then
IF()
returns
expr2
; otherwise it returns
expr3
.
```

`IF()`

returns a numeric or string value, depending on the context in which it is used.

**Note:** There is also an [IF statement](#) which differs from the

`IF()`

function described here.

## Examples

```
SELECT IF(1>2,2,3);
+-----+
| IF(1>2,2,3) |
+-----+
|            3 |
+-----+
```

```
SELECT IF(1<2,'yes','no');
+-----+
| IF(1<2,'yes','no') |
+-----+
| yes                |
+-----+
```

```
SELECT IF(STRCMP('test','test1'),'no','yes');
+-----+
| IF(STRCMP('test','test1'),'no','yes') |
+-----+
| no                                |
+-----+
```

## See Also

There is also an [IF statement](#), which differs from the  
`IF()`  
function described above.

### 1.1.12.6.5 IFNULL

#### Syntax

```
IFNULL(expr1,expr2)
NVL(expr1,expr2)
```

#### Contents

1. [Syntax](#)
2. [Description](#)
3. [Examples](#)
4. [See Also](#)

## Description

If

*expr1*  
is not NULL, IFNULL() returns  
*expr1*  
; otherwise it returns  
*expr2*  
. IFNULL() returns a numeric or string value, depending on the context in which it is used.

From [MariaDB 10.3](#), NVL() is an alias for IFNULL().

## Examples

```

SELECT IFNULL(1,0);
+-----+
| IFNULL(1,0) |
+-----+
|      1      |
+-----+

SELECT IFNULL(NULL,10);
+-----+
| IFNULL(NULL,10) |
+-----+
|          10     |
+-----+

SELECT IFNULL(1/0,10);
+-----+
| IFNULL(1/0,10) |
+-----+
|      10.0000   |
+-----+

SELECT IFNULL(1/0,'yes');
+-----+
| IFNULL(1/0,'yes') |
+-----+
| yes               |
+-----+

```

## See Also

- [NULL values](#)
- [IS NULL operator](#)
- [IS NOT NULL operator](#)
- [COALESCE function](#)
- [NULLIF function](#)
- [CONNECT data types](#)

## 1.1.12.6.6 NULLIF

### Syntax

`NULLIF(expr1,expr2)`

### Contents

1. [Syntax](#)
2. [Description](#)
3. [Examples](#)
4. [See Also](#)

### Description

Returns NULL if expr1 = expr2 is true, otherwise returns expr1. This is the same as `CASE WHEN expr1 = expr2 THEN NULL ELSE expr1 END`.

### Examples

```

SELECT NULLIF(1,1);
+-----+
| NULLIF(1,1) |
+-----+
|      NULL    |
+-----+

SELECT NULLIF(1,2);
+-----+
| NULLIF(1,2) |
+-----+
|          1    |
+-----+

```

## See Also

- [NULL values](#)
- [IS NULL operator](#)
- [IS NOT NULL operator](#)
- [COALESCE function](#)
- [IFNULL function](#)
- [CONNECT data types](#)

## 1.1.12.6.7 NVL

MariaDB starting with [10.3](#)

From [MariaDB 10.3](#), NVL is a synonym for [IFNULL](#).

## 1.1.12.6.8 NVL2

MariaDB starting with [10.3](#)

The NVL2 function was introduced in [MariaDB 10.3.0](#).

## Syntax

```
NVL2(expr1,expr2,expr3)
```

### Contents

1. [Syntax](#)
2. [Description](#)
3. [Examples](#)
4. [See Also](#)

## Description

The

NVL2

function returns a value based on whether a specified expression is NULL or not. If *expr1* is not NULL, then NVL2 returns *expr2*. If *expr1* is NULL, then NVL2 returns *expr3*.

## Examples

```
SELECT NVL2(NULL,1,2);
+-----+
| NVL2(NULL,1,2) |
+-----+
|          2     |
+-----+  
  
SELECT NVL2('x',1,2);
+-----+
| NVL2('x',1,2) |
+-----+
|          1     |
+-----+
```

## See Also

- [IFNULL \(or NVL\)](#)

## 1.1.12.7 Pseudo Columns

### 1.1.12.7.1 \_rowid

## Syntax

\_rowid

## Description

The

\_rowid  
pseudo column is mapped to the primary key in the related table. This can be used as a replacement of the  
rowid  
pseudo column in other databases. Another usage is to simplify sql queries as one doesn't have to know the name of the primary key.

## Examples

```
create table t1 (a int primary key, b varchar(80));  
insert into t1 values (1,"one"),(2,"two");  
select * from t1 where _rowid=1;
```

a	b
1	one

```
update t1 set b="three" where _rowid=2;  
select * from t1 where _rowid>=1 and _rowid<=10;
```

a	b
1	one
2	three

### 1.1.12.8 Secondary Functions

#### 1.1.12.8.1 Bit Functions and Operators

##### 1.1.12.8.1.1 Operator Precedence

The precedence is the order in which the SQL operators are evaluated.

The following list shows the SQL operator precedence. Operators that appear first in the list have a higher precedence. Operators which are listed together have the same precedence.

•

INTERVAL

•

BINARY

COLLATE

•

!

•

(unary minus), [[bitwise-not]] (unary bit inversion)

•  
    ||  
    (string concatenation)

•  
    ^

•  
    \*

,

/

,

DIV

,

%

,

MOD

•  
    -

,

+

•  
    -

<<

,

>>

•  
    &

•  
    |

•  
    =

(comparison),

<=>

,

>=

,

>

,

<=

,

<

,

<>

,

!=

,

IS

,

LIKE

,

REGEXP

,

IN

•

BETWEEN

,

CASE

,

WHEN

,

THEN

,

ELSE

,

END

•

NOT

•

&&

,

AND

•

XOR

•

||

(logical or),

OR

•

=

(assignment),

:=

Functions precedence is always higher than operators precedence.

In this page

CASE

refers to the [CASE operator](#), not to the [CASE statement](#)

•

If the

HIGH\_NOT\_PRECEDENCE

SQL\_MODE is set,

NOT

has the same precedence as

!

•

The

||

operator's precedence, as well as its meaning, depends on the

PIPES\_AS\_CONCAT

SQL\_MODE flag: if it is on,

||

can be used to concatenate strings (like the [CONCAT\(\)](#) function) and has a higher precedence.

The

=

operator's precedence depends on the context - it is higher when

=

is used as a comparison operator.

[Parenthesis](#) can be used to modify the operators precedence in an expression.

## Short-circuit evaluation

The

AND

,

OR

,

&&

and

||

operators support short-circuit evaluation. This means that, in some cases, the expression on the right of those operators is not evaluated, because its result cannot affect the result. In the following cases, short-circuit evaluation is used and

x()

is not evaluated:

•

FALSE AND x()

•

FALSE && x()

•

TRUE OR x()

•

TRUE || x()

•  
NULL BETWEEN x() AND x()

Note however that the short-circuit evaluation does *not* apply to

```
NULL AND x()  
. Also,  
BETWEEN  
's right operands are not evaluated if the left operand is  
NULL  
, but in all other cases all the operands are evaluated.
```

This is a speed optimization. Also, since functions can have side-effects, this behavior can be used to choose whether execute them or not using a concise syntax:

```
SELECT some_function() OR log_error();
```

## 1.1.12.8.1.2 &

### Syntax

```
&
```

### Description

Bitwise AND. Converts the values to binary and compares bits. Only if both the corresponding bits are 1 is the resulting bit also 1.

See also [bitwise OR](#).

### Examples

```
SELECT 2&1;  
+----+  
| 2&1 |  
+----+  
|   0 |  
+----+  
  
SELECT 3&1;  
+----+  
| 3&1 |  
+----+  
|   1 |  
+----+  
  
SELECT 29 & 15;  
+-----+  
| 29 & 15 |  
+-----+  
|      13 |  
+-----+
```

## 1.1.12.8.1.3 <<

### Syntax

```
value1 << value2
```

### Description

Converts a longlong ( [BIGINT](#) ) number ( *value1* ) to binary and shifts *value2* units to the left.

### Examples

```
SELECT 1 << 2;
+-----+
| 1 << 2 |
+-----+
|      4 |
+-----+
```

## 1.1.12.8.1.4 >>

### Syntax

```
value1 >> value2
```

### Description

Converts a longlong ( [BIGINT](#) ) number ( *value1* ) to binary and shifts *value2* units to the right.

### Examples

```
SELECT 4 >> 2;
+-----+
| 4 >> 2 |
+-----+
|      1 |
+-----+
```

## 1.1.12.8.1.5 BIT\_COUNT

### Syntax

```
BIT_COUNT(N)
```

### Description

Returns the number of bits that are set in the argument N.

### Examples

```
SELECT BIT_COUNT(29), BIT_COUNT(b'101010');
+-----+-----+
| BIT_COUNT(29) | BIT_COUNT(b'101010') |
+-----+-----+
|        4 |          3 |
+-----+-----+
```

## 1.1.12.8.1.6 ^

### Syntax

```
^
```

### Description

Bitwise XOR. Converts the values to binary and compares bits. If one (and only one) of the corresponding bits is 1 is the resulting bit also 1.

### Examples

```
SELECT 1 ^ 1;
+-----+
| 1 ^ 1 |
+-----+
|     0 |
+-----+

SELECT 1 ^ 0;
+-----+
| 1 ^ 0 |
+-----+
|      1 |
+-----+

SELECT 11 ^ 3;
+-----+
| 11 ^ 3 |
+-----+
|      8 |
+-----+
```

## 1.1.12.8.1.7 |

### Syntax

|

### Description

Bitwise OR. Converts the values to binary and compares bits. If either of the corresponding bits has a value of 1, the resulting bit is also 1.

See also [bitwise AND](#).

### Examples

```
SELECT 2|1;
+-----+
| 2|1 |
+-----+
|     3 |
+-----+

SELECT 29 | 15;
+-----+
| 29 | 15 |
+-----+
|      31 |
+-----+
```

## 1.1.12.8.1.8 ~

### Syntax

~

### Description

Bitwise NOT. Converts the value to 4 bytes binary and inverts all bits.

### Examples

```
SELECT 3 & ~1;
+-----+
| 3 & ~1 |
+-----+
|      2 |
+-----+

SELECT 5 & ~1;
+-----+
| 5 & ~1 |
+-----+
|      4 |
+-----+
```

## 1.1.12.8.1.9 Parentheses

Parentheses are sometimes called precedence operators - this means that they can be used to change the other [operator's precedence](#) in an expression. The expressions that are written between parentheses are computed before the expressions that are written outside. Parentheses must always contain an expression (that is, they cannot be empty), and can be nested.

For example, the following expressions could return different results:

- NOT a OR b
- NOT (a OR b)

In the first case,

NOT  
applies to  
a  
, so if  
a  
is  
FALSE  
or  
b  
is  
TRUE  
, the expression returns  
TRUE  
. In the second case,  
NOT  
applies to the result of  
a OR b  
, so if at least one of  
a  
or  
b  
is  
TRUE  
, the expression is  
TRUE  
.

When the precedence of operators is not intuitive, you can use parentheses to make it immediately clear for whoever reads the statement.

The precedence of the

NOT  
operator can also be affected by the  
HIGH\_NOT\_PRECEDENCE  
[SQL\\_MODE](#) flag.

## Other uses

Parentheses must always be used to enclose [subqueries](#).

Parentheses can also be used in a

[JOIN](#)

statement between multiple tables to determine which tables must be joined first.

Also, parentheses are used to enclose the list of parameters to be passed to built-in functions, user-defined functions and stored routines. However, when no parameter is passed to a stored procedure, parentheses are optional. For builtin functions and user-defined functions, spaces are not allowed between the function name and the open parenthesis, unless the

IGNORE\_SPACE

SQL\_MODE is set. For stored routines (and for functions if

IGNORE\_SPACE

is set) spaces are allowed before the open parenthesis, including tab characters and new line characters.

## Syntax errors

If there are more open parentheses than closed parentheses, the error usually looks like this:

```
ERROR 1064 (42000): You have an error in your SQL syntax; check the manual that
corresponds to your MariaDB server version for the right syntax to use near '' a
t line 1
```

Note the empty string.

If there are more closed parentheses than open parentheses, the error usually looks like this:

```
ERROR 1064 (42000): You have an error in your SQL syntax; check the manual that
corresponds to your MariaDB server version for the right syntax to use near ')'
at line 1
```

Note the quoted closed parenthesis.

## 1.1.12.8.1.10 TRUE FALSE

### Description

The constants TRUE and FALSE evaluate to 1 and 0, respectively. The constant names can be written in any lettercase.

### Examples

```
SELECT TRUE, true, FALSE, false;
+-----+-----+-----+
| TRUE | TRUE | FALSE | FALSE |
+-----+-----+-----+
|   1  |    1 |     0 |     0 |
+-----+-----+-----+
```

## 1.1.12.8.2 Encryption, Hashing and Compression Functions

### 1.1.12.8.2.1 AES\_DECRYPT

#### Syntax

```
AES_DECRYPT(crypt_str,key_str)
```

#### Description

This function allows decryption of data using the official AES (Advanced Encryption Standard) algorithm. For more information, see the description of

[AES\\_ENCRYPT\(\)](#)

### 1.1.12.8.2.2 AES\_ENCRYPT

#### Syntax

```
AES_ENCRYPT(str,key_str)
```

## Description

AES\_ENCRYPT()  
and

[AES\\_DECRYPT\(\)](#)

allow encryption and decryption of data using the official AES (Advanced Encryption Standard) algorithm, previously known as "Rijndael." Encoding with a 128-bit key length is used, but you can extend it up to 256 bits by modifying the source. We chose 128 bits because it is much faster and it is secure enough for most purposes.

AES\_ENCRYPT()  
encrypts a string  
*str*  
using the key  
*key\_str*  
, and returns a binary string.

AES\_DECRYPT()  
decrypts the encrypted string and returns the original string.

The input arguments may be any length. If either argument is NULL, the result of this function is also  
NULL

Because AES is a block-level algorithm, padding is used to encode uneven length strings and so the result string length may be calculated using this formula:

```
16 x (trunc(string_length / 16) + 1)
```

If

AES\_DECRYPT()  
detects invalid data or incorrect padding, it returns  
NULL  
. However, it is possible for  
AES\_DECRYPT()  
to return a non-  
NULL  
value (possibly garbage) if the input data or the key is invalid.

## Examples

```
INSERT INTO t VALUES (AES_ENCRYPT('text',SHA2('password',512)));
```

## 1.1.12.8.2.3 COMPRESS

### Syntax

```
COMPRESS(string_to_compress)
```

## Description

Compresses a string and returns the result as a binary string. This function requires MariaDB to have been compiled with a compression library such as zlib. Otherwise, the return value is always

NULL  
. The compressed string can be uncompressed with

[UNCOMPRESS\(\)](#)

The `have_compress` server system variable indicates whether a compression library is present.

## Examples

```
SELECT LENGTH(COMPRESS(REPEAT('a',1000)));
+-----+
| LENGTH(COMPRESS(REPEAT('a',1000))) |
+-----+
|                               21 |
+-----+

SELECT LENGTH(COMPRESS(''));
+-----+
| LENGTH(COMPRESS('')) |
+-----+
|                      0 |
+-----+

SELECT LENGTH(COMPRESS('a'));
+-----+
| LENGTH(COMPRESS('a')) |
+-----+
|                         13 |
+-----+

SELECT LENGTH(COMPRESS(REPEAT('a',16)));
+-----+
| LENGTH(COMPRESS(REPEAT('a',16))) |
+-----+
|                               15 |
+-----+
```

### 1.1.12.8.2.4 DECODE

### 1.1.12.8.2.5 DES\_DECRYPT

#### Syntax

```
DES_DECRYPT(crypt_str[,key_str])
```

#### Description

Decrypts a string encrypted with

```
DES_ENCRYPT()
```

. If an error occurs, this function returns  
NULL

This function works only if MariaDB has been configured with [TLS support](#).

If no

```
key_str  
argument is given,  
DES_DECRYPT()
```

examines the first byte of the encrypted string to determine the DES key number that was used to encrypt the original string, and then reads the key from the DES key file to decrypt the message. For this to work, the user must have the SUPER privilege. The key file can be specified with the

```
--des-key-file  
server option.
```

If you pass this function a

```
key_str  
argument, that string is used as the key for decrypting the message.
```

If the

```
crypt_str  
argument does not appear to be an encrypted string, MariaDB returns the given crypt_str.
```

## 1.1.12.8.2.6 DES\_ENCRYPT

### Syntax

```
DES_ENCRYPT(str[,{key_num|key_str}])
```

### Description

Encrypts the string with the given key using the Triple-DES algorithm.

This function works only if MariaDB has been configured with [TLS support](#).

The encryption key to use is chosen based on the second argument to

```
DES_ENCRYPT()  
, if one was given. With no argument, the first key from the DES key file is used. With a  
key_num  
argument, the given key number (0-9) from the DES key file is used. With a  
key_str  
argument, the given key string is used to encrypt  
str
```

The key file can be specified with the

```
--des-key-file  
server option.
```

The return string is a binary string where the first character is

```
CHAR(128 | key_num)  
. If an error occurs,  
DES_ENCRYPT()  
returns  
NULL
```

The 128 is added to make it easier to recognize an encrypted key. If you use a string key,

```
key_num  
is 127.
```

The string length for the result is given by this formula:

```
new_len = orig_len + (8 - (orig_len % 8)) + 1
```

Each line in the DES key file has the following format:

```
key_num des_key_str
```

Each

```
key_num  
value must be a number in the range from 0 to 9. Lines in the file may be in any order.  
des_key_str  
is the string that is used to encrypt the message. There should be at least one space between the number and the key. The first key is the  
default key that is used if you do not specify any key argument to  
DES_ENCRYPT()
```

You can tell MariaDB to read new key values from the key file with the FLUSH DES\_KEY\_FILE statement. This requires the RELOAD privilege.

One benefit of having a set of default keys is that it gives applications a way to check for the existence of encrypted column values, without giving the end user the right to decrypt those values.

### Examples

```
SELECT customer_address FROM customer_table  
WHERE crypted_credit_card = DES_ENCRYPT('credit_card_number');
```

### See Also

- [DES\\_DECRYPT\(\)](#)

## 1.1.12.8.2.7 ENCODE

### Syntax

```
ENCODE(str,pass_str)
```

### Description

ENCODE is not considered cryptographically secure, and should not be used for password encryption.

#### Encrypt

str  
using  
pass\_str  
as the password. To decrypt the result, use

[DECODE\(\)](#)

The result is a binary string of the same length as

str

The strength of the encryption is based on how good the random generator is.

It is not recommended to rely on the encryption performed by the ENCODE function. Using a salt value (changed when a password is updated) will improve matters somewhat, but for storing passwords, consider a more cryptographically secure function, such as [SHA2\(\)](#).

### Examples

```
ENCODE('not so secret text', CONCAT('random_salt','password'))
```

## 1.1.12.8.2.8 ENCRYPT

### Syntax

```
ENCRYPT(str[,salt])
```

### Description

Encrypts a string using the Unix crypt() system call, returning an encrypted binary string. The

salt

argument should be a string with at least two characters or the returned result will be NULL. If no salt argument is given, a random value of sufficient length is used.

It is not recommended to use ENCRYPT() with utf16, utf32 or ucs2 multi-byte character sets because the crypt() system call expects a string terminated with a zero byte.

Note that the underlying crypt() system call may have some limitations, such as ignoring all but the first eight characters.

If the `have_crypt` system variable is set to

NO

(because the crypt() system call is not available), the ENCRYPT function will always return NULL.

### Examples

```
SELECT ENCRYPT('encrypt me');  
+-----+  
| ENCRYPT('encrypt me') |  
+-----+  
| 4I5BsEx0lqTDk |  
+-----+
```

## 1.1.12.8.2.9 MD5

### Syntax

```
MD5(str)
```

### Description

Calculates an MD5 128-bit checksum for the string.

The return value is a 32-hex digit string, and as of MariaDB 5.5 , is a nonbinary string in the connection [character set and collation](#) , determined by the values of the [character\\_set\\_connection](#) and [collation\\_connection](#) system variables. Before 5.5, the return value was a binary string.

NULL is returned if the argument was NULL.

### Examples

```
SELECT MD5('testing');
+-----+
| MD5('testing') |
+-----+
| ae2b1fc... |
+-----+
```

## 1.1.12.8.2.10 PASSWORD

### Syntax

```
PASSWORD(str)
```

### Contents

1. [Syntax](#)
2. [Description](#)
3. [Examples](#)
4. [See Also](#)

### Description

The PASSWORD() function is used for hashing passwords for use in authentication by the MariaDB server. It is not intended for use in other applications.

Calculates and returns a hashed password string from the plaintext password *str* . Returns an empty string (>= MariaDB 10.0.4 ) if the argument was NULL.

The return value is a nonbinary string in the connection [character set and collation](#) , determined by the values of the [character\\_set\\_connection](#) and [collation\\_connection](#) system variables.

This is the function that is used for hashing MariaDB passwords for storage in the Password column of the [user table](#) (see [privileges](#) ), usually used with the [SET PASSWORD](#) statement. It is not intended for use in other applications.

Until MariaDB 10.3 , the return value is 41-bytes in length, and the first character is always \*\*. From MariaDB 10.4 , the function takes into account the authentication plugin where applicable (A [CREATE USER](#) or [SET PASSWORD](#) statement). For example, when used in conjunction with a user authenticated by the [ed25519 plugin](#) , the statement will create a longer hash:

```

CREATE USER edtest@localhost IDENTIFIED VIA ed25519 USING PASSWORD('secret');

CREATE USER edtest2@localhost IDENTIFIED BY 'secret';

SELECT CONCAT(user, '@', host, ' => ', JSON_DETAILED(priv)) FROM mysql.global_priv
 WHERE user LIKE 'edtest%\G
***** 1. row *****
CONCAT(user, '@', host, ' => ', JSON_DETAILED(priv)): edtest@localhost => {
...
  "plugin": "ed25519",
  "authentication_string": "ZIgUREUg5PVgQ6LskhXm0+eZLS0nC8be6HPjYWR4YJY",
...
}
***** 2. row *****
CONCAT(user, '@', host, ' => ', JSON_DETAILED(priv)): edtest2@localhost => {
...
  "plugin": "mysql_native_password",
  "authentication_string": "*14E65567ABDB5135D0CFD9A70B3032C179A49EE7",
...
}

```

The behavior of this function is affected by the value of the [old\\_passwords](#) system variable. If this is set to

```

1
(
0

```

is default), MariaDB reverts to using the [mysql\\_old\\_password authentication plugin](#) by default for newly created users and passwords.

## Examples

```

SELECT PASSWORD('notagoodpwd');
+-----+
| PASSWORD('notagoodpwd') |
+-----+
| *3A70EE9FC6594F88CE9E959CD51C5A1C002DC937 |
+-----+

```

```

SET PASSWORD FOR 'bob'@'%.loc.gov' = PASSWORD('newpass');

```

- [OLD\\_PASSWORD\(\)](#) - pre-MySQL 4.1 password function

## 1.1.12.8.2.11 PASSWORD

### Syntax

```
PASSWORD(str)
```

### Contents

- [Syntax](#)
- [Description](#)
- [Examples](#)
- [See Also](#)

### Description

The `PASSWORD()` function is used for hashing passwords for use in authentication by the MariaDB server. It is not intended for use in other applications.

Calculates and returns a hashed password string from the plaintext password `str`. Returns an empty string ( $\geq$  [MariaDB 10.0.4](#)) if the argument was `NULL`.

The return value is a nonbinary string in the connection [character set and collation](#), determined by the values of the [character\\_set\\_connection](#) and

`collation_connection` system variables.

This is the function that is used for hashing MariaDB passwords for storage in the `Password` column of the `user` table (see [privileges](#)), usually used with the `SET PASSWORD` statement. It is not intended for use in other applications.

Until [MariaDB 10.3](#), the return value is 41-bytes in length, and the first character is always `**`. From [MariaDB 10.4](#), the function takes into account the authentication plugin where applicable (A `CREATE USER` or `SET PASSWORD` statement). For example, when used in conjunction with a user authenticated by the [ed25519 plugin](#), the statement will create a longer hash:

```
CREATE USER edtest@localhost IDENTIFIED VIA ed25519 USING PASSWORD('secret');

CREATE USER edtest2@localhost IDENTIFIED BY 'secret';

SELECT CONCAT(user, '@', host, ' => ', JSON_DETAILED(priv)) FROM mysql.global_priv
  WHERE user LIKE 'edtest%'\G
***** 1. row *****
CONCAT(user, '@', host, ' => ', JSON_DETAILED(priv)): edtest@localhost => {
...
  "plugin": "ed25519",
  "authentication_string": "ZIGUREUg5PVgQ6LskhXm0+eZLS0nC8be6HPjYWR4YJY",
...
}
***** 2. row *****
CONCAT(user, '@', host, ' => ', JSON_DETAILED(priv)): edtest2@localhost => {
...
  "plugin": "mysql_native_password",
  "authentication_string": "*14E65567ABDB5135D0CFD9A70B3032C179A49EE7",
...
}
```

The behavior of this function is affected by the value of the `old_passwords` system variable. If this is set to

```
1
(
0
```

is default), MariaDB reverts to using the [mysql\\_old\\_password authentication plugin](#) by default for newly created users and passwords.

## Examples

```
SELECT PASSWORD('notagoodpwd');
+-----+
| PASSWORD('notagoodpwd') |
+-----+
| *3A70EE9FC6594F88CE9E959CD51C5A1C002DC937 |
+-----+
```

```
SET PASSWORD FOR 'bob'@'%.loc.gov' = PASSWORD('newpass');
```

## See Also

- [OLD\\_PASSWORD\(\)](#) - pre-MySQL 4.1 password function

## 1.1.12.8.2.12 SHA1

### Syntax

```
SHA1(str), SHA(str)
```

### Description

Calculates an SHA-1 160-bit checksum for the string

`str`

, as described in RFC 3174 (Secure Hash Algorithm).

The value is returned as a string of 40 hex digits, or NULL if the argument was NULL. As of [MariaDB 5.5](#), the return value is a nonbinary string in the connection `character set and collation`, determined by the values of the `character_set_connection` and `collation_connection` system variables. Before 5.5, the return value was a binary string.

## Examples

```
SELECT SHA1('some boring text');
+-----+
| SHA1('some boring text')           |
+-----+
| af969fc2085b1bb6d31e517d5c456def5cdd7093 |
+-----+
```

## 1.1.12.8.2.13 SHA2

### Syntax

```
SHA2(str,hash_len)
```

### Description

Given a string

*str*

, calculates an SHA-2 checksum, which is considered more cryptographically secure than its [SHA-1](#) equivalent. The SHA-2 family includes SHA-224, SHA-256, SHA-384, and SHA-512, and the

*hash\_len*

must correspond to one of these, i.e. 224, 256, 384 or 512. 0 is equivalent to 256.

The return value is a nonbinary string in the connection [character set and collation](#) , determined by the values of the [character\\_set\\_connection](#) and [collation\\_connection](#) system variables.

NULL is returned if the hash length is not valid, or the string

*str*

is NULL.

SHA2 will only work if MariaDB was has been configured with [TLS support](#) .

## Examples

```
SELECT SHA2('Maria',224);
+-----+
| SHA2('Maria',224)           |
+-----+
| 6cc67add32286412efcab9d0e1675a43a5c2ef3cec8879f81516ff83 |
+-----+

SELECT SHA2('Maria',256);
+-----+
| SHA2('Maria',256)           |
+-----+
| 9ff18ebe7449349f358e3af0b57cf7a032c1c6b2272cb2656ff85eb112232f16 |
+-----+

SELECT SHA2('Maria',0);
+-----+
| SHA2('Maria',0)           |
+-----+
| 9ff18ebe7449349f358e3af0b57cf7a032c1c6b2272cb2656ff85eb112232f16 |
+-----+
```

## 1.1.12.8.2.14 UNCOMPRESS

## 1.1.12.8.2.15 UNCOMPRESSED\_LENGTH

### 1.1.12.8.3 Information Functions

#### 1.1.12.8.3.1 BENCHMARK

## Syntax

```
BENCHMARK(count,expr)
```

## Description

The BENCHMARK() function executes the expression

expr  
repeatedly  
count

times. It may be used to time how quickly MariaDB processes the expression. The result value is always 0. The intended use is from within the [mysql client](#), which reports query execution times.

## Examples

```
SELECT BENCHMARK(1000000,ENCODE('hello','goodbye'));
+-----+
| BENCHMARK(1000000,ENCODE('hello','goodbye')) |
+-----+
|          0 |
+-----+
1 row in set (0.21 sec)
```

## 1.1.12.8.3.2 BINLOG\_GTIID\_POS

### Syntax

```
BINLOG_GTIID_POS(binlog_filename,binlog_offset)
```

### Description

The BINLOG\_GTIID\_POS() function takes as input an old-style [binary log](#) position in the form of a file name and a file offset. It looks up the position in the current binlog, and returns a string representation of the corresponding [GTID](#) position. If the position is not found in the current binlog, NULL is returned.

### Examples

```
SELECT BINLOG_GTIID_POS("master-bin.000001", 600);
```

### See Also

- [SHOW BINLOG EVENTS](#) - Show events and their positions in the binary log

## 1.1.12.8.3.3 CHARSET

### Syntax

```
CHARSET(str)
```

### Description

Returns the [character set](#) of the string argument. If

str  
is not a string, it is considered as a binary string (so the function returns 'binary'). This applies to  
NULL  
, too. The return value is a string in the utf8 [character set](#).

## Examples

```

SELECT CHARSET('abc');
+-----+
| CHARSET('abc') |
+-----+
| latin1          |
+-----+

SELECT CHARSET(CONVERT('abc' USING utf8));
+-----+
| CHARSET(CONVERT('abc' USING utf8)) |
+-----+
| utf8            |
+-----+

SELECT CHARSET(USER());
+-----+
| CHARSET(USER()) |
+-----+
| utf8           |
+-----+

```

## 1.1.12.8.3.4 COERCIBILITY

### Syntax

```
COERCIBILITY(str)
```

### Description

Returns the collation coercibility value of the string argument. Coercibility defines what will be converted to what in case of collation conflict, with an expression with higher coercibility being converted to the collation of an expression with lower coercibility.

Coercibility	Description	Example
0	Explicit	Value using a COLLATE clause
1	No collation	Concatenated strings using different collations
2	Implicit	Column value
3	Constant	USER() return value
4	Coercible	Literal string
5	Ignorable	NULL or derived from NULL

### Examples

```

SELECT COERCIBILITY('abc' COLLATE latin1_swedish_ci);
+-----+
| COERCIBILITY('abc' COLLATE latin1_swedish_ci) |
+-----+
|          0 |
+-----+

SELECT COERCIBILITY(USER());
+-----+
| COERCIBILITY(USER()) |
+-----+
|          3 |
+-----+

SELECT COERCIBILITY('abc');
+-----+
| COERCIBILITY('abc') |
+-----+
|          4 |
+-----+

```

## 1.1.12.8.3.5 COLLATION

# Syntax

COLLATION(str)

## Contents

1. [Syntax](#)
2. [Description](#)
3. [Examples](#)
4. [See Also](#)

## Description

Returns the collation of the string argument. If

str  
is not a string, it is considered as a binary string (so the function returns 'binary'). This applies to  
NULL  
, too. The return value is a string in the utf8 [character set](#).

See [Character Sets and Collations](#).

## Examples

```
SELECT COLLATION('abc');
+-----+
| COLLATION('abc') |
+-----+
| latin1_swedish_ci |
+-----+

SELECT COLLATION(_utf8'abc');
+-----+
| COLLATION(_utf8'abc') |
+-----+
| utf8_general_ci      |
+-----+
```

## See Also

- [String literals](#)
- [CAST\(\)](#)
- [CONVERT\(\)](#)

## 1.1.12.8.3.6 CONNECTION\_ID

### Syntax

CONNECTION\_ID()

## Description

Returns the connection ID (thread ID) for the connection. Every thread (including events) has an ID that is unique among the set of currently connected clients.

Until [MariaDB 10.3.1](#), returns

MYSQL\_TYPE\_LONGLONG  
, or [bigint\(10\)](#), in all cases. From [MariaDB 10.3.1](#), returns  
MYSQL\_TYPE\_LONG  
, or [int\(10\)](#), when the result would fit within 32-bits.

## Examples

```
SELECT CONNECTION_ID();
+-----+
| CONNECTION_ID() |
+-----+
|      3 |
+-----+
```

## See Also

- [SHOW PROCESSLIST](#)
- [INFORMATION\\_SCHEMA.PROCESSLIST](#)

## 1.1.12.8.3.7 CURRENT\_ROLE

### Syntax

```
CURRENT_ROLE, CURRENT_ROLE()
```

### Description

Returns the current role name. This determines your access privileges. The return value is a string in the utf8 character set .

If there is no current role, NULL is returned.

The output of

```
SELECT CURRENT_ROLE
```

is equivalent to the contents of the [ENABLED\\_ROLES](#) Information Schema table.

[USER\(\)](#) returns the combination of user and host used to login. [CURRENT\\_USER\(\)](#) returns the account used to determine current connection's privileges.

### Examples

```
SELECT CURRENT_ROLE;
+-----+
| CURRENT_ROLE |
+-----+
| NULL         |
+-----+

SET ROLE staff;

SELECT CURRENT_ROLE;
+-----+
| CURRENT_ROLE |
+-----+
| staff        |
+-----+
```

## 1.1.12.8.3.8 CURRENT\_USER

### Syntax

```
CURRENT_USER, CURRENT_USER()
```

### Description

Returns the user name and host name combination for the MariaDB account that the server used to authenticate the current client. This account determines your access privileges. The return value is a string in the utf8 character set .

The value of

```
CURRENT_USER()
```

can differ from the value of [USER\(\)](#) . [CURRENT\\_ROLE\(\)](#) returns the current active role.

## Examples

```
shell> mysql --user="anonymous"

select user(),current_user();
+-----+-----+
| user() | current_user() |
+-----+-----+
| anonymous@localhost | @localhost      |
+-----+-----+
```

When calling

CURRENT\_USER()  
in a stored procedure, it returns the owner of the stored procedure, as defined with  
DEFINER

## See Also

- [USER\(\)](#)
- [CREATE PROCEDURE](#)

## 1.1.12.8.3.9 DATABASE

### Syntax

```
DATABASE()
```

### Description

Returns the default (current) database name as a string in the utf8 [character set](#). If there is no default database, DATABASE() returns NULL. Within a [stored routine](#), the default database is the database that the routine is associated with, which is not necessarily the same as the database that is the default in the calling context.

SCHEMA() is a synonym for DATABASE().

To select a default database, the [USE](#) statement can be run. Another way to set the default database is specifying its name at [mysql](#) command line client startup.

## Examples

```
SELECT DATABASE();
+-----+
| DATABASE() |
+-----+
| NULL       |
+-----+

USE test;
Database changed

SELECT DATABASE();
+-----+
| DATABASE() |
+-----+
| test        |
+-----+
```

## 1.1.12.8.3.10 DECODE\_HISTOGRAM

### Syntax

```
DECODE_HISTOGRAM(hist_type,histogram)
```

## Description

Returns a string of comma separated numeric values corresponding to a probability distribution represented by the histogram of type

```
hist_type
(
SINGLE_PREC_HB
or
DOUBLE_PREC_HB
). The
hist_type
and
histogram
would be commonly used from the mysql.column\_stats table.
```

See [Histogram Based Statistics](#) for details.

## Examples

```
CREATE TABLE origin (
  i INT UNSIGNED NOT NULL AUTO_INCREMENT PRIMARY KEY,
  v INT UNSIGNED NOT NULL
);

INSERT INTO origin(v) VALUES
(1),(2),(3),(4),(5),(10),(20),
(30),(40),(50),(60),(70),(80),
(90),(100),(200),(400),(800);

SET histogram_size=10,histogram_type=SINGLE_PREC_HB;

ANALYZE TABLE origin PERSISTENT FOR ALL;
+-----+-----+-----+
| Table | Op      | Msg_type | Msg_text
+-----+-----+-----+
| test.origin | analyze | status    | Engine-independent statistics collected |
| test.origin | analyze | status    | OK
+-----+-----+-----+

SELECT db_name,table_name,column_name,hist_type,
hex(histogram),decode_histogram(hist_type,histogram)
FROM mysql.column_stats WHERE db_name='test' and table_name='origin';
+-----+-----+-----+-----+
| db_name | table_name | column_name | hist_type       | hex(histogram)      | decode_histogram(hist_type,histogram)
+-----+-----+-----+-----+
| test    | origin     | i           | SINGLE_PREC_HB | 0F2D3C5A7887A5C3D2F0 | 0.059,0.118,0.059,0.118,0.059,0.118,0.059,0.118,0
| test    | origin     | v           | SINGLE_PREC_HB | 000001060C0F161C1F7F | 0.000,0.000,0.004,0.020,0.024,0.012,0.027,0.024,0
+-----+-----+-----+-----+

SET histogram_size=20,histogram_type=DOUBLE_PREC_HB;

ANALYZE TABLE origin PERSISTENT FOR ALL;
+-----+-----+-----+
| Table | Op      | Msg_type | Msg_text
+-----+-----+-----+
| test.origin | analyze | status    | Engine-independent statistics collected |
| test.origin | analyze | status    | OK
+-----+-----+-----+

SELECT db_name,table_name,column_name,
hist_type,hex(histogram),decode_histogram(hist_type,histogram)
FROM mysql.column_stats WHERE db_name='test' and table_name='origin';
+-----+-----+-----+-----+
| db_name | table_name | column_name | hist_type       | hex(histogram)      | decode_histogram(hist_type,histogram)
+-----+-----+-----+-----+
| test    | origin     | i           | DOUBLE_PREC_HB | 0F0F2D2D3C3C5A5A78788787A5A5C3C3D2D2F0F0 | 0.05882,0.11765,0.05882,0.117
| test    | origin     | v           | DOUBLE_PREC_HB | 5200F600480116067E0CB30F1B16831CB81FD67F | 0.00125,0.00250,0.00125,0.018
+-----+-----+-----+-----+
```

## 1.1.12.8.3.11 DEFAULT

### Syntax

```
DEFAULT(col_name)
```

## Description

Returns the default value for a table column. If the column has no default value (and is not NULLABLE - NULLABLE fields have a NULL default), an error is returned.

For integer columns using [AUTO\\_INCREMENT](#),

0

is returned.

When using

DEFAULT

as a value to set in an [INSERT](#) or [UPDATE](#) statement, you can use the bare keyword

DEFAULT

without the parentheses and argument to refer to the column in context. You can only use

DEFAULT

as a bare keyword if you are using it alone without a surrounding expression or function.

## Examples

Select only non-default values for a column:

```
SELECT i FROM t WHERE i != DEFAULT(i);
```

Update values to be one greater than the default value:

```
UPDATE t SET i = DEFAULT(i)+1 WHERE i < 100;
```

When referring to the default value exactly in

UPDATE

or

INSERT

, you can omit the argument:

```
INSERT INTO t (i) VALUES (DEFAULT);
UPDATE t SET i = DEFAULT WHERE i < 100;
```

```
CREATE OR REPLACE TABLE t (
    i INT NOT NULL AUTO_INCREMENT,
    j INT NOT NULL,
    k INT DEFAULT 3,
    l INT NOT NULL DEFAULT 4,
    m INT,
    PRIMARY KEY (i)
);
```

```
DESC t;
```

Field	Type	Null	Key	Default	Extra
i	int(11)	NO	PRI	NULL	auto_increment
j	int(11)	NO		NULL	
k	int(11)	YES		3	
l	int(11)	NO		4	
m	int(11)	YES		NULL	

```
INSERT INTO t (j) VALUES (1);
INSERT INTO t (j,m) VALUES (2,2);
INSERT INTO t (j,l,m) VALUES (3,3,3);
```

```
SELECT * FROM t;
```

i	j	k	l	m
1	1	3	4	NULL
2	2	3	4	2
3	3	3	3	3

```
SELECT DEFAULT(i), DEFAULT(k), DEFAULT(l), DEFAULT(m) FROM t;
+-----+-----+-----+
| DEFAULT(i) | DEFAULT(k) | DEFAULT(l) | DEFAULT(m) |
+-----+-----+-----+
|      0 |      3 |      4 |    NULL |
|      0 |      3 |      4 |    NULL |
|      0 |      3 |      4 |    NULL |
+-----+-----+-----+

SELECT DEFAULT(i), DEFAULT(k), DEFAULT(l), DEFAULT(m), DEFAULT(j) FROM t;
ERROR 1364 (HY000): Field 'j' doesn't have a default value

SELECT * FROM t WHERE i = DEFAULT(i);
Empty set (0.001 sec)

SELECT * FROM t WHERE j = DEFAULT(j);
ERROR 1364 (HY000): Field 'j' doesn't have a default value

SELECT * FROM t WHERE k = DEFAULT(k);
+-----+-----+-----+
| i | j | k | l | m |
+-----+-----+-----+
| 1 | 1 | 3 | 4 | NULL |
| 2 | 2 | 3 | 4 |   2 |
| 3 | 3 | 3 | 3 |   3 |
+-----+-----+-----+

SELECT * FROM t WHERE l = DEFAULT(l);
+-----+-----+-----+
| i | j | k | l | m |
+-----+-----+-----+
| 1 | 1 | 3 | 4 | NULL |
| 2 | 2 | 3 | 4 |   2 |
+-----+-----+-----+

SELECT * FROM t WHERE m = DEFAULT(m);
Empty set (0.001 sec)

SELECT * FROM t WHERE m <=> DEFAULT(m);
+-----+-----+-----+
| i | j | k | l | m |
+-----+-----+-----+
| 1 | 1 | 3 | 4 | NULL |
+-----+-----+-----+
```

- CREATE TABLE DEFAULT Clause

## 1.1.12.8.3.12 FOUND\_ROWS

## Syntax

`FOUND_ROWS()`

## Description

A `SELECT` statement may include a `LIMIT` clause to restrict the number of rows the server returns to the client. In some cases, it is desirable to know how many rows the statement would have returned without the `LIMIT`, but without running the statement again. To obtain this row count, include a `SQL_CALC_FOUND_ROWS` option in the `SELECT` statement, and then invoke `FOUND_ROWS()` afterwards.

You can also use `FOUND_ROWS()` to obtain the number of rows returned by a `SELECT` which does not contain a `LIMIT` clause. In this case you don't need to use the `SQL_CALC_FOUND_ROWS` option. This can be useful for example in a `stored procedure`.

Also, this function works with some other statements which return a resultset, including `SHOW` , `DESC` and `HELP` . For `DELETE ... RETURNING` you should use `ROW_COUNT()` . It also works as a [prepared statement](#) , or after executing a prepared statement.

Statements which don't return any results don't affect FOUND\_ROWS() - the previous value will still be returned.

**Warning:** When used after a `CALL` statement, this function returns the number of rows selected by the last query in the procedure, not by the whole procedure.

Statements using the FOUND\_ROWS() function are not safe for replication.

# Examples

```
SHOW ENGINES;
+-----+-----+-----+-----+
| Engine | Support | Comment | Transactions | XA | Savepoint |
+-----+-----+-----+-----+
| InnoDB | DEFAULT | Supports transactions, row-level locking, and foreign keys | YES | YES | YES |
...
| SPHINX | YES | Sphinx storage engine | NO | NO | NO |
+-----+-----+-----+-----+
11 rows in set (0.01 sec)

SELECT FOUND_ROWS();
+-----+
| FOUND_ROWS() |
+-----+
|      11 |
+-----+

SELECT SQL_CALC_FOUND_ROWS * FROM tbl_name WHERE id > 100 LIMIT 10;

SELECT FOUND_ROWS();
+-----+
| FOUND_ROWS() |
+-----+
|      23 |
+-----+
```

- [ROW\\_COUNT\(\)](#)

## 1.1.12.8.3.13 LAST\_INSERT\_ID

### Syntax

```
LAST_INSERT_ID(), LAST_INSERT_ID(expr)
```

### Contents

1. [Syntax](#)
2. [Description](#)
3. [Examples](#)
4. [See Also](#)

### Description

`LAST_INSERT_ID()` (no arguments) returns the first automatically generated value successfully inserted for an `AUTO_INCREMENT` column as a result of the most recently executed `INSERT` statement. The value of `LAST_INSERT_ID()` remains unchanged if no rows are successfully inserted.

If one gives an argument to `LAST_INSERT_ID()`, then it will return the value of the expression and the next call to `LAST_INSERT_ID()` will return the same value. The value will also be sent to the client and can be accessed by the `mysql_insert_id` function.

For example, after inserting a row that generates an `AUTO_INCREMENT` value, you can get the value like this:

```
SELECT LAST_INSERT_ID();
+-----+
| LAST_INSERT_ID() |
+-----+
|      9 |
+-----+
```

You can also use `LAST_INSERT_ID()` to delete the last inserted row:

```
DELETE FROM product WHERE id = LAST_INSERT_ID();
```

If no rows were successfully inserted, `LAST_INSERT_ID()` returns 0.

The value of `LAST_INSERT_ID()` will be consistent across all versions if all rows in the `INSERT` or `UPDATE` statement were successful.

The currently executing statement does not affect the value of LAST\_INSERT\_ID(). Suppose that you generate an AUTO\_INCREMENT value with one statement, and then refer to LAST\_INSERT\_ID() in a multiple-row INSERT statement that inserts rows into a table with its own AUTO\_INCREMENT column. The value of LAST\_INSERT\_ID() will remain stable in the second statement; its value for the second and later rows is not affected by the earlier row insertions. (However, if you mix references to LAST\_INSERT\_ID() and LAST\_INSERT\_ID(expr), the effect is undefined.)

If the previous statement returned an error, the value of LAST\_INSERT\_ID() is undefined. For transactional tables, if the statement is rolled back due to an error, the value of LAST\_INSERT\_ID() is left undefined. For manual [ROLLBACK](#), the value of LAST\_INSERT\_ID() is not restored to that before the transaction; it remains as it was at the point of the ROLLBACK.

Within the body of a stored routine (procedure or function) or a trigger, the value of LAST\_INSERT\_ID() changes the same way as for statements executed outside the body of these kinds of objects. The effect of a stored routine or trigger upon the value of LAST\_INSERT\_ID() that is seen by following statements depends on the kind of routine:

- If a [stored procedure](#) executes statements that change the value of LAST\_INSERT\_ID(), the new value will be seen by statements that follow the procedure call.
- For [stored functions](#) and [triggers](#) that change the value, the value is restored when the function or trigger ends, so following statements will not see a changed value.

## Examples

```
CREATE TABLE t (
  id INTEGER UNSIGNED AUTO_INCREMENT PRIMARY KEY,
  f VARCHAR(1))
ENGINE = InnoDB;
```

```
INSERT INTO t(f) VALUES('a');
```

```
SELECT LAST_INSERT_ID();
+-----+
| LAST_INSERT_ID() |
+-----+
|          1 |
+-----+
```

```
INSERT INTO t(f) VALUES('b');
```

```
INSERT INTO t(f) VALUES('c');
```

```
SELECT LAST_INSERT_ID();
+-----+
| LAST_INSERT_ID() |
+-----+
|          3 |
+-----+
```

```
INSERT INTO t(f) VALUES('d'), ('e');
```

```
SELECT LAST_INSERT_ID();
+-----+
| LAST_INSERT_ID() |
+-----+
|          4 |
+-----+
```

```
SELECT * FROM t;
+-----+
| id | f    |
+-----+
| 1  | a    |
| 2  | b    |
| 3  | c    |
| 4  | d    |
| 5  | e    |
+-----+
```

```
SELECT LAST_INSERT_ID(12);
+-----+
| LAST_INSERT_ID(12) |
+-----+
|          12 |
+-----+
```

```
SELECT LAST_INSERT_ID();
+-----+
| LAST_INSERT_ID() |
+-----+
```

```

|           12 |
+-----+
INSERT INTO t(f) VALUES('f');

SELECT LAST_INSERT_ID();
+-----+
| LAST_INSERT_ID() |
+-----+
|          6 |
+-----+

SELECT * FROM t;
+-----+
| id | f    |
+-----+
| 1  | a    |
| 2  | b    |
| 3  | c    |
| 4  | d    |
| 5  | e    |
| 6  | f    |
+-----+

SELECT LAST_INSERT_ID(12);
+-----+
| LAST_INSERT_ID(12) |
+-----+
|          12 |
+-----+

INSERT INTO t(f) VALUES('g');

SELECT * FROM t;
+-----+
| id | f    |
+-----+
| 1  | a    |
| 2  | b    |
| 3  | c    |
| 4  | d    |
| 5  | e    |
| 6  | f    |
| 7  | g    |
+-----+

```

## 1.1.12.8.3.14 LAST\_VALUE

### Syntax

```
LAST_VALUE(expr,[expr,...])
```

```

LAST_VALUE(expr) OVER (
  [ PARTITION BY partition_expression ]
  [ ORDER BY order_list ]
)

```

### Contents

1. [Syntax](#)
2. [Description](#)
3. [Examples](#)
4. [See Also](#)

# Description

`LAST_VALUE()`  
evaluates all expressions and returns the last.

This is useful together with [setting user variables to a value with @var:=expr](#), for example when you want to get data of rows updated/deleted without having to do two queries against the table.

Since [MariaDB 10.2.2](#), `LAST_VALUE` can be used as a [window function](#).

Returns NULL if no last value exists.

## Examples

```
CREATE TABLE t1 (a int, b int);
INSERT INTO t1 VALUES(1,10),(2,20);
DELETE FROM t1 WHERE a=1 AND last_value(@a:=a,@b:=b,1);
SELECT @a,@b;
+-----+-----+
| @a   | @b   |
+-----+-----+
|     1 |    10 |
+-----+-----+
```

As a [window function](#):

```
CREATE TABLE t1 (
  pk int primary key,
  a int,
  b int,
  c char(10),
  d decimal(10, 3),
  e real
);

INSERT INTO t1 VALUES
( 1, 0, 1, 'one', 0.1, 0.001),
( 2, 0, 2, 'two', 0.2, 0.002),
( 3, 0, 3, 'three', 0.3, 0.003),
( 4, 1, 2, 'three', 0.4, 0.004),
( 5, 1, 1, 'two', 0.5, 0.005),
( 6, 1, 1, 'one', 0.6, 0.006),
( 7, 2, NULL, 'n_one', 0.5, 0.007),
( 8, 2, 1, 'n_two', NULL, 0.008),
( 9, 2, 2, NULL, 0.7, 0.009),
(10, 2, 0, 'n_four', 0.8, 0.010),
(11, 2, 10, NULL, 0.9, NULL);

SELECT pk, FIRST_VALUE(pk) OVER (ORDER BY pk) AS first_asc,
       LAST_VALUE(pk) OVER (ORDER BY pk) AS last_asc,
       FIRST_VALUE(pk) OVER (ORDER BY pk DESC) AS first_desc,
       LAST_VALUE(pk) OVER (ORDER BY pk DESC) AS last_desc
FROM t1
ORDER BY pk DESC;

+-----+-----+-----+-----+
| pk | first_asc | last_asc | first_desc | last_desc |
+-----+-----+-----+-----+
| 11 |      1 |     11 |      11 |      11 |
| 10 |      1 |     10 |      11 |      10 |
|  9 |      1 |      9 |      11 |       9 |
|  8 |      1 |      8 |      11 |       8 |
|  7 |      1 |      7 |      11 |       7 |
|  6 |      1 |      6 |      11 |       6 |
|  5 |      1 |      5 |      11 |       5 |
|  4 |      1 |      4 |      11 |       4 |
|  3 |      1 |      3 |      11 |       3 |
|  2 |      1 |      2 |      11 |       2 |
|  1 |      1 |      1 |      11 |       1 |
+-----+-----+-----+-----+
```

```

CREATE OR REPLACE TABLE t1 (i int);
INSERT INTO t1 VALUES (1),(2),(3),(4),(5),(6),(7),(8),(9),(10);

SELECT i,
    FIRST_VALUE(i) OVER (ORDER BY i ROWS BETWEEN CURRENT ROW and 1 FOLLOWING) AS f_1f,
    LAST_VALUE(i) OVER (ORDER BY i ROWS BETWEEN CURRENT ROW and 1 FOLLOWING) AS l_1f,
    FIRST_VALUE(i) OVER (ORDER BY i ROWS BETWEEN 1 PRECEDING AND 1 FOLLOWING) AS f_1p1f,
    LAST_VALUE(i) OVER (ORDER BY i ROWS BETWEEN 1 PRECEDING AND 1 FOLLOWING) AS f_1p1f,
    FIRST_VALUE(i) OVER (ORDER BY i ROWS BETWEEN 2 PRECEDING AND 1 PRECEDING) AS f_2p1p,
    LAST_VALUE(i) OVER (ORDER BY i ROWS BETWEEN 2 PRECEDING AND 1 PRECEDING) AS f_2p1p,
    FIRST_VALUE(i) OVER (ORDER BY i ROWS BETWEEN 1 FOLLOWING AND 2 FOLLOWING) AS f_1f2f,
    LAST_VALUE(i) OVER (ORDER BY i ROWS BETWEEN 1 FOLLOWING AND 2 FOLLOWING) AS f_1f2f
FROM t1;

```

i	f_1f	l_1f	f_1p1f	f_1p1f	f_2p1p	f_2p1p	f_1f2f	f_1f2f
1	1	2	1	2	NULL	NULL	2	3
2	2	3	1	3	1	1	3	4
3	3	4	2	4	1	2	4	5
4	4	5	3	5	2	3	5	6
5	5	6	4	6	3	4	6	7
6	6	7	5	7	4	5	7	8
7	7	8	6	8	5	6	8	9
8	8	9	7	9	6	7	9	10
9	9	10	8	10	7	8	10	10
10	10	10	9	10	8	9	NULL	NULL

## 1.1.12.8.3.15 PROCEDURE ANALYSE

### Syntax

```
analyse([max_elements[,max_memory]])
```

### Description

This procedure is defined in the sql/sql\_analyse.cc file. It examines the result from a query and returns an analysis of the results that suggests optimal data types for each column. To obtain this analysis, append PROCEDURE ANALYSE to the end of a `SELECT` statement:

```
SELECT ... FROM ... WHERE ... PROCEDURE ANALYSE([max_elements,[max_memory]])
```

For example:

```
SELECT col1, col2 FROM table1 PROCEDURE ANALYSE(10, 2000);
```

The results show some statistics for the values returned by the query, and propose an optimal data type for the columns. This can be helpful for checking your existing tables, or after importing new data. You may need to try different settings for the arguments so that PROCEDURE ANALYSE() does not suggest the ENUM data type when it is not appropriate.

The arguments are optional and are used as follows:

- `max_elements` (default 256) is the maximum number of distinct values that analyse notices per column. This is used by analyse to check whether the optimal data type should be of type ENUM; if there are more than `max_elements` distinct values, then ENUM is not a suggested type.
- `max_memory` (default 8192) is the maximum amount of memory that analyse should allocate per column while trying to find all distinct values.

## 1.1.12.8.3.16 ROWNUM

From MariaDB 10.6.1 , the  
ROWNUM()  
function is supported.

## Contents

1. [Syntax](#)
2. [Description](#)
3. [Examples](#)
4. [Optimizations](#)
5. [Other Changes Related to ROWNUM](#)
6. [Other Considerations](#)
7. [See Also](#)

## Syntax

ROWNUM()

In Oracle mode one can just use

ROWNUM  
, without the parentheses.

## Description

ROWNUM()  
returns the current number of accepted rows in the current context. Its main purpose is to emulate the  
ROWNUM  
[pseudo column in Oracle](#). For MariaDB native applications, we recommend the usage of [LIMIT](#) , as it is easier to use and gives more predictable results than the usage of  
ROWNUM()

The main difference between using

LIMIT  
and  
ROWNUM()  
to limit the rows in the result is that  
LIMIT  
works on the result set while  
ROWNUM  
works on the number of accepted rows (before any  
ORDER  
or  
GROUP BY  
clauses).

The following queries will return the same results:

```
SELECT * from t1 LIMIT 10;  
SELECT * from t1 WHERE ROWNUM() <= 10;
```

While the following may return different results based on in which orders the rows are found:

```
SELECT * from t1 ORDER BY a LIMIT 10;  
SELECT * from t1 ORDER BY a WHERE ROWNUM() <= 10;
```

The recommended way to use

ROWNUM  
to limit the number of returned rows and get predictable results is to have the query in a subquery and test for  
ROWNUM()  
in the outer query:

```
SELECT * FROM (select * from t1 ORDER BY a) WHERE ROWNUM() <= 10;
```

ROWNUM()  
can be used in the following contexts:

- `SELECT`
- `INSERT`
- `UPDATE`
- `DELETE`
- `LOAD DATA INFILE`

Used in other contexts,

`ROWNUM()`  
will return 0.

## Examples

```
INSERT INTO t1 VALUES (1,ROWNUM()),(2,ROWNUM()),(3,ROWNUM());

INSERT INTO t1 VALUES (1),(2) returning a, ROWNUM();

UPDATE t1 SET row_num_column=ROWNUM();

DELETE FROM t1 WHERE a < 10 AND ROWNUM() < 2;

LOAD DATA INFILE 'filename' into table t1 fields terminated by ','  

lines terminated by "\r\n" (a,b) set c=ROWNUM();
```

## Optimizations

In many cases where

`ROWNUM()`  
is used, MariaDB will use the same optimizations it uses with `LIMIT`.

`LIMIT`  
optimization is possible when using  
`ROWNUM`  
in the following manner:

- When one is in a top level
    - WHERE clause comparing `ROWNUM()` with a numerical constant using any of the following expressions:
      - `ROWNUM() < number`
      - `ROWNUM() <= number`
      - `ROWNUM() = 1`
- `ROWNUM()` can be also be the right argument to the comparison function.

In the above cases,

`LIMIT`  
optimization can be done in the following cases:

- For the current sub query when the `ROWNUM` comparison is done on the top level:

```
SELECT * from t1 WHERE ROWNUM() <= 2 AND t1.a > 0
```

- For an inner sub query, when the upper level has only a

`ROWNUM()`  
comparison in the  
WHERE  
clause:

```
SELECT * from (select * from t1) as t WHERE ROWNUM() <= 2
```

## Other Changes Related to ROWNUM

When

ROWNUM()  
is used anywhere in a query, the optimization to ignore  
ORDER BY  
in subqueries are disabled.

This was done to get the following common Oracle query to work as expected:

```
select * from (select * from t1 order by a desc) as t where rownum() <= 2;
```

By default MariaDB ignores any  
ORDER BY  
in subqueries both because the SQL standard defines results sets in subqueries to be un-ordered and because of performance reasons (especially when using views in subqueries). See [MDEV-3926](#) "Wrong result with GROUP BY ... WITH ROLLUP" for a discussion of this topic.

## Other Considerations

While MariaDB tries to emulate Oracle's usage of

ROWNUM()  
as closely as possible, there are cases where the result is different:

- When the optimizer finds rows in a different order (because of different storage methods or optimization). This may also happen in Oracle if one adds or deletes an index, in which case the rows may be found in a different order.

Note that usage of

ROWNUM()  
in functions or [stored procedures](#) will use their own context, not the caller's context.

- [LIMIT clause](#)

## 1.1.12.8.3.17 ROW\_COUNT

### Syntax

```
ROW_COUNT()
```

### Description

ROW\_COUNT() returns the number of rows updated, inserted or deleted by the preceding statement. This is the same as the row count that the mysql client displays and the value from the [mysql\\_affected\\_rows\(\)](#) C API function.

Generally:

- For statements which return a result set (such as [SELECT](#) , [SHOW](#) , [DESC](#) or [HELP](#) ), returns -1, even when the result set is empty. This is also true for administrative statements, such as [OPTIMIZE](#) .
- For DML statements other than [SELECT](#) and for [ALTER TABLE](#) , returns the number of affected rows.
- For DDL statements (including [TRUNCATE](#) ) and for other statements which don't return any result set (such as [USE](#) , [DO](#) , [SIGNAL](#) or [DEALLOCATE PREPARE](#) ), returns 0.

For [UPDATE](#) , affected rows is by default the number of rows that were actually changed. If the [CLIENT\\_FOUND\\_ROWS](#) flag to [mysql\\_real\\_connect\(\)](#) is specified when connecting to mysqld, affected rows is instead the number of rows matched by the WHERE clause.

For [REPLACE](#) , deleted rows are also counted. So, if REPLACE deletes a row and adds a new row, ROW\_COUNT() returns 2.

For [INSERT ... ON DUPLICATE KEY](#) , updated rows are counted twice. So, if INSERT adds a new rows and modifies another row, ROW\_COUNT() returns 3.

ROW\_COUNT() does not take into account rows that are not directly deleted/updated by the last statement. This means that rows deleted by foreign keys or triggers are not counted.

**Warning:** You can use ROW\_COUNT() with prepared statements, but you need to call it after EXECUTE, not after [DEALLOCATE PREPARE](#) , because the row count for allocate prepare is always 0.

**Warning:** When used after a [CALL](#) statement, this function returns the number of rows affected by the last statement in the procedure, not by the whole procedure.

**Warning:** After [INSERT DELAYED](#) , ROW\_COUNT() returns the number of the rows you tried to insert, not the number of the successful writes.

This information can also be found in the [diagnostics area](#) .

Statements using the ROW\_COUNT() function are not [safe for replication](#) .

## Examples

```
CREATE TABLE t (A INT);

INSERT INTO t VALUES(1),(2),(3);

SELECT ROW_COUNT();
+-----+
| ROW_COUNT() |
+-----+
|      3      |
+-----+

DELETE FROM t WHERE A IN(1,2);

SELECT ROW_COUNT();
+-----+
| ROW_COUNT() |
+-----+
|      2      |
+-----+
```

Example with prepared statements:

```
SET @q = 'INSERT INTO t VALUES(1),(2),(3);';

PREPARE stmt FROM @q;

EXECUTE stmt;
Query OK, 3 rows affected (0.39 sec)
Records: 3  Duplicates: 0  Warnings: 0

SELECT ROW_COUNT();
+-----+
| ROW_COUNT() |
+-----+
|      3      |
+-----+
```

## 1.1.12.8.3.18 SCHEMA

### Syntax

```
SCHEMA()
```

### Description

This function is a synonym for [DATABASE\(\)](#).

## 1.1.12.8.3.19 SESSION\_USER

### Syntax

```
SESSION_USER()
```

### Description

`SESSION_USER()` is a synonym for [USER\(\)](#).

## 1.1.12.8.3.20 SYSTEM\_USER

## Syntax

```
SYSTEM_USER()
```

## Description

SYSTEM\_USER() is a synonym for [USER\(\)](#).

## 1.1.12.8.3.21 USER

## Syntax

```
USER()
```

## Description

Returns the current MariaDB user name and host name, given when authenticating to MariaDB, as a string in the utf8 [character set](#).

Note that the value of USER() may differ from the value of [CURRENT\\_USER\(\)](#), which is the user used to authenticate the current client.

[CURRENT\\_ROLE\(\)](#)

returns the current active role.

SYSTEM\_USER()  
and  
SESSION\_USER  
are synonyms for  
USER()

Statements using the

USER()  
function or one of its synonyms are not [safe for statement level replication](#).

## Examples

```
shell> mysql --user="anonymous"

SELECT USER(),CURRENT_USER();
+-----+-----+
| USER() | CURRENT_USER() |
+-----+-----+
| anonymous@localhost | @localhost |
+-----+-----+
```

To select only the IP address, use [SUBSTRING\\_INDEX\(\)](#),

```
SELECT SUBSTRING_INDEX(USER(), '@', -1);
+-----+
| SUBSTRING_INDEX(USER(), '@', -1) |
+-----+
| 192.168.0.101 |
+-----+
```

## See Also

- [CURRENT\\_USER\(\)](#)

## 1.1.12.8.3.22 VERSION

## Syntax

## Description

Returns a string that indicates the MariaDB server version. The string uses the utf8 character set .

## Examples

```
SELECT VERSION();
+-----+
| VERSION()      |
+-----+
| 10.4.7-MariaDB |
+-----+
```

The

VERSION()  
string may have one or more of the following suffixes:

Suffix	Description
-embedded	The server is an embedded server (libmysqld).
-log	General logging, slow logging or binary (replication) logging is enabled.
-debug	The server is compiled for debugging.
-valgrind	The server is compiled to be instrumented with valgrind.

## Changing the Version String

Some old legacy code may break because they are parsing the

VERSION  
string and expecting a MySQL string or a simple version string like Joomla til API17, see MDEV-7780 .

From MariaDB 10.2 , one can fool these applications by setting the version string from the command line or the my.cnf files with --version=.... .

### 1.1.12.8.4 Miscellaneous Functions

#### 1.1.12.8.4.1 GET\_LOCK

## Syntax

```
GET_LOCK(str,timeout)
```

### Contents

1. [Syntax](#)
2. [Description](#)
3. [Examples](#)
4. [See Also](#)

## Description

Tries to obtain a lock with a name given by the string

```
str
, using a timeout of
timeout
seconds. Returns
1
if the lock was obtained successfully,
0
if the attempt timed out (for example, because another client has previously locked the name), or
NULL
if an error occurred (such as running out of memory or the thread was killed with mysqladmin kill).
```

A lock is released with [RELEASE\\_LOCK\(\)](#) , when the connection terminates (either normally or abnormally). A connection can hold multiple locks at the

same time, so a lock that is no longer needed needs to be explicitly released.

The `IS_FREE_LOCK` function returns whether a specified lock a free or not, and the `IS_USED_LOCK` whether the function is in use or not.

Locks obtained with

```
GET_LOCK()  
do not interact with transactions. That is, committing a transaction does not release any such locks obtained during the transaction.
```

It is also possible to recursively set the same lock. If a lock with the same name is set

```
n  
times, it needs to be released  
n  
times as well.
```

```
str  
is case insensitive for  
GET_LOCK()  
and related functions. If  
str  
is an empty string or  
NULL  
,  
GET_LOCK()  
returns  
NULL  
and does nothing. From MariaDB 10.2.2,  
timeout  
supports microseconds. Before then, it was rounded to the closest integer.
```

If the `metadata_lock_info` plugin is installed, locks acquired with this function are visible in the [Information Schema METADATA\\_LOCK\\_INFO](#) table.

This function can be used to implement application locks or to simulate record locks. Names are locked on a server-wide basis. If a name has been locked by one client,

```
GET_LOCK()  
blocks any request by another client for a lock with the same name. This allows clients that agree on a given lock name to use the name to perform cooperative advisory locking. But be aware that it also allows a client that is not among the set of cooperating clients to lock a name, either inadvertently or deliberately, and thus prevent any of the cooperating clients from locking that name. One way to reduce the likelihood of this is to use lock names that are database-specific or application-specific. For example, use lock names of the form
```

```
db_name.str  
or  
app_name.str
```

Statements using the

```
GET_LOCK  
function are not safe for statement-based replication.
```

The patch to permit multiple locks was [contributed by Konstantin "Kostja" Osipov](#) ([MDEV-3917](#)).

## Examples

```
SELECT GET_LOCK('lock1',10);  
+-----+  
| GET_LOCK('lock1',10) |  
+-----+  
| 1 |  
+-----+  
  
SELECT IS_FREE_LOCK('lock1'), IS_USED_LOCK('lock1');  
+-----+-----+  
| IS_FREE_LOCK('lock1') | IS_USED_LOCK('lock1') |  
+-----+-----+  
| 0 | 46 |  
+-----+-----+  
  
SELECT IS_FREE_LOCK('lock2'), IS_USED_LOCK('lock2');  
+-----+-----+  
| IS_FREE_LOCK('lock2') | IS_USED_LOCK('lock2') |  
+-----+-----+  
| 1 | NULL |  
+-----+-----+
```

Multiple locks can be held:

```
SELECT GET_LOCK('lock2',10);
+-----+
| GET_LOCK('lock2',10) |
+-----+
|          1 |
+-----+

SELECT IS_FREE_LOCK('lock1'), IS_FREE_LOCK('lock2');
+-----+
| IS_FREE_LOCK('lock1') | IS_FREE_LOCK('lock2') |
+-----+
|          0 |          0 |
+-----+

SELECT RELEASE_LOCK('lock1'), RELEASE_LOCK('lock2');
+-----+
| RELEASE_LOCK('lock1') | RELEASE_LOCK('lock2') |
+-----+
|          1 |          1 |
+-----+
```

It is possible to hold the same lock recursively. This example is viewed using the `metadata_lock_info` plugin:

```
SELECT GET_LOCK('lock3',10);
+-----+
| GET_LOCK('lock3',10) |
+-----+
|          1 |
+-----+

SELECT GET_LOCK('lock3',10);
+-----+
| GET_LOCK('lock3',10) |
+-----+
|          1 |
+-----+

SELECT * FROM INFORMATION_SCHEMA.METADATA_LOCK_INFO;
+-----+-----+-----+-----+-----+
| THREAD_ID | LOCK_MODE           | LOCK_DURATION | LOCK_TYPE | TABLE_SCHEMA | TABLE_NAME |
+-----+-----+-----+-----+-----+
|      46 | MDL_SHARED_NO_WRITE | NULL          | User lock  | lock3       |

## 1.1.12.8.4.2 INET6\_ATON

### Syntax

```
INET6_ATON(expr)
```

### Description

Given an IPv6 or IPv4 network address as a string, returns a binary string that represents the numeric value of the address.

No trailing zone ID's or trailing network masks are permitted. For IPv4 addresses, or IPv6 addresses with IPv4 address parts, no classful addresses or trailing port numbers are permitted and octal numbers are not supported.

The returned binary string will be `VARBINARY(16)` or `VARBINARY(4)` for IPv6 and IPv4 addresses respectively.

Returns NULL if the argument is not understood.

MariaDB starting with 10.5.0

From MariaDB 10.5.0 ,

INET6\_ATON

can take INET6 as an argument.

## Examples

```
SELECT HEX(INET6_ATON('10.0.1.1'));
+-----+
| HEX(INET6_ATON('10.0.1.1')) |
+-----+
| 0A000101 |
+-----+  
  
SELECT HEX(INET6_ATON('48f3::d432:1431:ba23:846f'));
+-----+
| HEX(INET6_ATON('48f3::d432:1431:ba23:846f')) |
+-----+
| 48F300000000000D4321431BA23846F |
+-----+
```

## 1.1.12.8.4.3 INET6\_NTOA

### Contents

1. [Syntax](#)
2. [Description](#)
3. [Examples](#)
4. [See Also](#)

## Syntax

```
INET6_NTOA(expr)
```

## Description

Given an IPv6 or IPv4 network address as a numeric binary string, returns the address as a nonbinary string in the connection character set.

The return string is lowercase, and is platform independent, since it does not use functions specific to the operating system. It has a maximum length of 39 characters.

Returns NULL if the argument is not understood.

## Examples

```

SELECT INET6_NTOA(UNHEX('0A000101'));
+-----+
| INET6_NTOA(UNHEX('0A000101')) |
+-----+
| 10.0.1.1 |
+-----+

SELECT INET6_NTOA(UNHEX('48F300000000000D4321431BA23846F'));
+-----+
| INET6_NTOA(UNHEX('48F300000000000D4321431BA23846F')) |
+-----+
| 48f3::d432:1431:ba23:846f |
+-----+

```

## 1.1.12.8.4.4 INET\_ATON

### Syntax

```
INET_ATON(expr)
```

### Description

Given the dotted-quad representation of an IPv4 network address as a string, returns an integer that represents the numeric value of the address. Addresses may be 4- or 8-byte addresses.

Returns NULL if the argument is not understood.

### Examples

```

SELECT INET_ATON('192.168.1.1');
+-----+
| INET_ATON('192.168.1.1') |
+-----+
| 3232235777 |
+-----+

```

This is calculated as follows:  $192 \times 256^3 + 168 \times 256^2 + 1 \times 256 + 1$

## See Also

- [INET6\\_ATON\(\)](#)
- [INET\\_NTOA\(\)](#)

## 1.1.12.8.4.5 INET\_NTOA

### Syntax

```
INET_NTOA(expr)
```

### Description

Given a numeric IPv4 network address in network byte order (4 or 8 byte), returns the dotted-quad representation of the address as a string.

### Examples

```
SELECT INET_NTOA(3232235777);
+-----+
| INET_NTOA(3232235777) |
+-----+
| 192.168.1.1           |
+-----+
```

192.168.1.1 corresponds to 3232235777 since  $192 \times 256^3 + 168 \times 256^2 + 1 \times 256 + 1 = 3232235777$

## See Also

- [INET6\\_NTOA\(\)](#)
- [INET\\_ATON\(\)](#)

## 1.1.12.8.4.6 IS\_FREE\_LOCK

### Syntax

```
IS_FREE_LOCK(str)
```

#### Contents

1. [Syntax](#)
2. [Description](#)
3. [See Also](#)

### Description

Checks whether the lock named

```
str  
is free to use (that is, not locked). Returns  
1  
if the lock is free (no one is using the lock),  
0  
if the lock is in use, and  
NULL  
if an error occurs (such as an incorrect argument, like an empty string or  
NULL  
).  
str  
is case insensitive.
```

If the [metadata\\_lock\\_info](#) plugin is installed, the [Information Schema metadata\\_lock\\_info](#) table contains information about locks of this kind (as well as [metadata locks](#) ).

Statements using the

```
IS_FREE_LOCK  
function are not safe for statement-based replication.
```

## See Also

- [GET\\_LOCK](#)
- [RELEASE\\_LOCK](#)
- [IS\\_USED\\_LOCK](#)
- [RELEASE\\_ALL\\_LOCKS](#)

## 1.1.12.8.4.7 IS\_IPV4

### Syntax

```
IS_IPV4(expr)
```

### Description

If the expression is a valid IPv4 address, returns 1, otherwise returns 0.

`IS_IPV4()` is stricter than `INET_ATON()`, but as strict as `INET6_ATON()`, in determining the validity of an IPv4 address. This implies that if `IS_IPV4` returns 1, the same expression will always return a non-NULL result when passed to `INET_ATON()`, but that the reverse may not apply.

## Examples

```
SELECT IS_IPV4('1110.0.1.1');
+-----+
| IS_IPV4('1110.0.1.1') |
+-----+
|          0          |
+-----+  
  
SELECT IS_IPV4('48f3::d432:1431:ba23:846f');
+-----+
| IS_IPV4('48f3::d432:1431:ba23:846f') |
+-----+
|          0          |
+-----+
```

## 1.1.12.8.4.8 IS\_IPV4\_COMPAT

### Syntax

```
IS_IPV4_COMPAT(expr)
```

### Description

Returns 1 if a given numeric binary string IPv6 address, such as returned by `INET6_ATON()`, is IPv4-compatible, otherwise returns 0.

MariaDB starting with 10.5.0

From MariaDB 10.5.0, when the argument is not `INET6`, automatic implicit `CAST` to `INET6` is applied. As a consequence,

now understands arguments in both text representation and binary(16) representation. Before MariaDB 10.5.0, the function understood only binary(16) representation.

## Examples

```
SELECT IS_IPV4_COMPAT(INET6_ATON('::10.0.1.1'));
+-----+
| IS_IPV4_COMPAT(INET6_ATON('::10.0.1.1')) |
+-----+
|          1          |
+-----+  
  
SELECT IS_IPV4_COMPAT(INET6_ATON('::48f3::d432:1431:ba23:846f'));
+-----+
| IS_IPV4_COMPAT(INET6_ATON('::48f3::d432:1431:ba23:846f')) |
+-----+
|          0          |
+-----+
```

## 1.1.12.8.4.9 IS\_IPV4\_MAPPED

### Syntax

```
IS_IPV4_MAPPED(expr)
```

### Description

Returns 1 if a given a numeric binary string IPv6 address, such as returned by `INET6_ATON()`, is a valid IPv4-mapped address, otherwise returns 0.

MariaDB starting with 10.5.0

From MariaDB 10.5.0 , when the argument is not INET6 , automatic implicit CAST to INET6 is applied. As a consequence,

IS\_IPV4\_MAPPED

now understands arguments in both text representation and binary(16) representation. Before MariaDB 10.5.0 , the function understood only binary(16) representation.

## Examples

```
SELECT IS_IPV4_MAPPED(INET6_ATON('::10.0.1.1'));
+-----+
| IS_IPV4_MAPPED(INET6_ATON('::10.0.1.1')) |
+-----+
|          0 |
+-----+

SELECT IS_IPV4_MAPPED(INET6_ATON('::ffff:10.0.1.1'));
+-----+
| IS_IPV4_MAPPED(INET6_ATON('::ffff:10.0.1.1')) |
+-----+
|          1 |
+-----+
```

## 1.1.12.8.4.10 IS\_IPV6

### Syntax

```
IS_IPV6(expr)
```

### Description

Returns 1 if the expression is a valid IPv6 address specified as a string, otherwise returns 0. Does not consider IPv4 addresses to be valid IPv6 addresses.

### Examples

```
SELECT IS_IPV6('48f3::d432:1431:ba23:846f');
+-----+
| IS_IPV6('48f3::d432:1431:ba23:846f') |
+-----+
|          1 |
+-----+
1 row in set (0.02 sec)

SELECT IS_IPV6('10.0.1.1');
+-----+
| IS_IPV6('10.0.1.1') |
+-----+
|          0 |
+-----+
```

## 1.1.12.8.4.11 IS\_USED\_LOCK

### Syntax

```
IS_USED_LOCK(str)
```

## Contents

1. [Syntax](#)
2. [Description](#)
3. [See Also](#)

## Description

Checks whether the lock named

```
str  
is in use (that is, locked). If so, it returns the connection identifier of the client that holds the lock. Otherwise, it returns  
NULL  
. .  
str  
is case insensitive.
```

If the `metadata_lock_info` plugin is installed, the [Information Schema metadata\\_lock\\_info](#) table contains information about locks of this kind (as well as [metadata locks](#) ).

Statements using the

```
IS_USED_LOCK  
function are not safe for statement-based replication.
```

## 1.1.12.8.4.12 MASTER\_GTID\_WAIT

### Syntax

```
MASTER_GTID_WAIT(gtid-list[, timeout])
```

### Description

This function takes a string containing a comma-separated list of [global transaction id's](#) (similar to the value of, for example, `gtid_binlog_pos` ). It waits until the value of `gtid_slave_pos` has the same or higher seq\_no within all replication domains specified in the gtid-list; in other words, it waits until the slave has reached the specified GTID position.

An optional second argument gives a timeout in seconds. If the timeout expires before the specified GTID position is reached, then the function returns -1. Passing NULL or a negative number for the timeout means no timeout, and the function will wait indefinitely.

If the wait completes without a timeout, 0 is returned. Passing NULL for the gtid-list makes the function return NULL immediately, without waiting.

The gtid-list may be the empty string, in which case `MASTER_GTID_WAIT()` returns immediately. If the gtid-list contains fewer domains than `gtid_slave_pos` , then only those domains are waited upon. If gtid-list contains a domain that is not present in `@@gtid_slave_pos` , then `MASTER_GTID_WAIT()` will wait until an event containing such domain\_id arrives on the slave (or until timed out or killed).

`MASTER_GTID_WAIT()` can be useful to ensure that a slave has caught up to a master. Simply take the value of `gtid_binlog_pos` on the master, and use it in a `MASTER_GTID_WAIT()` call on the slave; when the call completes, the slave will have caught up with that master position.

`MASTER_GTID_WAIT()` can also be used in client applications together with the `last_gtid` session variable. This is useful in a read-scaleout [replication](#) setup, where the application writes to a single master but divides the reads out to a number of slaves to distribute the load. In such a setup, there is a risk that an application could first do an update on the master, and then a bit later do a read on a slave, and if the slave is not fast enough, the data read from the slave might not include the update just made, possibly confusing the application and/or the end-user. One way to avoid this is to request the value of `last_gtid` on the master just after the update. Then before doing the read on the slave, do a `MASTER_GTID_WAIT()` on the value obtained from the master; this will ensure that the read is not performed until the slave has replicated sufficiently far for the update to have become visible.

Note that `MASTER_GTID_WAIT()` can be used even if the slave is configured not to use GTID for connections ([CHANGE MASTER TO master\\_use\\_gtid=no](#) ). This is because from MariaDB 10, GTIDs are always logged on the master server, and always recorded on the slave servers.

### Differences to MASTER\_POS\_WAIT()

- `MASTER_GTID_WAIT()` is global; it waits for any master connection to reach the specified GTID position. `MASTER_POS_WAIT()` works only against a specific connection. This also means that while `MASTER_POS_WAIT()` aborts if its master connection is terminated with `STOP SLAVE` or due to an error, `MASTER_GTID_WAIT()` continues to wait while slaves are stopped.
- `MASTER_GTID_WAIT()` can take its timeout as a floating-point value, so a timeout in fractional seconds is supported, eg. `MASTER_GTID_WAIT("0-1-100", 0.5)`. (The minimum wait is one microsecond, 0.000001 seconds).

- `MASTER_GTID_WAIT()` allows one to specify a timeout of zero in order to do a non-blocking check to see if the slaves have progressed to a specific GTID position (`MASTER_POS_WAIT()`) takes a zero timeout as meaning an infinite wait). To do an infinite `MASTER_GTID_WAIT()`, specify a negative timeout, or omit the timeout argument.
- `MASTER_GTID_WAIT()` does not return the number of events executed since the wait started, nor does it return `NULL` if a slave thread is stopped. It always returns either `0` for successful wait completed, or `-1` for timeout reached (or `NULL` if the specified gtid-pos is `NULL`).

Since `MASTER_GTID_WAIT()` looks only at the `seq_no` part of the GTIDs, not the `server_id`, care is needed if a slave becomes diverged from another server so that two different GTIDs with the same `seq_no` (in the same domain) arrive at the same server. This situation is in any case best avoided; setting `gtid_strict_mode` is recommended, as this will prevent any such out-of-order sequence numbers from ever being replicated on a slave.

## 1.1.12.8.4.13 MASTER\_POS\_WAIT

### Syntax

```
MASTER_POS_WAIT(log_name,log_pos[,timeout,[ "connection_name" ]])
```

### Description

This function is useful in [replication](#) for controlling primary/replica synchronization. It blocks until the replica has read and applied all updates up to the specified position (

`log_name,log_pos`

) in the primary log. The return value is the number of log events the replica had to wait for to advance to the specified position. The function returns `NULL` if the replica SQL thread is not started, the replica's primary information is not initialized, the arguments are incorrect, or an error occurs. It returns `-1` if the timeout has been exceeded. If the replica SQL thread stops while

`MASTER_POS_WAIT()`

is waiting, the function returns `NULL`. If the replica is past the specified position, the function returns immediately.

If a

`timeout`

`value` is specified,

`MASTER_POS_WAIT()`

stops waiting when

`timeout`

seconds have elapsed.

`timeout`

must be greater than `0`; a zero or negative

`timeout`

means no

`timeout`

.

The

`connection_name`

is used when you are using [multi-source-replication](#). If you don't specify it, it's set to the value of the `default_master_connection` system variable.

Statements using the `MASTER_POS_WAIT()` function are not [safe for replication](#).

## 1.1.12.8.4.14 NAME\_CONST

### Syntax

```
NAME_CONST(name,value)
```

### Description

Returns the given value. When used to produce a result set column,

`NAME_CONST()`

causes the column to have the given name. The arguments should be constants.

This function is used internally when replicating stored procedures. It makes little sense to use it explicitly in SQL statements, and it was not supposed to be used like that.

```
SELECT NAME_CONST('myname', 14);
+-----+
| myname |
+-----+
|   14   |
+-----+
```

## 1.1.12.8.4.15

## 1.1.12.8.4.16 RELEASE\_LOCK

### Syntax

```
RELEASE_LOCK(str)
```

### Contents

1. [Syntax](#)
2. [Description](#)
3. [Examples](#)
4. [See Also](#)

### Description

Releases the lock named by the string

str

that was obtained with [GET\\_LOCK\(\)](#). Returns 1 if the lock was released, 0 if the lock was not established by this thread (in which case the lock is not released), and

NULL

if the named lock did not exist. The lock does not exist if it was never obtained by a call to

[GET\\_LOCK\(\)](#)

or if it has previously been released.

```
str  
is case insensitive. If  
str  
is an empty string or  
NULL  
,  
RELEASE_LOCK()  
returns  
NULL  
and does nothing.
```

Statements using the RELEASE\_LOCK() function are not [safe for replication](#).

The [DO statement](#) is convenient to use with

```
RELEASE_LOCK()
```

### Examples

Connection1:

```
SELECT GET_LOCK('lock1',10);
+-----+
| GET_LOCK('lock1',10) |
+-----+
|           1          |
+-----+
```

Connection 2:

```
SELECT GET_LOCK('lock2',10);
```

+	-----+
	GET_LOCK('lock2',10)
+	-----+
	1
+	-----+

## Connection 1:

```
SELECT RELEASE_LOCK('lock1'), RELEASE_LOCK('lock2'), RELEASE_LOCK('lock3');

+-----+-----+
| RELEASE_LOCK('lock1') | RELEASE_LOCK('lock2') | RELEASE_LOCK('lock3') |
+-----+-----+
|           1 |             0 |        NULL |
+-----+-----+
```

From MariaDB 10.0.2 , it is possible to hold the same lock recursively. This example is viewed using the `metadata_lock_info` plugin:

```
SELECT GET_LOCK('lock3',10);
+-----+
| GET_LOCK('lock3',10) |
+-----+
|          1 |
+-----+

SELECT GET_LOCK('lock3',10);
+-----+
| GET_LOCK('lock3',10) |
+-----+
|          1 |
+-----+

SELECT * FROM INFORMATION_SCHEMA.METADATA_LOCK_INFO;
+-----+-----+-----+-----+-----+
| THREAD_ID | LOCK_MODE           | LOCK_DURATION | LOCK_TYPE | TABLE_SCHEMA | TABLE_NAME |
+-----+-----+-----+-----+-----+
|      46 | MDL_SHARED_NO_WRITE | NULL          | User lock  | lock3       |          |
+-----+-----+-----+-----+-----+

SELECT RELEASE_LOCK('lock3');
+-----+
| RELEASE_LOCK('lock3') |
+-----+
|          1 |
+-----+

SELECT * FROM INFORMATION_SCHEMA.METADATA_LOCK_INFO;
+-----+-----+-----+-----+-----+
| THREAD_ID | LOCK_MODE           | LOCK_DURATION | LOCK_TYPE | TABLE_SCHEMA | TABLE_NAME |
+-----+-----+-----+-----+-----+
|      46 | MDL_SHARED_NO_WRITE | NULL          | User lock  | lock3       |          |
+-----+-----+-----+-----+-----+

SELECT RELEASE_LOCK('lock3');
+-----+
| RELEASE_LOCK('lock3') |
+-----+
|          1 |
+-----+

SELECT * FROM INFORMATION_SCHEMA.METADATA_LOCK_INFO;
Empty set (0.000 sec)
```

#### See Also

- GET\_LOCK
  - IS\_FREE\_LOCK
  - IS\_USED\_LOCK
  - RELEASE\_ALL\_LOCKS

## 1.1.12.8.4.17 SLEEP

## Syntax

```
SLEEP(duration)
```

## Description

Sleeps (pauses) for the number of seconds given by the duration argument, then returns

- 0
- . If
- SLEEP()
- is interrupted, it returns
- 1
- . The duration may have a fractional part given in microseconds.

Statements using the SLEEP() function are not [safe for replication](#).

## Example

```
SELECT SLEEP(5.5);
+-----+
| SLEEP(5.5) |
+-----+
|      0 |
+-----+
1 row in set (5.50 sec)
```

## 1.1.12.8.4.18 SYS\_GUID

MariaDB starting with [10.6.1](#)

The SYS\_GUID function was introduced in [MariaDB 10.6.1](#) to enhance Oracle compatibility. Similar functionality can be achieved with the [UUID](#) function.

## Syntax

```
SYS_GUID()
```

## Description

Returns a 16-byte globally unique identifier (GUID), similar to the [UUID](#) function, but without the

character.

## Example

```
SELECT SYS_GUID();
+-----+
| SYS_GUID()           |
+-----+
| 2C574E45BA2811EBB265F859713E4BE4 |
+-----+
```

## See Also

- [UUID](#)
- [UUID\\_SHORT](#)
- [UUID data type](#)

## 1.1.12.8.4.19 UUID

## Syntax

## Contents

1. [Syntax](#)
2. [Description](#)
3. [Examples](#)
4. [See Also](#)

## Description

Returns a Universally Unique Identifier (UUID).

A UUID is designed as a number that is globally unique in space and time. Two calls to

```
UUID()
```

are expected to generate two different values, even if these calls are performed on two separate computers that are not connected to each other.

**UUID()** results are intended to be unique, but cannot always be relied upon to unpredictable and unguessable, so should not be relied upon for these purposes.

A UUID is a 128-bit number represented by a utf8 string of five hexadecimal numbers in

```
aaaaaaaa-bbbb-cccc-dddd-eeeeeeeeeee
```

format:

- The first three numbers are generated from a timestamp.
- The fourth number preserves temporal uniqueness in case the timestamp value loses monotonicity (for example, due to daylight saving time).
- The fifth number is an IEEE 802 node number that provides spatial uniqueness. A random number is substituted if the latter is not available (for example, because the host computer has no Ethernet card, or we do not know how to find the hardware address of an interface on your operating system). In this case, spatial uniqueness cannot be guaranteed. Nevertheless, a collision should have very low probability.

Currently, the MAC address of an interface is taken into account only on FreeBSD and Linux. On other operating systems, MariaDB uses a randomly generated 48-bit number.

Statements using the `UUID()` function are not [safe for replication](#).

The results are generated according to the "DCE 1.1:Remote Procedure Call" (Appendix A) CAE (Common Applications Environment) Specifications published by The Open Group in October 1997 ( [Document Number C706](#) ).

## Examples

```
SELECT UUID();
+-----+
| UUID()           |
+-----+
| cd41294a-afb0-11df-bc9b-00241dd75637 |
+-----+
```

- [UUID\\_SHORT\(\)](#) - Return short (64 bit) Universal Unique Identifier
- [SYS\\_GUID](#) - UUID without the
- character for Oracle compatibility
- [UUID data type](#)

## 1.1.12.8.4.20 UUID\_SHORT

### Syntax

```
UUID_SHORT()
```

## Contents

1. [Syntax](#)
2. [Description](#)
3. [Examples](#)
4. [See Also](#)

# Description

Returns a "short" universally unique identifier as a 64-bit unsigned integer (rather than a string-form 128-bit identifier as returned by the [UUID\(\)](#) function).

The value of

`UUID_SHORT()`

is guaranteed to be unique if the following conditions hold:

- The server\_id of the current host is unique among your set of master and slave servers
- - server\_id  
is between 0 and 255
- You don't set back your system time for your server between mysqld restarts
- You do not invoke
  - `UUID_SHORT()`  
on average more than 16 million times per second between mysqld restarts

The `UUID_SHORT()` return value is constructed this way:

```
(server_id & 255) << 56
+ (server_startup_time_in_seconds << 24)
+ incremented_variable++;
```

Statements using the `UUID_SHORT()` function are not [safe for statement-based replication](#).

## Examples

```
SELECT UUID_SHORT();
+-----+
| UUID_SHORT() |
+-----+
| 21517162376069120 |
+-----+
```

```
create table t1 (a bigint unsigned default(uuid_short()) primary key);
insert into t1 values(),();
select * from t1;
+-----+
| a      |
+-----+
| 98113699159474176 |
| 98113699159474177 |
+-----+
```

## 1.1.12.8.4.21 VALUES / VALUE

### Syntax

MariaDB starting with [10.3.3](#)

```
VALUE(col_name)
```

MariaDB until [10.3.2](#)

```
VALUES(col_name)
```

## Description

In an `INSERT ... ON DUPLICATE KEY UPDATE` statement, you can use the

```
VALUES(col_name)
function in the UPDATE clause to refer to column values from the INSERT portion of the statement. In other words,
VALUES(col_name)
in the
UPDATE
clause refers to the value of col_name that would be inserted, had no duplicate-key conflict occurred. This function is especially useful in
multiple-row inserts.
```

The

```
VALUES()
function is meaningful only in
INSERT ... ON DUPLICATE KEY UPDATE
statements and returns
NULL
otherwise.
```

In MariaDB 10.3.3 this function was renamed to

```
VALUE()
, because it's incompatible with the standard Table Value Constructors syntax, implemented in MariaDB 10.3.3 .
```

The

```
VALUES()
function can still be used even from MariaDB 10.3.3 , but only in
INSERT ... ON DUPLICATE KEY UPDATE
statements; it's a syntax error otherwise.
```

## Examples

MariaDB starting with 10.3.3

```
INSERT INTO t (a,b,c) VALUES (1,2,3),(4,5,6)
ON DUPLICATE KEY UPDATE c=VALUE(a)+VALUE(b);
```

MariaDB until 10.3.2

```
INSERT INTO t (a,b,c) VALUES (1,2,3),(4,5,6)
ON DUPLICATE KEY UPDATE c=VALUES(a)+VALUES(b);
```

## 1.1.12.9 Special Functions

### 1.1.12.9.1 Dynamic Columns Functions

#### 1.1.12.9.2 Galera Functions

##### 1.1.12.9.2.1 WSREP\_LAST\_SEEN\_GTID

MariaDB starting with 10.4.2

WSREP\_LAST\_SEEN\_GTID was added as part of Galera 4 in MariaDB 10.4.2 .

## Syntax

```
WSREP_LAST_SEEN_GTID()
```

## Description

Returns the Global Transaction ID of the most recent write transaction observed by the client.

The result can be useful to determine the transaction to provide to [WSREP\\_SYNC\\_WAIT\\_UPTO\\_GTID](#) for waiting and unblocking purposes.

## 1.1.12.9.2.2 WSREP\_LAST\_WRITTEN\_GTID

MariaDB starting with [10.4.2](#)

`WSREP_LAST_WRITTEN_GTID` was added as part of Galera 4 in [MariaDB 10.4.2](#).

### Syntax

```
WSREP_LAST_WRITTEN_GTID()
```

### Description

Returns the [Global Transaction ID](#) of the most recent write transaction performed by the client.

## 1.1.12.9.2.3 WSREP\_SYNC\_WAIT\_UPTO\_GTID

MariaDB starting with [10.4.2](#)

`WSREP_SYNC_WAIT_UPTO_GTID` was added as part of Galera 4 in [MariaDB 10.4.2](#).

### Syntax

```
WSREP_SYNC_WAIT_UPTO_GTID(gtid[,timeout])
```

### Description

Blocks the client until the transaction specified by the given [Global Transaction ID](#) is applied and committed by the node.

The optional *timeout* argument can be used to specify a block timeout in seconds. If not provided, the timeout will be indefinite.

Returns the node that applied and committed the Global Transaction ID,

`ER_LOCAL_WAIT_TIMEOUT`

if the function is timed out before this, or

`ER_WRONG_ARGUMENTS`

if the function is given an invalid GTID.

The result from [WSREP\\_LAST\\_SEEN\\_GTID](#) can be useful to determine the transaction to provide to `WSREP_SYNC_WAIT_UPTO_GTID` for waiting and unblocking purposes.

## 1.1.12.9.3 Geographic Functions

### 1.1.12.9.3.1 Geometry Constructors

#### 1.1.12.9.3.1.1 BUFFER

A synonym for [ST\\_BUFFER](#).

#### 1.1.12.9.3.1.2 CONVEXHULL

A synonym for [ST\\_CONVEXHULL](#).

#### 1.1.12.9.3.1.3 GEOMETRYCOLLECTION

### Syntax

```
GeometryCollection(g1,g2,...)
```

### Description

Constructs a [WKB](#) `GeometryCollection`. If any argument is not a well-formed WKB representation of a geometry, the return value is `NULL`.

## Examples

```
CREATE TABLE gis_geometrycollection (g GEOMETRYCOLLECTION);
SHOW FIELDS FROM gis_geometrycollection;
INSERT INTO gis_geometrycollection VALUES
(GeomCollFromText('GEOMETRYCOLLECTION(POINT(0 0), LINESTRING(0 0,10 10)))'),
(GeometryFromWKB(AsWKB(GeometryCollection(Point(44, 6), LineString(Point(3, 6), Point(7, 9))))),
(GeomFromText('GeometryCollection()')),
(GeomFromText('GeometryCollection EMPTY')));
```

### 1.1.12.9.3.1.4 LINESTRING

#### Syntax

```
LineString(pt1,pt2,...)
```

#### Description

Constructs a [WKB](#) LineString value from a number of WKB [Point](#) arguments. If any argument is not a WKB Point, the return value is

NULL  
. If the number of [Point](#) arguments is less than two, the return value is  
NULL

## Examples

```
SET @ls = 'LineString(1 1,2 2,3 3)';
SELECT AsText(EndPoint(GeomFromText(@ls)));
+-----+
| AsText(EndPoint(GeomFromText(@ls))) |
+-----+
| POINT(3 3)                         |
+-----+
